Chapter 1
Addendum for Rev 6 of MPC5746R

1.1 Overview....7

1.2 Introduction....11

1.2.1 Block diagrams.... 11

1.2.2 Feature list....13

1.3 Standby SRAM Regulator.... 14

1.4 INTC Master Protection Register (INTC_MPROT)....16

1.5 Clocking....18

1.5.1 Clock generation 18

1.5.2 Peripheral Clocks 20

1.6 CMU Control Status Register (CMU_CSR)....21

1.7 Aux Clock 0 Divider Configuration 4 (MC_CGM_AC0_DC4).... 23

1.8 Software Watchdog Timer (SWT)....24

1.8.1 Features.... 24

1.8.2 SWT Control Register (SWT_CR).... 24

1.8.3 Time-out....27

1.9 Enhanced Modular IO Subsystem (eMIOS200)....27

1.9.1 Modes of operation.... 27

1.9.2 eMIOS UC B register n (eMIOS_Bn)....28

1.9.3 eMIOS CNT register n (eMIOS_CNTn).... 29

1.9.4 eMIOS UC Control register n (eMIOS_Cn)....30

1.10 FEC interface selection....35

1.11 SENT Receiver (SRX)....36

1.11.1 Channel 'n' Configuration Register (n=0 to (CH-1)) (SRX_CHn_CONFIG)....36

1.11.2 Input programmable filter.... 40

1.11.3 Pause pulse diagnostic.... 40

Section number	Title	Page

1.12 SIPI Error Register (SIPI_ERR)..... 44

1.13 PLL configuration example..... 46

1.14 LINFlexD..... 47

1.14.1 Introduction..... 47

1.14.2 LIN mode features..... 47

1.14.3 DMA Tx Enable Register (LINFlexD_DMATXE)..... 48

1.14.4 DMA Rx Enable Register (LINFlexD_DMARXE)..... 49

1.15 'Destructive' Bidirectional Reset Enable (MC_RGM_DBRE)..... 50

1.16.1 Voltage Monitoring..... 53

1.16.2 ADC Interface..... 53

1.17 Power Management Controller..... 53

1.17.1 PMC introduction..... 53

1.17.2 Reset Enable Control Register (PMC_REE)..... 53

1.17.3 Reset Type (Destructive / Functional) Selection Register (PMC_RES)..... 56

1.17.4 ADC Channel Select Register (PMC_ADC_CS)..... 59

1.17.5 ADC Interface..... 60

1.18 Power Control Unit (MC_PCU)..... 62

1.18.1 Introduction..... 62

1.18.2 Functional description..... 62

1.19 NXMC block connections..... 62

1.20 Power..... 64

1.21 Fault Collection and Control Unit (FCCU)..... 64

1.21.1 Available FCCU output signals..... 64

1.21.2 FCCU failure inputs from other modules..... 64

1.22 Self-Test Control Unit (STCU2)..... 73

1.22.1 STCU2 chip-specific module information..... 73

1.22.2 STCU2 Off-Line MBIST Status Medium Register (STCU2_MBSM)..... 74

1.23 PMC protected registers..... 76

1.24 BAR execution protection....77
1.25 Password and Device Security Module (PASS)....77
1.25.1 Password and Device Security Module (PASS) chip-specific module information....77
1.25.2 Life Cycle Status Register (PASS_LCSTAT)....79
1.25.3 Debug Disable (DD)....81

Chapter 1
Addendum for Rev 6 of MPC5746R

1.1 Overview

This addendum describes corrections or updates to the MPC5746R Reference Manual. The currently available version of the MPC5746R Reference Manual is Revision 6.

Navigation tip: When navigating this PDF file using the hyperlinks, pressing the ALT and "left arrow" keys simultaneously will return you to the previously viewed page.

Table 1-1. MPC5746RRM Rev6 Addendum

Location	Description
Chapter 2, Introduction	
Page 99	• In "Peripherals allocation" figure, changed PMC_DIG to PMC. • See Block diagrams

Page 102	• In "Feature list" table, updated the following:
	  • Under MPC5746R Column, for Core Frequency row, changed “200MHz" to “200/150MHz)"
	  • Under MPC5745R Column, for Core Frequency row, changed “150MHz (Note 2)" to “200/150MHz"
	  • Under MPC5746R Column, for DSPI row, changed “5+2MSB Support" to “5+2MSB Support (Note 4)"
	  • Under MPC5746R Column, for Package row, changed “MAPBGA252" to “LQFP176 or MAPBGA252"
	• See Feature list

Chapter 3, Embedded memories	
Page 106	• In "Standby SRAM Regulator" section, changed "description in the Power Management Controller digital interface (PMC_dig)" to "description in the Power Management Controller (PMC). • See Standby SRAM Regulator
Chapter 17, Interrupt Controller (INTC)	
Page 446	• Updated last sentence in INTC_MPROT[MPROT] field description from "Once MPROT is enabled by a master, only that master may modify INTC_MPROT" to "Once MPROT is enabled for a master, only that master may modify INTC_MPROT" • See INTC Master Protection Register (INTC_MPROT)
Chapter 22, Clocking	

Table continues on the next page...

Table 1-1. MPC5746RRM Rev6 Addendum (continued)

Location	Description
Page 643	• In Clock distribution figure, changed SIUL2_SCR0[FEC_MODE] as selector for TXCLK_REF_CLK instead of IOMUX. • See Clock generation
Page 655	• In Clock generation figure, changed the name of eTPU2_CLK to eTPU_CLK, eTPU2+ to eTPU, REACT to REACM2, and GLITCH_FILTER to IGF. • See Peripheral Clocks
Chapter 24, Clock Monitor Unit (CMU)	
Page 690	• In CSR[SFM] field, added the following note "MSR[MD] must be written before enabling frequency measurement (CSR[SFM] = 1). Do not write MDR[MD] while CSR[SFM] = 1." • In CSR[RCDIV] field, added the following note "Ensure clock source for CLKMN0_RMT is off before writing CMU_CSR[RCDIV]". • See CMU Control Status Register (CMU_CSR)
Chapter 25, Clock Generation Module (MC_CGM)	
Page 723	• In Aux Clock 0 Divider Configuration 4 register, changed the width of MC_CGM_AC0_DC4[DIV] from 6 to 4. • See Aux Clock 0 Divider Configuration 4 (MC_CGM_AC0_DC4)
Chapter 40, Software Watchdog Timer (SWT)	
Page 1203, 1205, and 1215	• In the "Features" section, changed "Programmable selection of reset or interrupt..." to "Programmable selection of reset request or interrupt..." in list item. • See Features • In the "SWT_CR field descriptions" table, revised all the MAPn field descriptions. • In "SWT_CR[ITR]" field description, changed the spelled-out name from "Interrupt Then Reset" to "Interrupt Then Reset Request". • See SWT Control Register (SWT_CR). • In "Time-out" section, changed "The Interrupt Then Reset bit (SWT_CR[ITR])..." to "The SWT_CR[ITR] bit..." in first sentence. • See Time-out
Chapter 42 Enhanced Modular IO Subsystem (eMIOS200)	

Page 1239, 1249, 1250, 1251 and 1277	• Deleted "QDEC" reference from the following sections:
	  • Modes of operation
	  • eMIOS UC B register n (eMIOS_Bn)
	  • eMIOS CNT register n (eMIOS_CNTn)
	  • Deleted "Quadrature Decode (QDEC) Mode" section.
	• See Modes of operation, eMIOS UC B register n (eMIOS_Bn), eMIOS CNT register n (eMIOS_CNTn)
	• In eMIOS_Cn[EDPOL] bit description deleted the notes and "QDEC" reference
	• See eMIOS UC Control register n (eMIOS_Cn)

Chapter 50, SIPI	
Page 2130	• In SIPI_ERR[TOEx] field description, changed "0 Timeout error occurred 1 Timeout error didn't occur" to "0 Timeout error didn't occur 1 Timeout error occurred" • See SIPI Error Register (SIPI_ERR)
Chapter 51, LVDS Fast Asynchronous Serial Transmission (LFAST) – Interprocessor Communications	
Page 2220	• Added the section "PLL Configuration example". • See PLL configuration example
Chapter 52, Fast Ethernet Controller (FEC)	
Page 2221	• Added a note regarding the recommended clock setup before FEC is operational. • See FEC interface selection
Chapter 53, SENT Receiver (SRX)	

Table continues on the next page...

Table 1-1. MPC5746RRM Rev6 Addendum (continued)

Location	Description
Page 2342, 2359, and 2363	• In "Channel 'n' Configuration Register" changed the description of FIL_CNT field from "Only one bit should be set in this field and the output of filter will be offset by twice the same number of clocks plus additional 3 clocks due to synchronization. Default value is '4'" to "Only one bit should be set in this field. Output of the filter is equal to 2*FIL_CNT +4". • See Channel 'n' Configuration Register (n=0 to (CH-1)) (SRX_CHn_CONFIG) • In "Input programmable filter" section, changed the FIL_CNT value to 1. • See Input programmable filter • In "Pause pulse diagnostic" section, added figure SENT receiver resynchronization. • See Pause pulse diagnostic
Chapter 54, LINFlexD	
Page 2372 and 2374	• In "Introduction" and "LIN mode features" sections, added support for LINFlexD protocol feature 2.2. • See Introduction and LIN mode features
Page 2460	• In DMA Tx Enable Register, updated the note in Reserved field from "The number of reserved.....TX_CH_NUM used in this device" to "The number of reserved.....DMA_TX_CH_NUM used in this device" and changed the note in LINFlexD_DMATXE[DTE] field from "The actual size of the register.....(soft reset) in Idle state" to "The number of DTE bit.... (soft reset) in Idle state". • See DMA Tx Enable Register (LINFlexD_DMATXE) • In DMA Rx Enable Register, updated the note in Reserved field from "The number of reserved.....RX_CH_NUM used in this device" to "The number of reserved.....DMA_RX_CH_NUM used in this device" and changed the note in LINFlexD_DMARXE[DRE] field from "The actual size of the register.....(soft reset) in Idle state" to "The number of DTE bit.... (soft reset) in Idle state". • See DMA Rx Enable Register (LINFlexD_DMARXE)
Chapter 56, Reset Generation Module (MC_RGM)	
Page 2496	• In 'Destructive' Bidirectional Reset Enable register, changed the access of MC_RGM_DBRE[BE_PMC_STF] from R/W to RO. • See 'Destructive' Bidirectional Reset Enable (MC_RGM_DBRE)
Chapter 59, Power Management	
Page 2562 and 2567	• In "Voltage Monitoring" section, changed "descriptions in the PMC_dig" to "descriptions in the PMC". • See Voltage Monitoring and ADC Interface • In "ADC interface" section, deleted the table ADC interface. • See ADC Interface
Chapter 60, Power Management Controller (PMC)	
Page 2572, 2592, 2595 and 2599	• In "PMC introduction" section, changed "The PMC_dig block contains" to "The PMC block contains". • See PMC introduction • In "PMC_REE", "PMC_RES", and "PMC_ADC_CS" registers, changed the reset footnote from "The reset value is chip-specific. Refer to the PMC_dig chip-specific module information for the reset value" to "The reset value is chip-specific. Refer to the See the chip-specific PMC information for the reset value". • See Reset Enable Control Register (PMC_REE), Reset Type (Destructive / Functional) Selection Register (PMC_RES), and ADC Channel Select Register (PMC_ADC_CS)
Chapter 61, Power Control Unit (MC_PCU)	
Page 2607 and 2608	• In "Introduction" section, changed "This microcontroller has.....control the analog PMC" to "This microcontroller has.....control the PMC.". • See Introduction

Table continues on the next page...

Table 1-1. MPC5746RRM Rev6 Addendum (continued)

Location	Description
	• In "Functional description" section, changed "PMC_dig" to "PMC". • See Functional description
Chapter 63, Calibration and Debug	

Page 2762	• In "NXMC block connections" section, added the following footnotes:
	  • To provide Nexus data trace messaging from bus masters on the master ports of the crossbar (XBAR) that do not inherently have a trace client, a Nexus Crossbar Multi-Master Client (NXMC) monitors traffic into the master port of the XBAR. Two NXMCs are implemented: one for the fast masters and one for the slow masters.
	  • NXMC clients are connected between E2E-ECC master client and AXBS. Therefore any corrupted data, correctable (single bit error) or un-correctable data (multi bit error), is traced without any trace error information. ECC errors are captured in MEMU.
	• See NXMC block connections

Chapter 75, Functional Safety	
Page 3218	• In Power section, changed "see Power Management Controller digital interface (PMC_dig)" to "see Power Management Controller (PMC)". • See Power
Chapter 78, Fault Collection and Control Unit (FCCU)	
Page 3276	• In Available FCCU output signals section added the note "The FCCU EOUT signals can toggle after LBIST execution during reset.". • See Available FCCU output signals.

Page 3278	• In FCCU Fault Inputs table updated the description of the following NCF Index:
	  • Changed the word Critical to Unrecoverable in Description of NCF Index 6
	  • Changed the word Non Critical to Recoverable in Description of NCF Index 7
	  • Changed the Description from "Critcal Fault in case LBIST or MBIST control signals go to wrong condition during User application" to "The fault in case the self-test was wrongly triggered without STCU programming" for NCF Index 8
	• See FCCU failure inputs from other modules.

Chapter 79, Self-Test Control Unit (STCU2)	
Page 3351	• In "STCU2 chip-specific module information" section added the note "Before running either online or offline self-test, user needs to mask the core LVD, but should enable the core LVDs before running the application via SW through the PMC_REE register". • See STCU2 chip-specific module information.
Page 3405	• In STCU2 Off-Line MBIST Status Medium register, changed the note from "This bit is meaningful when the related bit of the STCU2_MBEL register reports the MBIST is finished" to "This bit is meaningful when the related bit of the STCU2_MBEM register reports the MBIST is finished". • See STCU2 Off-Line MBIST Status Medium Register (STCU2_MBSM).
Chapter 80, Register Protection (REG_PROT)	
Page 3455	• Changed the name of section from "PMC_DIG protected registers" to "PMC protected registers" and changed the name of the table from "Protected PMC_dig registers" to "Protected PMC registers". • See PMC protected registers.
Chapter 81 Security	
Page 3481	• In "BAR execution protection" section deleted the text "But by default this error is masked.....the register is locked". • See BAR execution protection.
Chapter 82 Password and Device Security Module (PASS)	

Table continues on the next page...

Table 1-1. MPC5746RRM Rev6 Addendum (continued)

Location	Description
Page 3489	• In "Password and Device Security Module (PASS) chip-specific module information", added the note " For availability of RL0, RL1, and RL2 (Flash Region Lock bit fields) definitions in Password Group n Lock n Status Registers for the device, please refer to the Flash_Block_Assignment sheet in the pdf attachments". • See Password and Device Security Module (PASS) chip-specific module information
Page 3491	• Deleted the section "External signal description".
Page 3494	• In PASS_LCSTAT[JUN] bit, deleted the text "(In life cycle FA, the JUN bit will always be 0.)". • See Life Cycle Status Register (PASS_LCSTAT)
Page 3506	• In "Debug Disable (DD)" section, updated the text from "Debug Disable is an optional feature that, once the life cycle is In Field or beyond" to "Debug Disable is an optional feature that, once the life cycle is In Field". • See Debug Disable (DD)

1.2 Introduction

1.2.1 Block diagrams

The figures below are the top-level block diagrams. They show the general interconnection of functional modules through the crossbar switch and provide an indication of the modules that connect to external pins.

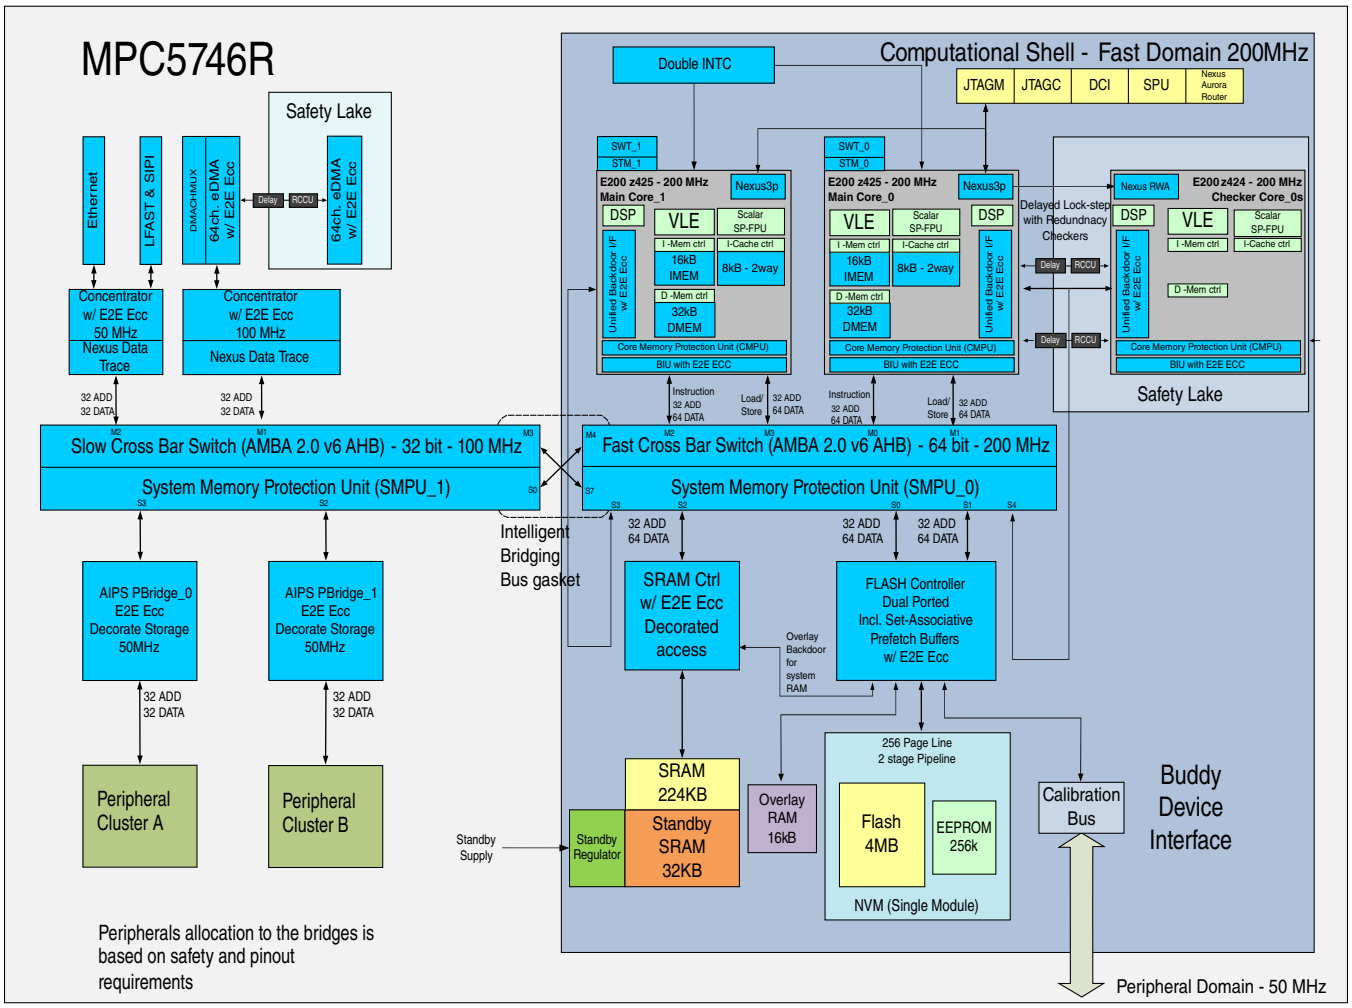

Figure 1-1. Core block diagram

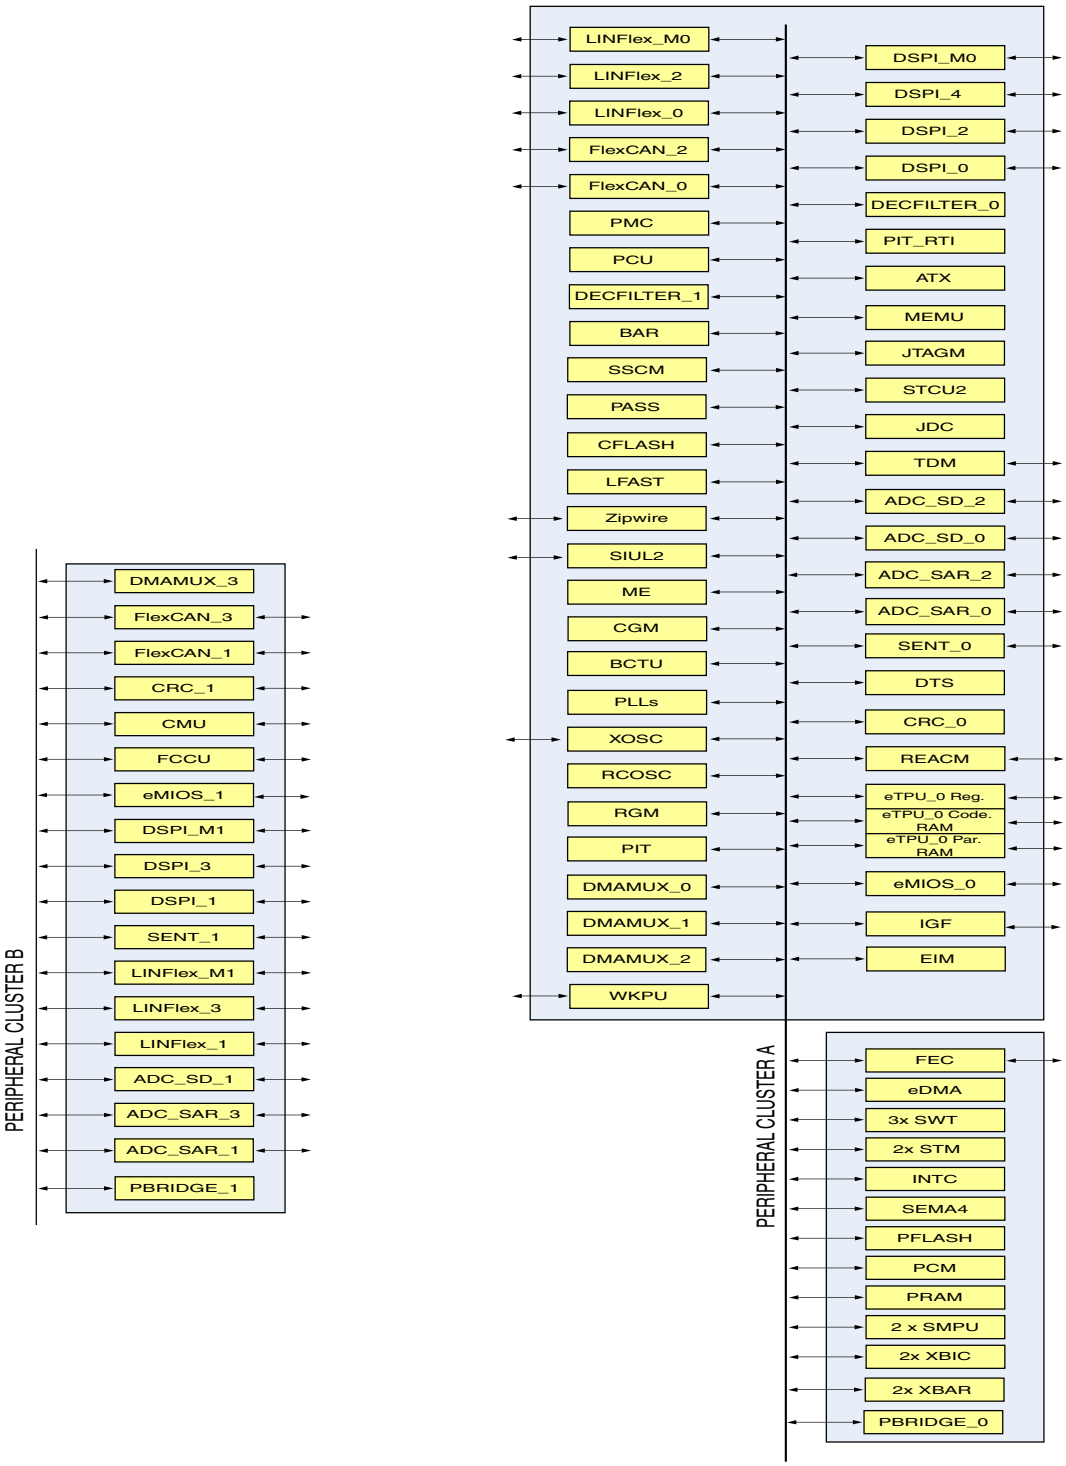

Figure 1-2. Peripherals allocation

1.2.2 Feature list

The following table lists a summary of major features of the device.

Table 1-2. Features list

Feature	MPC5746R	MPC5745R	MPC5743R
Main core	2	2	1[1]
Locked step core	1	1	1
Flash	4256KB + 16KB	3232KB + 16KB	2208KB + 16KB
EEPROM	2x64KB + 8x16KB	2x64KB + 8x16KB	2x64KB + 8x16KB
System RAM	256KB (including standby RAM)	192KB (including standby RAM)	128KB (including standby RAM)
I-CACHE	8KB/core	8KB/core	8KB/core
Local IRAM	16KB/core	16KB/core	16KB/core
Local DRAM	32KB/core	32KB/core	32KB/core
Stby RAM	32KB	32KB	32KB
Overlay RAM	16KB	16KB	16KB
Core freq	200/150MHz[2]	200/150MHz [2]	200MHz
SAR	4	4	4
SD ADC	3	3	3
Decimation Filters	2	2	2
eTPU	32ch x 2	32ch x 2	32ch x 2
Reaction module	10ch	10ch	10ch
DMA controller	64ch	64ch	64ch
FlexCAN	4	4	4
LINFlex	4+2MSB support	4+2MSB support	3+2MSB support[3]
DSPI	5+2MSB support[4]	5+2MSB support[4]	4+2MSB support[5]
Ethernet	10/100MBPS	10/100MBPS	10/100MBPS
SENT	6ch	6ch	6ch
Package	LQFP176 or MAPBGA252 MAPBGA292 Emulation Device	LQFP176 or MAPBGA252	LQFP176 or LQFP144

1. Core0 + Locked step core will be supported. Core 1 will be used for BAF execution at start-up only.
2. 256 BGA package supports 200MHz operation.
3. LINFlex 3 is not supported.
4. For 176 LQFP DSPI 4 is not supported.
5. DSPI 4 is not supported. For 144 LQFP, DSPI M1 is also not supported.

1.3 Standby SRAM Regulator

A total of 32 KB of the system SRAM on the device can remain powered when the rest of the device is powered down. This is achieved with the dedicated VDDSTBY pin in the packages. When the standby RAM is powered by VDDSTBY, the RAM is not operational, but the contents are retained.

The Standby RAM regulator has the following key features:

- Automatic, safe switching between operational (VDD_LV) and standby (VDDSTBY) supplies
- Internal regulation of the high voltage VDDSTBY supply to the low voltage standby RAM supply
- Brownout detection (minimum RAM data retention voltage violation) and reporting via a S/W clearable register bit

The Standby RAM regulator block diagram is given in Figure 1-3.

There are two primary modes of operation with the standby RAM feature:

- Standby RAM feature is not required in the application - in this case, the VDDSTBY pin is connected to ground, and the standby RAM on the device is supplied by VDD_LV and will behave as normal RAM for all conditions.
- Standby RAM feature is required in the application - in this case, the VDDSTBY pin is connected to a voltage within the range given in the device data sheet. The VDDSTBY pin is assumed to be connected to a constant supply, and present before and after the power up/down of the device LV and HV supplies. When the VDD_LV supply to the RAM is above the LV operational voltage threshold, the standby RAM is fully operational and behaves exactly the same as the non-standby system RAM. When the VDD_LV supply falls below the LV Detect threshold, the RAM low voltage supply is switched to the standby supply. See the device data sheet for min/max VDDSTBY values, LV supply thresholds, and the operational and brownout detection voltages.

The brownout detection feature of the standby RAM regulator informs the user if any voltage dip caused a RAM retention failure in standby mode. The brownout detector monitors the supply to the RAM array, and sets a latch in the PMC digital interface, when the voltage falls below the minimum RAM retention voltage given in the device data sheet. The latch is set on power up of the device. S/W then clears the latch by following the instructions in PMC_ADC_CS[STND_BY_RAM_BR_DETCT] description in the Power Management Controller (PMC) chapter. If the minimum RAM retention voltage is violated, the latch will be set again. The latch is set on every power-up of VDD_LV unless VDDSTBY is present and within the specified ranges in the data sheet.

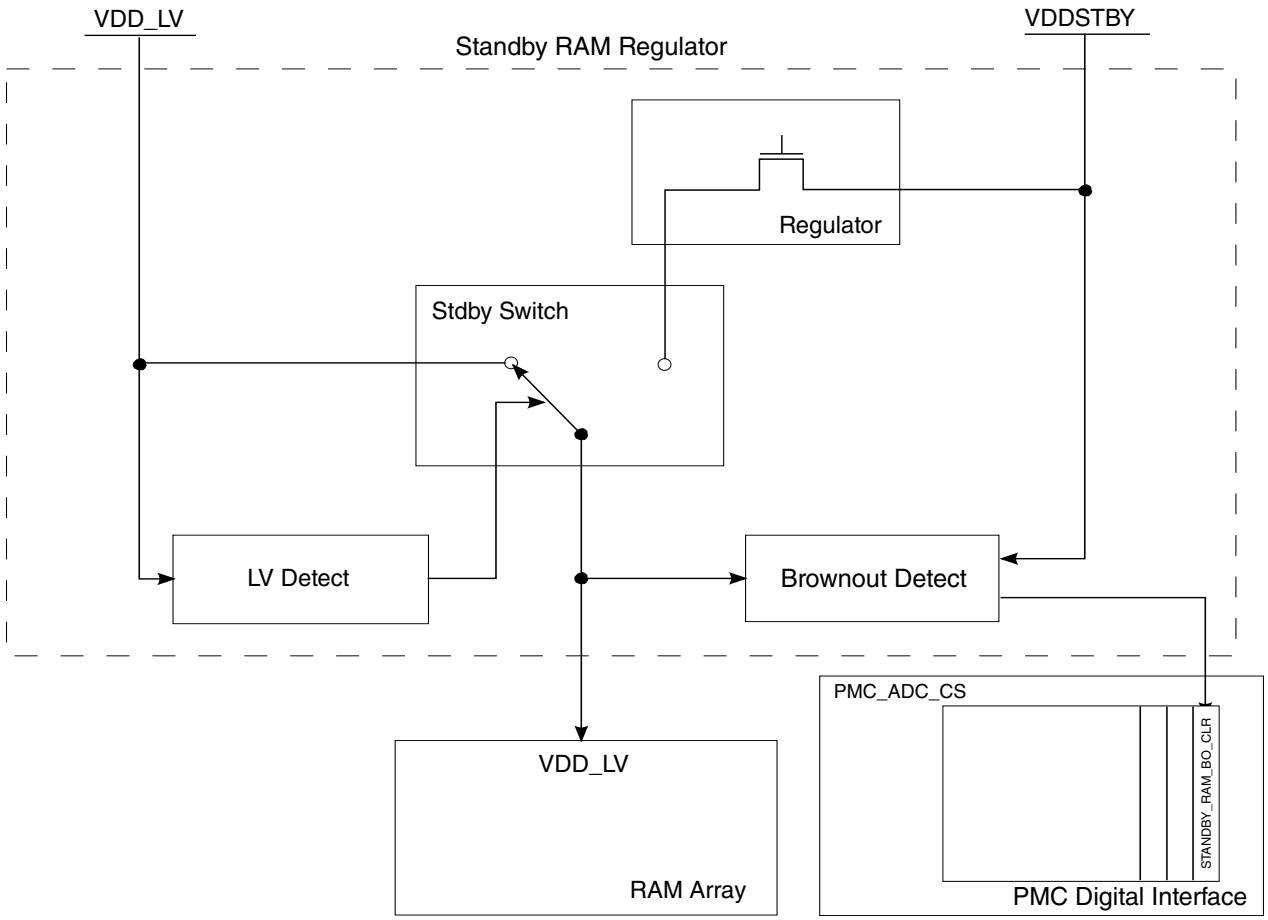

Figure 1-3. Standby RAM regulator block diagram

1.4 INTC Master Protection Register (INTC_MPROT)

The Master Protection Register is used to protect cores from writing to other cores INTC registers.

Address: 0h base + 4h offset = 4h

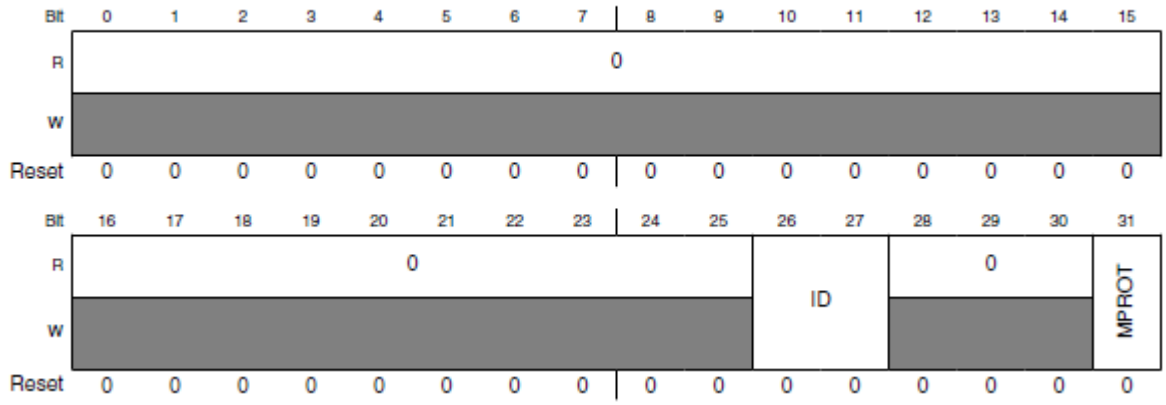

Table 1-3. INTC_MPROT field descriptions

Field	Description
0–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26-27 ID	ID. This register can only be updated if MPROT=0 or if processor master ID=ID. When MPROT is set, the ID should also be updated to indicate which master can write to any register in the INTC memory map. Only the field values related to core bus masters can be selected. Non-core bus masters cannot be selected and would result in a bus access error. 00 master0 (reset default) 01 master1 10 master2 11 master3
28-30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 MPROT	Master Protection Controls what programming space a given master can write to. If MPROT is disabled, then all masters can write to any valid entry of the INTC memory map. If MPROT is enabled, INTC_MPROT[ID] can write to any valid entry of the INTC memory map but other masters can only write to their assigned resources. Once MPROT is enabled for a master, only that master may modify INTC_MPROT. 0 Master programming space protection disabled 1 Master programming space protection enabled

1.5 Clocking

1.5.1 Clock generation

The top-level clock generation architecture is given in the following figure. All clock selectors and dividers in the figure are located and programmed in the Clock Generation Module (MC_CGM). All dividers are integer dividers (1, 2, 3, …, n) with the ranges shown in Clock generation .

NOTE

CMU_0…CMU_9, CMU_12 in Clock generation use IRCOSC for their reference clock. However, the user can select XOSC as the reference in CMU_0 for monitoring IRCOSC.

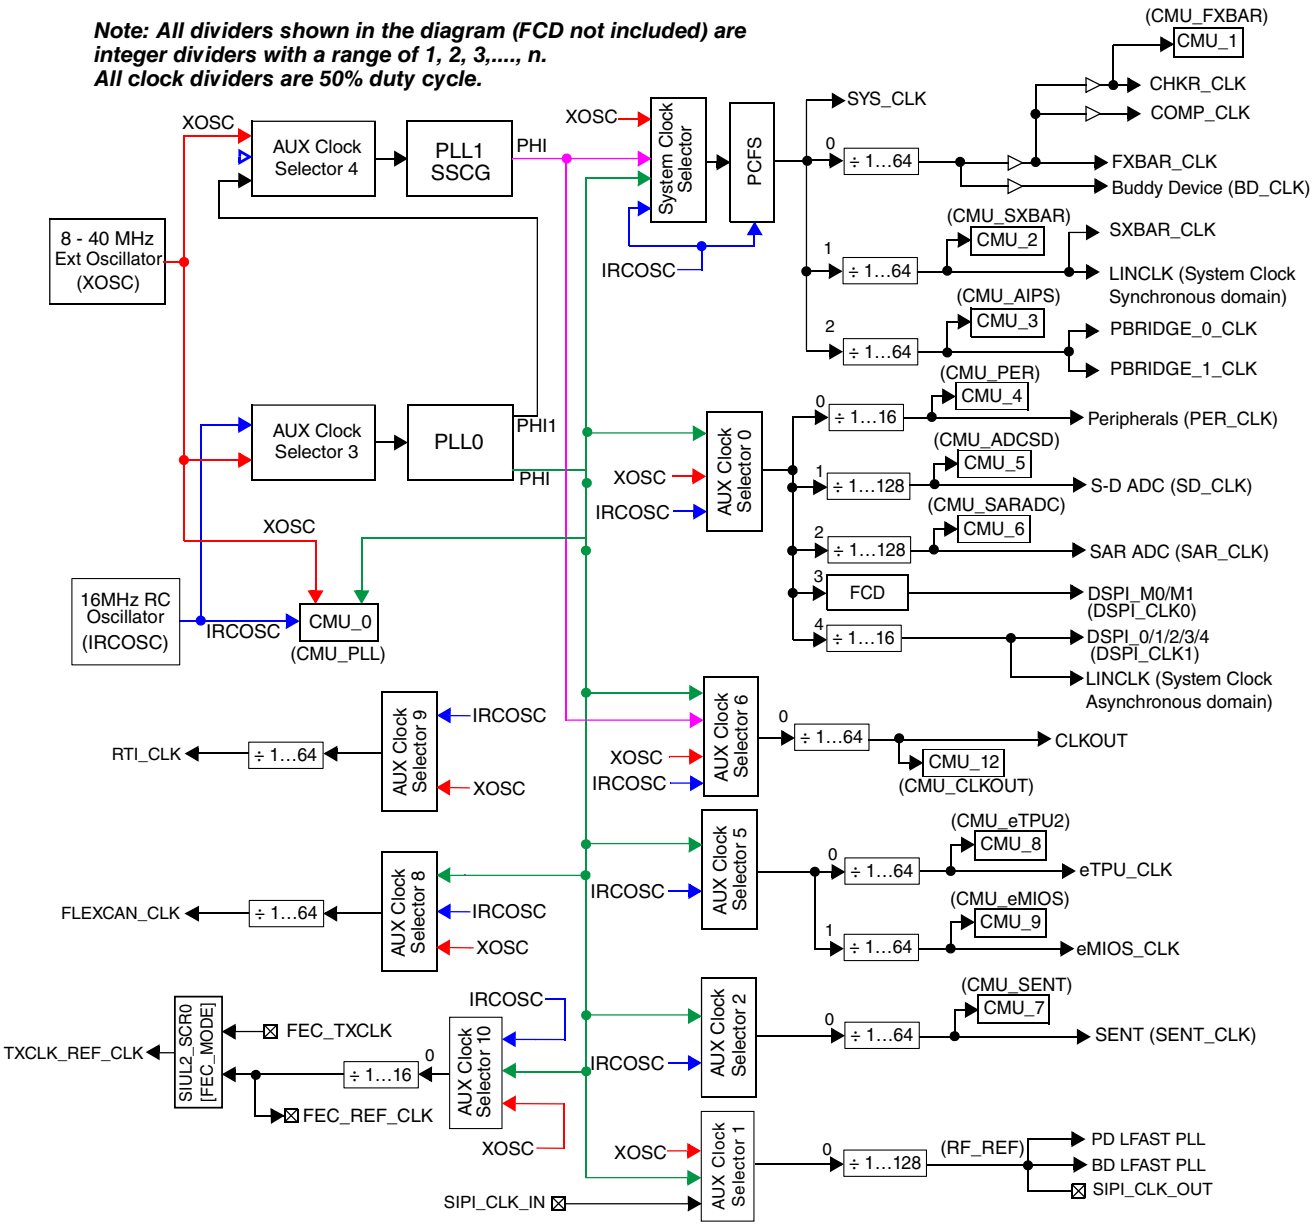

Figure 1-4. Clock generation

NOTE

Default clock source for all Auxillary Clock Selectors is the IRCOSC. User must configure MC_CGM_AC*n*_SC[SELCTL] before enabling the corresponding module functionality.

IRCOSC is the default clock for PLL1, but a PLL lock cannot be achieved using IRCOSC as the reference for PLL1.

NOTE

PBRIDGE_x_CLK may be referred to as "AIPS_CLK" elsewhere in this document.

NOTE

Do not bring out the ADC clock (XOSC + PLL0) or its component (XOSC and PLL0) on the CLKOUT pad when the ADC is in use using the same clock.

1.5.2 Peripheral Clocks

The following figure shows the clock distribution to the core and peripheral modules.

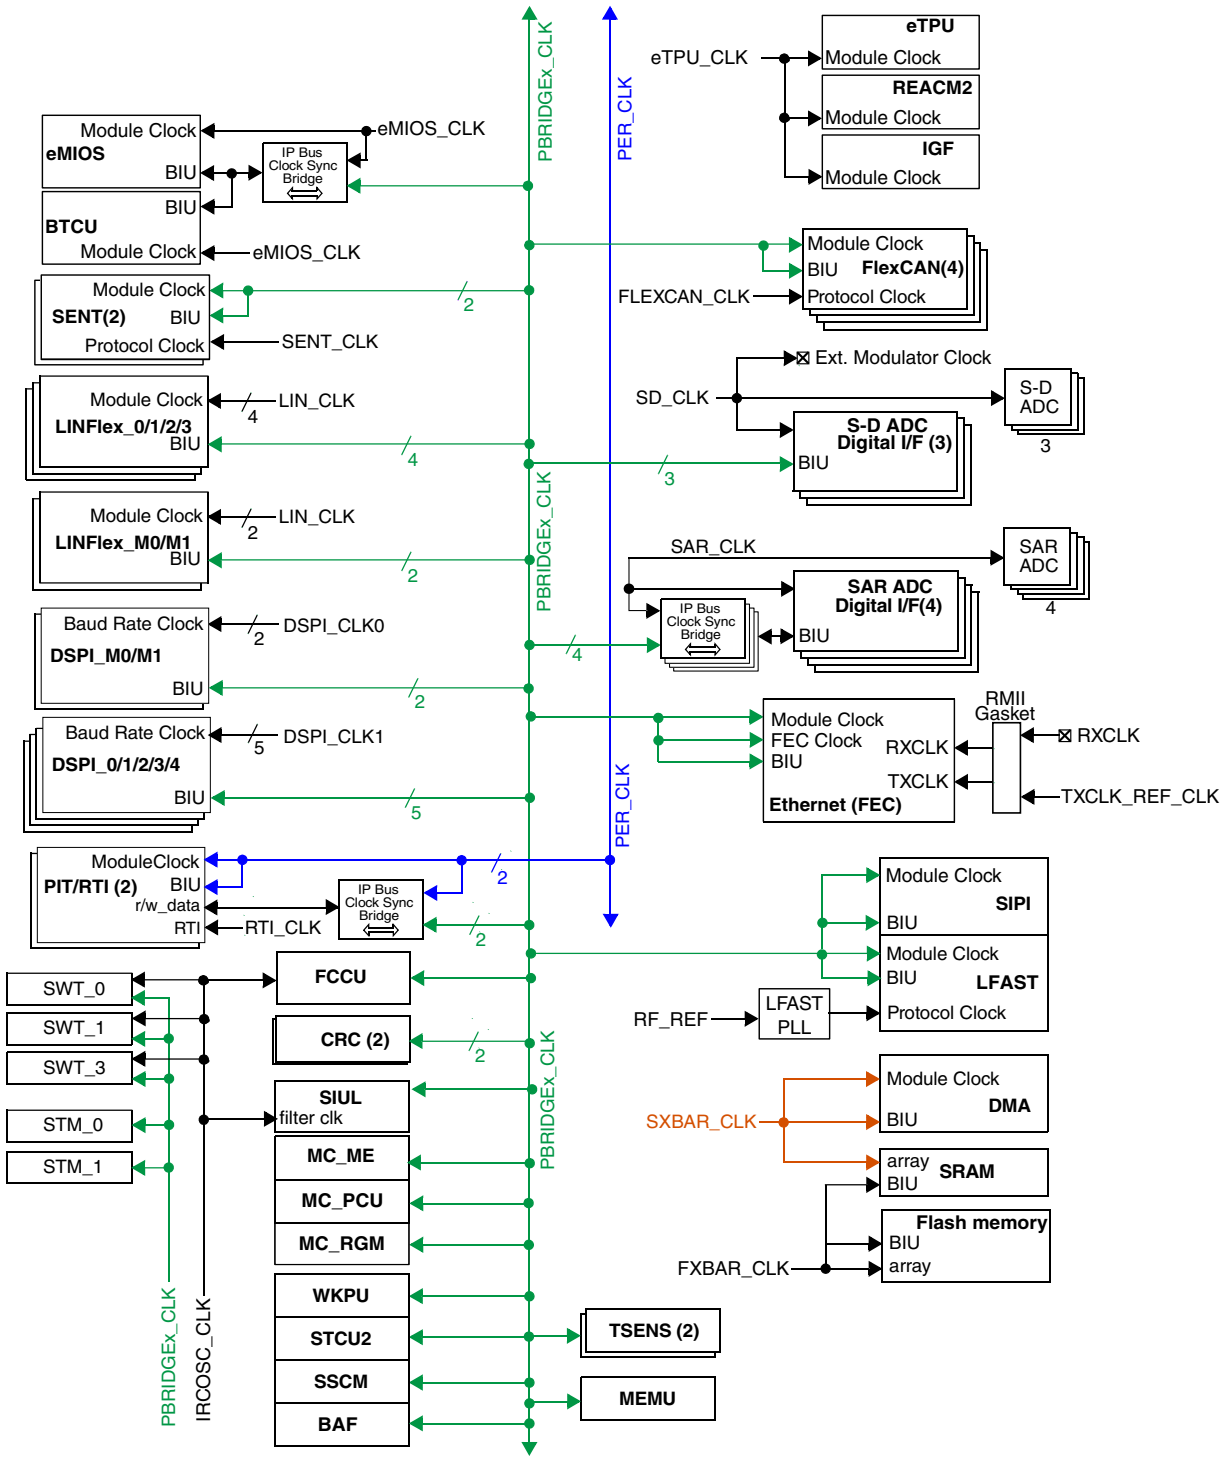

Figure 1-5. Clock distribution

1.6 CMU Control Status Register (CMU_CSR)

Address: 0h base + 0h offset = 0h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0								SFM	0						
W																
Reset	0	0	0	0	0	0	0	0	0*	0	0	0	0	0	0	0

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0						CKSEL1		0					RCDIV		CME
W																
Reset	0	0	0	0	0	0	0*	0*	0	0	0	0	0	0*	0*	0

* Notes:
- RCDIV field: Not all CMU blocks will utilize this feature. See the “Clocking” chapter for CMU implementation details.
- CKSEL1 field: Not all CMU blocks will utilize this feature. See the “Clocking” chapter for CMU implementation details.
- SFM field: Not all CMU blocks will utilize this feature. See the “Clocking” chapter for CMU implementation details.

Table 1-4. CMU_CSR field descriptions

Field	Description
0–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8 SFM	Start frequency measure. The software can only set this bit to start a clock frequency measure. It is reset by hardware when the measure is ready in the CMU_FDR. **Note**: MSR[MD] must be written before enabling frequency measurement (CSR[SFM] = 1). Do not write MDR[MD] while CSR[SFM] = 1. 0 Frequency measurement is completed or not yet started 1 Frequency measurement is not completed
9–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22–23 CKSEL1	Frequency measure clock selection bit. CKSEL1 selects the clock to be measured by the frequency meter. This only affects CMU instances that utilizes clock metering. Not all CMU blocks will utilize this feature. See the “Clocking” chapter for device specific CMU implementation details. 00 CLKMT0_RMN is selected 01 Reserved 10 Reserved 11 CLKMT0_RMN is selected
24–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29–30 RCDIV	These bits specify the CLKMT0_RMN division factor. The output clock frequency is $f_{CLKMT0_RMN} \div 2^{CMU_CSR[RCDIV]}$. This output clock is used as reference clock to compare with CLKMN0_RMT for crystal clock monitor feature. **NOTE**: Ensure clock source for CLKMN0_RMT is off before writing CMU_CSR[RCDIV]. 00 CLKMT0_RMN ÷ 1 (No division) 01 CLKMT0_RMN ÷ 2 10 CLKMT0_RMN ÷ 4

Table continues on the next page...

Table 1-4. CMU_CSR field descriptions (continued)

Field	Description
	11 CLKMT0_RMN ÷ 8
31 CME	CLKMN1 monitor enable. 0 CLKMN1 monitor is disabled 1 CLKMN1 monitor is enabled

1.7 Aux Clock 0 Divider Configuration 4 (MC_CGM_AC0_DC4)

This register controls auxilliary clock 0 divider 4.

NOTE

Byte and half-word write accesses are not allowed for this register. Such an access will not result in an exception, however the value will not be loaded with the new value.

Address: 0h base + 118h offset = 118h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	DE	0											DIV			
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 1-5. MC_CGM_AC0_DC4 field descriptions

Field	Description
0 DE	Divider reserved Enable 0 Disable auxiliary clock 0 divider reserved 1 Enable auxiliary clock 0 divider reserved
1–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12–15 DIV	Divider reserved Division Value - For DSPI not supporting MSC. Divider range between 1 to 16. The divided DSPI 1 clock output will be generated such that it will have a period 'DIV + 1' times that of the auxiliary clock 0. If DE is set to '0' (divider reserved is disabled), any write access to the DIV field is ignored
16–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

1.8 Software Watchdog Timer (SWT)

1.8.1 Features

The SWT has the following features:

- 32-bit time-out register to set the time-out period
- Programmable selection of window mode or regular servicing
- Programmable selection of reset request or interrupt on an initial time-out
- Programmable selection of the servicing mode
- Master access protection
- Hard and soft configuration lock bits
- Reset configuration inputs allow timer to be enabled out of reset

1.8.2 SWT Control Register (SWT_CR)

Address: 0h base + 0h offset = 0h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	MAP0	MAP1	MAP2	MAP3	MAP4	MAP5	MAP6	MAP7	0

Table 1-6. SWT_CR field description

Field	Description
0	Master Access Protection for Master 0.
MAP0	The number of this field corresponds to the logical ID of the bus master. The platform bus master assignments are device specific. For the masters with the logical IDs to which the MAPn fields correspond, see the chip-specific information for the Crossbar Switch.

Table continues on the next page...

Table 1-6. SWT_CR field description (continued)

Field	Description
	0 Access for the master is not enabled 1 Access for the master is enabled
1 MAP1	Master Access Protection for Master 1. The platform bus master assignments are device specific. For the masters with the logical IDs to which the MAPn fields correspond, see the chip-specific information for the Crossbar Switch. 0 Access for the master is not enabled 1 Access for the master is enabled
2 MAP2	Master Access Protection for Master 2. The number of this field corresponds to the logical ID of the bus master. The platform bus master assignments are device specific. For the masters with the logical IDs to which the MAPn fields correspond, see the chip-specific information for the Crossbar Switch. 0 Access for the master is not enabled 1 Access for the master is enabled
3 MAP3	Master Access Protection for Master 3. The number of this field corresponds to the logical ID of the bus master. The platform bus master assignments are device specific. For the masters with the logical IDs to which the MAPn fields correspond, see the chip-specific information for the Crossbar Switch. 0 Access for the master is not enabled 1 Access for the master is enabled
4 MAP4	Master Access Protection for Master 4. The number of this field corresponds to the logical ID of the bus master. The platform bus master assignments are device specific. For the masters with the logical IDs to which the MAPn fields correspond, see the chip-specific information for the Crossbar Switch. 0 Access for the master is not enabled 1 Access for the master is enabled
5 MAP5	Master Access Protection for Master 5. The number of this field corresponds to the logical ID of the bus master. The platform bus master assignments are device specific. For the masters with the logical IDs to which the MAPn fields correspond, see the chip-specific information for the Crossbar Switch. 0 Access for the master is not enabled 1 Access for the master is enabled
6 MAP6	Master Access Protection for Master 6. The number of this field corresponds to the logical ID of the bus master. The platform bus master assignments are device specific. For the masters with the logical IDs to which the MAPn fields correspond, see the chip-specific information for the Crossbar Switch. 0 Access for the master is not enabled 1 Access for the master is enabled
7 MAP7	Master Access Protection for Master 7. The number of this field corresponds to the logical ID of the bus master. The platform bus master assignments are device specific. Not all MAPn fields are implemented. See the device configuration section for master ports that are implemented on the crossbar switch. 0 Access for the master is not enabled

Table continues on the next page...

Table 1-6. SWT_CR field description (continued)

Field	Description
	1 Access for the master is enabled
8–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21–22 SMD	Service Mode 00 Fixed Service Sequence: The watchdog is serviced by writing the fixed sequence 0xA602, 0xB480 to SWT_SR. 01 Keyed Service Sequence: The watchdog is serviced by writing two pseudorandom key values to SWT_SR. 10 Reserved—do not use. Writing a value can cause the SWT not to be serviced. 11 Reserved—do not use. Writing this value can cause the SWT not to be serviced.
23 RIA	Reset on Invalid Access **NOTE**: For a description of how this chip implements SWT reset requests resulting from SWT invalid accesses, see the chip-specific SWT information. 0 Invalid access to the SWT generates a bus error 1 Invalid access to the SWT causes a reset request if WEN is 1
24 WND	Window Mode 0 Regular mode: service sequence can be done at any time 1 Windowed mode: service sequence is valid only when the down counter is less than the value in the SWT_WN register
25 ITR	Interrupt Then Reset Request **NOTE**: For a description of how this chip implements SWT reset requests and interrupt requests resulting from SWT time-outs, see the chip-specific SWT information. 0 Generate a reset request on a time-out 1 Generate an interrupt on an initial time-out; generate a reset request on a second consecutive timeout
26 HLK	Hard Lock This bit is cleared only at reset. 0 SWT_CR, SWT_TO, SWT_WN and SWT_SK are read/write registers if SLK is 0 1 SWT_CR, SWT_TO, SWT_WN and SWT_SK are read-only registers
27 SLK	Soft Lock This bit is cleared by writing the unlock sequence to the service register. 0 SWT_CR, SWT_TO, SWT_WN and SWT_SK are read/write registers if HLK is 0 1 SWT_CR, SWT_TO, SWT_WN and SWT_SK are read-only registers
28 Reserved	Reserved This field is reserved.
29 STP	Stop Mode Control Allows the watchdog timer to be stopped when the device enters stop mode. 0 SWT counter continues to run in stop mode 1 SWT counter is stopped in stop mode
30	Debug Mode Control

Table continues on the next page...

Table 1-6. SWT_CR field description (continued)

Field	Description
FRZ	Allows the watchdog timer to be stopped when the device enters debug mode. 0 SWT counter continues to run in debug mode 1 SWT counter is stopped in debug mode
31 WEN	Watchdog Enabled 0 SWT is disabled 1 SWT is enabled

1.8.3 Time-out

The SWT_CR[ITR] bit controls the SWT's action taken when a time-out occurs.

- If the SWT_CR[ITR] bit is 0, the SWT generates a reset request immediately on any time-out.
- If the SWT_CR[ITR] bit is 1, an initial time-out causes the SWT to generate an interrupt and load the down counter with the time-out period.
  - The interrupt is indicated by the Time-out Interrupt Flag (SWT_IR[TIF]).
  - Clear the interrupt by writing 1 to SWT_IR[TIF].

  If the service sequence is not written before the second consecutive time-out, the SWT generates a reset request.

1.9 Enhanced Modular IO Subsystem (eMIOS200)

1.9.1 Modes of operation

The Unified Channels can be configured to operate in the following modes:

- General-Purpose Input/Output (GPIO)
- Single-Action Input Capture (SAIC)
- Single-Action Output Compare (SAOC)
- Input Pulse-Width Measurement (IPWM)

- Input Period Measurement (IPM)
- Double-Action Output Compare (DAOC)
- Pulse/Edge Accumulation (PEA)
- Pulse/Edge Counting (PEC)
- Windowed Programmable Time Accumulation (WPTA)
- Modulus Counter (MC)
- Modulus Counter Buffered (MCB)
- Output Pulse-Width and Frequency Modulation (OPWFM)
- Output Pulse-Width and Frequency Modulation Buffered (OPWFMB)
- Center Aligned Output Pulse Width Modulation with Dead Time Insertion (OPWMC)
- Center Aligned Output Pulse Width Modulation with Dead Time Insertion Buffered (OPWMCB)
- Output Pulse-Width Modulation (OPWM)
- Output Pulse-Width Modulation Buffered (OPWMB)
- Output Pulse-Width Modulation with Trigger (OPWMT)

These modes are described in Unified Channel modes of operation.

Each channel can have a specific set of modes.

1.9.2 eMIOS UC B register n (eMIOS_Bn)

Depending on the mode of operation, internal registers B1[0:23] or B2[0:23] can be assigned to address EMIOS_Bn. Both B1 and B2 are cleared by reset. The table below summarizes the EMIOS_Bn writing and reading accesses for all operation modes. Values not listed are reserved. For more information see the “UC Modes of Operation” section.

Depending on the channel configuration, it may have an EMIOS_B register or not. EMIOS_B register is required for the following modes: DAOC, IPM, IPWM, OPWM, OPWMB, OPWFM, OPWMT, OPWFMB, OPWMC, OPWMCB, MC, MCB, PEA, PEC, WPTA.

The following table summarizes the EMIOS_An, EMIOS_Bn, and EMIOS_ALTAn writing and reading accesses for all operation modes. Values not listed are reserved. For more information, see the “UC Modes of Operation” section.

Table 1-7. EMIOS_An, EMIOS_Bn and EMIOS_ALTAn values assignment

Operation mode	Register access					
	Write	Read	Write	Read	Alt write	Alt read
GPIO	A1, A2	A1	B1, B2	B1	A2	A2
SAIC[1]	–	A2	B2	B2	–	–
SAOC[1]	A2	A1	B2	B2	–	–
IPWM	–	A2	–	B1	–	–
IPM	–	A2	–	B1	–	–
DAOC	A2	A1	B2	B1	–	–
PEA	A1	A2	–	B1	–	–
PEC[1]	A1	A1	B1	B1	–	A2
WPTA	A1	A1	B1	B1	–	A2
MC[1]	A2	A1	B2	B2	–	–
OPWFM	A2	A1	B2	B1	–	–
OPWMC	A2	A1	B2	B1	–	–
OPWM	A2	A1	B2	B1	–	–
OPWMT	A2	A1	B2	B1	A2	A2
MCB[1]	A2	A1	B2	B1	–	–
OPWFMB	A2	A1	B2	B1	–	–
OPWMCB	A2	A1	B2	B1	–	–
OPWMB	A2	A1	B2	B1	–	–

1. In these modes, the register EMIOS_Bn is not used, but B2 can be accessed.

1.9.3 eMIOS CNT register n (eMIOS_CNTn)

When GPIO mode is selected or the channel is frozen, the EMIOS_CNTn register is read/write. For all others modes, the EMIOS_CNTn is a read-only register. When entering some operation modes, this register is automatically cleared (refer to the “UC Modes of Operation” section for details).

EMIOS_CNTn register is required for the following modes:

- OPWFM
- OPWFMB
- OPWMC
- OPWMCB

- PEA
- PEC
- WPTA
- MC
- MCB

For other modes, the internal counter is not used. Therefore, depending on the modes available in a channel, the internal counter may be absent.

1.9.4 eMIOS UC Control register n (eMIOS_Cn)

The UC Control register gathers several read/write control bits affecting the UC operation conditions.

NOTE

This register does not include a FORCMB bit for Channel Types A and C.

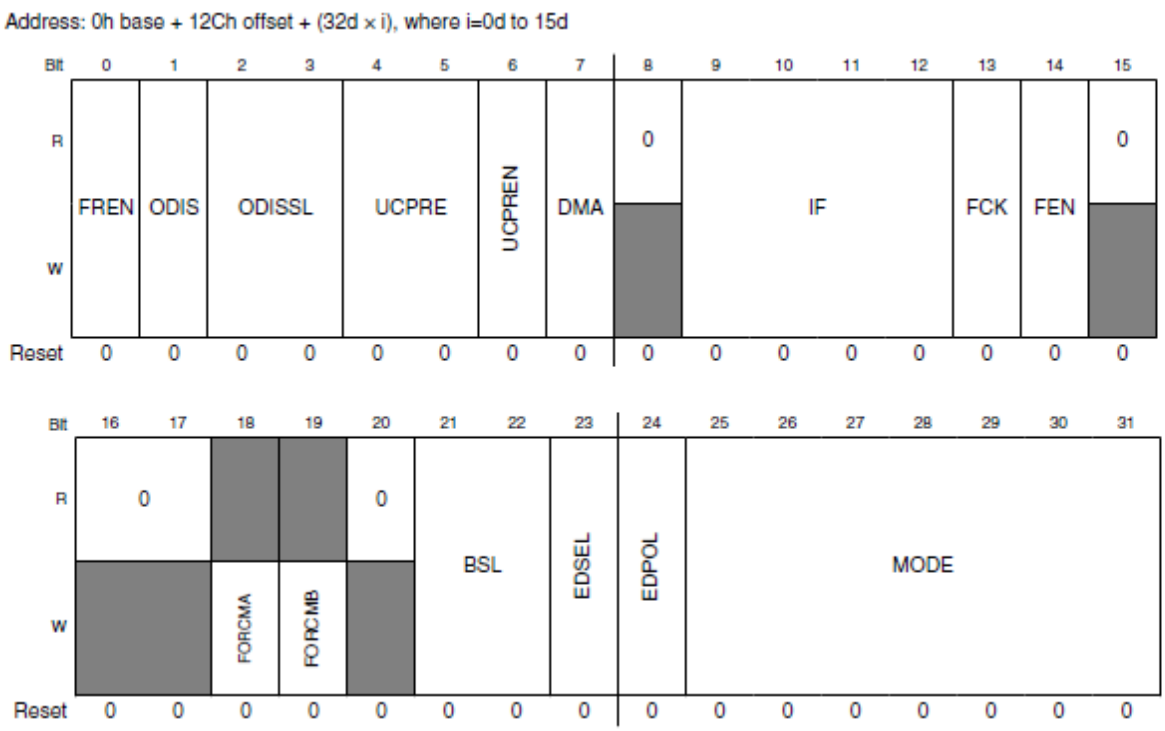

Table 1-8. eMIOS_Cn field descriptions

Field	Description
0 FREN	Freeze Enable bit.

Table continues on the next page...

Table 1-8. eMIOS_Cn field descriptions (continued)

Field	Description
	The FREN bit, if set and validated by FRZ bit in EMIOS_MCR register allows the channel to enter freeze state, freezing all registers values when in debug mode and allowing the MCU to perform debug functions. 0 Normal operation 1 Freeze UC registers values
1 ODIS	Output Disable bit. The ODIS bit allows disabling the output pin when running any of the output modes with the exception of GPIO mode. 0 The output pin operates normally 1 If the selected Output Disable Input signal is asserted, the output pin goes to EDPOL for OPWFMB and OPWMB modes and to the complement of EDPOL for other output modes, but the Unified Channel continues to operate normally, i.e., it continues to produce FLAG and matches. When the selected Output Disable Input signal is negated, the output pin operates normally.
2-3 ODISSL	Output Disable select bits. The ODISSL[0:1] bits select one of the four output disable input signals, as shown in the following table. **Table 1-9. UC ODISSL selection** ODISSL[0:1] / input signal 00 / Output Disable Input 0 01 / Output Disable Input 1 10 / Output Disable Input 2 11 / Output Disable Input 3 1. Filter latency (the difference in time between the input and the response) is 3 clock edges. 2. The input signal is synchronized before arriving to the digital filter. 3. Not all devices support all counter buses. See the Device Configuration chapter for details. 4. Not all modes of operation are supported. See the configuration information for details. 5. b = adjust parameters for the mode of operation. Refer to “UC Modes of Operation” section for details.
4-5 ACKE3	Prescaler bits. The UCPRE[0:1] bits select the clock divider value for the internal prescaler of Unified Channel, as shown in the following table. **Table 1-10. UC Internal Prescaler clock divider** UCPRE[0:1] / Divide ratio 00 / 1 01 / 2 10 / 3 11 / 4 1. Filter latency (the difference in time between the input and the response) is 3 clock edges. 2. The input signal is synchronized before arriving to the digital filter. 3. Not all devices support all counter buses. See the Device Configuration chapter for details. 4. Not all modes of operation are supported. See the configuration information for details. 5. b = adjust parameters for the mode of operation. Refer to “UC Modes of Operation” section for details.
6	Prescaler Enable bit.

Table continues on the next page...

Table 1-8. eMIOS_Cn field descriptions (continued)

Field	Description
UCPREN	The UCPREN bit enables the prescaler counter. 0 Prescaler disabled (no clock) 1 Prescaler enabled
7 DMA	Direct Memory Access bit. The DMA bit selects if FLAG generation will be used as an interrupt or as a DMA request. 0 Flag/overrun assigned to Interrupt request. 1 Flag/overrun assigned to DMA request.
8 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
9-12 IF	Input Filter bits. The IF[0:3] bits control the programmable input filter, selecting the minimum input pulse width that can pass through the filter, as shown in the following table. For output modes, these bits have no meaning. **Table 1-11. UC Input Filter bits** IF[0:3] / Minimum input Pulse width [filter clock periods] 0000 / bypassed 0001 / 02 0010 / 04 0100 / 08 1000 / 16 All others / Reserved 1. Filter latency (the difference in time between the input and the response) is 3 clock edges. 2. The input signal is synchronized before arriving to the digital filter. 3. Not all devices support all counter buses. See the Device Configuration chapter for details. 4. Not all modes of operation are supported. See the configuration information for details. 5. b = adjust parameters for the mode of operation. Refer to “UC Modes of Operation” section for details.
13 FCK	Filter Clock select bit. The FCK bit selects the clock source for the programmable input filter. 0 Prescaled clock 1 eMIOS module clock
14 FEN	FLAG Enable bit. The FEN bit allows the Unified Channel FLAG bit to generate an interrupt signal or a DMA request signal (the type of signal to be generated is defined by the DMA bit). 0 Disable (FLAG does not generate an interrupt request) 1 Enable (FLAG generates an interrupt request)
15–17 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
18	Force Match A bit.

Table continues on the next page...

Table 1-8. eMIOS_Cn field descriptions (continued)

Field	Description
FORCMA	For output modes, the FORCMA bit is equivalent to a successful comparison on comparator A (except that the FLAG bit is not set). This bit is cleared by reset and is always read as zero. This bit is valid for every output operation mode which uses comparator A, otherwise it has no effect. For input modes, the FORCMA bit is not used and writing to it has no effect. 0 Has no effect. 1 Force a match at comparator A
19 FORCMB	Force Match B bit. For output modes, the FORCMB bit is equivalent to a successful comparison on comparator B (except that the FLAG bit is not set). This bit is cleared by reset and is always read as zero. This bit is valid for every output operation mode which uses comparator B, otherwise it has no effect. 0 Has not effect 1 Force a match at comparator B
20 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
21–22 BSL	Bus Select bits. The BSL[0:1] bits are used to select either one of the counter buses or the internal counter to be used by the Unified Channel , as shown in the following tables.

Table 1-12. UC BSL bits

BSL[0:1]	Selected bus
00	All channels: counter bus[A]
01	Channels 0 to 7: counter bus[B]
	Channels 8 to 15: counter bus[C]
	Channels 16 to 23: counter bus[D]
	Channels 24 to 31: counter bus[E]
10	Reserved
11	All channels: internal counter

1. Filter latency (the difference in time between the input and the response) is 3 clock edges.
2. The input signal is synchronized before arriving to the digital filter.
3. Not all devices support all counter buses. See the Device Configuration chapter for details.
4. Not all modes of operation are supported. See the configuration information for details.
5. b = adjust parameters for the mode of operation. Refer to “UC Modes of Operation” section for details.

23 EDSEL	Edge Selection bit. For input modes, the EDSEL bit selects whether the internal counter is triggered by both edges of a pulse or just by a single edge as defined by the EDPOL bit . When not shown in the mode of operation description, this bit has no effect. 0 – Single edge triggering defined by the EDPOL bit 1 – Both edges triggering{mts_ipi_slv_saic} For GPIO in mode, the EDSEL bit selects if a FLAG can be generated. 0 – A FLAG is generated as defined by the EDPOL bit

Table continues on the next page...

Table 1-8. eMIOS_Cn field descriptions (continued)

Field	Description
	1 – No FLAG is generated For SAOC mode, the EDSEL bit selects the behavior of the output flip-flop at each match. 0 – The EDPOL value is transferred to the output flip-flop 1 – The output flip-flop is toggled
24 EDPOL	Edge Polarity bit. For input modes, the EDPOL bit asserts which edge triggers either the internal counter or an input capture or a FLAG . When not shown in the mode of operation description, this bit has no effect. 0 – Trigger on a falling edge 1 – Trigger on a rising edge For output modes, the EDPOL bit is used to select the logic level on the output pin . 0 – A match on comparator A clears the output flip-flop, while a match on comparator B sets it 1 – A match on comparator A sets the output flip-flop, while a match on comparator B clears it
25-31 MODE	Mode selection bits. The MODE bits select the mode of operation of the Unified Channel, as shown in the following table. Values not listed are reserved. **NOTE**: If a reserved value is written to the mode bit field, the results are unpredictable.

Table 1-13. UC MODE bits

MODE[0:6]	Mode of operation
0000000	General purpose Input/Output mode (input)
0000001	General purpose Input/Output mode (output)
0000010	Single Action Input Capture
0000011	Single Action Output Compare
0000100	Input Pulse Width Measurement
0000101	Input Period Measurement
0000110	Double Action Output compare (with FLAG set on B match)
0000111	Double Action Output compare (with FLAG set on both match)
0001000	Pulse/Edge Accumulation (continuous)
0001001	Pulse/Edge Accumulation (single shot)
0001010	Pulse/Edge Counting (continuous)
0001011	Pulse/Edge Counting (single shot)
0001110	Windowed Programmable Time Accumulation
0001111	Reserved
001000b[-1]	Modulus Counter (Up counter with clear on match start)
001001b	Modulus Counter (Up counter with clear on match end)
00101bb[-1]	Modulus Counter (Up/Down counter)
00110b0[-1]	Output Pulse Width and Frequency Modulation (immediate update)
00110b1[-1]	Output Pulse Width and Frequency Modulation (next period update)

Table 1-8. eMIOS_Cn field descriptions

Field	Description
	Table 1-13. UC MODE bits (continued)

MODE[0:6]	Mode of operation
00111b0[-1]	Center Aligned Output Pulse Width Modulation (with trail edge dead-time)
00111b1[-1]	Center Aligned Output Pulse Width Modulation (with lead edge dead-time)
01000b0[-1]	Output Pulse Width Modulation (immediate update)
01000b1[-1]	Output Pulse Width Modulation (next period update)
0100100 through 0100101	Reserved
0100110	Output Pulse Width Modulation with Trigger
0100111 through 1001111	Reserved
101000b[-1]	Modulus Counter Buffered (Up counter)
101001b[-1]	Reserved
10101bb[-1]	Modulus Counter Buffered (Up/Down counter)
10110b0[-1]	Output Pulse Width and Frequency Modulation Buffered
10110b1[-1]	Reserved
10111b0[-1]	Center Aligned Output Pulse Width Modulation Buffered (with trail edge dead-time)
10111b1[-1]	Center Aligned Output Pulse Width Modulation Buffered (with lead edge dead-time)
11000b0[-1]	Output Pulse Width Modulation Buffered
1100001 through 1111111	Reserved

1. Filter latency (the difference in time between the input and the response) is 3 clock edges.
2. The input signal is synchronized before arriving to the digital filter.
3. Not all devices support all counter buses. See the Device Configuration chapter for details.
4. Not all modes of operation are supported. See the configuration information for details.
5. b = adjust parameters for the mode of operation. Refer to “UC Modes of Operation” section for details.

1.10 FEC interface selection

On this chip, the FEC interface depends on the settings of the RCR (in the FEC) and SIUL2_SCR0 (in the SIUL2), as shown in the following table.

Table 1-14. FEC interface selection

RCR[MII_MODE]	SIUL2_SCR0[FEC_MODE]	Interface used by the FEC
0	0 or 1	7-wire
1	0	RMII
	1	MII-Lite[1]

1. MII-Lite supported only on BGA packages. Full MII is not supported on this chip.

NOTE

It is required to setup the system clocks recommended in System clock frequency limitations before FEC is operational.

1.11 SENT Receiver (SRX)

1.11.1 Channel 'n' Configuration Register (n=0 to (CH-1)) (SRX_CHn_CONFIG)

This register (CHn_CONFIG) provides the configurability for interrupt assertion for various events and error as explained in Channel 'n' Status Register (n=0 to (CH-1)) (SRX_CHn_STATUS) and control bits for selection of various receive options that might be required by the user software. This register also configures the width of noise glitches (on the sensor input) to be filtered out by the input programmable filter.

User must program the contents of this register before enabling the channel by writing to the corresponding channel enable bit in the Channel Enable Register (SRX_CHNL_EN).

Address: 0h base + 68h offset + (16d × i), where i=0d to 1d

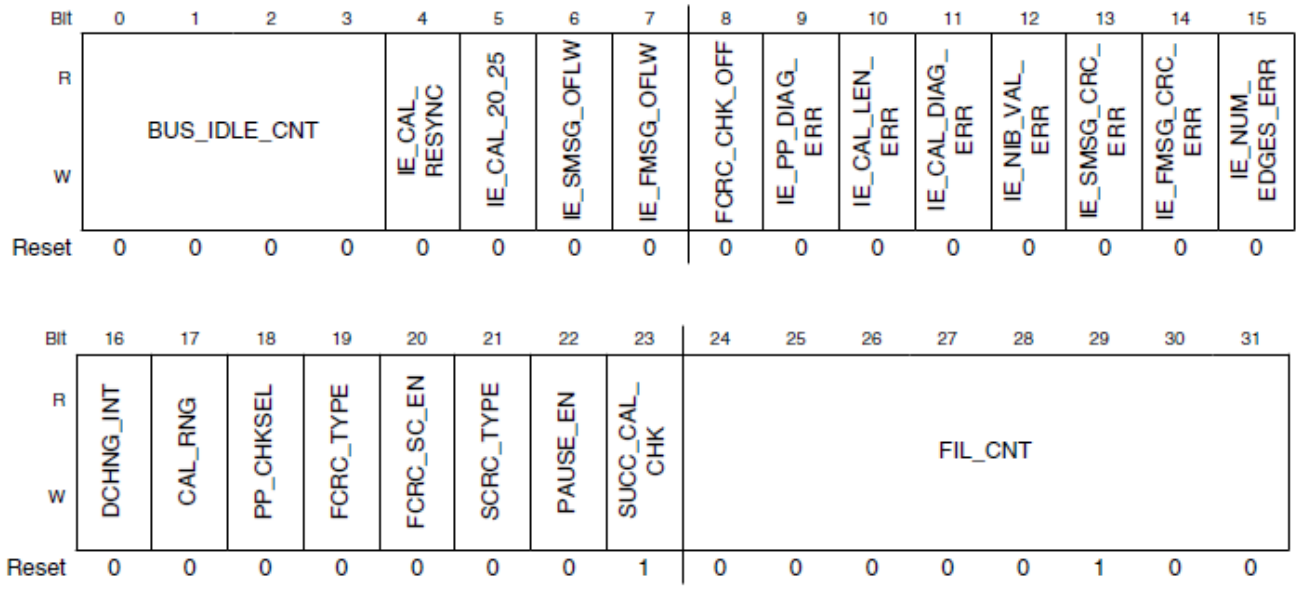

Table 1-15. SRX_CHn_CONFIG field descriptions

Field	Description
0–3 BUS_IDLE_CNT	Bus Idle Count. This register value defines the maximum allowable idle period on the sensor interface of this channel. The value is defined as follows: 0000 Disabled. 0001 127*2 Receiver Clock Tick Counts 0010 127*4 Receiver Clock Tick Counts 0100 127*8 Receiver Clock Tick Counts 1000 127*16 Receiver Clock Tick Counts
4 IE_CAL_ RESYNC	Successive Calibration Check Resynchronized Interrupt Enable: This bit enables interrupt assertion when Successive Calibration diagnosis has failed three times in case of "Option 2" being selected for Successive Calibration Check Method and the check resynchronizes the take the third message to be correct. 0 Interrupt is disabled 1 Interrupt is enabled
5 IE_CAL_20_25	Calibration Variation 20 - 25% Interrupt Enable. This bit enables interrupt assertion when corresponding status bit is set. 0 Interrupt is disabled 1 Interrupt is enabled
6 IE_SMSG_OFLW	Slow Serial Message Overflow Interrupt Enable. This bit enables interrupt assertion when overflow occurs on reception of Slow Serial Messages in corresponding channel 0 Interrupt is disabled 1 Interrupt is enabled

Table continues on the next page...

Table 1-15. SRX_CHn_CONFIG field descriptions (continued)

Field	Description
7 IE_FMSG_OFLW	Fast Message Overflow Interrupt Enable. This bit enables interrupt assertion when overflow occurs on reception of Fast Messages in corresponding channel. 0 Interrupt is disabled 1 Interrupt is enabled
8 FCRC_CHK_ OFF	Fast Message CRC Check Off: This bit can be used to switch off CRC check in Fast Message 0 Check is enabled 1 Check is disabled/off
9 IE_PP_DIAG_ ERR	Ratio of calibration pulse length to message length varies by more than ±1.5625% between two frames. Valid for messages with pause pulse. This bit enables interrupt assertion when its respective diagnostic check fails on the corresponding channel. 0 Interrupt is disabled 1 Interrupt is enabled
10 IE_CAL_LEN_ ERR	Calibration pulse is wider than 56 ticks ±25%. This bit enables interrupt assertion when its respective diagnostic check fails on the corresponding channel. 0 Interrupt is disabled 1 Interrupt is enabled
11 IE_CAL_DIAG_ ERR	Successive Calibration pulses differ by more than ±1.56%. SAE spec defines it be 1.5625% but the accuracy of this check depends on the protocol clock. For instance for 62.5 MHz, this check will fail for 1.56% and passes for 1.55%. This bit enables interrupt assertion when its respective diagnostic check fails on the corresponding channel. 0 Interrupt is disabled 1 Interrupt is enabled
12 IE_NIB_VAL_ ERR	Any nibble data value <0 or >15. This bit enables interrupt assertion when its respective diagnostic check fails on the corresponding channel. 0 Interrupt is disabled 1 Interrupt is enabled
13 IE_SMSG_CRC_ ERR	Checksum error in Slow Serial Message. This bit enables interrupt assertion when its respective diagnostic check fails on the corresponding channel. 0 Interrupt is disabled 1 Interrupt is enabled
14 IE_FMSG_CRC_ ERR	Checksum error in Fast Message. This bit enables interrupt assertion when its respective diagnostic check fails on the corresponding channel. 0 Interrupt is disabled 1 Interrupt is enabled
15 IE_NUM_ EDGES_ERR	Checksum error in Fast Message. This bit enables interrupt assertion when its respective diagnostic check fails on the corresponding channel. 0 Interrupt is disabled 1 Interrupt is enabled
16 DCHNG_INT	Enable for Interrupt on Reception of Fast Message with Changed Data: This bit is used to enable storing and generating corresponding DMA or Message Ready Interrupt Request for Fast Message only when any of the data nibbles after different from previously received Fast Message on that

Table continues on the next page...

Table 1-15. SRX_CHn_CONFIG field descriptions (continued)

Field	Description
	channel. If a new Fast Message is received that has same values for all data nibbles as that of previous message then the current message will be discarded and will not be stored in the buffer, and neither Fast Message Ready Interrupt nor DMA request will be generated. 0 All Fast Messages will be received even if data nibbles are same 1 Only Fast Messages with differing values of data nibbles will be received
17 CAL_RNG	Valid Calibration Pulse Range Selection: This bit is used to control whether 20% variation or 25% variation in Calibration Pulse will be tolerated when detecting a Calibration Pulse 0 20% variation is acceptable 1 25% variation is acceptable
18 PP_CHKSEL	Pause Pulse Diagnostic Check Selection: This bit controls which diagnostic checks to run when messages are enabled to be received with pause pulses. 0 Both Successive Calibration Pulse Check and Pause Pulse Diagnostic are run 1 Only Pause Pulse Diagnostic is run. Successive Calibration Pulse Check is disabled.
19 FCRC_TYPE	Fast Message CRC Type. This indicates the type of CRC method to be used for CRC Diagnostic Check on the received fast messages 0 Recommended implementation (additional 0 data nibble XORed with the rest of the nibbles) 1 Legacy implementation (no additional 0 data nibble is XORed)
20 FCRC_SC_EN	Fast Message CRC Status and Communication Nibble Enable. This bit enables the inclusion of Status and Communication Nibble when CRC is calculated for Fast Messages. 0 Status and Communication Nibble not included in CRC calculation 1 Status and Communication Nibble is included in CRC calculation
21 SCRC_TYPE	Slow Serial Message CRC Type. This indicates the type of CRC method to be used for CRC Diagnostic Check on the received slow serial messages. 0 Recommended implementation (additional 0 data nibble XORed with the rest of the nibbles) 1 Legacy implementation (no additional 0 data nibble XORed)
22 PAUSE_EN	Pause Pulse Enable. Enables the channel receiver to detect a pause pulse. 0 Detection of Pause Pulse is disabled 1 Detection of Pause Pulse enabled
23 SUCC_CAL_ CHK	Successive Calibration Pulse Check Method. This bit indicates the method to be used for performing the successive calibration pulse check. Default value is 1. 0 Option 2 i.e. Low Latency Option as per SAE Specification 1 Option 1 i.e. Preferred but High Latency Option as per SAE Specification
24–31 FIL_CNT	Input Filter Sample Count. This indicates twice the number of Protocol Clock (of High Frequency Receiver Clock) cycles required for channel input from device's pad to remain stable before it is sampled as 0 or 1. This field defines the width of glitches to be filtered out by the input programmable filter on that channel. Only one bit should be set in this field. Output of the filter is equal to 2*FIL_CNT+4'. 0 No filtering. Input from device's pad is only synchronized 1 Non-Zero Filtering is enabled

1.11.2 Input programmable filter

The Input Programmable Filter ensures that only valid input pin transitions are received by the SENT Receiver module. The input programmable filter is an 8-bit programmable up counter that increments on the high frequency receiver clock. The sensor input signal from device's pad is synchronized by high frequency receiver clock. When a state change occurs in the sensor input signal, the 8-bit counter resets and starts counting up on the high frequency receiver clock. As long as the new state is stable on the pin, the counter remains incrementing. If a counter overflows occurs, the new pin value (i.e. sensor input) is validated and latched in the filtered output flop (also running on high frequency receiver clock). If the opposite edge appears on the sensor input before validation (i.e. overflow), the counter is reset and the input is not passed onto the filtered output. At the next pin transition, the counter starts counting again. Any pulse that is shorter than a full range of the masked counter is regarded as a glitch and it is not passed on to the filter output. The number of samples (or the match value of the up counter) is programmable by the user in the channel's configuration register. When zero is programmed into the registers, it bypasses the filter and the synchronized input is output as the filtered output. A non-zero value delays the filtered output by the number of clocks proportional to the programmed value in the Channel Configuration Register. A timing diagram of the input filter when FIL_CNT is 1, is shown in the following figure.

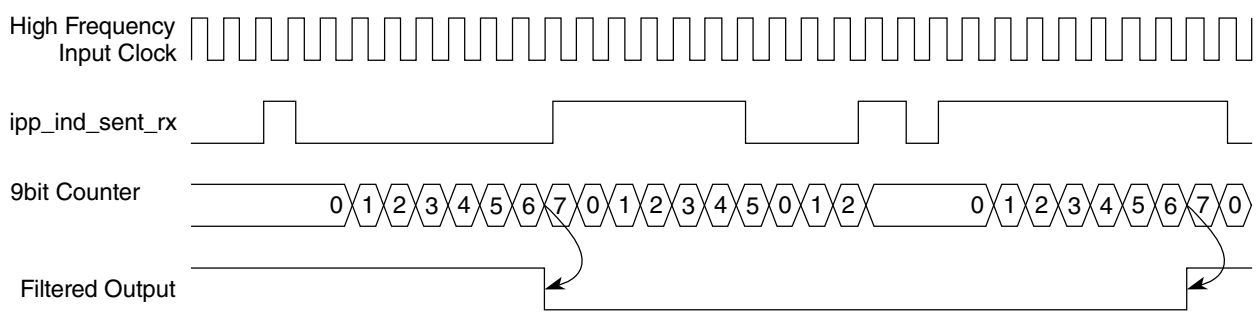

Figure 1-6. Input programmable filter timing diagram

1.11.3 Pause pulse diagnostic

The pause pulse diagnostic checks whether the ratio of calibration pulse length to full message length (including pause pulse) varies from one message to another by less than 1.5625% (as per spec). In order to have reduced latency of operation, message reception is not gated due to this check and no messages are discarded. However, when this check fails, a status bit is asserted to let the software know of this condition. The successive calibration pulse check can be configured to operate along with this check. This configurability is added to avoid conflicting results from the two checks.

There can be some inaccuracy in measuring pause pulse length as SAE specification specifies maximum clock drift/jitter up to maximum nibble length only and the frequency of high frequency receiver clock (protocol clock) used, allows clock compensation logic to ensure accuracy up to maximum nibble length. Hence there could be some inaccuracy in this check when sampling pause pulses that are larger than the maximum nibble pulse length.

This check will assert the PP_DIAG_ERR status bit on failure. This check does not run when reception of pause pulse is disabled.

When the Single Edge Nibble Transmission (SENT) Receiver (SRX) is configured to receive a pause pulse (Channel ‘n' Configuration Register - CHn_CONFIG[PAUSE_EN] = 1) and the length of the pause pulse from the sensor is in range of the valid calibration pulse length, the NUM_EDGES error can get asserted spuriously (Channel ‘n' Status Register - CHn_STATUS(NUM_EDGES_ERR] = 1) when there is any diagnostic error (other than number of expected edges error) or overflow in the incoming messages from the sensor.

Software can distinguish a spurious NUM_EDGES_ERR error from a real one by monitoring other error bits. The following tables will help distinguish between a false and real assertion of NUM_EDGES_ERR error and other errors. Software should handle the first error detected as per application needs and other bits can be evaluated based on these tables. Table 1 contains information due to erratum behavior and Table 2 below contains clarification of normal NUM_EDGES_ERR behavior.

Table 1-16. Behavior of NUM_EDGES_ERR

First Error Detected	Other error bits asserted	Cause for extra error bits getting asserted	Action
NIB_VAL_ERR	NUM_EDGES_ERR asserted twice	Upon detection of the first error, the state machine goes into a state where it waits for a calibration pulse, the first NUM_EDGES_ERR error is for the current message as the state machine does not detect an end of message. The second error comes when both the Pause pulse and the Calibration pulse are seen as back to back calibration pulses and no edges in between.	Ignore both NUM_EDGES_ERR error
FMSG_CRC_ERR	NUM_EDGES_ERR asserted twice	Upon detection of the first error, the state machine goes into a state where it waits for a calibration pulse, the first NUM_EDGES_ERR error is for the current message as	Ignore both NUM_EDGES_ERR errors

Table continues on the next page...

Table 1-16. Behavior of NUM_EDGES_ERR (continued)

		the state machine does not detect an end of message. The second error comes when both the Pause pulse and the Calibration pulse are seen as back to back calibration pulses and no edges in between.	
CAL_LEN_ERR	NUM_EDGES_ERR asserted once	Since the calibration pulse is not detected as a valid calibration pulse, the internal edges counter does not detect the end of one message and start of bad message (which has CAL_LEN_ERR); hence the NUM_EDGES_ERR gets asserted.	Ignore NUM_EDGES_ERR error

Resynchronization of SENT Receiver in case of any diagnostic error is shown in figure Figure 1-7.

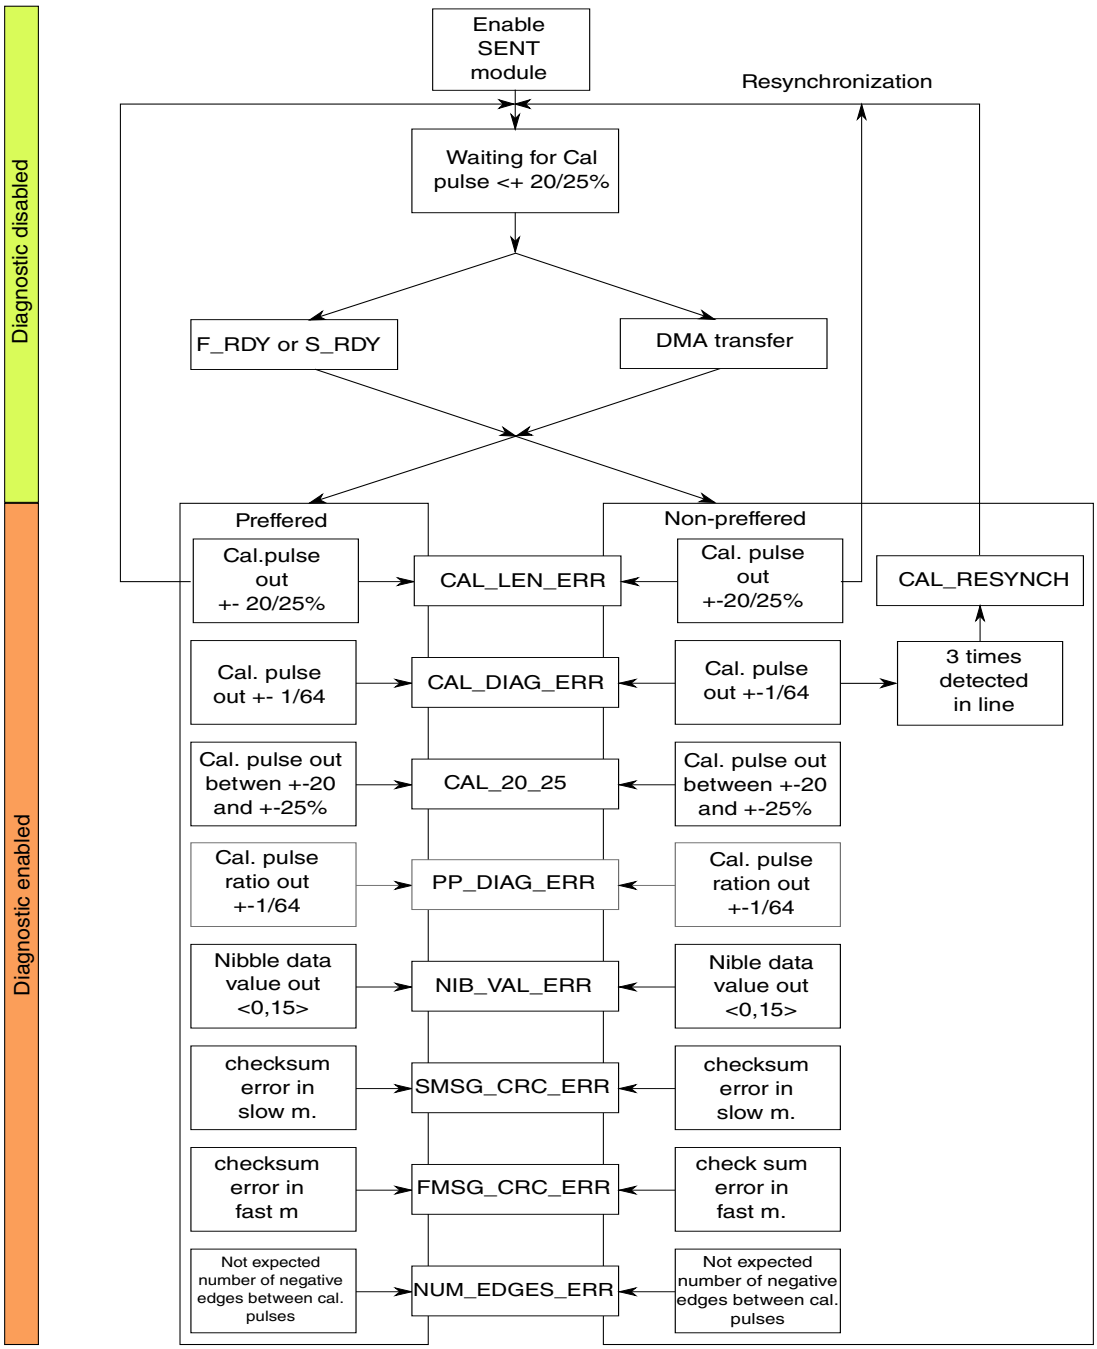

Figure 1-7. SENT receiver resynchronization

Table 1-17. Expected behavior, clarification of NUM_EDGES_ERR cases

First Error Detected	Other error bits asserted	Cause for extra error bits getting asserted	Action
NUM_EDGES_ERR (when edges are less than expected)	NIB_VAL_ERR is asserted	When the actual number of edges in the message are less than expected, then a pause pulse gets detected as a nibble since the state machine expects nibbles	Ignore the NIB_VAL_ERR

Table continues on the next page...

Table 1-17. Expected behavior, clarification of NUM_EDGES_ERR cases (continued)

		when actually there is a pause pulse present. This generates NIB_VAL_ERR.	
NUM_EDGES_ERR (when edges are more than expected)	NIB_VAL_ERR and PP_DIAG_ERR are asserted	When the actual number of edges in a message are more than expected, then after receiving the programmed number of data nibbles, the state machine expects a pause pulse. However, the pause pulse comes later and gets detected as a nibble and hence NIB_VAL_ERR is asserted. Since the message length is not correct, PP_DIAG_ERR is also asserted.	Ignore NIB_VAL_ERR and PP_DIAG_ERR

1.12 SIPI Error Register (SIPI_ERR)

This register contains the error bits for the last transaction(s) for all the channels. Communication errors are generated only for out of range address accesses, areas that are read only and where accesses do not lead to generation of transfer errors. Also, writing to read only registers will not generate errors.

Address: 0h base + B0h offset = B0h

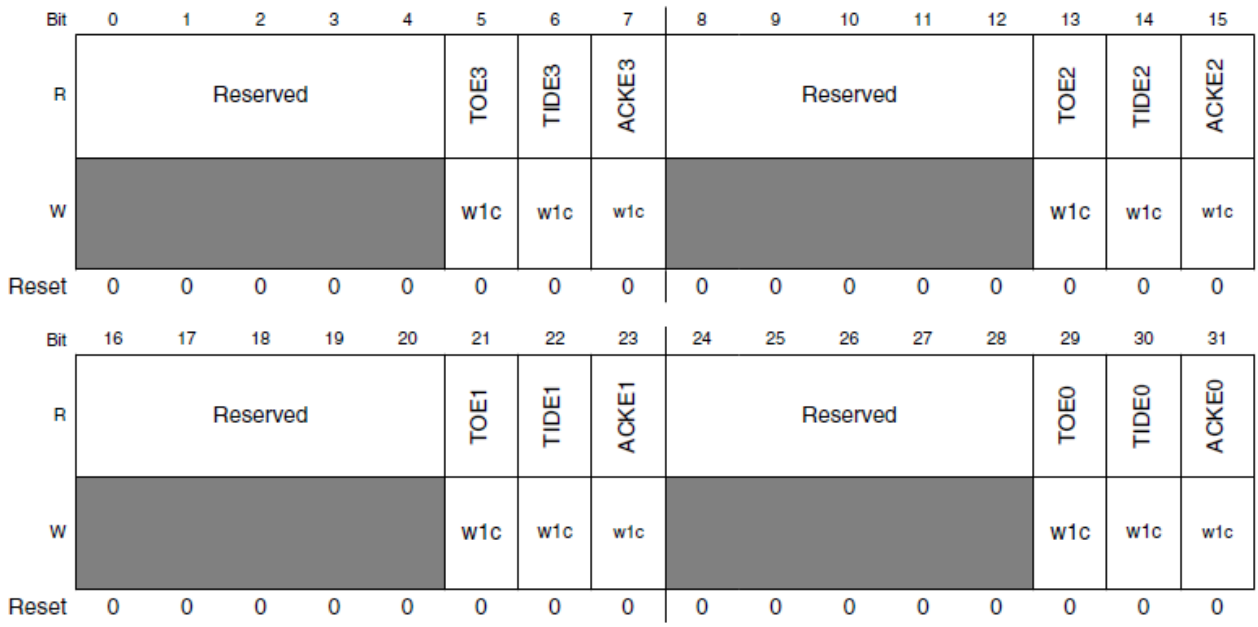

Table 1-18. SIPI_ERR field descriptions

Field	Description
0–4 Reserved	This field is reserved.
5 TOE3	Timeout Error for Channel 3. 0 Timeout error didn't occur 1 Timeout error occurred
6 TIDE3	Transaction ID Error for Channel 3. 0 Received transaction ID matched with the stored ID 1 Received transaction ID didn't match with the stored ID
7 ACKE3	Acknowledge Error for Channel 3. 0 Acknowledge received is correct. 1 Acknowledge received is not correct.
8-12 Reserved	This field is reserved.
13 TOE2	Timeout Error for Channel 2. 0 Timeout error didn't occur 1 Timeout error occurred
14	Transaction ID Error for Channel 2.

Table continues on the next page...

Table 1-18. SIPI_ERR field descriptions (continued)

Field	Description
TIDE2	0 Received transaction ID matched with the stored ID 1 Received transaction ID didn't match with the stored ID
15 ACKE2	Acknowledge Error for Channel 2. 0 Acknowledge received is correct. 1 Acknowledge received is not correct.
16-20 Reserved	This field is reserved.
21 TOE1	Timeout Error for Channel 1. 0 Timeout error didn't occur 1 Timeout error occurred

30 TIDE0	Transaction ID Error for Channel 0. 0 Received transaction ID matched with the stored ID 1 Received transaction ID didn't match with the stored ID
31 ACKE0	Acknowledge Error for Channel 0. 0 Acknowledge received is correct. 1 Acknowledge received is not correct.

1.13 PLL configuration example

This is a typical configuration for 320 MHZ LFAST high-speed clock when the reference clock is 20 MHz.

1. Program the LFAST_PLLCR[FBDIV] for the Feedback Division factor, in this case 15 (divide by 16)
2. Program the LFAST_PLLCR[PREDIV] for the Division factor for PLL Reference Clock, in this case 0 (divide by 1)

3. Program the LFAST_PLLCR[SWPON] to 1, for switching the PLL ON

$$\text{PLL Clock} = \left(\frac{\text{clk_in}}{\text{d3g_pll_pre_div}}\right) \times (\text{d3g_pll_feedback_div} + 0.5) \quad \text{where d3g_pll_fraction_div_en=1}$$

Equation 1. PLL1 Output Frequency

The user should wait for:

1. The LFAST_PLLLSR[PLLDIS] =’0’, indicating that the PLL is enabled
2. Then, the LFAST_PLLLSR[PLDCR] =’1’, indicating that the PLL is locked and ready for use

$$\text{PLL Clock} = \left(\frac{\text{clk_in}}{\text{d3g_pll_pre_div}}\right) \times (\text{d3g_pll_feedback_div}) \quad \text{where d3g_pll_fraction_div_en=0}$$

Equation 2. PLL Output Frequency

1.14 LINFlexD

1.14.1 Introduction

The LINFlexD controller is designed to manage a high number of LIN messages efficiently with a minimum of CPU load. To reduce the CPU loading in Master mode, LINFlexD autonomously handles the LIN messages once software has triggered the header transmission, until the next header transmission request in transmitter mode or until checksum reception in the receiver mode.

The LINFlexD supports LIN protocol version 1.3, 2.0, 2.1 , and 2.2. It also consists of an 8-byte buffer for transmission/reception data.

The LINFlexD also provides support for some of the basic UART transfers of 8-bit, 9-bit, 16-bit, and 17-bit frames and also 12-bit data frame + parity reception in UART mode for MSC support.

The LINFlexD supports multi-channels and parametric DMA Tx/Rx interface in LIN/ UART operating mode.

1.14.2 LIN mode features

- Supports LIN protocol version 1.3, 2.0, 2.1, and 2.2
- Bit rates up to 20 Kbit/s (LIN protocol)
- Master/Slave mode

- Classic and Enhanced Checksum calculation and check
- Single 8-byte buffer or FIFO for Transmission/Reception
- Timeout management
- Identifier filters
- DMA interface
- Supports a maximum of 16 possible identifiers
- Master mode with autonomous message handling
- Extended frame mode for in-application programming purposes
- Wakeup event on dominant bit detection
- True LIN field state machine
- Advanced LIN error detection
- Header, response, and frame timeout
- Slave mode
  - Autonomous header handling
  - Autonomous transmit/receive data handling
- Identifier filters for autonomous message handling in Slave mode
- Separate clock for baud rate calculation
  - The relationship “(2/3)* LIN_CLK > PBRIDGEx_CLK > 1/3*LIN_CLK” should be maintained.

1.14.3 DMA Tx Enable Register (LINFlexD_DMATXE)

This register enables the DMA TX interface. This register can be written and read by software anytime.

The address offset depends on no_of_filters. Refer to chip configuration details to see the number of filters used in the device.

Address: 0h base + 98h offset = 98h

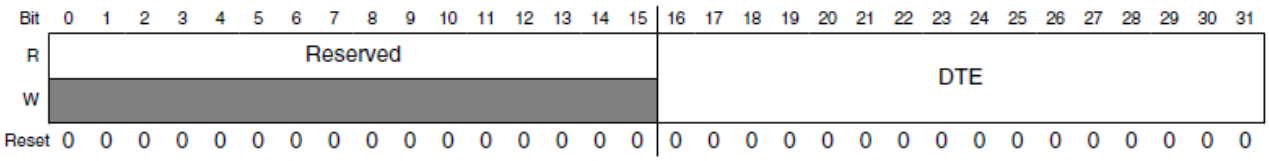

Table 1-19. LINFlexD_DMATXE field descriptions

Field	Description
0–15 Reserved	This field is reserved. Reserved **NOTE**: The number of reserved bits varies, and is equal to 32 - $2^{TX_CH_NUM}$. These lies from 0 to (31 - $2^{TX_CH_NUM}$). Refer to the chip configuration details for the value of TX_CH_NUM used in this device.
16–31 DTE	DMA Tx channel Y enable **NOTE**: The actual size of the register DMATXE depends on the value of the static parameter TX_CH_NUM. The size is [$2^{TX_CH_NUM}$ - 1 : 0]. The position of these bits are (32 - $2^{TX_CH_NUM}$) to 31. When DMATXE = 0x00000000, the DMA TX interface FSM is forced (soft reset) in Idle state. **NOTE**: Refer to the chip configuration details for the value of TX_CH_NUM used in this device. 0 DMA Tx channel Y disabled 1 DMA Tx channel Y enabled

1.14.4 DMA Rx Enable Register (LINFlexD_DMARXE)

This register enables the DMA RX interface. This register can be written and read by software any time.

The address offset depends on no_of_filters. Refer to device configuration chapter to see the number of filters used in the device.

Address: 0h base + 9Ch offset = 9Ch

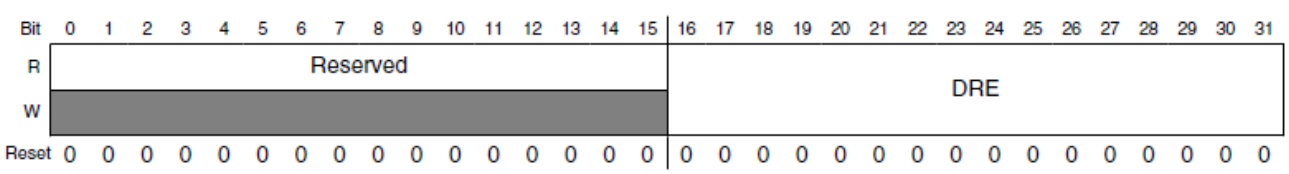

Table 1-20. LINFlexD_DMARXE field descriptions

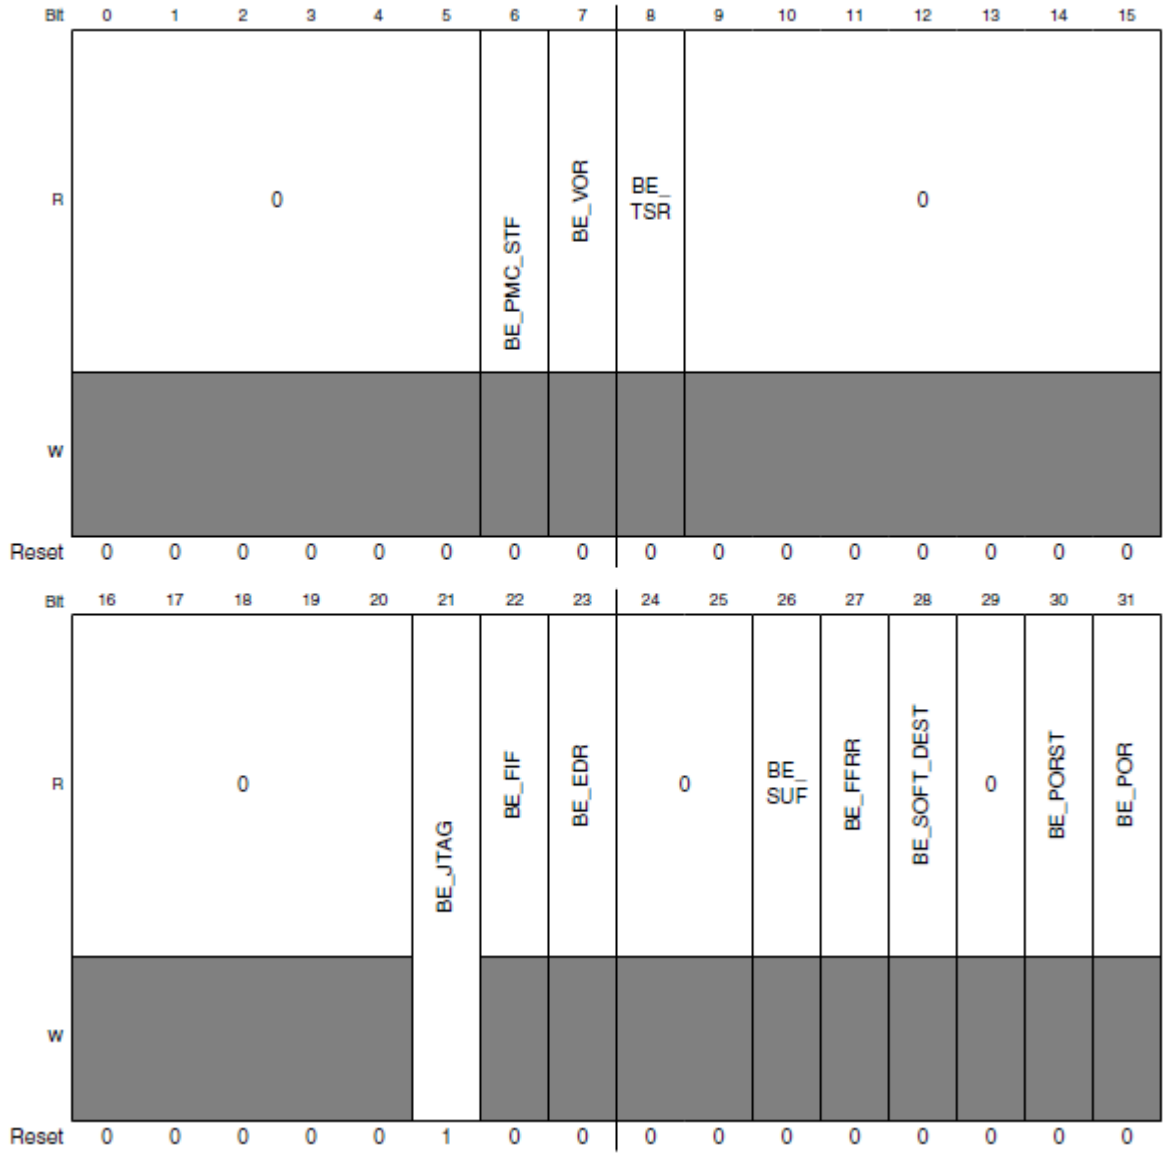
Field	Description
0–15 Reserved	This field is reserved. Reserved

Table continues on the next page...

Table 1-20. LINFlexD_DMARXE field descriptions (continued)



Field	Description
	NOTE: The number of reserved bits varies, and is equal to 32-DMA_RX_CH_NUM. Refer to the chip configuration details for the value of DMA_RX_CH_NUM used in this device.
16–31 DRE	DMA Rx channel Y enable. The number of DRE bits varies, and is equal to DMA_RX_CH_NUM. When DMARXE = 0x00000000, the DMA RX interface FSM is forced (soft reset) in idle state. **NOTE**: Refer to the chip configuration details for the value of DMA_RX_CH_NUM used in this device. 0 DMA Rx channel Y disabled 1 DMA Rx channel Y enabled

1.15 'Destructive' Bidirectional Reset Enable (MC_RGM_DBRE)

This register enables the generation of an external reset on 'destructive' reset. It can be accessed in read/write in either supervisor mode or test mode. It can be accessed in read only in user mode.

This register is reset only on power-on.

Address: 0h base + 30h offset = 30h

This register enables the generation of an external reset on 'destructive' reset. It can be accessed in read/write in either supervisor mode or test mode. It can be accessed in read only in user mode.

This register is reset only on power-on.

Table 1-21. MC_RGM_DBRE field descriptions

Field	Description
BE_PMC_STF	0 RESET_B is asserted on a PMC Selt Test Failure 'destructive' reset event if the reset is enabled
7 BE_VOR	Bidirectional Reset Enables for Voltage Out of Range 'Destructive' Reset 0 RESET_B is asserted on a Voltage Out of Range 'destructive' reset event if the reset is enabled
8 BE_TSR	Bidirectional Reset Enables for Temperature sensor 'Destructive' Reset 0 RESET_B is asserted on a Temperature sensor 'destructive' reset event if the reset is enabled
9–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21 BE_JTAG	Bidirectional Reset Enables for JTAG destructive reset 'Destructive' Reset 0 RESET_B is asserted on a JTAG 'destructive' reset event if the reset is enabled 1 RESET_B is not asserted on a JTAG destructive reset event
22 BE_FIF	Bidirectional Reset Enables for Flash Initialization Failure 'Destructive' Reset 0 RESET_B is asserted on a Flash Initialization Failure 'destructive' reset event if the reset is enabled
23 BE_EDR	Bidirectional Reset Enables for 'Functional' reset Escalation 'Destructive' Reset 0 RESET_B is asserted on a 'Functional' reset Escalation 'destructive' reset event if the reset is enabled
24–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26 BE_SUF	Bidirectional Reset Enables for STCU Unrecoverable Fault 'Destructive' Reset 0 RESET_B is asserted on an STCU Unrecoverable Fault 'destructive' reset event if the reset is enabled
27 BE_FFRR	Bidirectional Reset Enables for FCCU Failure to React reset 'Destructive' Reset 0 RESET_B is asserted on an FCCU Failure to React reset 'destructive' reset event if the reset is enabled
28 BE_SOFT_DEST	Bidirectional Reset Enables for Software 'Destructive' Reset 0 RESET_B is asserted on a Software destructive reset 'destructive' reset event if the reset is enabled
29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30 BE_PORST	Bidirectional Reset Enables for External PowerOn reset 'Destructive' Reset 0 RESET_B is asserted on an External PowerOn reset 'destructive' reset event if the reset is enabled
31 BE_POR	Bidirectional Reset Enables for Power On 'Destructive' Reset 0 RESET_B is asserted on a Power On 'destructive' reset event if the reset is enabled

1.16 Power Management

1.16.1 Voltage Monitoring

The PMC senses the supply voltages continuously to keep the chip in safe operating range. Destructive or functional reset, depending on the PMC_RES register, or alternatively interrupts, are triggered when the voltage exceeds or falls below the limits defined by recommended electrical operating conditions. Please refer to the PMC_REE and PMC_RES register descriptions in the PMC chapter for more details.

1.16.2 ADC Interface

The ADC interface provides the PMC internal voltages for diagnostic purposes. The analog multiplexer and the buffer is inside the PMC. The SAR ADC0 converts the selected voltage, which can then be evaluated by the CPU. Refer to the PMC chapter, PMC_ADC_CS register description for details. See the Table 1-25.

1.17 Power Management Controller

1.17.1 PMC introduction

The power management controller (PMC) consists of two blocks: an analog power management block (and a digital controller for the analog block).

The PMC block contains all of the registers and digital logic to generate all of the enable signals, trim control bits, reset generation, and test mode logic for the analog block. The PMC digital logic also contains the controls for PMC analog outputs to be sensed with the ADC module.

In addition, the PMC digital logic contains the enable signals, trim bits and other registers for the temperature sensor. There are also several custom interfaces to various other blocks: The Reset Generation Module (RGM) block receives the LVD values during POR to use for phase transition conditions.

1.17.2 Reset Enable Control Register (PMC_REE)

This Reset Event Enable Register controls whether the voltage detect signal event will cause a reset or not. If the desired flag bit is enabled, the voltage detect event causes a reset to be generated when the selected voltage passes the trigger event. These bits are loaded from the flash during the boot sequence. If the flash loaded bits are programmed to be enabled (set), these bits cannot be disabled (cleared).

NOTE

This register is cleared on POR.

Address: 0h base + E0h offset = E0h

Table 1-24. PMC_ADC_CS field descriptions

Field	Description
31–10	This field is reserved.

Table continues on the next page...

Table 1-24. PMC_ADC_CS field descriptions (continued)

Field	Description
Reserved	This read-only field is reserved and always has the value 0.
9 STND_BY_ RAM_BO_CLR	Standby RAM Brownout clear bit. A write on this bit will generate one clock wide pulse. It is self clear pulse.
8 STND_BY_ RAM_BR_ DETCT	Standby RAM Brownout Detection register bit. This bit is W1C type. To clear this field, first write 1 to STND_BY_RAM_BO_CLR and then write 1 to this field (STND_BY_RAM_BR_DETCT). These two writes need to be separate write instructions.
7–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
ADC_CHSE	Analog-to-Digital Converter Channel Select. These bits are used to control the analog PMC's test mux going to the ADC. This is to probe the internal node voltages of the PMC for testing, calibration and characterization purposes by one of the ADCs of the SoC. To see what voltages are output from PMC in this ADC interface, please refer to Table 15. **NOTE**: While changing internal PMC signal exposed on ADC interface for diagnostics, it is required to change mux select lines to '000000' before changing to next valid combination. This is needed to avoid transient short circuit b/w internal nodes in PMC and a false LVD / HVD / POR assertion. This must be handled through software.

1.17.5 ADC Interface

ADC Interface is to probe the internal node voltages of PMC for testing, calibration and characterization purpose by one of the ADCs of the SoC. There will be a dedicated ADC channel for this interface.

PMC signals are buffered to ensure correct ADC sampling.

Node to be probed through ADC can be selected using bit "pmc_adc_ch_sel[5:0]".

Table 1-25. ADC Interface

S.No.	pmc_adc_ch_sel[5:0]	ADC Channel Output	Expected Value
0	6'b000000	ADC Channel OFF	
1	6’b011110	por085_c sense value	1.25V (CORE Supply)
2	6’b011101	por085_c reference value	0.915V
3	6’b011100	por098_c sense value	1.25V (CORE Supply)

1.18 Power Control Unit (MC_PCU)

1.18.1 Introduction

The function of this module is simply to map the PMC digital interface IP into its address space.

The MC_PCU module plays a different role in this microcontroller than it does in other microcontrollers. Instead of directly providing an interface to configure and control power distribution to various segments ("power domains") of the chip, the MC_PCU acts as an integration module.

This microcontroller has a single power domain, Power Domain 0, which is managed by the Power Management Controller (PMC). The 16K address space consists of a single MC_PCU power domain status register and registers that configure and control the PMC.

1.18.2 Functional description

Please see the PMC chapter for specific details on the PMC control registers.

1.19 NXMC block connections

To provide Nexus data trace messaging from bus masters on the master ports of the crossbar (XBAR) that do not inherently have a trace client, a Nexus Crossbar Multi-Master Client (NXMC) monitors traffic into the master port of the XBAR. Two NXMCs are implemented: one for the fast masters and one for the slow masters. Trace messages transmitted over the Nexus interface (or stored in trace memory) include which NXMC generated the message as well as an identifier for the pre-concentrator source of the message. In addition to XBAR bus master trace capability, the NXMC also allows for in-

circuit trace capability that can be used to trace the Sequence Processing Unit (SPU) counter values. The two external hardware watchpoint triggers of each NXMC are used to generate timestamps (four total—two from each NXMC) for events from the SPU.[1]

The following figure shows a block diagram illustrating the NXMC integration.

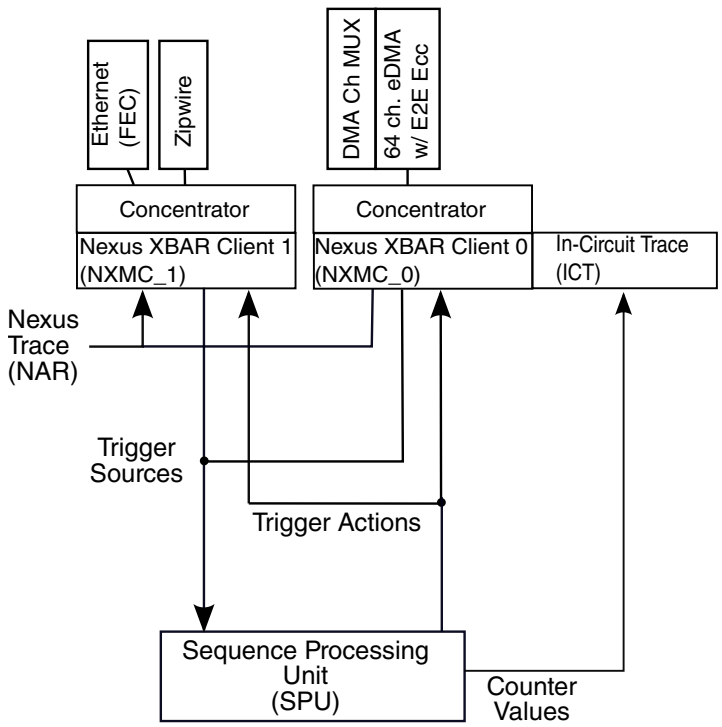

Figure 1-8. NXMC integration block diagram

The values of the trace master ID or in-circuit client ID, along with the Nexus message source identifier for the different clients are shown in the following table.[2]

Table 1-26. NXMC source and master client IDs

Client		Nexus trace source ID (SRC)	Trace master ID or In-circuit trace client ID (MASTER)
In-Circuit Trace	SPU	0b1011	0b0000
XBAR Client 0 Concentrator	eDMA Controller	0b1100	0b0011
(fast masters)	Reserved		All other values
XBAR Client 1 Concentrator	Ethernet	0b1101	0b0100
(slow masters)	Zipwire		0b1000
	Reserved		All other values

1. To provide Nexus data trace messaging from bus masters on the master ports of the crossbar (XBAR) that do not inherently have a trace client, a Nexus Crossbar Multi- Master Client (NXMC) monitors traffic into the master port of the XBAR. Two NXMCs are implemented: one for the fast masters and one for the slow masters.
2. NXMC clients are connected between E2E-ECC master client and AXBS. Therefore any corrupted data, correctable (single bit error) or in-correctable data (multi bit error), is traced without any trace error information. ECC errors are captured in MEMU.

1.20 Power

There are two types of voltage supervisors on the MPC5746R, Low Voltage Detect (LVD) and High Voltage Detect (HVD) monitors. Safety relevant voltages (recommended operating voltages), are supervised for voltage levels that are out of correct operating voltage ranges. Since any voltage running outside of the correct operating voltage range has the potential to disable the failure indication mechanisms of the MCU, the indication of these voltage variations can be used to cause a direct transition of the MCU into the safe state (reset assertion) (see "Power Management Controller (PMC)" and "Power Control Unit (MC_PCU)" chapters for details on power monitoring).

1.21 Fault Collection and Control Unit (FCCU)

1.21.1 Available FCCU output signals

The following table shows the available FCCU output signals implemented on this chip.

Table 1-27. FCCU output signals

FCCU output signal name	Chip-top signal name
EOUT[0]	ERROR0
EOUT[1]	ERROR1

NOTE

The FCCU EOUT signals can toggle after LBIST execution during reset.

1.21.2 FCCU failure inputs from other modules

The following table shows the different failure input signals of the FCCU, how they can be tested, and their default configuration after reset.

NOTE

All the faults shown in the following table require a long functional reset.

NOTE

FCCU Fault Channels 22, 23, and 24 may be asserted after reset. FCCU Fault Channels 51, 52, 69 through 84, 92, and 93 may be asserted during the execution of MBIST and LBIST. Before running MBIST or LBIST, these channels should be configured to NO REACTION. If any of these channels become asserted during MBIST or LBIST testing, the fault should simply be cleared and no further action should be taken.

Table 1-28. FCCU Fault Inputs

NCF Index	Default Reaction Configuration at POR or Destructive Reset	Source	Error Reaction Path Check	Description
0	No Reaction	Temp sensor	Using PMC_TS_FIR register to set the fault at source + Via FCCU Fake bit	Temperature Sensor Event Triggered by PMC_ESR_TD[TEMP1_2, TEMP1_0, TEMP0_2, TEMP0_0] and PMC_TS_FIR[TSNS_FAULT] . For details, see the descriptions of the PMC_ESR_TD and PMC_TS_FIR registers.
1	No Reaction	PMC	Using PMC FIR register to set the fault at source + Via FCCU Fake bit	LVD event to FCCU Triggerred by PMC_LVD_HVD_EVENT_STATUS[LVD_PMC, LVD_SAR_ADC, LVD_IO, LVD_FLASH, LVD_CORE_HOT, LVD_CORE_COLD] and PMC_FIR[LVD_FAULT]. For details, see the descriptions of the PMC_LVD_HVD_EVENT_STATUS and PMC_FIR registers.
2	No Reaction	PMC	Using PMC FIR register to set the fault at source + Via FCCU Fake bit	HVD Event to FCCU Triggered by PMC_LVD_HVD_EVENT_STATUS[HVD_FLASH, HVD_HV, HVD_CORE]. For details, see the descriptions of the PMC_LVD_HVD_EVENT_STATUS register.
3	No Reaction	PMC	Using PMC FIR register to set the fault at source + Via FCCU Fake bit	PMC Self Test Failure Event PMC hard/soft self-test failed: LVD/HVD **NOTE:** When this occurs, single LVD or HVD self-tests should be executed to identify which detection mechanism failed in the SOC: LVD or HVD. For details, see the description of the PMC_SELF_TEST_UM_VD_REG register as well as the flag bits associated to NCF3 (PMC_SELF_TEST_UM_VD_REG [ST_RESULT]). Self test bit definition indicates all valid values for PMC_SELF_TEST_UM_VD_REG[VD_ST_CTRL]

93	No Reaction	Core0/1 ICACHE/TAG MBIST	Via FCCU Fake bit to set the fault at error path	Mbist multi bit error of ICACHE(Core0 or Core1)
94	No Reaction	SRAM MBIST	Via FCCU Fake bit to set the fault at error path	Mbist Multibit error of SRAM
95	No reaction	All Peripheral RAM MBIST	Via FCCU Fake bit to set the fault at error path	Mbist multi bit error from all peripheral RAM

1.22 Self-Test Control Unit (STCU2)

1.22.1 STCU2 chip-specific module information

This section describes the chip-specific implementation of the STCU2 module.

NOTE

Before running either online or offline self-test, user needs to mask the core LVD, but should enable the core LVDs before running the application via SW through the PMC_REE register.

1.22.2 STCU2 Off-Line MBIST Status Medium Register (STCU2_MBSM)

The STCU2_MBSM register includes the results corresponding to the execution of the selected Off-Line MBIST in the range NMCUT = 32-63.

The size of the register depends on the number of BISTed RAMs/ROMs.

Address: 0h base + 48h offset = 48h

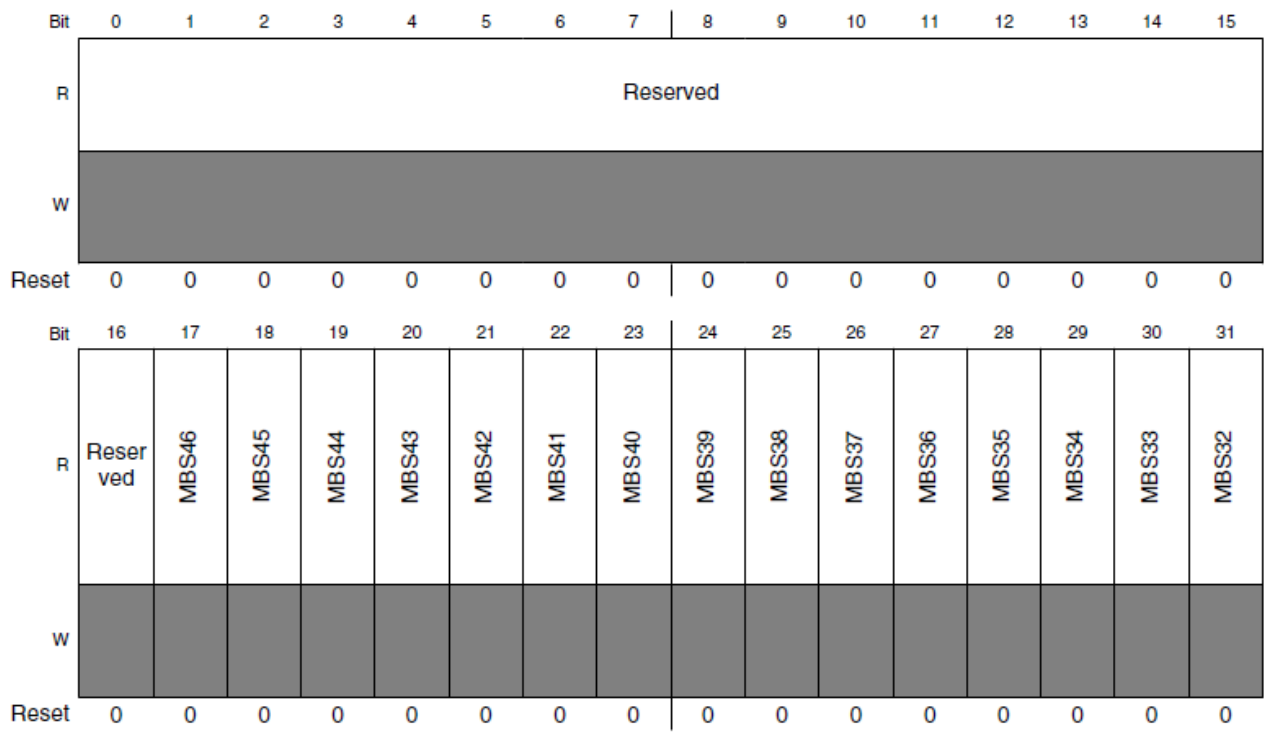

Table 1-29. MBSM field descriptions

Field	Description
0–16 Reserved	This field is reserved.
17 MBS46	MBSx: Off-Line status (NMCUT range = 32 to 63) of the selected MBIST **NOTE**: This bit is meaningful when the related bit of the STCU2_MBEM register reports the MBIST is finished). 0 Failed NMCUT BIST execution 1 No Fault detected during the NMCUT BIST execution

Table continues on the next page...

Table 1-29. MBSM field descriptions (continued)

Field	Description
18 MBS45	MBSx: Off-Line status (NMCUT range = 32 to 63) of the selected MBIST **NOTE**: This bit is meaningful when the related bit of the STCU2_MBEM register reports the MBIST is finished). 0 Failed NMCUT BIST execution 1 No Fault detected during the NMCUT BIST execution
19 MBS44	MBSx: Off-Line status (NMCUT range = 32 to 63) of the selected MBIST **NOTE**: This bit is meaningful when the related bit of the STCU2_MBEM register reports the MBIST is finished). 0 Failed NMCUT BIST execution 1 No Fault detected during the NMCUT BIST execution
20 MBS43	MBSx: Off-Line status (NMCUT range = 32 to 63) of the selected MBIST **NOTE**: This bit is meaningful when the related bit of the STCU2_MBEM register reports the MBIST is finished). 0 Failed NMCUT BIST execution 1 No Fault detected during the NMCUT BIST execution
21 MBS42	MBSx: Off-Line status (NMCUT range = 32 to 63) of the selected MBIST **NOTE**: This bit is meaningful when the related bit of the STCU2_MBEM register reports the MBIST is finished). 0 Failed NMCUT BIST execution 1 No Fault detected during the NMCUT BIST execution
22 MBS41	MBSx: Off-Line status (NMCUT range = 32 to 63) of the selected MBIST **NOTE**: This bit is meaningful when the related bit of the STCU2_MBEM register reports the MBIST is finished). 0 Failed NMCUT BIST execution 1 No Fault detected during the NMCUT BIST execution
23 MBS40	MBSx: Off-Line status (NMCUT range = 32 to 63) of the selected MBIST **NOTE**: This bit is meaningful when the related bit of the STCU2_MBEM register reports the MBIST is finished). 0 Failed NMCUT BIST execution 1 No Fault detected during the NMCUT BIST execution
24 MBS39	MBSx: Off-Line status (NMCUT range = 32 to 63) of the selected MBIST **NOTE**: This bit is meaningful when the related bit of the STCU2_MBEM register reports the MBIST is finished). 0 Failed NMCUT BIST execution 1 No Fault detected during the NMCUT BIST execution
25 MBS38	MBSx: Off-Line status (NMCUT range = 32 to 63) of the selected MBIST **NOTE**: This bit is meaningful when the related bit of the STCU2_MBEM register reports the MBIST is finished). 0 Failed NMCUT BIST execution 1 No Fault detected during the NMCUT BIST execution

Table continues on the next page...

Table 1-29. MBSM field descriptions (continued)

Field	Description
26 MBS37	MBSx: Off-Line status (NMCUT range = 32 to 63) of the selected MBIST **NOTE**: This bit is meaningful when the related bit of the STCU2_MBEM register reports the MBIST is finished). 0 Failed NMCUT BIST execution 1 No Fault detected during the NMCUT BIST execution
27 MBS36	MBSx: Off-Line status (NMCUT range = 32 to 63) of the selected MBIST **NOTE**: This bit is meaningful when the related bit of the STCU2_MBEM register reports the MBIST is finished). 0 Failed NMCUT BIST execution 1 No Fault detected during the NMCUT BIST execution
28 MBS35	MBSx: Off-Line status (NMCUT range = 32 to 63) of the selected MBIST **NOTE**: This bit is meaningful when the related bit of the STCU2_MBEM register reports the MBIST is finished). 0 Failed NMCUT BIST execution 1 No Fault detected during the NMCUT BIST execution
29 MBS34	MBSx: Off-Line status (NMCUT range = 32 to 63) of the selected MBIST **NOTE**: This bit is meaningful when the related bit of the STCU2_MBEM register reports the MBIST is finished). 0 Failed NMCUT BIST execution 1 No Fault detected during the NMCUT BIST execution
30 MBS33	MBSx: Off-Line status (NMCUT range = 32 to 63) of the selected MBIST **NOTE**: This bit is meaningful when the related bit of the STCU2_MBEM register reports the MBIST is finished). 0 Failed NMCUT BIST execution 1 No Fault detected during the NMCUT BIST execution
31 MBS32	MBSx: Off-Line status (NMCUT range = 32 to 63) of the selected MBIST **NOTE**: This bit is meaningful when the related bit of the STCU2_MBEM register reports the MBIST is finished). 0 Failed NMCUT BIST execution 1 No Fault detected during the NMCUT BIST execution

1.23 PMC protected registers

Table 1-30. Protected PMC registers

Register	Register size (bits)	Offset from module base address	Protected size (bits)
TS_IER	32	A4h	32
REE_TD	32	ACh	32

Table continues on the next page...

Table 1-30. Protected PMC registers (continued)

Register	Register size (bits)	Offset from module base address	Protected size (bits)
RES_TD	32	B0h	32
CTL_TD	32	B4h	32
TS_FIR	32	C0h	32
FIR	32	D4h	32
PMC_VD_INTR_ENB	32	D8h	32
PMC_REE	32	E0h	32
PMC_RES	32	E4h	32
ADC_CS	32	E8h	32

1.24 BAR execution protection

The BAR (Boot Assist ROM) is ROM-based code, mapped within the AIPS space, which is used during FSL production phase. The BAR code makes it possible to upload data into the system RAM by reading the data directly from a GPIO port. During FSL Production test, the boot CPU1 processor starts executing from the BAR code. After FSL Production test, the CPU1 always starts executing the BAF code. After JDP/FSL Production lifecycle, it is not possible to accidentally or maliciously jump to the BAR code, since the access to this memory area is considered illegal.

The BAR ROM code hardware is designed to always generate an Illegal Peripheral Access Error when it is accessed. This is the same error that is caused by accessing a 'reserved' location in any peripheral.

1.25 Password and Device Security Module (PASS)

1.25.1 Password and Device Security Module (PASS) chip-specific module information

The PASS module is used to implement password-based read and write protection for flash blocks. Up to four levels of password protection can be implemented for each flash block.

NOTE

The registers discussed in this section are initialized via DCF records, so the reset values depend on user settings.

Each password group defined in the DCF records has a set of four LOCK*n* registers association with it—PASS_LOCK*n*_PG*n*. The bits of these registers are associated with specific flash blocks. The mapping is shown in the attached Flash Block Assignment spreadsheet.

NOTE

Password Challenge passwords and JTAG passwords that are all 0's or all 1's are invalid.

NOTE

For availability of RL0, RL1, and RL2 (Flash Region Lock bit fields) definitions in Password Group n Lock n Status Registers for the device, please refer to the Flash_Block_Assignment sheet in the pdf attachments.

The following table shows the the Debug Interface Access scenarios on this chip.

Table 1-31. Debug Interface Enable Truth Table

Input Conditions					Outcome
Lifecycle	**Production Disable mode**	**DCF Censorship**	**Debug Enable (LOCK3[DBL] bit)**	**JTAG Password**	**Debug Interface Enable**
Customer Delivery	Don't Care	Don't Care	Don't Care	Don't Care	Enabled
OEM Production	Don't Care	Not censored	Don't Care	Don't Care	Enabled
		Censored	Unlocked (DBL=0)	Don't Care	Enabled
			Locked (DBL=1)	Matched	Enabled
				Not Matched	Blocked
In Field	Off	Not censored	Don't Care	Don't Care	Enabled
		Censored	Unlocked (DBL=0)	Don't Care	Enabled
			Locked (DBL=1)	Matched	Enabled
				Not Matched	Blocked
	On	Don't Care	Don't Care	Don't Care	Blocked
Failure Analysis	Don't Care	Not censored	Don't Care	Don't Care	Enabled
		Censored	Unlocked (DBL=0)	Don't Care	Enabled
			Locked (DBL=1)	Matched	Enabled
				Not Matched	Blocked

The following table summarizes the scenarios of read lock (RL) region protection on this chip.

Table 1-32. Flash memory read protection truth table

Inputs				Outputs	
Life Cycle	**Censorship DCF client**	**Debug Interface**	**LOCK3[RLx]**	**Read Protected RL[0] (UTest)**	**Read Protected RL[3:1] (other regions)**
Customer Delivery	Don't care	Don't care	Don't care	Readable	Readable
OEM Production or In Field	0x55AA	Don't care	Don't care	Readable	Readable
	Any other value	Blocked	Don't care	Readable	Readable
		Enabled	Locked	Read Blocked	Read Blocked
			Unlocked	Readable	Readable
Failure Analysis	0x55AA	Don't care	Don't care	Readable	Readable
	Any other value	Don't care	Locked	Readable	Read Blocked
			Unlocked	Readable	Readable

The following table indicates byte-to-byte correspondence between UTEST DCF address and JTAG_PASSWORD.

Table 1-33. JTAG_PASSWORD register bit correspondence

UTEST Address Offset	Register Bit Position (MSB is 255)
0x00	JTAG_PASSWORD[7:0]
0x01	JTAG_PASSWORD[15:8]
...	...
0x1E	JTAG_PASSWORD[247:240]
0x1F	JTAG_PASSWORD[255:248]

1.25.2 Life Cycle Status Register (PASS_LCSTAT)

The Life Cycle Status Register reflects the production status and DCF Censorship client status of the device. It is possible to mature the device (move the device life cycle forward), but never to revert the life cycle to an earlier state.

The reset value of the LCSTAT register LIFE field derives from an external life cycle management module (like SSCM). It is a 3-bit life cycle. This register simply displays the life cycle input from external blocks.

Address: 0h base + 0h offset = 0h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	CNS	JUN	1	0												
W																
Reset	*	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0													LIFE		
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1

* Notes:
- CNS field: Reset value depends on the Censorship DCF client

Table 1-34. PASS_LCSTAT field description

Field	Description
0 CNS	This field indicates whether the DCF Censorship client has been written with a DCF record to 0x55AA or if the DCF Censorship client contains any other value than 0x55AA. The bit can be set (or cleared) via DCF Record in UTest Flash. **NOTE**: If no DCF record has been written to affect the value of the CNS bit, its reset value will be 1. 1 DCF Censorship Client value is anything other than 0x55AA. 0 DCF Censorship client value is 0x55AA.
1 JUN	This field indicates whether the device has been temporarily uncensored. Successful transmission of the JTAG password sets this bit to '1', otherwise it will be 0. Unsuccessful transmission clears this bit.
2 Reserved	This field is reserved. This read-only field is reserved and always has the value 1.
3-28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29-31 LIFE	The life cycle setting is manipulated externally (SSCM). Pass displays a 3-bit input life cycle 000 Failure Analysis 001 Reserved 010 OEM Production 011 Customer Delivery 100 Reserved 101 Reserved

Table 1-34. PASS_LCSTAT field description

Field	Description
	110 Freescale Production 111 In Field

1.25.3 Debug Disable (DD)

Debug Disable is an optional feature that, once the life cycle is In Field overrides all other debug controls and disables the debug interface. The Debug Disable feature has a higher priority than Censorship, JTAG password and the PASS LOCK3[DBL] bit.

Chapter 1
Addendum for Rev 6 of MPC5746R

1.1 Overview

This addendum describes corrections or updates to the MPC5746R Reference Manual. The currently available version of the MPC5746R Reference Manual is Revision 6.

Navigation tip: When navigating this PDF file using the hyperlinks, pressing the ALT and "left arrow" keys simultaneously will return you to the previously viewed page.

Table 1-1. MPC5746RRM Rev6 Addendum

Location	Description
Chapter 6, Device Configuration Format (DCF) Records	
Page 134	• Added row to DCF clients table with description "Software Tamper Region Override Disable". Modified following row's DCF Address. • See DCF clients.
Page 137	• Added recommendation to program DCF_UTEST_Miscellaneous DCF client only one time. • Updated DCF_UTEST_Miscellaneous DCF client figure and field descriptions: Changed reserved fields at 15, 19, and 24:26 from RO to RW and changed corresponding descriptions. • Added note to DCF_UTEST_Miscellaneous[OSC_EN] field description. • See DCF_UTEST_Miscellaneous DCF client.
Page 140	• Updated DCF_PMC_REE_TD DCF client figure and field descriptions: Changed reserved field at 26:27 from RO to RW and changed corresponding description. • See DCF_PMC_REE_TD DCF client.
Page 141	• In the DCF_IVPR0 DCF client description, added two notes. • Changed the position of the Vector Base field in the diagram and changed the corresponding offsets in the field description table. • See DCF_IVPR0 DCF client.
Page 141	• In the DCF_IVPR1 DCF client description, replaced the first note and added a third note regarding IVPR1_CPU1 and BAF. • Changed the position of the Vector Base field in the diagram and changed the corresponding offsets in the field description table. • See DCF_IVPR1 DCF client.

Table continues on the next page...

Table 1-1. MPC5746RRM Rev6 Addendum (continued)

Location	Description
Page 142	• In description for DCF_SELFTEST_CONFIG_IPS_1 DCF client, added statements about how the register is reset and when it is loaded by the SSCM. • Updated figure and field descriptions: Changed reserved fields at 1:9, 12:14, 15, 16:18, and 20:31 from RO to RW and changed corresponding descriptions. • Moved the "Reserved" bit that is to be set when running LBIST from the bit 0 position to the bit 31 position. The bit 0 position is now "Reserved" and is read/write zero always. • See DCF_SELFTEST_CONFIG_IPS_1 DCF client.

Page 143	• Updated DCF_SELFTEST_CONFIG_IPS_2 DCF client figure and descriptions:
	  • In description, added statements about how the register is reset and when it is loaded by the SSCM.
	  • Changed reserved fields at 0:1 and 17:19 from RO to RW and changed corresponding descriptions.
	  • Changed the order of the System_MUX_Divider_*n*_Division_Value fields in the diagram and field description table.
	  • Changed width of Aux_MUX_0_Divider_4_Division_Value and Aux_MUX_0_Divider_3_Division_Value fields to three bits.
	• See DCF_SELFTEST_CONFIG_IPS_2 DCF client.

Page 144	• In description for DCF_SELFTEST_CONFIG_IPS_3 DCF client, added statements about how the register is reset and when it is loaded by the SSCM. • Updated figure and field descriptions: Changed reserved fields at 0:4 and 14:16 from RO to RW and changed corresponding descriptions. • See DCF_SELFTEST_CONFIG_IPS_3 DCF client.
Page 145	• In description for DCF_SELFTEST_CONFIG_IPS_4 DCF client, added statements about how the register is reset and when it is loaded by the SSCM. • Updated figure and field descriptions: Changed reserved field at 0:7 from RO to RW and changed corresponding description. • See DCF_SELFTEST_CONFIG_IPS_4 DCF client.
Page 146	• Updated DCF_ERROR0_PAD_SELECT DCF client figure and field descriptions: Changed reserved fields at 0:1, 4:5, 9, and 16:27 from RO to RW and changed corresponding descriptions. • See DCF_ERROR0_PAD_SELECT DCF client.
Page 147	• Updated DCF_ERROR1_PAD_SELECT DCF client figure and field descriptions: Changed reserved fields at 0:1, 4:5, 9, and 16:27 from RO to RW and changed corresponding descriptions. • See DCF_ERROR1_PAD_SELECT DCF client.
Chapter 7, e200z4d Core Complex Overview	
Page 155	• Added the following note: "IMEM and DMEM must be initialized, regardless of whether they are used." • See Local memory features
Chapter 17, Interrupt Controller (INTC)	

Page 397	• In the "Interrupt sources" table, made the following changes to align to the terms used in the eTPU chapter.
	  • Changed "eTPU Engine 0 and 1" to "eTPU Engine 1 and 2".
	  • Changed "ETPU_MCRAB[MGEA,MGEB,ILFA,ILFB,SCMMISF]" to "eTPU_SCR_MCR[MGE1,MGE2,ILF1,ILF2,SCMMISF]".
	  • Changed "eTPU Engine 0" to "eTPU Engine 1".

Table continues on the next page...

Table 1-1. MPC5746RRM Rev6 Addendum (continued)

Location	Description
	• Changed "eTPU Engine 1" to "eTPU Engine 2". • Changed ETPU_CISR_0 to eTPU_GCR_CISR_ENG1. • Changed ETPU_CISR_1 to eTPU_GCR_CISR_ENG2. • See INTC interrupt sources.
Chapter 18, Enhanced Direct Memory Access (eDMA)	
Page 605	• Added Lockstep section. • See Lockstep.
Chapter 22, Clocking	
Page 659	• Removed both notes at end of "LINFlex clocking" section. • See LINFlex clocking.
Chapter 23, Dual PLL Digital Interface (PLLDIG)	

Page 665	• Updated the clock configuration equations:
	  • The equation "PLL1 PHI Output Frequency" is now two equations, depending upon the value of PLLDIG_PLL1FD[FDEN].
	  • The equation "PLL1 VCO Frequency" is now two equations, depending upon the value of PLLDIG_PLL1FD[FDEN].
	• See Clock configuration.

Chapter 24, Clock Monitor Unit (CMU)	
Page 695	• Added a note in the CMU_MDR register field description for the MD field. • See CMU Measurement Duration Register (CMU_MDR).
Chapter 25, Clock Generation Module (MC_CGM)	
Page 751	• Added note about system clock divider configuation. • See System Clock Dividers.
Page 758	• Added procedures to avoid undefined system behavior to end of section. • See Auxiliary Clock Generation.
Chapter 43, Enhanced Time Processing Unit (eTPU)	
Page 1319	• Numerous updates have been made throughout this chapter, which is included in its entirety. See eTPU chapter. • See Enhanced Time Processing Unit (eTPU) changes for the list of changes in the eTPU chapter.
Chapter 46, Body Cross-triggering Unit (BCTU)	
Page 1781	• In the "Introduction" section, changed "The BCTU has 32 trigger inputs" to "Up to 32 trigger inputs are available." • See BCTU Introduction.
Page 1787	• In the BCTU "Memory Map" section, deleted the BCTU_SFTRGR3 register. • See BCTU memory map.
Chapter 48, De-serial Serial Peripheral Interface (DSPI)	
Page 1991	• In the Status Register (DSPI_SR), changed TXRXS bitfield access from W1C to RO. • See Status Register (DSPI_SR)
Page 2043	• In the "Modified SPI/DSI Transfer Format (MTFE = 1, CPHA = 1)" section, added a note regarding operation in MTFE Enabled Mode (configuration of frame size and masking of extra bits during POP operation). • See Modified SPI/DSI Transfer Format (MTFE = 1, CPHA = 1)
Chapter 55, Reset and Boot	

Table continues on the next page...

Table 1-1. MPC5746RRM Rev6 Addendum (continued)

Location	Description
Page 2481	• Changed "All processes that need to be done in PHASE2[DEST] are completed" to "All processes that need to be done in PHASE2[FUNC] are completed". • See *PHASE2[FUNC]* Phase: flash initial configuration.
Page 2481	• Changed both occurrences of "shortened external 'functional' reset event" to "shortened 'functional' reset event". • See *PHASE3[FUNC]* Phase: device configuration monitoring.
Page 2483	• In the DEVICE CONFIG row, changed RESET to ON in the P1 and P2 [DEST] columns and changed HOLD to LOAD in the P3[FUNC] column. • See Module status during reset sequence.
Page 2483	• Added footnote (6) about ADC reset to the "other modules including cores" table entry. • Corrected footnote numbering throughout table. • See Module status during reset sequence.
Chapter 56, Reset Generation Module (MC_RGM)	
Page 2486	• Edited the two lists of reset sources on left side of "MC_RGM Block Diagram". • See Figure 1-3.
Chapter 57, Boot Assist Flash (BAF)	
Page 2555	• The section [BAF NMI event handling] has been moved and its content completely replaced/corrected. The previous revision incorrectly described the workaround for an issue in which the device may latch pending FCCU NMI events generated during a device reset. • See BAF NMI event handling.
Chapter 58, System Status and Configuration Module (SSCM)	
Page 2576	• Added a new paragraph regarding discernment between the boot location and other valid RCHW locations. • See System Status and Configuration Module (SSCM) chip-specific module information.
Page 2584	• Added a Note regarding the case of a multibit ECC error on the DCF start record during DCF Scanning. • See ECC error monitoring.
Chapter 59, Power Management	
Page 2590	• Changed "within the PMU" to "within the PMC". • See Power Management Controller (PMC).
Page 2591	• Added supplies VSS_HV_ADV_SAR, VSS_HV_ADV_SD, VDD_HV_IO_JTAG, VDD_HV_IO_FEC, VDD_HV_IO_MSC, VDD_LV_BD, VDD_HV_IO_BD, and VDDSTBY to the "Supply concept" diagram. • See Figure 1-4.
Chapter 60, Power Management Controller (PMC)	
Page 2601	• Changed title of chapter from "Power Management Controller digital interface (PMC_dig)" to "Power Management Controller (PMC)".
Page 2601	• Changed the title of Section 60.1 from "PMC_dig chip-specific module information" to "Chip-specific PMC information". • Changed "The Power Management Unit (PMU)" to "The PMC". • Changed "within the PMU" to "within the PMC". • See Chip-specific PMC information.

Table continues on the next page...

Table 1-1. MPC5746RRM Rev6 Addendum (continued)

Location	Description

Page 2601	• In the "PMC_dig chip-specific module information" section:
	  • In the "PMC register values defined by DCF clients" subsection:
	  • Renamed this subsection (was "PMC registers whose reset values can be defined by DCF clients").
	  • Change the existing sentence to "The following PMC registers are defined by the corresponding DCF clients:".
	  • Added the sentence "Refer to Table 6-5, DCF Clients".
	  • Added a note to verify the PMC_REE register value against the DCF_PMC_REE_CTRL DCF client value after any reset, and to update it if the verification fails.
	  • Removed the "PMC registers with chip-specific reset values" subsection.
	• See PMC register values defined by DCF clients.

Pages 2607-2608	• Added a note in the PMC_ESR_TD register field descriptions for TEMP1_2 and TEMP0_2. • See Temperature Event Status register (PMC_ESR_TD).

Page 2632	• Throughout the "LVD-HVD self test mechanism" section/subsections:
	  • Changed all instances of "VD_UTST[field_name]" to "PMC_SELF_TEST_UM_VD_REG[field_name]".
	  • Changed instance of "VD_ST_CTRL[ST_MODE]" to "PMC_SELF_TEST_UM_VD_REG[ST_MODE]".
	• See LVD-HVD self test mechanism.

Chapter 62, Mode Entry Module (MC_ME)	
Page 2724	• Updated the field names in the "MC_ME_CS field descriptions" table to match the implementation. • See Core Status (MC_ME_CS)
Chapter 70, JTAG Master (JTAGM)	
Page 3057	• In "JTAGM_MCR" text, added a note regarding an unexpected interrupt that will occur if the Idle Interrupt is enabled after the end of frame transfer. • See Module Configuration Register (JTAGM_MCR)
Page 3058	• In "JTAGM_MCR field descriptions", changed the TCKSEL 010 field value to Reserved. • See Module Configuration Register (JTAGM_MCR)
Pages 3061-3062	• In the "Data Out Register 0/1/2/3 (JTAGM_DOR0/1/2/3)" sections, added the stipulation that writing to these registers when DTM = 0 may cause unintended results. • See Data Out Register 0/1/2/3 (JTAGM_DOR0/1/2/3)
Chapter 77, Memory Error Management Unit (MEMU)	

Page 3273	• In the "Corresponding error sources for system RAM OFLW0 register" table:
	  • Added the following note to the "Core0 Instruction TCM error" row: "This error source could be triggered if Core0 IMEM is not initialized before Core0 is started."
	  • Added the following note to the "Core1 Instruction TCM error" row: "This error source could be triggered after reset."
	• See Table 1-15

Chapter 78, Fault Collection and Control Unit (FCCU)	

Table continues on the next page...

Table 1-1. MPC5746RRM Rev6 Addendum (continued)

Location	Description
Page 3305	• Numerous updates have been made throughout the chapter, which is included in its entirety. See FCCU chapter. • See Fault Collection and Control Unit (FCCU) changes for the list of changes in the FCCU chapter.
Chapter 79, Self-Test Control Unit (STCU2)	

Page 3392	• Updated the "AUTOLOCK_VALUE for register write access via STCU2_SKC" section:
	  • Renamed this section.
	  • Replaced this section with new content.
	  • Added DCF_COMPLETION value of 16.
	  • Updated AUTOLOCK_VALUE to 1024.
	• See AUTOLOCK_VALUE for register write access and DCF_COMPLETION value for DCF write completion.

Chapter 82, Password and Device Security Module (PASS)	
Page 3520	• Added the "JTAG_PASSWORD register bit correspondence" table and its introductory sentence. • See Password and Device Security Module (PASS) chip-specific module information.
Chapter 83, Tamper Detection Module (TDM)	
Page 3560	• Added paragraph "When attempting to update the TDM diary and erase flash blocks..." • See Flash erase counter and tamper detection.
Attachment: Flash_Block_Assignment.xlsx	
"LOCK Register Def." tab	• In the 'LOCK0 Register' table, changed the "Register Bit Name" of bit number 1 from "Reserved" to "ATSL".
"LOCK Register Def." tab	• In the 'LOCK1 Register' table, updated cells Y24-AE24 and Y25-AE25.
Attachment: IO_Signal_Description_and_Input_Multiplexing_Tables.xlsx	
"IO Signal Table" tab, cell T1500	• Changed the Pad State During Reset of PJ[14] from "Output/Low" to "Input/Pull-up".
Attachment: Memory_Map_Tables.xlsx	
"NVM and overlay memory map" tab	• In the "Large Flash Blocks - no overlay" section, updated the rows with start addresses 0x010C0000 - 0x01340000.
"UTEST memory map" tab	• Corrected the UTEST NVM addresses for Temperature Sensor 2 Calibration coefficients K1-K4, locations 0x004000C4 - 0x004000CF.

1.2 Device Configuration Format (DCF) Records

1.2.1 DCF clients

Table 1-2. DCF Clients

DCF CS[14:0]	DCF Address [16:2]	DCF Client Description	Reset Value of DCF Client	IPS Read Direct Access	DCF Client Special Strategy	Flash Special Strategy	DCF Order Dependency	UTEST Flash Memory Space
Tamper Detect								
000_0000_0001_0000	0000000_0000000	Diary Base Address	0xFFFFFFFF	no	Write Once + Write ‘0’ only	None	None	8
000_0000_0001_0000	0000000_0000001	Tamper Region Override	0x00	no	Write ‘1’ only	None	None	8
000_0000_0001_0000	0000000_0000010	Software Tamper Region Override Disable	0x00000000	no	Write Once + Write '1' only	None	None	8
000_0000_0001_0000	0000000_0000011-0000111	Reserved						

1.2.2 DCF_UTEST_Miscellaneous DCF client

The DCF_UTEST_Miscellaneous register controls miscellaneous functionalities.

The DCF_UTEST_Miscellaneous DCF client represents the chip-specific device configuration. Therefore, we recommend that you program this client only one time, to avoid undesirable chip behavior.

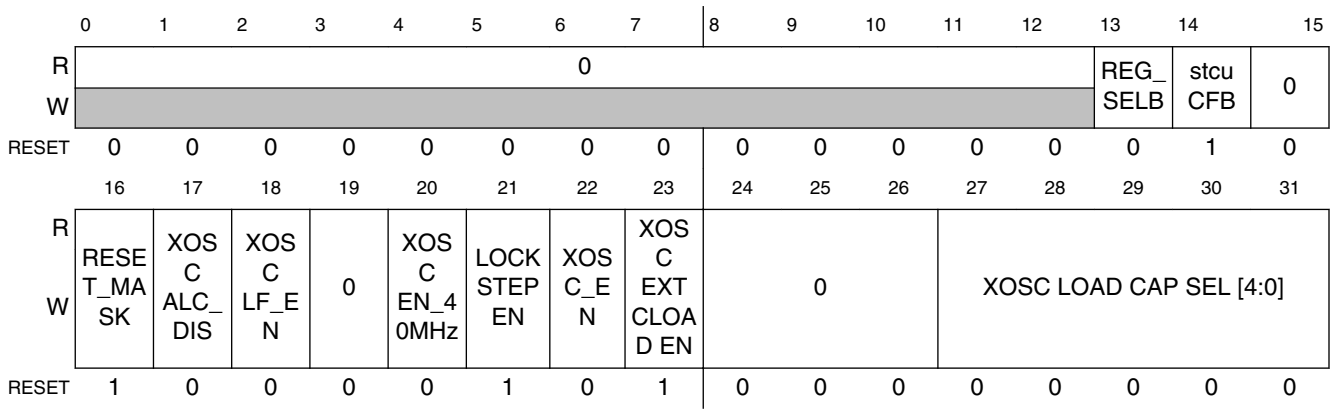

Table 1-3. DCF_UTEST_Miscellaneous Field Description

Field	Name	Description
0-12	Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13	REG_SELB	If this bit is set to 0, internal regulation will be selected. If not external regulation is selected.
14	stcu CFB	If this is set to 1, critical fault during offline LBIST run will generate a destructive reset.
15	Reserved	This field is reserved. This read-write field must always be written with the value 0.
16	RESET_MASK	Active Low reset Mask bit. 1- RESET PIN enabled, 0-RESET Pin Disabled Level Controller
17	XOSC ALC_DIS	Active high to disable Automatic Level Controller
18	XOSC LF_EN	Active high when oscillator is used for low frequency (~8MHz)
19	Reserved	This field is reserved. This read-write field must always be written with the value 0.
20	XOSC EN_40MHz	Selects 20MHz against 40MHz XOSC. Set this bit to enable the 40Mhz mode.
21	LOCKSTEP EN	Enables Safety Core to be in lockstep with Checker Core. Value 0 = Lockstep disabled, Value 1 = Lockstep enabled
22	XOSC_EN	Enables XOSC. **NOTE:** If XOSC is enabled via this field, then VDD_HV_IO_JTAG must be within the operating range before the RESET pin is released.
23	XOSC EXT CLOAD EN	Selects XOSC internal capacitor (ok for 20-40MHz operation) or external (required for 4-16MHz operation). Set to 1 if external capacitors are used.
24-26	Reserved	This field is reserved. This read-write field must always be written with the value 0.
27-31	XOSC LOAD CAP SEL [4:0]	5 Trim bits to program the load capacitance at crystal pins

1.2.3 DCF_PMC_REE_TD DCF client

The DCF_PMC_REE_TD register controls whether the temperature detect signal event causes a reset.

If the desired flag bit is enabled, the temperature detect event causes a reset to be generated when the selected temperature passes the trigger event.

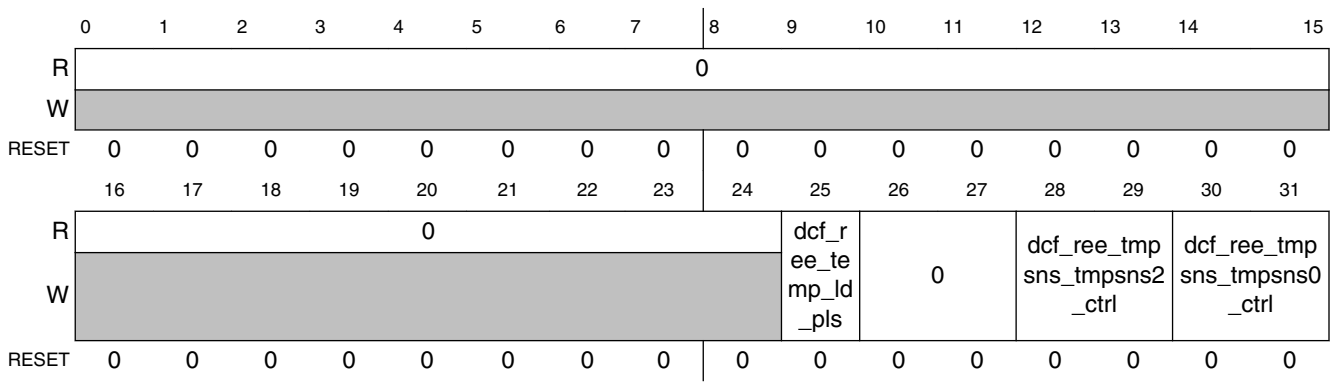

Table 1-4. DCF_PMC_REE_TD Field Description

Field	Name	Description
0-24	Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25	dcf_ree_temp_ld_pls	Set this bit to 1 so that values uploaded becomes effective.
26-27	Reserved	This field is reserved. This read-write field must always be written with the value 0.
28-29	dcf_ree_tmpsns_tmpsns2_ctrl	Defines whether a temperature detect assertion generates a system reset. This is associated with the temperature for the temperature sensor point (150C). • 00: Temperature sensor detect event does not cause system reset. • 01: Temperature sensor 0 detect causes system reset. • 10: Temperature sensor 1 detect causes system reset. • 11: Temperature sensor 0 and 1 detect causes system reset.
30-31	dcf_ree_tmpsns_tmpsns0_ctrl	Defines whether a temperature detect assertion generates a system reset. This is associated with the temperature for the cold temperature sensor,when the temperature exceeds its corresponding threshold. • 00: Temperature sensor detect event does not cause system reset. • 01: Temperature sensor 0 detect causes system reset. • 10: Temperature sensor 1 detect causes system reset. • 11: Temperature sensor 0 and 1 detect causes system reset.

1.2.4 DCF_IVPR0 DCF client

The DCF_IVPR0 is the reset interrupt vector prefix register DCF client for Main Core_0.

NOTE

- The DCF client value is applied as the core IVPR reset value if the core is reset and PFLASH_PFCR3[BAF_DIS] is written with 1.
- The value in this DCF client is left-shifted by 8 bits before programmed to the Core_1 IVPR.

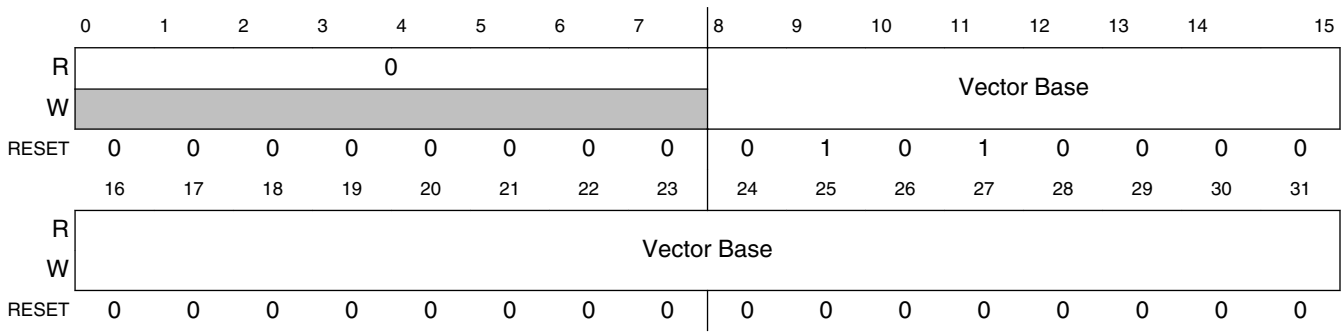

Table 1-5. DCF_IVPR0 Field Description

Field	Name	Description
0-7	Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8-31	Vector Base	This field is used to define the base location of the vector table, aligned to a 256 byte boundary. This field provides the high-order 24 bits of the location of all interrupt handlers (unless hardware vectoring is used). The vector offset value appropriate for the type of exception being processed is concatenated with the IVPR Vector Base to form the address of the handler in memory. For hardware-vectored interrupts, the value of the supplied interrupt vector is logically OR'ed with the low order bits of the Vec Base Field to determine the interrupt handler address. **NOTE:** dcf_ivpr[31:8] -> core.ivpr[8:31]

1.2.5 DCF_IVPR1 DCF client

The DCF_IVPR1 is the reset interrupt vector prefix register DCF client for Main Core_1.

NOTE

- The DCF client value is applied as the core IVPR reset value if the core is reset and PFLASH_PFCR3[BAF_DIS] is written with 1.

- The value in this DCF client is left-shifted by 8 bits before programmed to the Core_1 IVPR.
- IVPR1_CPU1 - BAF set IVPR1 for CPU1 DCF Client can be used to apply an IVPR reset value for core1 after POR.

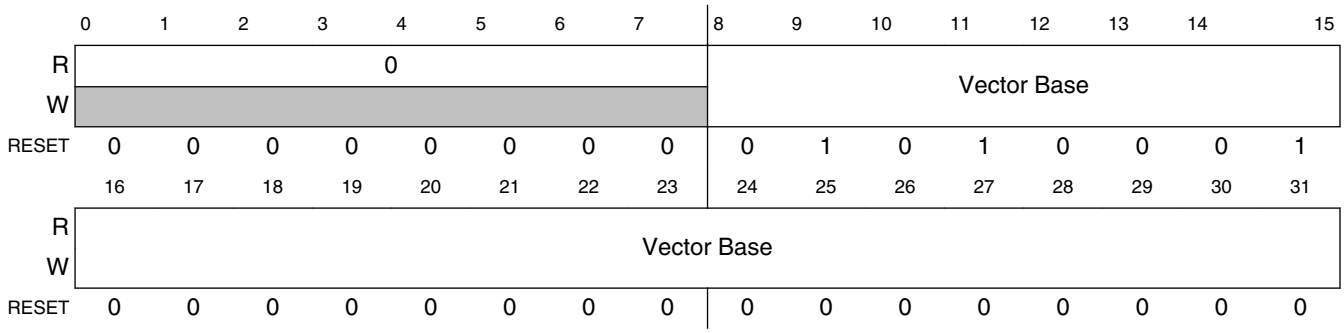

Table 1-6. DCF_IVPR1 Field Description

Field	Name	Description
0-7	Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8-31	Vector Base	This field is used to define the base location of the vector table, aligned to a 256 byte boundary. This field provides the high-order 24 bits of the location of all interrupt handlers (unless hardware vectoring is used). The vector offset value appropriate for the type of exception being processed is concatenated with the IVPR Vector Base to form the address of the handler in memory. For hardware-vectored interrupts, the value of the supplied interrupt vector is logically OR'ed with the low order bits of the Vec Base Field to determine the interrupt handler address. **NOTE:** dcf_ivpr[31:8] -> core.ivpr[8:31]

1.2.6 DCF_SELFTEST_CONFIG_IPS_1 DCF client

The DCF_SELFTEST_CONFIG_IPS_1 register controls the fault Model for LBIST and selects which PLL would be used for LBIST testing if any.

This register is reset by destructive reset only. The DCF client is loaded by the SSCM only if the DCF client has been previously reset.

Address: 0x11_1111_1110_0000 base + 0x0 offset

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0										PLL_LOCK1	PLL_LOCK0	0			1
W																
RESET	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

Table 1-7. DCF_SELFTEST_CONFIG_IPS_1 Field Description

Field	Name	Description
0-9	Reserved	This field is reserved. This read-write field must always be written with the value 0.
10	PLL_LOCK1	Program this bit to "1" if PLL1 is to be used for Selftest. Only one of bits 20 and 21 should be programmed "1".
11	PLL_LOCK0	Program this bit to "1" if PLL0 is to be used for Selftest . Only one of bits 20 and 21 should be programmed "1".
12-14	Reserved	This field is reserved. This read-write field must always be written with the value 0.
15	Reserved	This field is reserved. This read-write field must always be written with the value 1.
16-18	Reserved	This field is reserved. This read-write field must always be written with the value 0.
19	config[1]	Program this bit to "1" if stuck-At LBIST is required to be run. In this mode PLL is locked at 200 Mhz but all partitions are run at 50 Mhz at 4 seperate edges of 200 Mhz so as to reduce the peak power.
20-30	Reserved	This field is reserved. This read-write field must always be written with the value 0.
31	Reserved	This field is reserved. Set this bit when running LBIST.

1.2.7 DCF_SELFTEST_CONFIG_IPS_2 DCF client

The DCF_SELFTEST_CONFIG_IPS_2 register controls the division values for the dividers.

The division value set by these fields is the bit value + 1. (0b000 sets the division value to 1, 0b001 sets the division value to 2, and so on.)

This register is reset by destructive reset only. The DCF client is loaded by the SSCM only if the DCF client has been previously reset.

Address: 0x11_1111_1110_0000 base + 0x100 offset

Table 1-8. DCF_SELFTEST_CONFIG_IPS_2 Field Description

Field	Name	Description
0-1	Reserved	This field is reserved. This read-write field must always be written with the value 0.
2-4	Aux_MUX_0_Divider_4_Division_Value	Sets the division value of the divider.
5-7	Aux_MUX_0_Divider_3_Division_Value	Sets the division value of the divider.
8-10	Aux_MUX_0_Divider_2_Division_Value	Sets the division value of the divider.
11-13	Aux_MUX_0_Divider_1_Division_Value	Sets the division value of the divider.
14-16	Aux_MUX_0_Divider_0_Division_Value	Sets the division value of the divider.
17-19	Reserved	This field is reserved. This read-write field must always be written with the value 0.
20-22	System_MUX_Divider_0_Division_Value	Sets the division value of the divider.
23-25	System_MUX_Divider_1_Division_Value	Sets the division value of the divider.
26-28	System_MUX_Divider_2_Division_Value	Sets the division value of the divider.
29-31	System_MUX_Divider_3_Division_Value	Sets the division value of the divider.

1.2.8 DCF_SELFTEST_CONFIG_IPS_3 DCF client

The DCF_SELFTEST_CONFIG_IPS_3 register controls the division values for the dividers.

The division value set by these fields is the bit value + 1. (0b000 sets the division value to 1, 0b001 sets the division value to 2, and so on.)

This register is reset by destructive reset only. The DCF client is loaded by the SSCM only if the DCF client has been previously reset.

Address: 0x11_1111_1110_0000 base + 0x1000 offset

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Table 1-9. DCF_SELFTEST_CONFIG_IPS_3 Field Description

Field	Name	Description
0-4	Reserved	This field is reserved. This read-write field must always be written with the value 0.
5-7	Aux_Mux_10_Divider_0_Division_Value	Sets the division value of the divider.
8-10	Aux_Mux_9_Divider_0_Division_Value	Sets the division value of the divider.
11-13	Aux_Mux_8_Divider_0_Division_Value	Sets the division value of the divider.
14-16	Reserved	This field is reserved. This read-write field must always be written with the value 0.
17-19	Aux_Mux_6_Divider_0_Division_Value	Sets the division value of the divider.
20-22	Aux_Mux_5_Divider_1_Division_Value	Sets the division value of the divider.
23-25	Aux_Mux_5_Divider_0_Division_Value	Sets the division value of the divider.
26-28	Aux_Mux_2_Divider_0_Division_Value	Sets the division value of the divider.
29-31	Aux_Mux_1_Divider_0_Division_Value	Sets the division value of the divider.

1.2.9 DCF_SELFTEST_CONFIG_IPS_4 DCF client

The DCF_SELFTEST_CONFIG_IPS_4 register controls the LBIST shift length for each partition.

This register is reset by destructive reset only. The DCF client is loaded by the SSCM only if the DCF client has been previously reset.

Address: 0x11_1111_1110_0000 base + 0x1100 offset

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R W	0								LBIST_W1_Shift_Length						LBIST_W0_Shift_Length	
RESET	0	0	0	0	0	0	0	0	1	1	0	1	1	1	1	1

	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	(LBIST_W0_Shift_Length)				LBIST_L1_Shift_Length						LBIST_L0_Shift_Length					
RESET	0	1	1	1	1	1	0	1	1	1	1	1	0	1	1	1

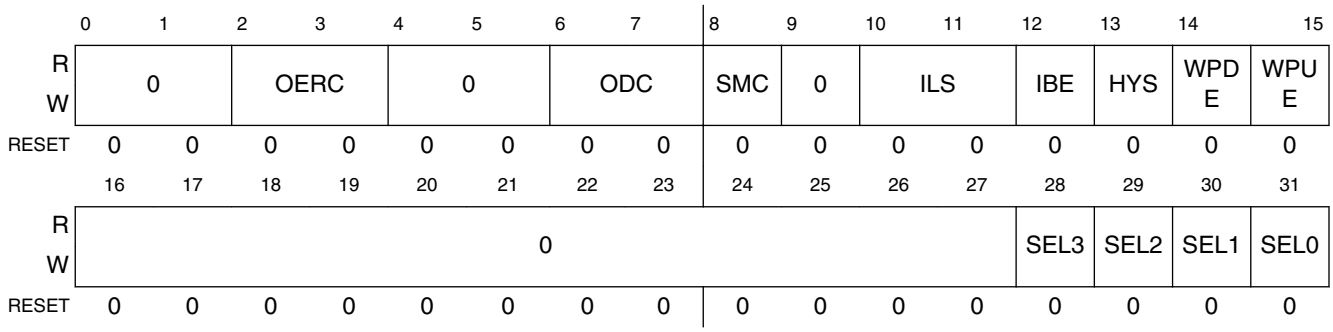

Table 1-10. DCF_SELFTEST_CONFIG_IPS_4 Field Description

Field	Name	Description
0-7	Reserved	This field is reserved. This read-write field must always be written with the value 0.
8-13	LBIST_W1_Shift_Length	Sets the LBIST shift length of the W1 partition.
14-19	LBIST_W0_Shift_Length	Sets the LBIST shift length of the W0 partition.
20-25	LBIST_L1_Shift_Length	Sets the LBIST shift length of the L1 partition.
26-31	LBIST_L0_Shift_Length	Sets the LBIST shift length of the L0 partition.

1.2.10 DCF_ERROR0_PAD_SELECT DCF client

The DCF_ERROR0_PAD_SELECT_CONTROL register selects either the functional muxing or the EOUT functionality on pads PJ[11], PJ[1], PI[0], and PH[0]. This is done at boot time according to the SELn bits of this DCF client:

- If ERROR0 OUT is selected (i.e., the SELn bits are set), the PAD controls of the pad are governed by this DCF client.
- If functional muxing is selected (i.e., the SELn bits are not set), the PAD controls are governed by the SIUL2_MSCRn register.

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	0												SEL3	SEL2	SEL1	SEL0
RESET	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 1-11. DCF_ERROR0_PAD_SELECT_CONTROL Field Descriptions

Field	Name	Description
0-1	Reserved	This field is reserved. This read-write field must always be written with the value 0.
2-3	OERC	Sets the Output Edge Rate Control when ERROR0 OUT is enabled. The function is the same as the corresponding field in SiUL2_MSCRn.
4-5	Reserved	This field is reserved. This read-write field must always be written with the value 0.
6-7	ODC	Sets the Output Drive Control when ERROR0 OUT is enabled. The function is the same as the corresponding field in SiUL2_MSCRn.
8	SMC	Sets the Safe Mode Control when ERROR0 OUT is enabled. The function is the same as the corresponding field in SiUL2_MSCRn.
9	Reserved	This field is reserved. This read-write field must always be written with the value 0.
10-11	ILS	Sets the Input Level Selection when ERROR0 OUT is enabled. The function is the same as the corresponding field in SiUL2_MSCRn.
12	IBE	Sets the Input Buffer Enable when ERROR0 OUT is enabled. The function is the same as the corresponding field in SiUL2_MSCRn.
13	HYS	Sets the Input Hysteresis when ERROR0 OUT is enabled. The function is the same as the corresponding field in SiUL2_MSCRn.
14	WPDE	Sets the Weak Pulldown Enable when ERROR0 OUT is enabled. The function is the same as the corresponding field in SiUL2_MSCRn.
15	WPUE	Sets the Weak Pullup Enable when ERROR0 OUT is enabled. The function is the same as the corresponding field in SiUL2_MSCRn.
16-27	Reserved	This field is reserved. This read-write field must always be written with the value 0.
28	SEL3	Enable ERROR0 OUT on PJ[11] irrespective of SIUL2_MSCRn[SSS] settings and override the pad setting as defined in this register.
29	SEL2	Enable ERROR0 OUT on PJ[1] irrespective of SIUL2_MSCRn[SSS] settings and override the pad setting as defined in this register
30	SEL1	Enable ERROR0 OUT on PI[0] irrespective of SIUL2_MSCRn[SSS] settings and override the pad setting as defined in this register
31	SEL0	Enable ERROR0 OUT on PH[0] irrespective of SIUL2_MSCRn[SSS] settings and override the pad setting as defined in this register

There is no hardware restriction on the programming of the SELn bits. All the four pads can be simultaneously be programmed as ERROR0 OUT Pins.

1.2.11 DCF_ERROR1_PAD_SELECT DCF client

The DCF_ERROR1_PAD_SELECT_CONTROL register selects either the functional muxing or the EOUT functionality on pads PJ[0], PI[1], and PH[3]. This is done at boot time according to the SELn bits of this DCF client:

- If ERROR1 OUT is selected (i.e., the SELn bits are set), the PAD controls of the pad are governed by this DCF client.
- If functional muxing is selected (i.e., the SELn bits are not set), the PAD controls are governed by the SIUL2_MSCR register.

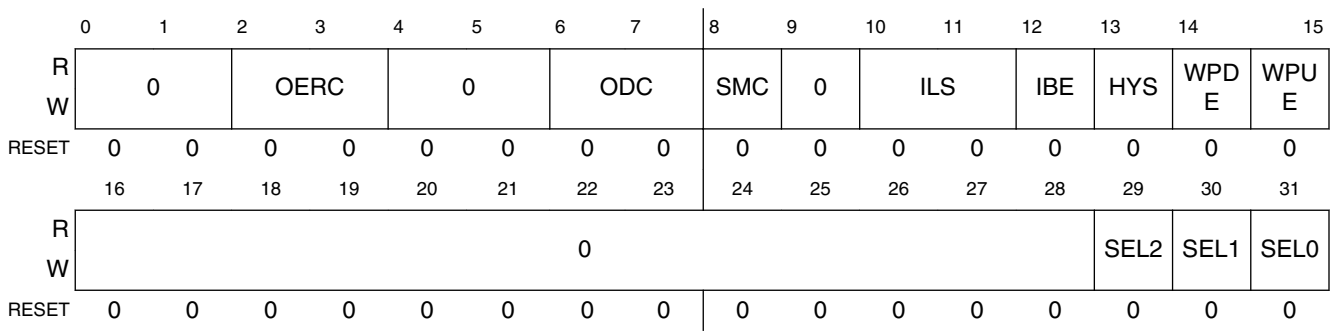

Table 1-12. DCF_ERROR1_PAD_SELECT_CONTROL Field Descriptions

Field	Name	Description
0-1	Reserved	This field is reserved. This read-write field must always be written with the value 0.
2-3	OERC	Sets the Output Edge Rate Control when ERROR0 OUT is enabled. The function is the same as the corresponding field in SiUL2_MSCRn.
4-5	Reserved	This field is reserved. This read-write field must always be written with the value 0.
6-7	ODC	Sets the Output Drive Control when ERROR0 OUT is enabled. The function is the same as the corresponding field in SiUL2_MSCRn.
8	SMC	Sets the Safe Mode Control when ERROR0 OUT is enabled. The function is the same as the corresponding field in SiUL2_MSCRn.
9	Reserved	This field is reserved. This read-write field must always be written with the value 0.
10-11	ILS	Sets the Input Level Selection when ERROR0 OUT is enabled. The function is the same as the corresponding field in SiUL2_MSCRn.
12	IBE	Sets the Input Buffer Enable when ERROR0 OUT is enabled. The function is the same as the corresponding field in SiUL2_MSCRn.
13	HYS	Sets the Input Hysteresis when ERROR0 OUT is enabled. The function is the same as the corresponding field in SiUL2_MSCRn.
14	WPDE	Sets the Weak Pulldown Enable when ERROR0 OUT is enabled. The function is the same as the corresponding field in SiUL2_MSCRn.

Table continues on the next page...

Table 1-12. DCF_ERROR1_PAD_SELECT_CONTROL Field Descriptions (continued)

Field	Name	Description
15	WPUE	Sets the Weak Pullup Enable when ERROR0 OUT is enabled. The function is the same as the corresponding field in SiUL2_MSCRn.
16-28	Reserved	This field is reserved. This read-write field must always be written with the value 0.
29	SEL2	Enable ERROR1 OUT on PJ[0] irrespective of SIUL2_MSCRn[SSS] settings and override the pad setting as defined in this register.
30	SEL1	Enable ERROR1 OUT on PI[1] irrespective of SIUL2_MSCRn[SSS] settings and override the pad setting as defined in this register.
31	SEL0	Enable ERROR1 OUT on PH[3] irrespective of SIUL2_MSCRn[SSS] settings and override the pad setting as defined in this register.

There is no hardware restriction on the programming of the SELn bits. All three pads can be simultaneously be programmed as ERROR1 OUT Pins.

1.3 Local memory features

The features of the Local Instruction and Data Memories are as follows:

- Local instruction and data memories (IMEM, DMEM) with shared AHB 2.v6 64-bit slave interface
  - e200z425n3—16 KB IMEM, 32 KB DMEM
  - e200z424—No IMEM, No DMEM
- Support for zero wait-state access relative to cache hit timings
- Support for multi-bit (SECDED) ECC with correction/scrubbing capability
- 4-entry ECC R-M-W Store Buffer for DMEM
- 32-bit address bus plus attributes and control
- Separate uni-directional 64-bit read data bus and (for DMEM only) 64-bit write data bus

NOTE

IMEM and DMEM must be initialized, regardless of whether they are used.

1.4 INTC interrupt sources

The following table defines the interrupt sources for the INTC on this chip. All IRQ numbers not specifically listed are not used.

Table 1-13. Interrupt sources

IRQ #	Offset	Source description	Source name
0	1000	Software settable flag 0	INTC_SSCIR0[CLR0]
1	1004	Software settable flag 1	INTC_SSCIR0[CLR1]
2	1008	Software settable flag 2	INTC_SSCIR0[CLR2]
3	100C	Software settable flag 3	INTC_SSCIR0[CLR3]
4	1010	Software settable flag 4	INTC_SSCIR0[CLR4]
5	1014	Software settable flag 5	INTC_SSCIR0[CLR5]
6	1018	Software settable flag 6	INTC_SSCIR0[CLR6]
7	101C	Software settable flag 7	INTC_SSCIR0[CLR7]
8	1020	Software settable flag 8	INTC_SSCIR0[CLR8]
9	1024	Software settable flag 9	INTC_SSCIR0[CLR9]
10	1028	Software settable flag 10	INTC_SSCIR0[CLR10]
11	102C	Software settable flag 11	INTC_SSCIR0[CLR11]
12	1030	Software settable flag 12	INTC_SSCIR0[CLR12]
13	1034	Software settable flag 13	INTC_SSCIR0[CLR13]
14	1038	Software settable flag 14	INTC_SSCIR0[CLR14]
15	103C	Software settable flag 15	INTC_SSCIR0[CLR15]

936	1EA0	DECFIL_1_Out	ipi_int_dec_filter_1_out
937	1EA4	DECFIL_1_Err	ipi_int_dec_filter_1_err

1.5 Lockstep

This chip contains an eDMA Checker which, when enabled, operates in Lockstep mode with the primary eDMA, executing the exact same transfer profiles. The eDMA Checker checks to ensure the primary eDMA is operating correctly. A block diagram is shown below.

1.5.1 Initialization

To prevent the eDMA Checker from generating a false comparison error after power-on-reset, the eDMA's data output buffer must be initialized prior to enabling the Checker. To initialize the eDMA data output buffer, the eDMA must perform one or more 32-bit data transfers using any data value.

1.5.2 Errors

To handle source-address errors (SAE), perform the following steps.

1. Fix the addressing error.
2. Clear the error bit in "Enable Error Interrupt RegisterLow (DMA_ERRL)" or "Error Interrupt Register High (DMA_ERRH)".
3. Start the channel in a normal fashion.

NOTE

"Error Status Register (DMA_ES)" is read-only; the bits cannot be cleared. It saves the last recorded error. The VLD bit shows

the user whether any error bits in the Error Registers are set, thus indicating an error occurred that has not been cleared.

1.6 LINFlex clocking

The LINFlex protocol clock (LINCLK) domain selection may be configured via soft DCF client programming...

[*Content deleted for brevity.*]

In either mode the LINCLK must be enabled by setting the Auxiliary Clock 0 Divider Configuration Register (MC_CGM_AC0_DC4) Divider Enable (DE) bit to 0b1.

1.7 Clock configuration

The relationship between input and output frequency is determined by programming the PLL0DV, PLL1DV, and PLL1FD registers, and calculated according to the following equations:

$$f_{pll0_phi} = f_{pll0_ref} \times \left(\frac{PLL0DV[MFD]}{PLL0DV[PREDIV] \times PLL0DV[RFDPHI]} \right)$$

Equation 1. PLL0 PHI Output Frequency

$$f_{pll0_phi1} = f_{pll0_ref} \times \left(\frac{PLL0DV[MFD]}{PLL0DV[PREDIV] \times PLL0DV[RFDPHI1]} \right)$$

Equation 2. PLL0 PHI1 Output Frequency

$$f_{pll1_phi} = f_{pll1_ref} \times \left(\frac{PLL1DV[MFD] + \frac{PLL1FD[FRCDIV]}{2^{12}} + \frac{1}{2^{13}}}{2 \times PLL1DV[RFDPHI]} \right)$$

Equation 3. PLL1 PHI Output Frequency (PLLDIG_PLL1FD[FDEN] = 1b)

$$f_{pll1_phi} = f_{pll1_ref} \times \left(\frac{PLL1DV[MFD]}{2 \times PLL1DV[RFDPHI]} \right)$$

Equation 4. PLL1 PHI Output Frequency (PLLDIG_PLL1FD[FDEN] = 0b)

The relationship between the VCO frequency (f_{VCO}) and the output frequency of the PLLs is determined by the configuration of the PLL1DV, PLL1FD, and PLL0DV registers, according to the following equations:

$$f_{pll0_VCO} = f_{pll0_ref} \times \left(\frac{PLL0DV[MFD] \times 2}{PLL0DV[PREDIV]}\right)$$

Equation 5. PLL0 VCO Frequency

$$f_{pll1_VCO} = f_{pll1_ref} \times \left(PLL1DV[MFD] + \frac{PLL1FD[FRCDIV]}{2^{12}} + \frac{1}{2^{13}}\right)$$

Equation 6. PLL1 VCO Frequency (PLLDIG_PLL1FD[FDEN] = 1b)

$$f_{pll1_VCO} = f_{pll1_ref} \times PLL1DV[MFD]$$

Equation 7. PLL1 VCO Frequency (PLLDIG_PLL1FD[FDEN] = 0b)

NOTE

f_{pll0_phi1} is the reference clock generated by PLL0 for PLL1

When programming the PLLs, user software must not violate the maximum system clock frequency or max/min VCO frequency specification of PLL0 and PLL1. Furthermore, the PLL0DV[PREDIV] value must not be set to any value that causes the input frequency to the phase detector of analog PLL blocks to go below the prescribed ranges.

The lock signal and PLL*n*SR[LOCK] flag are immediately negated if the fields of the PLL*n*DV registers are changed without powering down the analog PLLs.

When any of these events occur, an internal timer is initialized to count 64 cycles of the PLL input clock. During this period (64 cycles and a few extra clock cycles for synchronization, for example, 64 to 72 cycles), the PLL*n*SR[LOCK] flag is held negated. After the timer expires, the PLL*n*SR[LOCK] flag reflects the value coming from the PLL lock detection circuitry. To prevent an immediate reset, the PLL*n*CR[LOLRE] bit of the respective PLLs must be cleared before doing any of the above operations.

Note

The PLL must be powered down and powered up by configuring, then executing, a mode change in the MC_ME_<*mode*>_MC before PLL0DV[PREDIV], PLL0DV[MFD], PLL1DV[MFD], or the input clocks are modified.

The recommended procedure to program the PLLs and engage normal mode is shown in Initialization information.

Coming out of reset, PLL1 and PLL0 are off and in bypass mode. The recommended procedure to program the PLLs and engage normal mode is described in the 'Clocking' chapter.

1.8 CMU Measurement Duration Register (CMU_MDR)

Added the following note in the CMU_MDR register field description for the MD field:

Only values that do not cause a CMU_FDR[FD] overflow shall be written to CMU_MDR[MD]. There is no internal status of a CMU_FDR[FD] overflow.

1.9 System Clock Dividers

The MC_CGM generates the following derived clocks from the system clock.

- Fast XBAR clock - controlled by the **CGM_SC_DC0** register
- Slow XBAR clock - controlled by the **CGM_SC_DC1** register
- AIPS clock - controlled by the **CGM_SC_DC2** register

NOTE

All masters, except the cores, must not be active during system clock divider configuration.

1.10 Auxiliary Clock Generation

Added the following content at the end of the section.

The following procedures avoid undefined system behavior.

Auxiliary clock enable procedure:

1. Software needs to ensure the clock source is enabled and available (for example, oscillator stable, PLL locked).
2. Configure IRC clock source in selector registers (MC_CGM_AC*x*_SC).
3. Configure the appropriate clock source selector registers (MC_CGM_AC*x*_SC).
4. Configure and enable any corresponding auxiliary clock dividers (MC_CGM_AC*x*_DC*n*). This should be done in an atomic 32-bit wide register access.

Auxiliary clock disable procedure:

1. Software needs to ensure that the state of the module driven by this clock allows to disable the clock.
2. Disable auxiliary clock dividers (MC_CGM_AC*x*_DC*n*[DE] = 0).
3. Wait for at least 27 system clock cycles to allow divider configuration to complete.

In the event a switch to a different clock source is required, while auxiliary clock has been configured and used, the above auxiliary clock disable procedure followed by the above auxiliary clock enable procedure should be applied.

In the event the clock divider value requires to be altered, while auxiliary clock has been configured and used, this can be done by changing the value in the corresponding clock divider configuration register (MC_CGM_AC*x*_DC*n*).

Before any clock source is switched off, all clock divider need to be disabled.

1.11 eTPU chapter

See Chapter 2, Enhanced Time Processing Unit (eTPU) for an updated eTPU chapter, and Appendix A for a listing of all the changes in that chapter.

1.12 BCTU Introduction

The Body Cross-triggering Unit (BCTU) is a module that is used to trigger the on chip ADCs. The trigger sources are generated by on chip timer modules. Usually in Body domain of applications the timers used are the enhanced Modular IO Sub-system (eMIOS), enhanced Time Processing Unit (ETPU),and the Programmable Interrupt Timer (PIT). In addition to triggering ADC single conversions, the BCTU also implements a LIST—a set of registers programmed by software that stores ADC channel numbers—that triggers several conversions based on a single trigger occurrence. Up to 32 trigger inputs are available. The CPU can also be a source of conversion triggers, thus implementing a software trigger control. Up to 4 ADC modules are supported. The conversion results are stored in a register which is available for CPU read access. Figure below shows the BCTU top level diagram (the figure is not included in this RMAD because it was not modified).

1.13 BCTU memory map

Updated the "BCTU memory map" table as shown below.

Before:

22C	Software Trigger register 1 (BCTU_SFTRGR1)	32	R/W	0000_0000h	46.6.5/1799
234	Software Trigger register 1 (BCTU_SFTRGR3)	32	R/W	0000_0000h	46.6.6/1802
23C	ADC0 Result Data register (BCTU_ADC0DR)	32	R	0000_0000h	46.6.7/1806

After:

22C	Software Trigger register 1 (BCTU_SFTRGR1)	32	R/W	0000_0000h	46.6.5/1799
23C	ADC0 Result Data register (BCTU_ADC0DR)	32	R	0000_0000h	46.6.7/1806

Figure 1-1. BCTU memory map changes

1.14 Status Register (DSPI_SR)

In the Status Register (DSPI_SR), changed TXRXS bitfield access from W1C to RO.

Address: 0h base + 2Ch offset = 2Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	TCF	TXRXS	SPITCF	EOQF	TFUF	DSITCF	TFFF	BSYF	CMDTCF	DPEF	SPEF	DDIF	RFOF	TFIWF	RFDF	CMDFFF
W	w1c		w1c	w1c	w1c	w1c	w1c		w1c	w1c	w1c	w1c	w1c	w1c	w1c	w1c
Reset	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0	1

R	TXCTR				TXNXTPTR				RXCTR				POPNXTPTR			
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 1-2. Status Register (DSPI_SR)

1.15 Modified SPI/DSI Transfer Format (MTFE = 1, CPHA = 1)

Added the following note:

NOTE

When MTFE=1 with continuous SCK enabled (MCR [CONT_SCKE] =1) in master mode, configure CTAR[LSBFE]=0 for correct operations while receiving unequal length frames. If PUSHR[CONT] is also set for back to back frame transfer, also configure the frame size of the first frame as less than or equal to the frame size of the next frame. In this scenario, make sure that for all received frames, the bits are read equal to their respective frame sizes and any extra bits during POP operation are masked.

1.16 *PHASE2[FUNC]* Phase: flash initial configuration

This phase is entered on exit from ***PHASE1[FUNC]***. The reset state machine exits ***PHASE2[FUNC]*** and enters ***PHASE3[FUNC]*** on verification of the following:

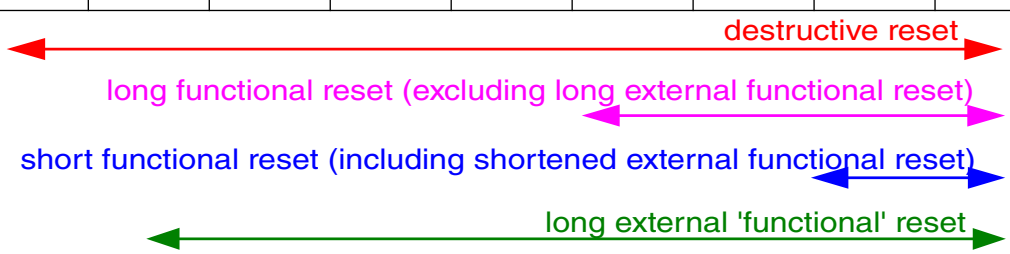
- All processes that need to be done in ***PHASE2[FUNC]*** are completed

During this phase, the reset is released to the flash which can start its initial configuration. Watchdog is monitoring execution ensuring reset in case of flash configuration failure.

This phase is duplication of ***PHASE2[DEST]*** after self-test.

1.17 *PHASE3[FUNC]* Phase: device configuration monitoring

This phase is entered either on exit from ***PHASE2[FUNC]*** or immediately from ***IDLE*** on an enabled, shortened 'functional' reset event. The reset state machine exits ***PHASE3[FUNC]*** and enters ***IDLE*** on verification of the following:



- All processes that need to be done in ***PHASE3[FUNC]*** are completed. In particular PORST and RESET pin are not forced low externally.
- A minimum number of cycles have elapsed since the last enabled, shortened 'functional' reset event

After ***PHASE3[FUNC]*** internal actions have been completed, it is possible to maintain the device within ***PHASE3[FUNC]*** by forcing either PORST or RESET pin low. This can be used for debug purpose to connect through JTAG to the internal debugger.

1.18 Module status during reset sequence

The following table is providing status of main modules during the different reset phases:

Table 1-14. Module status during reset phases

Module	PHASE								
	P0 (RED)	P1 [DEST] (RED)	P2 [DEST] (RED)	P3 [DEST] (RED)	IDLE [DEST] (RED)	P1 [FUNC] (PURPLE)	P2 [FUNC] (PURPLE)	P3 [FUNC] (BLUE)	IDLE [FUNC] (WHITE)
Internal RCOSC	ON	ON	ON	ON	ON	ON	ON	ON	ON
Power management controller	ON	ON	ON	ON	ON	ON	ON	ON	ON
Reset management controller	ON[1]	ON	ON	ON	ON	ON	ON	ON	ON
system watchdog	RESET	RESET	ON	RESET	LBIST[2]	RESET	ON	RESET	ON[3]
flash module	RESET	RESET	ON	ON	LBIST	RESET	ON	ON	ON
OSC	RESET	RESET	RESET	ON[3]	ON[3]	ON[3]	ON[3]	ON[3]	ON[3]
DEVICE CONFIG	RESET	ON	ON	LOAD	HOLD	HOLD	HOLD	LOAD	HOLD
SSCM	RESET	RESET	RESET	ON	ON	RESET	RESET	ON	ON
FCCU	RESET	RESET	CONFIG	CONFIG	LBIST	RESET/ON[4]	CONFIG/ON	CONFIG/ON	ON
STCU	RESET	RESET	CONFIG	CONFIG	ON	IDLE	IDLE	IDLE	IDLE[5]
pit_rti_1 timer	RESET	RESET	RESET	RESET	LBIST	IDLE/ON	IDLE/ON	IDLE/ON	IDLE/ON
other modules including cores[6]	RESET	RESET	RESET	RESET	LBIST	RESET	RESET	RESET	ON[7]
Debug Modules	RESET	RESET	RESET	RESET	RESET	ON	ON	ON	ON
									

1. RESET only during POR.
2. STCU time-out monitoring LBIST/MBIST execution
3. Depending on flash configuration
4. FCCU remains ON during functional reset, it is instead reset in PHASE1[FUNC] if coming from IDLE[DEST]
5. Can be triggered by SW

6. The ADC is reset as described in the table, but the ADC_CALBISTREG and ADC_OFSGNUSR registers and the ADC_MSR[CALIBRTD] field are only reset by PHASE1[FUNC] or PHASE1[DEST].
7. After enabling from BAF

1.19 Overview

The reset generation module (MC_RGM) centralizes the different reset sources and manages the reset sequence of the chip. It provides a register interface and a reset sequencer. Various registers are available to monitor and control the chip reset sequence. The reset sequencer is a state machine which controls the different phases (***PHASE0***, ***PHASE1***, ***PHASE2***, ***PHASE3***, and ***IDLE***) of the reset sequence and the reset signals generated in the system.

The following figure shows the MC_RGM block diagram.

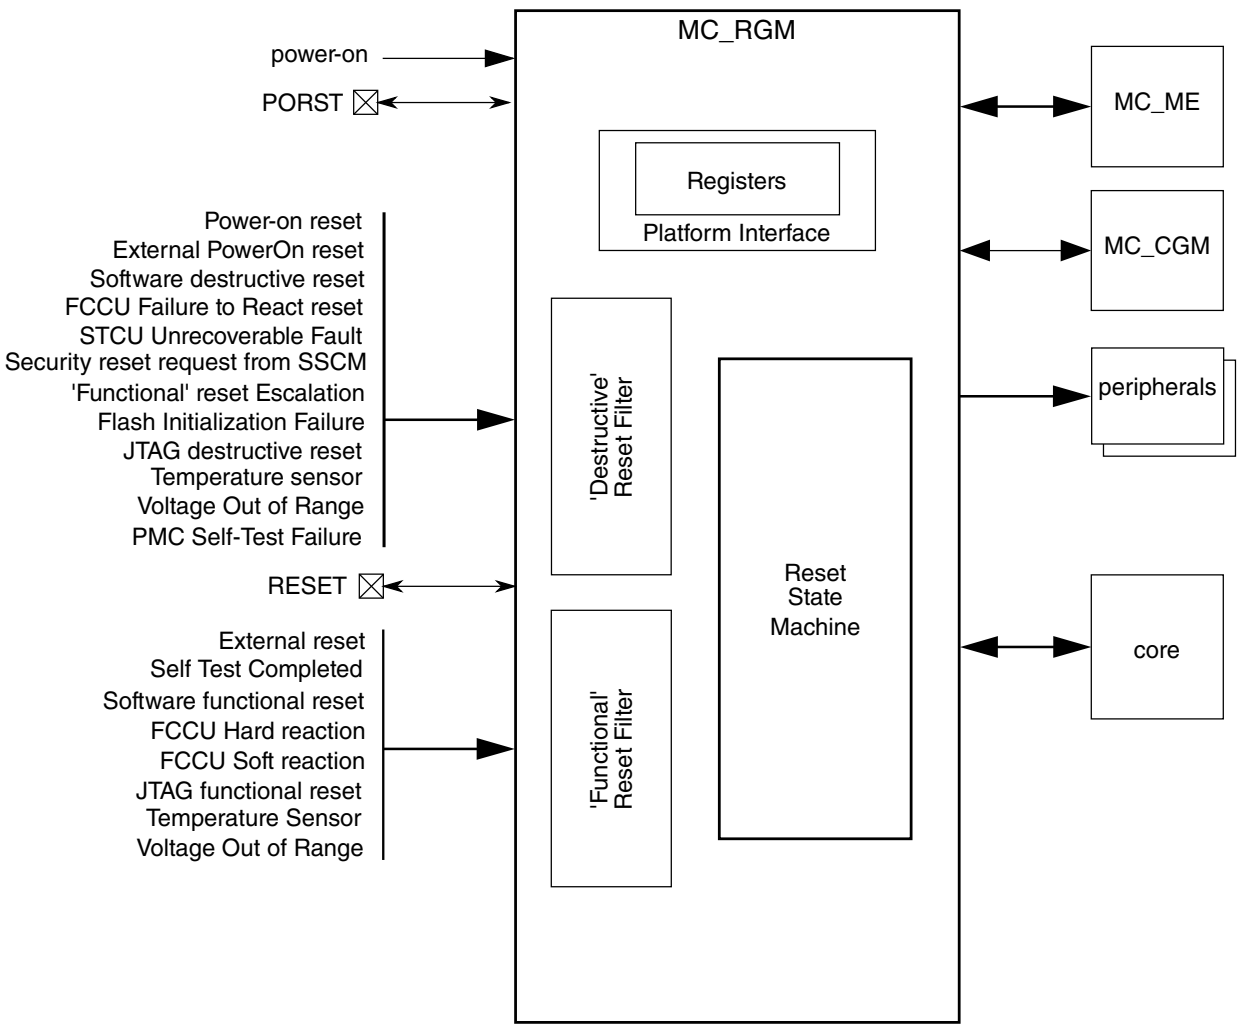


Figure 1-3. MC_RGM Block Diagram

Peripheral resets cannot be controlled individually.

1.20 BAF NMI event handling

The BAF executes under various conditions such as Power-On-Reset (POR), Destructive Reset or any Functional Reset (Long or Short). Due to device configuration, there can be a case where pending FCCU NMI events are latched in the device when the BAF starts execution. These NMI events are masked until a mode transition is completed after reset. The BAF issues a mode transition before it passes control to the application. So, in such case the application may get an NMI exception before it executes its first instruction. Application IVPR can be installed before it gets control by using DCF DCF_IVPR0 for CPU0.

1.21 System Status and Configuration Module (SSCM) chip-specific module information

Added the following paragraph to this section following Table 58-2:

The device will search for valid RCHW locations in the order shown in Table 58-2, "SSCM startup information addresses", and will use the first valid entry to determine the boot location. Care must be taken that a location is not accidentally written with a valid RCHW marker when the intended location is only searched later.

1.22 ECC error monitoring

Added the following:

NOTE

During DCF Scanning, if multibit ECC error on DCF start record and DCF start record pattern is corrupted then, SSCM will not be able to identify that as a valid start record and will ignore the flash region as well. In this case, an ECC error address would be logged in FCCU or MEMU. SoC software can monitor FCCU or MEMU for any address of start record. If any start record address found in FCCU or MEMU address log then software should generate a security reset.

1.23 Power Management Controller (PMC)

The Power Management Controller implements a linear voltage regulator to generate the internal 1.25V digital supply from an external 3.5V to 5.5V supply and monitors various supply voltages of the MPC5746R chip for functional safety purposes. An additional regulator for the flash block is also within the PMC to provide the necessary 3.3V source to the FLASH module. Another internal regulator is present and generates a clean 1.26V supply for the LFAST PLL, as shown in the diagram in the next section. Depending on the supply voltages, power-on-reset (POR) and destructive/functional resets may be generated.

The PMC connects to the Reset Generation Module (MC_RGM), the Fault Collection Control Unit (FCCU) and the flash memory controller. The on-chip ADC receives signals from the PMC for diagnostic purposes.

1.24 Supply Concept

Some supplies may already be connected internally inside the package depending on the package type, mainly in order to save pins in low pin count packages.

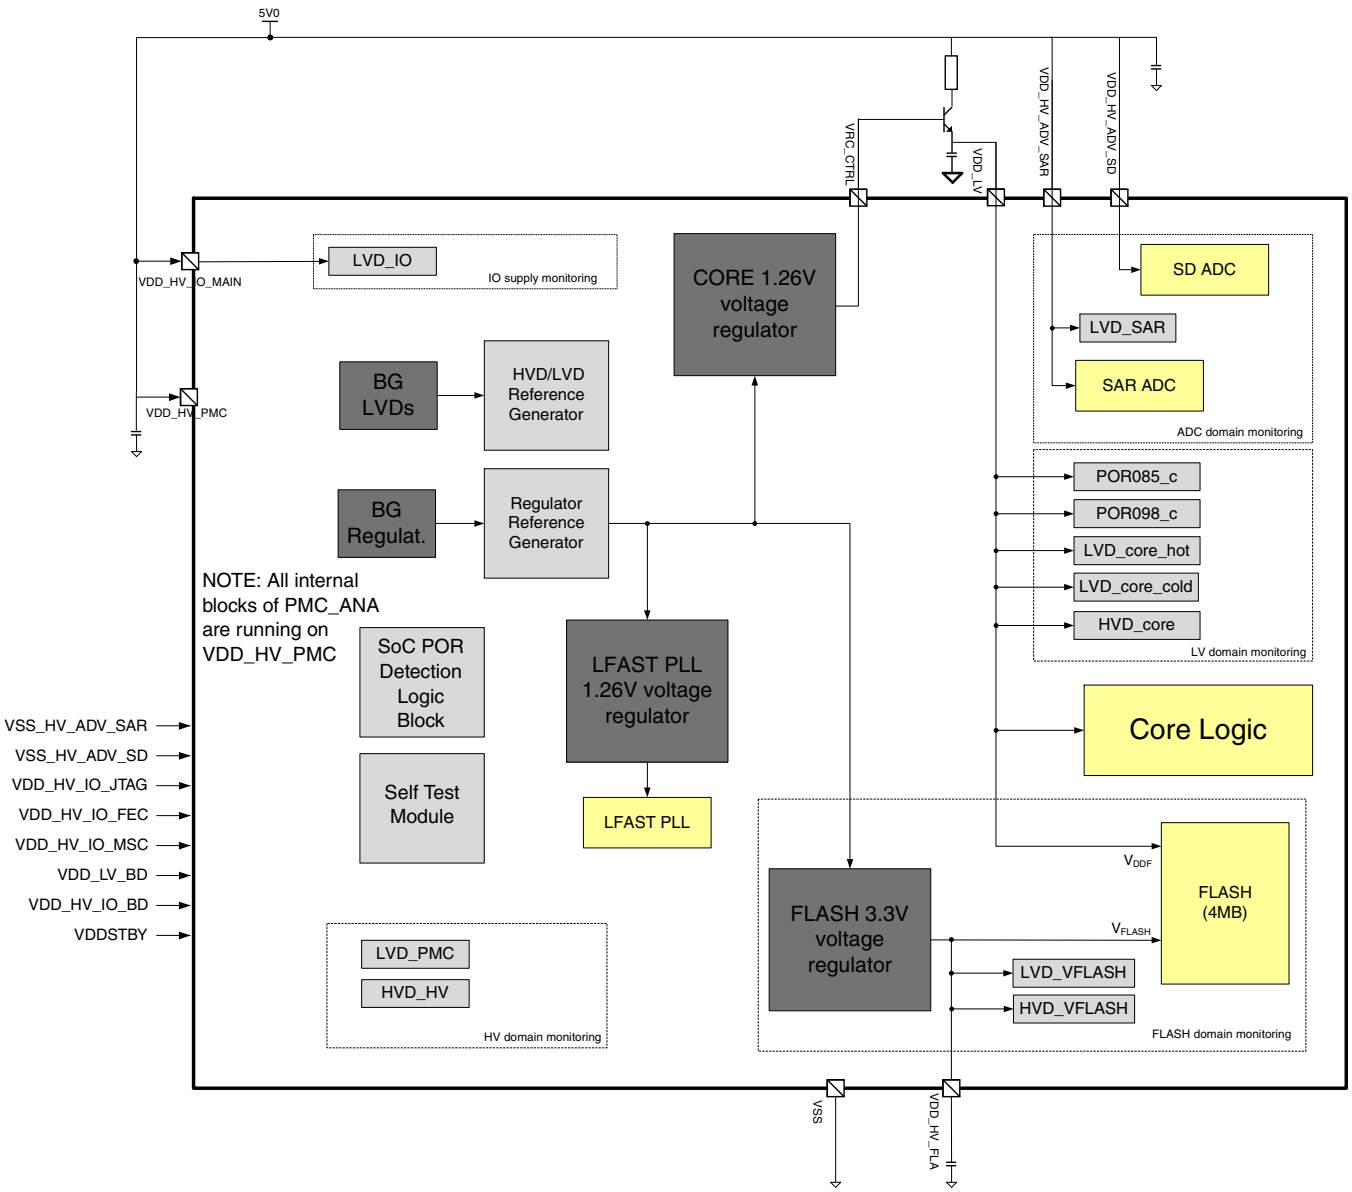

Figure 1-4. Supply concept

1.25 Chip-specific PMC information

The PMC implements a linear voltage regulator to generate the internal 1.25V digital supply from an external 3.5V to 5.5V supply. It also contains an option to bypass this regulator and instead use an externally supplied 1.25V input.

An additonal regulator for the flash block is also within the PMC to provide the 3.3V source necessary to the FLASH module.

Various voltage monitors also reside within the PMC, allowing the visibility of internal regualting points and external supplies. Other functional blocks such as the Power On reset (POR) are also available.

1.26 PMC register values defined by DCF clients

The following PMC registers are defined by the corresponding DCF clients:

- **PMC_REE_TD**: DCF_PMC_REE_TD DCF client
- **PMC_REE**: DCF_PMC_REE_CTRL DCF client
- **PMC_RES**: DCF_PMC_RES_CTRL DCF client

Refer to Table 6.5, DCF clients.

NOTE

It is recommended to verify the PMC_REE register value against the DCF_PMC_REE_CTRL DCF client value after any reset. If the values do not match, then write the DCF_PMC_REE_CTRL DCF client value into PMC_REE register.

1.27 Temperature Event Status register (PMC_ESR_TD)

Added the following Note to the PMC_ESR_TD register field descriptions for TEMP1_2 and TEMP0_2:

This temperature sensor status flag might become set when the ADC supply varies below its LVD level and its LVD destructive reset is masked.

1.28 LVD-HVD self test mechanism

The PMC implements an LVD/HVD self test mechanism for use in satisfying safety goals. The digital block assists and controls the analog block during its performance of the self test.

Currently, three self test modes (described in the following sections) are supported by the analog block (based on the mode specified by the PMC_SELF_TEST_UM_VD_REG[ST_MODE] register bit).

The self test status and result are provided in the PMC_SELF_TEST_UM_VD_REG[ST_DONE, ST_RESULT] register fields, respectively.

1.28.1 Default mode

The self test is always performed during start up (i.e power on). The self test starts during the phase 3 RGM state, when the SSCM has completed reads from the Flash memory. A counter is provided that starts from zero and increments by one after an 8 µs time gap. The counter value is the source for the output “pmc_lvd_self_test” signal, which is provided to the analog block.

Meanwhile, the LVD/HVD indication from the analog block is latched in the PMC_SELF_TEST_UM_VD_REG register. At the end of the self test (i.e. when all of the LVDs/HVDs have been tested), the PMC_SELF_TEST_UM_VD_REG[ST_DONE] status bit is set to '1' and all of the bits in the PMC_SELF_TEST_UM_VD_REG register are checked for ‘1’. One or more bits not set to '1' generates a fault indication to the FCCU block, and the PMC_SELF_TEST_UM_VD_REG[ST_RESULT] register bit is set to ‘0’. In the case where all of the register bits are set to '1', the test is considered to be PASSED, the PMC_SELF_TEST_UM_VD_REG[ST_RESULT] register bit is set to ‘1’, and no fault indications are provided to the FCCU.

This startup self test function also provides gating of the reset phase3 exit in RGM. This means the RGM will not be able to exit from phase3 until the self test is successfully completed.

NOTE

The total run time of the LVD self test is equal to: ‘time required per LVD (20 µs)’ times 'number of LVDs (23)' = 460 µs.

1.28.2 Software-triggered self test

This mode is entered by software by writing '01' to the PMC_SELF_TEST_UM_VD_REG[ST_MODE] register 2-bit field. The complete self test, as is performed in default mode, is repeated. The difference is that the self test in this mode is initiated by the host while the self test in default mode is started automatically during power on.

1.28.3 Single voltage detect test

This mode is entered by software writing '10' to the PMC_SELF_TEST_UM_VD_REG[ST_MODE] register 2-bit field, which results in the assertion of the “pmc_lvd_self_test” input. The test completes after the prescribed time gap has elapsed. The PASS/FAIL result is then updated based on the corresponding LVD output tripping, or not.

NOTE

During the running of the LVD self test, all of the LVD and HVD outputs are masked including some PORs that are also under self test. Therefore, they will have no effect on POR generation, or in any reset and/or fault generation.

1.29 Core Status (MC_ME_CS)

Updated the field names in the "MC_ME_CS field descriptions" table to match the implementation.

MC_ME_CS field descriptions

Field	Description
0–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29 S_COREC	Core Status - This bit specifies the current status of an additional core which is controlled by the MC_ME. 0 Core is disabled 1 Core is running
30 S_CORE0	Core Status - This bit specifies the current status of an additional core which is controlled by the MC_ME. 0 Core is disabled 1 Core is running
31 S_CORE1	Core Status - This bit specifies the current status of an additional core which is controlled by the MC_ME. 0 Core is disabled 1 Core is running

Figure 1-5. MC_ME_CS field descriptions

1.30 Module Configuration Register (JTAGM_MCR)

The following note was added to this section.

NOTE

An unexpected interrupt will occur if the Idle Interrupt is enabled after the end of frame transfer. The interrupt occurs after a JTAGM frame has completed when the JTAGM Idle Interrupt was not enabled (JTAGM_MCR[IIE] = 0b0), if the JTAGM module is then configured to enable interrupts (JTAGM_MCR[IIE] = 0b1). To clear any previous interrupts, set the Idle bit (JTAGM_SR[Idle]) before enabling a JTAGM idle interrupt (e.g. setting JTAGM_MCR[IIE] = 0b1).

1.31 Module Configuration Register (JTAGM_MCR)

Changed the MCR[TCKSEL] 010 field value to Reserved.

27–29 TCKSEL	TCK clock frequency selection. When the JTAGM is enabled, this bit should not be programmed with 000. 000 Reserved 001 Reserved 010 Reserved 011 TCK is system clock ÷ 4 100 TCK is system clock ÷ 5 101 TCK is system clock ÷ 6 110 TCK is system clock ÷ 7 111 TCK is system clock ÷ 8

Figure 1-6. JTAGM_MCR field descriptions

1.32 Data Out Register 0/1/2/3 (JTAGM_DOR0/1/2/3)

Added the stipulation that writing to these registers when DTM = 0 may cause unintended results. Updated the register field descriptions as shown below.

Data Out Register 0 (JTAGM_DOR0)

- TMS_HIGH: Higher word of data for TMS, bits 59-28. Writeable by software only when DTM = 1. Writing to this register when DTM = 0 may cause unintended results.

Data Out Register 1 (JTAGM_DOR1)

- TMS_LOW: Lower word of data for TMS, bits 27-0. Writeable by software only when DTM = 1. Writing to this register when DTM = 0 may cause unintended results. TMS_LOW[0] is shifted out first.

Data Out Register 2 (JTAGM_DOR2)

- TDI_HIGH: Higher word of data for TDI, bits 59-28. Writeable by software only when DTM = 1. Writing to this register when DTM = 0 may cause unintended results.

Data Out Register 3 (JTAGM_DOR3)

- TDI_LOW: Lower word of data for TDI, bits 27-0. Writeable by software only when DTM = 1. Writing to this register when DTM = 0 may cause unintended results. TDI_LOW[0] is shifted out first.
- Send: Send bit. When this bit is set, data is sent to the DCI. It is a self-clearing bit and is always read as 0. Writeable by software only when DTM = 1. Writing to this register when DTM = 0 may cause unintended results.

1.33 Concurrent overflow register (OFLW) implementation

Table 1-15. Corresponding error sources for system RAM OFLW0 register

Bit number	Error source
3	Core0 Instruction TCM error (Note: This error source could be triggered if Core0 IMEM is not initialized before Core0 is started)
9	Core1 Instruction TCM error (Note: This error source could be triggered after reset)

1.34 FCCU chapter

See Chapter 3, Fault Collection and Control Unit (FCCU) for an updated FCCU chapter, and Appendix A for a listing of all the changes in that chapter.

1.35 AUTOLOCK_VALUE for register write access and DCF_COMPLETION value for DCF write completion

Register write-access watchdog timer refers to two clock-cycle values related to the STCU2's write-access watchdog. The following table provides these values on this chip.

Clock-cycle value	Number of STCU2 clock cycles
AUTOLOCK_VALUE	1024
DCF_COMPLETION	16

1.36 Password and Device Security Module (PASS) chip-specific module information

The following table indicates byte-to-byte correspondence between UTEST DCF address and JTAG_PASSWORD.

Table 1-16. JTAG_PASSWORD register bit correspondence

UTEST Address Offset	Register Bit Position (MSB is 255)
0x00	JTAG_PASSWORD[7:0]
0x01	JTAG_PASSWORD[15:8]
...	...
0x1E	JTAG_PASSWORD[247:240]
0x1F	JTAG_PASSWORD[255:248]

1.37 Flash erase counter and tamper detection

The following content has been added to this section, before the first note:

When attempting to update the TDM diary and erase flash blocks, set MCR[PECIE] in the Embedded Flash Memory registers to enable interrupt notification for program and erase operations. Then clear MCR[PECIE] to service the interrupt after each program or erase operation. This sequence must be executed before attempting to update the TDM diary, and then again before attempting to erase the unlocked flash blocks.

Chapter 2
Enhanced Time Processing Unit (eTPU)

2.1 Enhanced Time Processing Unit (eTPU) chip-specific module information

2.1.1 Configuration

eTPU is an intelligent, semi-autonomous co-processor designed for timing control. Operating in parallel with the Host CPU, the eTPU processes instructions, real-time input events, performs output waveform generation, and accesses shared data without Host intervention. Consequently, for each timer event, the Host CPU setup and service times are minimized or eliminated.

The eTPU2+ is an enhanced version of the eTPU2 targeted at C55 devices.

2.1.2 Device-specific information

- Dual (64 channels, dual core) Engine
- Shared Code Memory (SCM) error detection, error correction
- Shared Data Memory (SDM) error detection, error correction
- Class 3 Nexus support
- GTBE is a logical OR with the eMIOS GTBE
- Channels used to trigger the ADC subsystem
- Channels used to enable the Reaction Module modulation
- Channels with DMA request
- Channel output buffers are controlled through SIUL2, and cannot be controlled with microcode.
- Six latency monitors in each of 2 engines.

2.1.3 Register reset values

Some eTPU registers on this device have a different reset value, which overrides the corresponding reset value that is shown in the body of the eTPU documentation, as shown in the following table.

Table 2-1. Reset value overrides

Register	Reset value override
eTPU_SCR_MCR	000B_0000h
eTPU_SCR_ECR_ENG1	5000_0000h
eTPU_SCR_ECR_ENG2	5000_0000h
eTPU_TBR_TBCR_ENG1	2000_0000h
eTPU_TBR_TBCR_ENG2	2000_0000h
eTPU_TBR_STAC_ENG1	0000_0200h
eTPU_TBR_STAC_ENG2	0100_0300h

2.1.4 Memory

The eTPU is a true Harvard architecture machine that implements separate code and data memories. The eTPU engines share the same code and data memories. To meet the safety goals, the memories have ECC.

Memory characteristics:

- Code memory 24k with ECC. The code memory can only be accessed with 32-bit accesses so only 7 bits of ECC are implemented. The module size is 6144 locations x 39-bits wide.
- Data memory 6k with ECC. The data memory can be accessed as bytes, and cycles for updating the ECC are not allowed, so 20 bits of ECC are implemented. The required module size is 1536 locations x 52 bits wide.

2.1.5 Clocking

The eTPU is clocked by the non-FM clock used for the peripherals.

The eTPU BIU can optionally run at double the clock speed of the other peripheral on the AIPS. Double clock speed can be used in cases where higher eTPU processing throughput is needed.

2.1.6 Debug

The eTPU implements Nexus class 3 debug, accessed through the same Nexus debug port pins used for core debug.

2.1.7 STAC bus

The eTPU timebases and angle counter can be exported to eMIOS through the STAC bus.

Table 2-2. STAC server ID

Engine	Timebase	Server ID
1	TCR1	0
1	TCR2	2
2	TCR1	1
2	TCR2	3

NOTE

If the STAC-bus Export/Import feature is used, the clock ratio of eTPU : eMIOS should be 1:1 or 2:1, such as the following:

- eTPU 100MHz : eMIOS 100MHz
- eTPU 200MHz : eMIOS 100MHz

This applies whether the STAC-bus Export/Import is used from eTPU to eMIOS or used between eTPUs.

2.1.8 Input connections

The channel inputs are connected to:

- External pins,
- SD ADC trigger outputs,
- BCTU trigger outputs, and the
- Input glitch filter.

Channels with more than 1 input source are connected through the IOMUX (see SIUL2 chapter).

The TCRCLK input is connected to the same input as channel 0.

2.1.9 Output connections

The channel outputs are connected to:
- External pins
- ADC triggers
- Decimation filters

2.2 Introduction

eTPU is an intelligent, semi-autonomous co-processor designed for timing control. Operating in parallel with the Host CPU, the eTPU processes instructions and real-time input events, performs output waveform generation, and accesses shared data without Host intervention. Consequently, for each timer event, the Host CPU setup and service times are minimized or eliminated.

High-level assembler, compiler and documentation allows customers to develop their own functions on the eTPU.

eTPU architecture aims at high resolution timing capabilities. From a system perspective, high resolution timing is limited by Host CPU overhead required for servicing timing tasks such as period measurement, pulse measurement, pulse width modulated waveform generation, etc. On the eTPU, high resolution timing is achieved by three main capabilities:

- Reduced latency: pin actions are immediate.
- Reduce or eliminate host interrupt service time.
- Double action channel capability reducing the channel request rate.

eTPU provides higher resolution than the Host CPU can achieve and creates no Host overhead for servicing timing tasks.

Latency is the interval from occurrence of an event to the start of event servicing. eTPU can service its own events without interrupting the Host. There are two types of timing events:

- Input pin transition.
- Selected Time Base match, i.e., a selected Time Base counter reached or exceeded a pre-programmed value.

Service time is the time spent servicing an event. In general, in microcontrollers the service time is constrained because the instruction set is not optimized for time function synthesis. The eTPU instruction set is optimized, so that time functions can be implemented with much fewer instructions than the Host CPU. Instructions execute faster, service time is reduced and program memory compacted.

Instructions executed by the eTPU are connected directly to the eTPU timing hardware and allow parallelism of hardware related actions.

2.2.1 Overview

The figure below shows a top-level eTPU block diagram. It displays a dual eTPU Engine configuration.

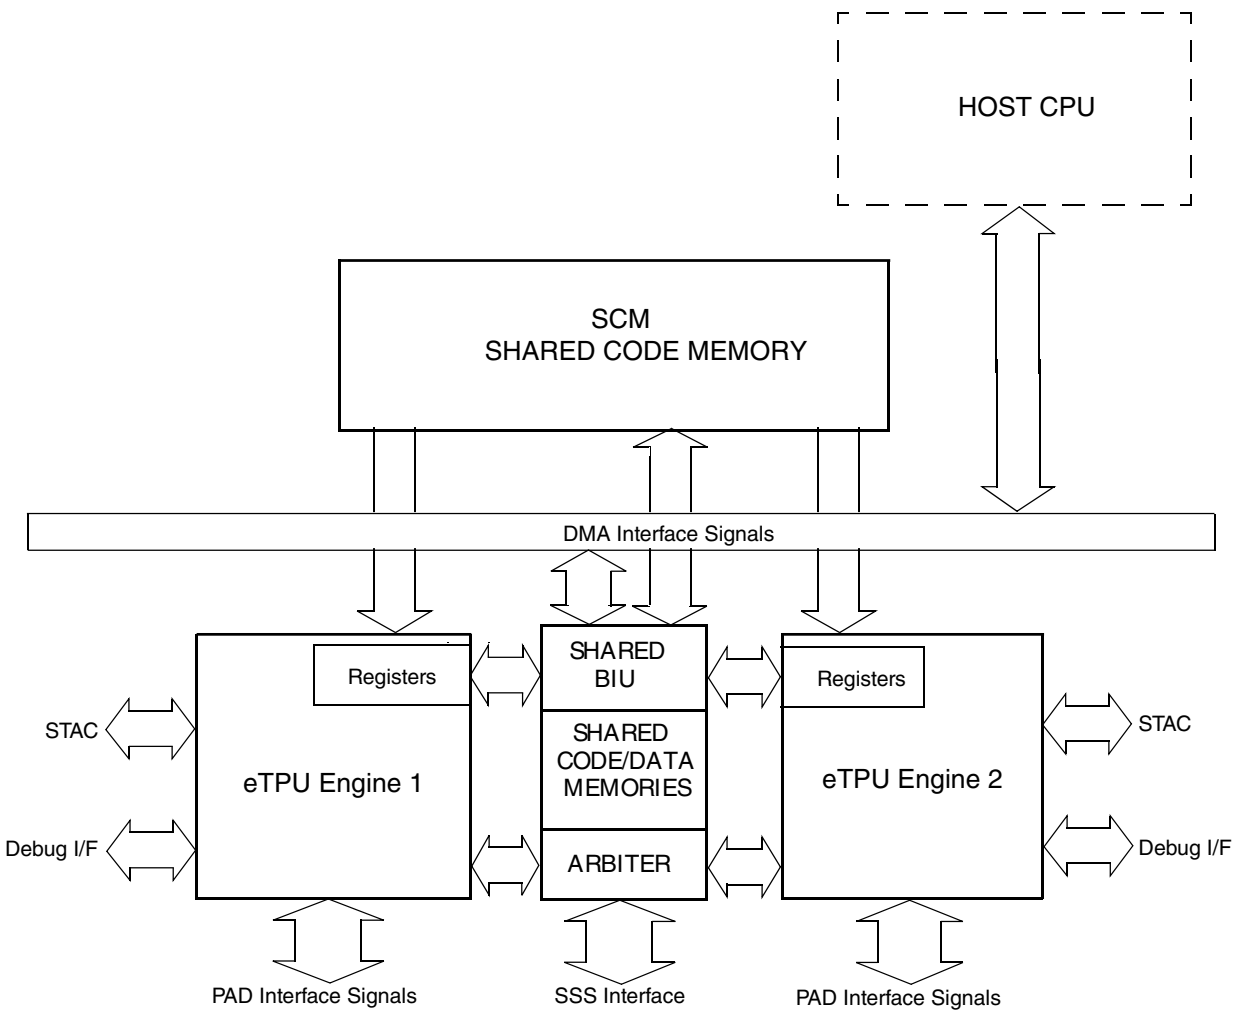

Figure 2-1. eTPU Block Diagram

eTPU Engine is responsible for processing input pin transitions and output pin waveform generation based on the **Time Bases**. Each eTPU Engine has its own microprocessor and dedicated hardware for processing signals on I/O pins and can also interface with external time bases through the STAC bus.

Both eTPU Engine CPUs, hereafter called **microengines**, fetch microinstructions from a **Shared Code Memory - SCM**.

Shared Data Memory - **SDM -** holds eTPU application parameters and work data. It is accessed by Host and both microengines.

Bus Interface Unit - BIU - allows Host to access eTPU registers, SCM and SDM.

Each I/O signal pair is associated with a dedicated **Channel**, which provides hardware for input signal processing and output signal generation, in relationship with selected Time Bases.

The eTPU, as a microprocessed subsystem, works much like a typical real-time system: it runs microengine code from instruction memory (SCM) to handle specific events, accessing data memory (SDM) for parameters, work data and application state info; events may originate from I/O Channels (due to pin transitions and/or time base matches), Host CPU requests or inter-channel requests; events that call for local eTPU processing activate the microengine by issuing a **Service Request**. The Service Request microcode may set an interrupt to the Host CPU. I/O channel events cannot directly interrupt the Host CPU.

Each Channel is associated with a **Function**, which defines its behavior: the Function is a software entity consisting, within the eTPU, of a set of microengine routines that attend to Service Requests. The Function routines are also responsible for Channel configuration. Function routines reside in SCM, which may contain several Functions. A Function may be assigned to several Channels, but a Channel can be associated with just one Function at a given moment. The association between Functions and Channels is defined by Host CPU, and is explained in detail in Functions and threads.

eTPU hardware supplies resource sharing features that support concurrency:

- A hardware **Scheduler** dispatches the Service Request microengine routines based on a set of priorities defined by the Host CPU. Each Channel has its associated priority.
- A Service Request routine cannot be interrupted until it ends. This sequence of uninterrupted instruction execution is called a **Thread**.

- Channel-specific context (registers and flags) is automatically switched between the end of a Thread and the beginning of the next one.
- SDM arbitration, a dual-parameter coherency controller and semaphores can be used to ensure coherent access to eTPU data shared by both eTPU Engines and Host CPU.

2.2.1.1 eTPU Engine

Each eTPU Engine consists of all blocks that are duplicated in a dual eTPU configuration: two 24-bit time bases, 32 independent timer channels, a task scheduler, a microengine, and a Host interface. In addition, a 32-bit Shared Data Memory (SDM) is used for two eTPU Engines data storage and for passing information between the eTPU Engines and the Host CPU.

The following figure shows the block diagram for the eTPU Engine.

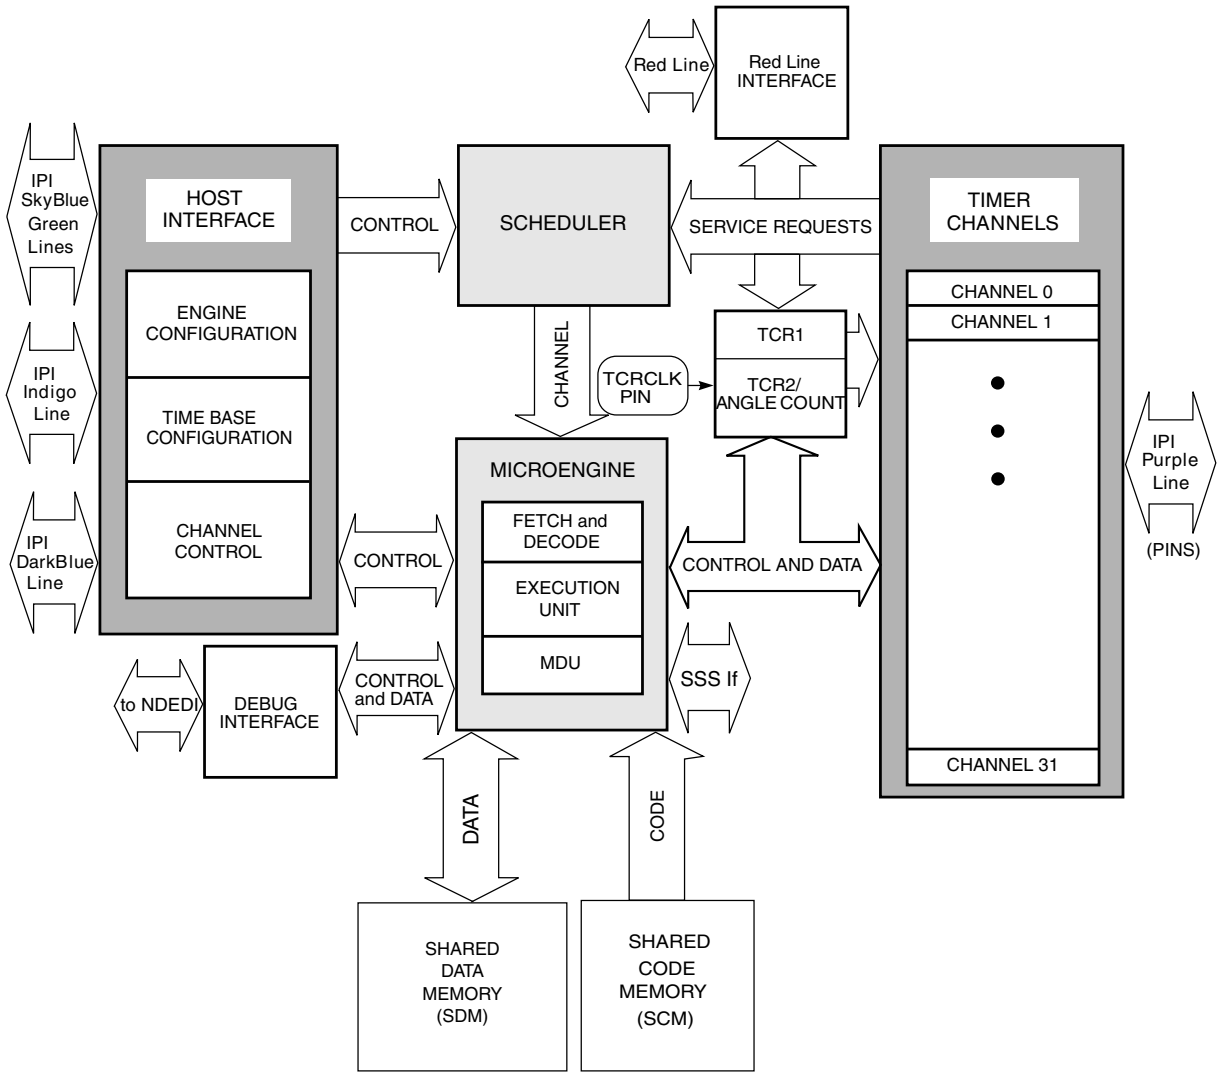

Figure 2-2. eTPU Engine Block Diagram

eTPU Engines 1 and 2 are sometimes called eTPU 1 and eTPU 2 for short throughout this chapter.

2.2.1.1.1 Time Bases

Two 24-bit counters TCR1 and TCR2 provide reference time bases for all match and input capture events. Prescalers for both time bases are controlled by the Host CPU through bit fields in the eTPU Engine configuration registers. The eTPU is able to export/import time to/from TCR1 or TCR2 in accordance to the STAC bus specification.

The clock for each of TCR1 and TCR2 clock can be independently derived from the eTPU clock or from an external input via the TCRCLK clock pin. In addition, the TCR2 timebase can be derived from special angle-clock hardware which enables implementing angle-based functions. This feature is added to support advanced angle based engine control applications.

For further details refer to Time bases.

2.2.1.1.2 eTPU Timer Channels

Each eTPU Engine has 32 independent channels, each corresponding to an Input/Output signal pair. The channel time resolution is 24 bits, and are all identical.

Each channel consists of logic which supports two events and output controls. The event logic contains two 24-bit capture registers, two 24-bit match registers, greater-equal and equal-only comparators. Supporting two events enables many combinations of double action functions (for example the channel can handle two events with a single microcode service).

The channel configuration can be changed immediately by the microengine. Each channel can perform double capture, double match and other capture-match combinations. Channel modes available can do ordered or unordered match. Some modes are also provided that can block one match by the occurrence of the other. Service request can be generated on one or both of the match events.

Input signal can be separated from output signal in each channel. They can, optionally, be combined in a single I/O pin driver. An output buffer enable is controlled by the SIU (or SIUL). Digital filters are provided for the input signals, with distinct filtering modes available.

Each channel can use any time base or angle counter for either match or capture operation. For example, a match on TCR1 can capture the value of TCR2. The channels can request service from the microengine due to recognized pin transitions (input events) or timebase matches.

The eTPU channels also support the basic single-action operations found on TPU3 functionality with the exception that time resolution is 24-bits.

Channel configuration combinations:

- Single input capture, no match (TPU3 functionality)
- Single input capture with single match timeout (TPU3 functionality)
- Single input capture with double match timeout with several double match sub-modes
- Double input capture with single or double match timeout with several double match sub-modes
- Single output match (TPU3 functionality)

- Double output match with several double match sub-modes
- Input-dependent output generation

The double match functionality has various combinations for generation of service request and determining pin actions. For more details refer to Enhanced Channels.

In addition to the predefined channel configurations above, the user can also program its own channel configuration, defining how input captures, matches and service-requests are related.

2.2.1.1.3 Host interface

The Host interface allows the Host CPU to control the operation of the eTPU. The Host CPU must initialize the eTPU by writing to the appropriate Host interface registers to assign a Function and priority to each channel. In addition, the Host writes to the Host Service Request and channel configuration registers to further define Function operation for each initialized channel. Refer to Host interface for a detailed description.

When the SCM is implemented by RAM, the Host must first initialize it with the proper microcode program prior to enabling any eTPU Function, and then enable eTPU access (which also disables Host access).

2.2.1.1.4 Shared Data Memory - SDM

The SDM works as data RAM which can be accessed by the Host CPU and up to two eTPU Engines. This memory is used for information transfer between the Host CPU and the eTPU, as data storage for the eTPU microcode program or for communication between the two eTPU Engines. SDM width is 32 bits, and is accessible by the Host as byte, 16-bit or 32-bit wide. eTPU can access it as full 32-bits, lower 24-bits or upper byte (8-bit).

The host can also access the SDM space mirrored in other area with Parameter Sign Extension (PSE). Parameter Sign Extension accesses differ from the usual host accesses to the original SDM area as follows:

- Writes are effective only to the lower 3 bytes of a word: the word's most significant byte is kept unaltered in SDM.
- Reads return the lower 3 bytes of a word sign-extended to 32 bits, i.e.: the most significant bit of the word's 2nd most significant byte is copied in all 8 bits of the most significant read byte.

Each eTPU channel can be associated with a variable number of parameters located in the SDM, according to its selected Function. In addition, the SDM can be fully shared between two eTPU Engines, enabling direct communication between them.

High flexibility of the SDM utilization is achieved as follows:

- Each channel has a programmable base address pointing to the address of its first parameter with two parameter granularity. This way the SDM can be partitioned according to the actual function needs.
- The microcode can access the first 128 parameters of the selected channel in channel relative access mode.
- Each Engine can access all the SDM address space in indirect addressing mode. Blocks of data are easily transferred using stack operation.
- Absolute addressing mode can access the first 256 parameters (TPU3 functionality), implementing a shared pool of parameters holding global variables.

In the Host address space each parameter occupies four bytes. eTPU usage of the upper byte is achieved by having a 32-bit P register which can access the upper byte, the lower 24 bits or all the 32 bits. The microcode can switch between access sizes at any time.

Each Function may require a different number of parameters. During the eTPU initialization the Host has to program channel base addresses, allocating proper parameters for each channel according to its selected Function.

2.2.1.1.5 Shared Subsystem Area

The Shared Subsystem (SSS) area is a memory map region used by both the host and the eTPU to access registers of the reaction channel, giving the user the option to control them by the host, the eTPU code, or a combination of both.

2.2.1.1.6 Scheduler

Out of reset, all channels are disabled. The Host CPU makes a channel active by assigning it one of three priorities: high, middle, or low. The Scheduler determines the order in which channels are serviced based on channel number and assigned priority. The priority mechanism, implemented in hardware, ensures that all requesting channels are serviced. For additional details refer to Scheduler.

2.2.1.1.7 Microengine

eTPU microengine is a simple RISC implementation which performs each instruction in a microcycle of two eTPU clocks, while prefetching the next instruction through an instruction pipeline. Instruction execution time is constant unless it gets wait states from the SDM arbitration. Two eTPU Engines share code memory without having any performance degradation by interleaving their accesses (the Shared Code Memory has one-clock access time).

Instruction width is 32 bits. The microengine instruction set provides basic arithmetic and logic operations, flow control (jumps and subroutine calls), SDM access, and Channel configuration and control. The instruction formats are defined in such a way that allow particular combinations of two or three of these operations with unconflicting resources to be executed in parallel in the same microcycle.

Microengine has also an independent Multiply/Divide/MAC unit that performs these complex operations in parallel with other microengine instructions.

Channel functionality is tightly integrated to the instruction set through Channel Control operations and conditional Branch operations, which support jumps/calls on Channel-specific conditions. This allows quick and terse Channel configuration and control code, contributing to reduced service time.

Detailed description can be found in Microengine.

2.2.1.1.8 Dual eTPU Engine System

A typical eTPU implementation includes two eTPU Engines sharing SDM and the same code in SCM.

The two eTPU Engines share the Bus Interface Unit (BIU) and the data memory (SDM) which enable Host-eTPU and eTPU Engine-Engine communication. The shared BIU includes coherency logic which supports dual parameter (8 bytes) coherency in transfers between Host and eTPU, using a temporary parameter area within the SDM. More details on this can be found on Parameter sharing and coherency.

2.2.2 Features

The following sections show eTPU features and enhancements.

2.2.2.1 eTPU Feature Summary

The eTPU includes these distinctive features:

- up to 32 channels for each eTPU Engine, each channel is associated with an Input/ Output signal pair.
  - enhanced input digital filters on the input pins for improved noise immunity. The eTPU digital filter can use 2 samples, 3 samples or work in continuous mode.
  - identical, orthogonal channels, except for channel 0: each channel can perform any time function. Each time function can be assigned to more than one channel at a given time, so each signal can have any functionality. Channel 0 has the same capabilities of the others, but can also work with special Angle Counter logic (see below).
  - Link Service Request allows activation of a Channel function by request of another channel, even between eTPU Engines.
  - Host Service Request allows activation of a Channel function by Host CPU request
  - each channel has an event mechanism which supports single and double action functionality in various combinations. It includes two 24-bit capture registers, two 24-bit match registers, 24-bit greater-equal and equal-only comparators.
- Two independent 24-bit time bases for channel synchronization:
  - first time base clocked by eTPU clock with programmable prescaler division from 1 to 512 (in steps of 2), or by output of second time base prescaler.
  - first time base can also be clocked by external signal with programmable prescaler division of 1 to 256.
  - second time base clocked by external signal with programmable prescaler division from 1 to 64.
  - second time base external clock source can be replaced by eTPU clock divided by 8.
  - both time bases can be exported or imported via Shared Time and Counter bus.
  - second time base counter can work as an Angle counter, enabling angle based applications to match angle instead of time.
  - second time base can also be used as a pulse accumulator gated by external signal.
- Event-Triggered RISC processor (microengine):
  - 3 stage pipeline implementation (fetch, decoding and execution), with separate instruction memory - SCM - and data memory - SDM (Harvard architecture)

- fixed-length instruction execution in one microcycle of two eTPU clocks
- interleaved SCM access in dual eTPU Engine avoids contention in time for instruction memory
- SCM address space of up to 16K positions (64 Kbytes) (see chip-specific eTPU information)
- SDM with interleaved access in dual eTPU Engine avoids contention for data memory
- SDM address space (both Engines) of up to 8 Kbytes (see chip-specific eTPU information)
- instruction set with embedded Channel support, including specialized Channel control subinstructions and conditional branching on Channel-specific flags.
- channel-oriented addressing: channel-bound address mode with Host configured Channel Base Address allows channel data isolation, independent of microengine application code.
- channel-bound data address space of up to 128 32-bit parameters (512 bytes)
- global parameter address mode allows access to common Channel data of up to 256 32-bit parameters (1024 bytes)
- support for indirect and stacked data access schemes.
- parallel execution of: data access, ALU, Channel control and flow control subinstructions in selected combinations.
- 32-bit microengine registers and 24-bit resolution ALU, with 1 microcycle addition and subtraction, absolute value, bitwise logical operations on 24-bit, 16-bit, or byte operands; single bit manipulation, shift and rotate operations, sign extension and conditional execution.
- additional 24-bit Multiply/MAC/Divide unit which supports all signed/unsigned Multiply/MAC combinations, and unsigned 24-bit Divide. The MAC/Divide unit works in parallel with the regular microcode commands.

- Resource sharing features support channel sharing of channel registers, memory and microengine time:
  - hardware Scheduler works as a "task management" unit, dispatching event service routines by predefined, Host-configured priority.

- automatic Channel context switch when a "task switch" occurs, i.e., one Function Thread ends and another begins to service a request from other Channel: Channel-specific registers, flags and parameter base address are automatically loaded for the next serviced channel.
- individual channel priority setting in 3 levels: high, middle and low.
- Scheduler priority scheme allows calculation of worst case latency for event servicing and ensures servicing all channels by preventing permanent blockage.
- SDM shared between Host CPU and both eTPU Engines, supporting communication either between Channels and Host or inter-channel.
- hardware implementation of 4 Semaphores supports resource sharing between both eTPU Engines.
- Hardware semaphores directly supported by the microengine instruction set.
- dual parameter coherency hardware support allows atomic (to host) access to 2 parameters by microengine(s) in back-to-back accesses.
- coherent dual-parameter controller allows atomic (to microengines) accesses to 2 parameters by the host.

- Development support features:
  - Nexus class 3 debug support (optional, associated with the eTPU-Nexus Block NDEDI).
  - Software breakpoints.
  - Debug interface supporting single-step execution, forced microinstruction execution, Hardware breakpoints and watchpoints on several conditions.
- Safety support features:
  - SCM (code memory) continuous signature-check built-in self test (MISC - Multiple Input Signature Calculator), runs concurrently with eTPU normal operation.
  - See eTPU Plus Enhancements over eTPU) for additional safety features.

2.2.2.2 eTPU Enhancements over TPU3

- 32 orthogonal channels with enhanced functionality. Full support for double action with double match and double transition sub-mode combinations.

- Input and Output features separated in channel logic and microinstructions, allowing input and output signals to be processed separately or combined.
- Increased time resolution and execution unit to 24 bits.
- Increased linear code memory, shared by two eTPU Engines, configurable up to 16K positions (64 KB).
- Increased SDM address range (8 KB each Engine) and width (32 bits per parameter). The SDM can be dynamically allocated to support variable number of parameters for each channel. Each channel can have access to at least 256 parameters.
- The SDM is fully shared by two eTPU Engines (SDM), supporting direct inter-engine communication with the help of hardware semaphores.
- Enhanced arithmetic operations, including add/subtract with carry, absolute value, multiple shift and rotate, conditional execution with variable operand widths.
- Enhanced logic operations, including bitwise operations (and, or, xor) and bit manipulation, with conditional execution. Support for read-modify-write of any bit in the SDM.
- Hardware for Multiply/MAC/Divide, running in parallel to execution of other operations. The 24-bit divide result is available after 13 other unrelated instructions. Multiplication supports any data width of both operands (8, 16 or 24 bits), signed or unsigned. A 24x24 Multiply/MAC result is available after four other unrelated instructions. A 24x8 Multiply/MAC result is available after one other unrelated instruction.
- Supports export/import of time bases from other sources through the real time bus (STAC - Shared Time and Counter bus). This internal bus is used for sharing real time data between multiple peripherals.
- Contains angle clock hardware, supported by microcode, which can provide a 24-bit angle bus instead of time bus. This feature enables the eTPU to run angle based engine control applications.
- More interrupt types. Each eTPU channel can generate a data transfer request interrupt, in addition to regular interrupts, and one global exception interrupt. Data Transfer requests can be used either as interrupt sources or DMA requests. This feature takes advantage of DMA peripherals which off-load the Host. Interrupt Overflow status is also provided.
- Improved visibility to the Host (pin states, time bases, serviced channel).

- An edge case of priority inversion on TPU3 Scheduler was resolved.
- Supports channel link requests between eTPU Engines.

2.2.2.3 eTPU Plus Enhancements over eTPU

eTPU Plus features include the enhancements below in addition to all eTPU features

- TCR1, channel logic and digital filters (both channel and TCRCLK) now have an option to run at divisions of full eTPU clock speed, besides eTPU clock / 2 (see T2/T4 channel timing).
- Channels support unordered transitions: transition B can now be detected before transition A. Related to this enhancement, TDLA and TDLB can now be independently negated by microcode (see Channel Mode Logic and Event Flags)
- Channel logic can now work on full eTPU clock, allowing faster response with slow clocks (see T2/T4 channel timing).
- Added a new User Programmable Channel Mode: the blocking, enabling, service request and capture characteristics of this channel mode can be programmed via microcode (see General Channel registers).
- Microinstructions now provide an option to issue Interrupt and Data Transfer requests selected by CHAN. They can also be requested simultaneously at the same instruction (see Channel Interrupt and Data Transfer Requests).
- Channel Flags 0 and 1 can now be tested for branching, besides selecting the entry point (see Branch Operations).
- Channel digital filters can be bypassed, and can be clocked by full eTPU clock (see Bypass Mode).

Backward compatibility is maintained so that all legacy object code (both Host and microcode) runs on eTPU Plus without modification.

2.2.2.4 eTPU2 enhancements over eTPU Plus

eTPU2 features include the enhancements below in addition to all eTPU Plus enhancements and eTPU features.

- Scheduler priority-passing mechanism can now be disabled (see Priority passing disabling).
- New Watchdog mechanism kills threads over a programmable timeout (see Watchdog).

- New counter allows microengine load information collection for performance analysis (see Idle Counter).
- Channels 1 and 2 (besides channel 0) can now be selected to control the EAC (see the TBCR_ENG1 and TBCR_ENG2 eTPU Time Base Configuration Registers).
- Timebase prescalers are now reset when the GTBE input is negated, guaranteeing synchronization with eMIOS in all cases (see GTBE - Global Time Base Enable).
- New MISC flag indicates when an SCM signature calculation round is completed. This allows measuring of the average MISC scan period in a real application situation (see the eTPU Module Configuration Register - MCR).
- New channel TCCEA flag allows continuous capture even after TDLA is set, making it fully compatible with TPU behavior (see TCCEA - Transition Continuous Capture Enable).
- New branch condition PRSS tells the pin state at the time when a channel (match or transition) service request occurred (see Pin Control Registers).
- MRLEA/B can now be negated independently by microcode (see Disable Matches).
- New Engine Relative address mode allows a function to access SDM address space common to one engine, but distinct between engines (see Engine Relative Addressing Mode under SDM Addressing Modes).
- Memory error support for Code (SCM) and Data (SDM) memories: error detection, correction, and hardware-assisted soft-error fixing (see Memory error support).
- Sharing of microengine and host accesses to subsystem modules (for instance, the Reaction Module), allowing their control by the eTPU, the host, or both (see Shared Subsystems support).

Backward compatibility is maintained so legacy object code (both Host and microcode) runs on eTPU2 without modification.

2.2.2.5 eTPU2 Plus enhancements over eTPU2

eTPU2 Plus features include the enhancements listed below in addition to all eTPU features, eTPU Plus enhancements and eTPU2 enhancements.

- New Latency Monitor allows latency measurements, either for individual channels or channels combined in a single priority (High, Medium or Low).
- Watchdog can now be configured to disable thread forced ending and channel blocking, allowing it to monitor thread lengths with no interference on the application.

- EAC Angle Tick Generator can now be clocked by the TCR2 prescaler output, as an alternative to the TCR1 clock.
- EAC now supports up to 7 missing teeth on hardware.

Backward compatibility is maintained so legacy object code (both Host and microcode) runs on eTPU2 Plus without modification.

2.2.3 Modes of operation

eTPU can be seen as capable of working in the following modes:

- **User Configuration Mode**

  User has the ability to program the eTPU Cores with User Time Functions, having access to the Shared Code Memory (SCM).

- **User Mode**

  User does not access the eTPU Shared Code Memory:

  - Use of predefined eTPU Functions
  - No need for eTPU Core programming ability

- **Debug Mode**

  User debugs eTPU code, accessing special Trace/Debug features via Nexus interface:

  - hardware breakpoint/watchpoint setting
  - access to internal registers
  - single-step execution
  - forced instruction execution
  - software breakpoint insertion and removal.

- **Module Disable Mode**

  eTPU Engine clocks are stopped through a register write to the MDIS field in eTPU Engine 1 Configuration Register (eTPU_SCR_ECR_ENG1) and eTPU Engine 2 Configuration Register (eTPU_SCR_ECR_ENG2), saving power. Input sampling stops. eTPU Engines can be in Module Disable Mode independently. Module Disable Mode stops only the Engine clock, so that the Shared BIU, and Global

Channel registers can be accessed, and interrupts and DMAs can be cleared and enabled/disabled. An Engine only enters Module Disable Mode when any currently running thread is finished (see Functions and threads).

- **Stop Mode**

  Stop Mode is entered when eTPU answers device stop request assertion with stop acknowledge. The definition of which clocks are stopped is made at the MCU level, which defines whether or not registers can be accessed, interrupts and DMA requests cleared.

These modes are loosely selected: there is no unique register field or signals to choose between them. Some features of one mode can be used with features of other mode(s). More on this subject can be found on eTPU mode selection below.

Note

Throughout this chapter, an engine is said to be "stopped" if it is either in Module Disable mode or Stop mode.

2.2.3.1 eTPU mode selection

User and User Configuration are the production operating modes, and differ from each other only in access to SCM. User programmability is only possible with a RAM SCM.

On chips where the SCM is implemented as a RAM, it can either be accessed directly from IP-Bus for code loading, or for software breakpoint setting . On chips with a ROM SCM, an internal SCM Emulation RAM may be used, depending on the specific MCU implementation, to replace ROM SCM for test or debug purposes. SCM Emulation RAM is selected in a MCU-specific way. For more details, see .

Debug Mode is characterized by the use of the debug interface features. Specifically, Nexus blocks provide Nexus class 3 debug features. For more information on debug features, refer to Development support features.

Module Disable Mode is entered by setting the MDIS field in eTPU Engine 1 Configuration Register (eTPU_SCR_ECR_ENG1) and eTPU Engine 2 Configuration Register (eTPU_SCR_ECR_ENG2). eTPU Engines can be individually stopped going into Module Disable Mode (there is one eTPU_SCR_ECR register for each Engine). Each engine can leave Module Disable Mode by writing MDIS=0 (which can only be done if VIS=0).

Stop Mode is activated by IP-Bus (device stop request). In this case, the eTPU waits for both eTPU Engines to enter in stop mode, and then asserts the stop acknowledge line. eTPU leaves Stop Mode when device stop request is negated, but only if VIS=0. If device stop request is negated and VIS=1, eTPU will leave Stop Mode as soon as VIS=0.

Note

An Engine can stay in Module Disable mode when it leaves Stop Mode if its bit MDIS=1, even if the other leaves it.

2.3 Detailed signal descriptions

Detailed signal descriptions are presented in the following sections.

2.3.1 eTPU channel output signals

Each channel output signal is associated with a channel. The microcode may affect the logic level of an output signal[1] by implementing one of two actions:

- Specify the logic level output to the signal when there is a match or a transition.
- Immediately force a logic level.

The output signal may also be forced to a logic level, independently of the output value from the channel logic, by one of the four (each Engine) output disable input signals (see eTPU channel output disable signals).

The output buffer enable signals are not used.

2.3.2 eTPU channel input signals

Each channel input signal is associated with a channel. The microcode can directly control the effect of the transition edge. Each channel can be programmed to sense a transition when a rising and/or falling edge is detected. The channel logic can also process two transition events, and relate these events to each other and to other programmed timer events. The edge sensitivities of the two transition events are configured independently by microcode. For further information refer to Enhanced Channels and Transition Detection and Pin Action Control.

1. Note that the minimum pulse width is one microcycle (two eTPU clocks), and slow pads may not be able to transfer it on time. For generation of very short pulses the eTPU pads have to be programmed by the system integration for fast operation mode with the voltage levels defined for fast pad operation in the MCU technology.

Each channel input signal has an associated synchronizer made of two flip-flops sampling the signal on every other eTPU clock[2], followed by a digital filter. This digital filter can work in three sub-modes, whose purpose is to filter out noise pulses that have width less then a programmed value of eTPU clocks, preventing these transitions from being input to the transition detect logic. The synchronizer and digital filter are guaranteed to pass pulses that are greater than a programmed value. All channel input filters in one Engine work on the same mode and sampling clock. For more information on channel input filters, refer to Enhanced Digital Filter - EDF . In one of the Angle Modes, the output of the digital filter of channel 0 is replaced by the output of TCRCLK signal digital filter (see EAC - eTPU Angle Counter).

2.3.3 Time Base Clock Signal — TCRCLK

TCRCLK is an input signal used to control the Time Bases TCR1 and TCR2. There is one independent TCRCLK input for each Engine. For pulse accumulator operations TCRCLK can be used as a gate for a counter based on the eTPU clock divided by eight. For Angle operations TCRCLK can be used to get the tooth transition indications in Angle Mode. Further details can be found on Time bases and EAC - eTPU Angle Counter.

Like the channel input signals, the TCRCLK signal has an associated synchronizer followed by a digital filter. This digital filter can work in two sub-modes, whose purpose is to filter out noise pulses that have width less then a programmed value of eTPU clocks, preventing these transitions from being input to the transition detect logic. The synchronizer and digital filter are guaranteed to pass pulses that are greater than a programmed value. The clock and operation sub-mode of the TCRCLK filter is configured independently of the other channel input filters, through the TCRCF field in eTPU Engine 1 Time Base Configuration Register (eTPU_TBR_TBCR_ENG1) and eTPU Engine 2 Time Base Configuration Register (eTPU_TBR_TBCR_ENG2). For more information on filter sub-modes, see TCRCLK digital filter. In one of the Angle Modes, the output of the digital filter of channel 0 is replaced with the output of TCRCLK signal digital filter (see EAC - eTPU Angle Counter).

2.3.4 eTPU channel output disable signals

Each of these 4 input signals are used to force the outputs of a group of 8 channels to an inactive level. When an ODIS input is active, all the channels in its group of 8 that have their fields ODIS=1 in eTPU Channel n Configuration Register for Engine 1 (eTPU_CCCR_C*n*CR_ENG1) and eTPU Channel n Configuration Register for Engine 2

2. Sampled on the T4 microcycle phase, see Microcycle and I/O timing.

(eTPU_CCCR_C*n*CR_ENG2) have their outputs forced to the opposite of the value specified in bit OPOL of the same register. Therefore, channels can be individually selected to be affected by the output disable signals, as well as their disabling forced polarity (see 'Pin State Input/Output Logic' figure in Pin Control Registers).

See the chip-specific eTPU information for details on the output channel disable group definition.

In a Dual-engine eTPU there are 8 output disable signals for the 64 channels.

2.4 Memory map/register definition

The guideline for the description of all bits and fields throughout the“Memory Map/ Register Definition” section is to provide only a brief explanation (without examples or method of use) of the features, since it will be used mainly as a reference for the reader that is studying the “Functional Description" section, where those features are explained in detail.

2.5 Memory map

The eTPU System simplified memory map is shown in Table 2-3. Each of the register areas shown may have their own reserved address areas.

Table 2-4 shows a detailed memory map. Offsets are relative to the eTPU Base address, which is MCU-dependent.

See the chip-specific eTPU information about accessing eTPU registers in chip-level Stop mode.

SCM unused area is decoded and returns a fixed opcode, determined by eTPU SCM Off-range Data Register (eTPU_SCR_SCMOFFDATAR).

Table 2-3. High-level memory map

Offset	Use
0x00 – 0x1F	System Configuration Registers
0x20 – 0x2F	eTPU 1 Time Base Registers
0x30 – 0x3F	Reserved[1]
0x40 – 0x4F	eTPU 2 Time Base Registers
0x50 – 0x5F	Reserved[1]
0x60 – 0x6F	eTPU 1 Extra Engine Registers
0x70 – 0x7F	eTPU 2 Extra Engine Registers

Table continues on the next page...

Table 2-3. High-level memory map (continued)

Offset	Use

0xC1A	eTPU_SSIR_SSS8IR - eTPU SSS 8 Integration Register
0xC1C	eTPU_SSIR_SSS9IR - eTPU SSS 9 Integration Register
0x1000-0x3FFF	Reserved
0x4000 - 0x7FFF	Shared Subsystems area - SSS
0x8000 - 0xBFFF[3]	Shared Data Memory - SDM
0xC000 - 0xFFFF[3]	Shared Data Memory - SDM - PSE mirror [4]
0x10000-1FFFF[-1]	Shared Code Memory - SCM[7]

1. This register is not implemented in some MCUs; see SCMOFFDATAR.
2. These registers are not implemented in some MCUs; see Memory error support.
3. The actual SDM size is MCU-dependent (see the chip-specific eTPU information). SDM is allocated from the starting value of the given range of offsets.
4. Parameter Sign Extension access area, see Parameter Access.
5. The actual SCM size is MCU-dependent (see the chip-specific eTPU information). SCM is allocated from the starting value of the given range of offsets. When the size is not the maximum, the unused SCM address range returns the value of SCMOFFDATAR.
6. The actual SCM size is MCU-dependent (see the chip-specific eTPU information). SCM is allocated from the starting value of the given range of offsets. When the size is not the maximum, the unused SCM address range returns the value of SCMOFFDATAR.
7. SCM access is available only when eTPU_SCR_MCR[VIS]=1, under certain conditions (see MCR).

2.6 System Configuration memory map and registers

eTPU_SCR memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	eTPU Module Configuration Register (eTPU_SCR_MCR)	32	R/W	See section	2.6.1/92

2.6.1 eTPU Module Configuration Register (eTPU_SCR_MCR)

This register is global to both eTPU engines, and resides in the shared BIU. It gathers global configuration and status in the eTPU system, including global exception. It is also used for configuring the SCM (shared code memory) operation and test.

Address: 0h base + 0h offset = 0h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

* Notes:
- SCMSIZE field: See the chip-specific eTPU information for this field's reset value.

eTPU_SCR_MCR field descriptions

Field	Description
0 GEC	Global Exception Clear. This write-only bit negates global exception request and clears global exception status bits SDMERR, SSAERR, SCMERR, WDTO1/2, MGE1/2, ILF1/2, LTO1/2, and SCMMISF. GEC works the same way with either one or both Engines in Module Disable Mode. 0 Keep Global Exception request and status bits SDMERR, SCMERR, WDTO1/2, ILF1/2, MGE1/2, LTO1/2, and SCMMISF as is. 1 Negate Global Exception, clear status bits SDMERR, SCMERR, WDTO1/2, ILF1/2, MGE1/2, LTO1/2, and SCMMISF.
1 SDMERR	SDM Read Error This flag indicates that an SDM non-correctable read error occurred on a microengine or host (including CDC) read, generating a Global Exception. This bit is cleared by writing 1 to GEC. 0 No Global Exception pending because of SDM read error. 1 Global Exception requested by SDM read error is pending.
2 WDTO1	Watchdog 1 Timeout. Flag WDTO1 indicates that a Watchdog Timeout occurred in engine 1, generating a Global Exception. This bit is cleared by writing 1 to GEC. 0 No Global Exception pending because of Watchdog timeout. 1 Global Exception requested by Watchdog timeout.
3 WDTO2	Watchdog 2 Timeout. Flag WDTO2 indicates that a Watchdog Timeout occurred in engine 2, generating a Global Exception. This bit is cleared by writing 1 to GEC. 0 No Global Exception pending because of Watchdog timeout. 1 Global Exception requested by Watchdog timeout.
4 MGE1	Microcode Global Exception Engine 1. This bit indicates that a global exception was asserted by microcode executed on engine 1. The determination of the reason why the global exception was asserted is application dependent: it can be coded in an SDM status parameter, for instance. This bit is cleared by writing 1 to GEC. 0 No microcode-requested global exception pending. 1 Global exception requested by microcode is pending.
5 MGE2	Microcode Global Exception Engine 2. This bit indicates that a global exception was asserted by microcode executed on engine 2. The determination of the reason why the global exception was asserted is application dependent: it can be coded in an SDM status parameter, for instance. This bit is cleared by writing 1 to GEC. 0 No microcode-requested global exception pending. 1 Global exception requested by microcode is pending.
6 ILF1	Illegal Instruction Flag for Engine 1. The ILFA1 flag is set by the microengine to indicate that an illegal instruction was decoded in Engine 1. This bit is cleared by host writing 1 to GEC. See Illegal instructions for more details.

Table continues on the next page...

eTPU_SCR_MCR field descriptions (continued)

Field	Description
	0 Illegal Instruction not detected. 1 Illegal Instruction detected by Engine 1.
7 ILF2	Illegal Instruction Flag for Engine 2. The ILFA2 flag is set by the microengine to indicate that an illegal instruction was decoded in Engine 2. This bit is cleared by host writing 1 to GEC. See Illegal instructions for more details. 0 Illegal Instruction not detected. 1 Illegal Instruction detected by Engine 2.
8 Reserved	Reserved. This field is reserved.
9 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
10 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
11–15 SCMSIZE	SCM Size = 64 Kbytes. This read-only field holds the number of 2 KB SCM Blocks minus 1. See the chip-specific eTPU information for this field's reset value.
16 LTO1	Latency Timeout for Engine 1. The LTO1 flag indicates the latency measured by the Latency Monitor of Engine 1 surpassed the specified maximum. See Latency Monitor for details. This bit is cleared by writing 1 to GEC. 0 No latency timeout detected by Engine 1’s Latency Monitor. 1 Latency timeout detected by Engine 1's Latency Monitors.
17 LTO2	Latency Timeout for Engine 2. The LTO2 flag indicates the latency measured by the Latency Monitor of Engine 2 surpassed the specified maximum. See Latency Monitor for details. This bit is cleared by writing 1 to GEC. 0 No latency timeout detected by Engine 2’s Latency Monitor. 1 Latency timeout detected by Engine 2's Latency Monitors.
18–19 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
20 SCMMISC	SCM MISC Complete flag. Flag SCMMISC indicates that MISC has completed the evaluation of the SCM signature since reset or since the last time it was cleared. SCMMISC is cleared by writing 1 to it, and is not cleared when MISC is disabled (SCMMISEN=0). SCMMISC asserts at the end of the SCM memory scan, either if the signature matches or not.

Table continues on the next page...

eTPU_SCR_MCR field descriptions (continued)

Field	Description
	0 MISC has not yet completed an SCM signature calculation and compare since the last time SCMMISC was cleared. 1 MISC completed at least one SCM signature calculation and compare since the last time SCMMISC was cleared.
21 SCMMISF	SCM MISC Flag. The SCMMISF bit is set by the SCM MISC (Multiple Input Signature Calculator) logic to indicate that the calculated signature does not match the expected value, at the end of a MISC iteration. See SCM Test - Multiple Input Signature Calculator for more details. This bit is cleared when Global Exception is cleared by writing 1 to GEC. 0 Signature mismatch not detected. 1 MISC has read entire SCM array and the expected signature in eTPU MISC Compare Register (eTPU_SCR_MISCCMPR) does not match the value calculated.
22 SCMMISEN	SCM MISC Enable. The SCMMISEN bit is used for enabling/disabling the operation of the MISC logic. SCMMISEN is readable and writable at any time. The MISC logic will only operate when this bit is set to 1. When the bit is reset, the MISC address counter is set to the initial SCM address. When enabled, the MISC will continuously cycle through the SCM addresses, reading each and calculating a CRC. In order to save power, the MISC can be disabled by clearing the SCMMISEN bit. See SCM Test - Multiple Input Signature Calculator for more details. SCMMISEN resets automatically when MISC logic detects an error, i.e., when SCMMISF transitions from 0 to 1, disabling the MISC operation. 0 MISC operation disabled. The MISC logic is reset to its initial state. 1 MISC operation enabled.
23 SCMERR	SCM Read Error. This flag indicates that an SCM non-correctable read error occurred on a host or microengine (including MISC) read, generating a Global Exception. This bit is cleared by writing 1 to GEC. 0 No Global Exception pending because of SCM read error. 1 Global Exception requested by SCM read error is pending.
24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25 VIS	SCM Visibility Bit. VIS bit turns SCM visible to the IP-Bus and resets MISC state (but SCMMISEN keeps its value). This bit is write protected when any of the Engines is not halted or stopped. When VIS=1, the MDIS bits in the eTPU Memory Error Support registers are write protected. 0 SCM is not visible to the slave bus. Accessing SCM address space issues a bus error, writes are protected and reads are meaningless. 1 SCM is visible to the slave bus. MISC state is reset.
26–30 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

eTPU_SCR_MCR field descriptions (continued)

Field	Description
31 GTBE	Global Time Base Enable. GTBE enables time bases in both Engines, allowing them to be started synchronously. **NOTE:** Global Time Base Enable action may also depend on other blocks, as explained in GTBE - Global Time Base Enable. **NOTE:** When GTBE is turned off with Angle Mode enabled, the EAC must be reinitialized before GTBE is turned on again. The EAC reinitialization procedure is described in Restarting angle logic. 0 Time bases in both Engines are disabled to run. 1 Time bases in both Engines are enabled to run.

2.6.2 eTPU Coherent Dual-Parameter Controller Register (eTPU_SCR_CDCR)

This register configures and controls dual-parameter coherent transfers. For more information, see Coherent Dual-parameter Controller (CDC).

Address: 0h base + 4h offset = 4h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R W	STS	CTBASE							PBBASE							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	PWIDTH	PARM0							WR	PARM1						
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

eTPU_SCR_CDCR field descriptions

Field	Description
0 STS	Start Bit. This bit is set by the host in order to start the data transfer between the parameter buffer pointed by PBBASE and the target addresses selected by the concatenation of fields CTBASE and PARM0/1. The host receives wait-states until the data transfer is complete, when this bit is reset by the coherency logic (see Coherent Dual-parameter Controller (CDC)). Therefore, host always reads STS as 0.

Table continues on the next page...

eTPU_SCR_CDCR field descriptions (continued)

Field	Description
	0 Write does not start a coherent transfer. 1 Write starts a coherent transfer.
1–5 CTBASE	Channel Transfer Base. This field concatenates with fields PARM0 and PARM1 to determine the absolute word offset (from the SDM base) of the parameters to be transferred: Parameter 0 word address = {CTBASE, PARM0} + SDM base word address. Parameter 1 word address = {CTBASE, PARM1} + SDM base word address.
6–15 PBBASE	Parameter Buffer Base Address. This field points to the base address of the parameter buffer location, with granularity of 2 parameters (8 bytes). The host (byte) address of the first parameter in the buffer is PBBASE * 8 + SDM Base Byte Address. The microengine absolute (word) address of the first parameter in the buffer is PBBASE * 2.
16 PWIDTH	Parameter Width Selection. This bit selects the width of the parameters to be transferred between the PB and the target address. 0 Transfer 24-bit parameters. The upper byte remains unchanged in the destination address. 1 Transfer 32-bit parameters. All 32 bits of the parameters are written in the destination address.
17–23 PARM0	Channel Parameter number 0. The PARM0 and PARM1 fields in concatenation with CTBASE determine the word address offset (from the SDM base) of the parameters that are destination or source (defined by WR) of the coherent transfer. The word SDM address offset of the parameters are {CTBASE, PARM0/1}. **NOTE:** PARM0 and PARM1 allow non-contiguous parameters to be transferred coherently. The parameter pointed by {CTBASE, PARM0} is the first transferred.
24 WR	Read/Write selection. This bit selects the direction of the coherent data transfer. 0 Read operation. Data transfer is from the selected SDM address to the PB. 1 Write operation. Data transfer is from the PB to the selected SDM address.
25–31 PARM1	Channel Parameter number 1. The PARM0 and PARM1 fields in concatenation with CTBASE determine the word address offset (from the SDM base) of the parameters that are destination or source (defined by WR) of the coherent transfer. The word SDM address offset of the parameters are {CTBASE, PARM0/1}. **NOTE:** PARM0 and PARM1 allow non-contiguous parameters to be transferred coherently. The parameter pointed by {CTBASE, PARM0} is the first transferred.

2.6.3 eTPU MISC Compare Register (eTPU_SCR_MISCCMPR)

This register holds the 32-bit signature expected from the whole SCM array. This register must be written by the host with the 32-bit word to be compared against the calculated signature at the end of the MISC cycle. This register is global to both eTPU Engines. For more detail, see SCM Test - Multiple Input Signature Calculator.

Address: 0h base + Ch offset = Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	ETPUMISCCMP																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

eTPU_SCR_MISCCMPR field descriptions

Field	Description
0–31 ETPUMISCCMP	Expected Multiple Input Signature Register value. For details, see SCM Test - Multiple Input Signature Calculator.

2.6.4 eTPU SCM Off-range Data Register (eTPU_SCR_SCMOFFDATAR)

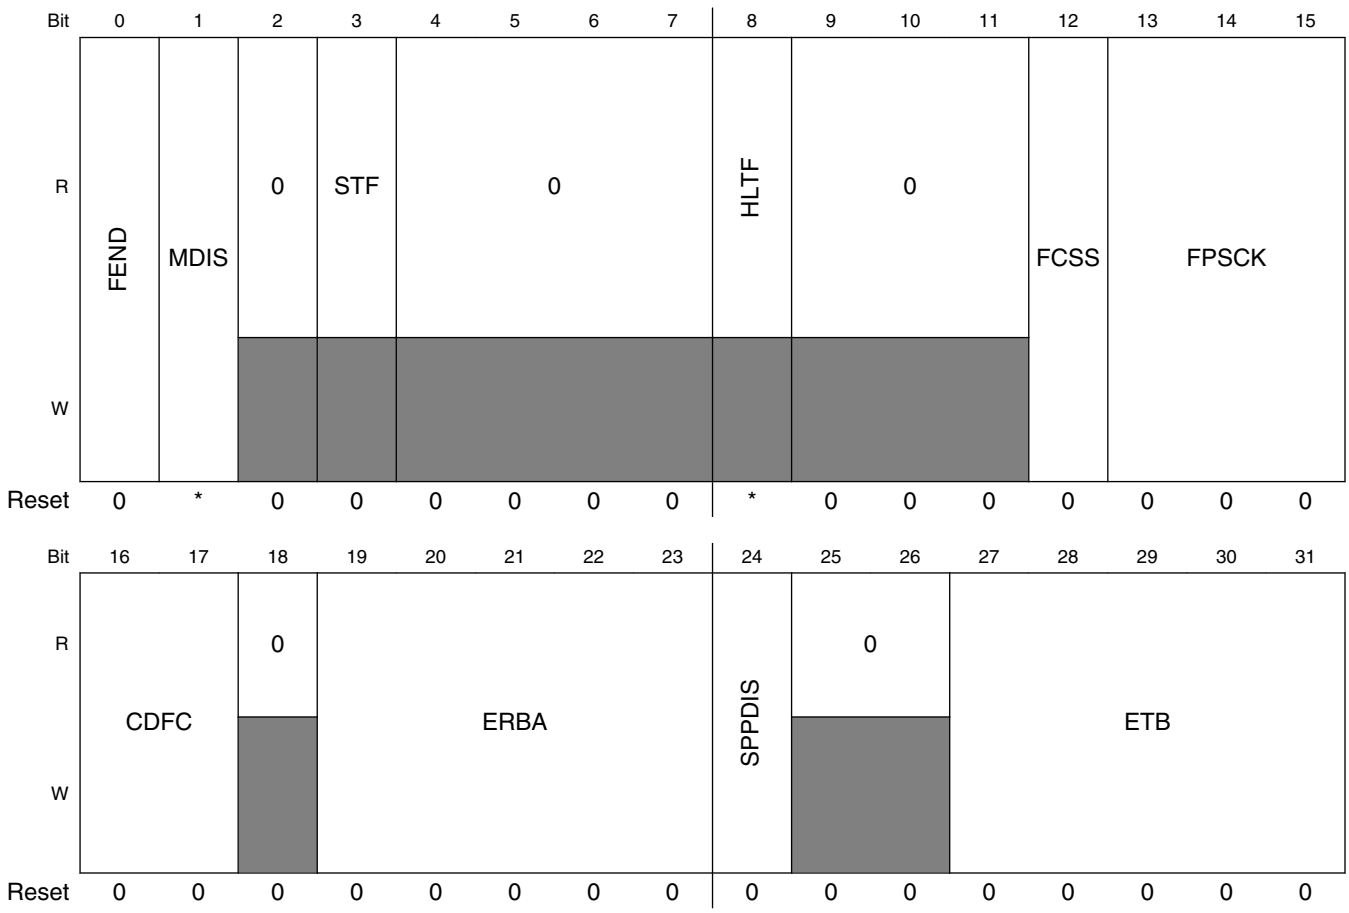
This register holds the 32-bit value returned when SCM array is accessed at non-implemented addresses, either by the Host or by the microengine. This register can be written by the host with the 32-bit instruction to be executed by the microengine to recover from runaway code. This register is global to both eTPU Engines. For more detail see SCM Off-range data.

Address: 0h base + 10h offset = 10h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	ETPUSCMOFFDATAR																															
Reset	1	1	1	1	0	0	1	1	0	1	1	1	0	1	1	1	0	1	0	1	1	1	1	1	1	1	1	1	1	0	1	1

eTPU_SCR_SCMOFFDATAR field descriptions

Field	Description
0–31 ETPUSCMOFFDATAR	SCM Off-range read data value. See SCM Off-range data.



2.6.5 eTPU Engine 1 Configuration Register (eTPU_SCR_ECR_ENG1)

This register holds configuration and status fields for engine 1.

NOTE

See Register Reset Values in the chip-specific eTPU information.

Address: 0h base + 14h offset = 14h

* Notes:

- HLTF field: HLTF field reset value is 1 if, after a reset, the eTPU Nexus debug support is on and a breakpoint request is asserted. Otherwise the reset value is 0.
- MDIS field: Reset value is 1.

eTPU_SCR_ECR_ENG1 field descriptions

Field	Description
0 FEND	Force End. FEND assertion terminates any current running thread as if an END instruction have been executed (see Ending Current Thread - END). This bit is self-negating when the thread ends.

Table continues on the next page...

eTPU_SCR_ECR_ENG1 field descriptions (continued)

Field	Description
	NOTE: Only on rare occasions (e.g., during a long stall, see Microengine Stall) FEND can be read as 1, because it negates as soon as the end begins execution. Writing FEND = 1 is ignored and FEND stays 0 when the microengine is in TST, halted, stopped, or idle (no thread executing). 0 Normal operation. 1 Ends any ongoing thread.
1 MDIS	Module Disable Bit. When MDIS is set, the Engine shuts down its internal clocks, going into Module Disable Mode. TCR1 and TCR2 cease to increment, and input sampling stops. The Engine asserts the stop flag (STF) bit to indicate that it has stopped. However, the BIU continues to run, and the Host can access all registers except for the channel registers (see channel registers starting with eTPU Channel n Configuration Register for Engine 1 (eTPU_CCCR_C*n*CR_ENG1)) **NOTE:** The Timebase registers can still be read with MDIS=1, but writes are ineffective and a Bus Error is issued. Global Channel Registers and SDM can be accessed normally. After MDIS is set, even before STF asserts, data read from the channel registers is not meaningful and writes are ineffective, issuing a Bus Error. When the MDIS bit is asserted while the microcode is executing, the eTPU will stop when the thread is complete. Stop completes on the next eTPU clock after the stop condition is valid. **NOTE:** Once MDIS is switched from 1 to 0 or vice versa, it must not write a different value until STF changes accordingly. The MDIS bit is write-protected when VIS=1. See Register Reset Values in the chip-specific eTPU information. 0 eTPU Engine runs. 1 Commands Engine to stop its clocks.
2 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
3 STF	Stop Flag Bit. Each Engine asserts its stop flag (STF) to indicate that it has stopped. Only then the host can assume that the Engine has actually stopped. The eTPU system is fully stopped when the STF bits of both eTPU Engines are asserted. In case of a stop request, the eTPU responds by acknowledging stop only after both eTPU 1 and eTPU 2 have been stopped. Engine only stops when any ongoing thread is complete also in this case. Summarizing Engine stop conditions, which STF reflects: STF_1 := (after stop completed) MDIS_1 | device stop request. STF_2 := (after stop completed) MDIS_2 | device stop request. STF_1 and STF_2 mean STF bit from engine 1 and STF bit from engine 2, respectively. See Register Reset Values in the chip-specific eTPU information. 0 Engine is operating. 1 Engine has stopped (after the local MDIS bit has been asserted, or after the IP-Bus stop line has been asserted).

Table continues on the next page...

eTPU_SCR_ECR_ENG1 field descriptions (continued)

Field	Description
4–7 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
8 HLTF	Halt Mode Flag. If eTPU Engine entered halt state, this flag is asserted. The flag remains asserted while the microengine is in halt state, even during a single-step or forced instruction execution. See Development support features for further details about entering Halt Mode. 0 eTPU Engine is not halted. 1 eTPU Engine is halted.
9–11 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
12 FCSS	Filter Clock Source Selection Speeds up the filter clock source before the prescaler, allowing more input capture resolution at minimum prescaling. **NOTE:** FCSS=1 also makes the channel work on T2/T4 timing mode (see T2/T4 channel timing). 0 Use eTPU clock / 2 as EDF clock source before prescaler. 1 Use eTPU clock as EDF clock source before prescaler
13–15 FPSCK	Filter Prescaler Clock Control. FPSCK controls the prescaling of the clocks used in digital filters for the channel input signals and TCRCLK input, as shown in the table below. Filtering can be controlled independently by each engine, but all input digital filters in the same engine have same clock prescaling. For more details, see Filter clock prescaler. A new value written to FPSCK only becomes effective when the filter prescaler finishes the current count.
16–17 CDFC	Channel Digital Filter Control.

Table 2-5. Filter prescaler clock control

Filter control	Sample on system clock divided by:	
	FCSS = 0	FCSS = 1
000	2	1
001	4	2
010	8	4
011	16	8
100	32	16
101	64	32
110	128	64
111	256	128

Table continues on the next page...

eTPU_SCR_ECR_ENG1 field descriptions (continued)

<table>
<tr><th>Field</th><th>Description</th></tr>
<tr><td></td><td>These bits select a digital filtering mode for the channels when configured as inputs for improved noise immunity (refer to the table below). The eTPU has three digital filtering modes for the channels which provide programmable trade-off between signal latency and noise immunity (see Enhanced Digital Filter - EDF). Changing CDFC during eTPU normal input channel operation is not recommended since it changes the behavior of the transition detection logic while executing its operation.
Table 2-6. Channel digital filter control
<table>
<tr><th>CDFC</th><th>Selected digital filter</th></tr>
<tr><td>00</td><td>TPU2/3 Two Sample Mode: Using the filter clock which is the system clock divided by (2, 4, 8,..., 256) as a sampling clock (selected by FPSCK), comparing two consecutive samples which agree with each other sets the input signal state. This is the default reset state.</td></tr>
<tr><td>01</td><td>eTPU bypass mode: the input signal is taken unfiltered, also making the channels work on T2/T4 timing mode.[3]</td></tr>
<tr><td>10</td><td>eTPU Three Sample Mode: Similar to the TPU2/3 two sample mode, but comparing three consecutive samples which agree with each other sets the input signal state.</td></tr>
<tr><td>11</td><td>eTPU Continuous Mode: Signal need to be stable for the whole filter clock period. This mode compares all the values at the rate of eTPU clock (FCSS=1) or eTPU clock divided by two(FCSS=0), between two consecutive filter clock pulses. Signal needs to be continuously stable for the entire period. If all the values agree with each other, input signal state is updated.</td></tr>

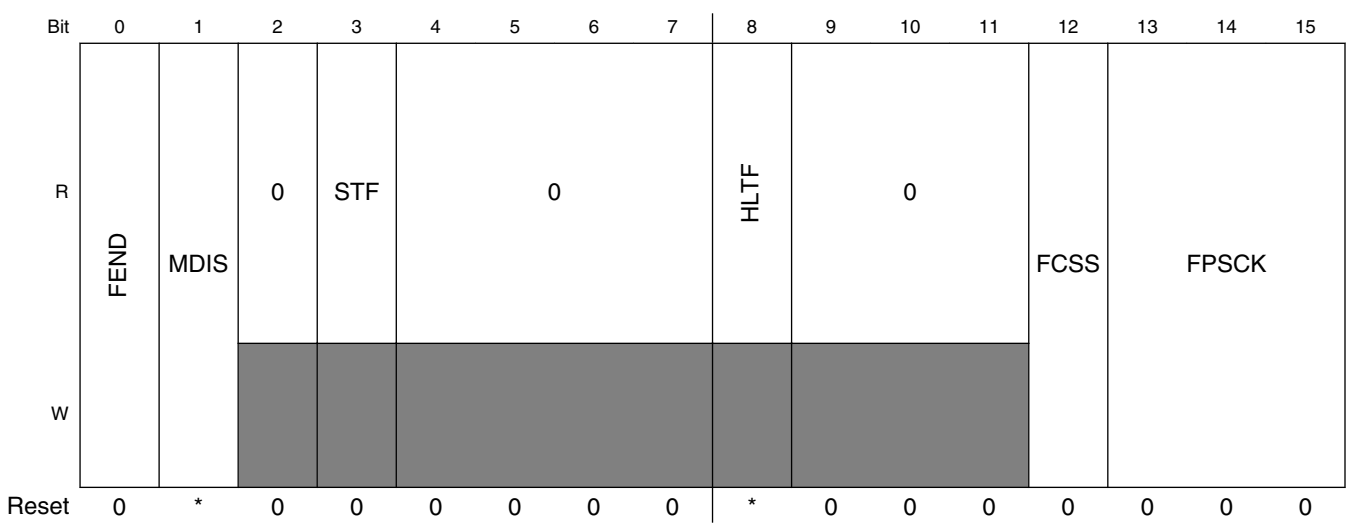
eTPU_SCR_ECR_ENG1 field descriptions (continued)

Field	Description
	The field determines the location of the microcode entry table for the eTPU functions in SCM (see Entry Points). The following table shows the entry table base address options.

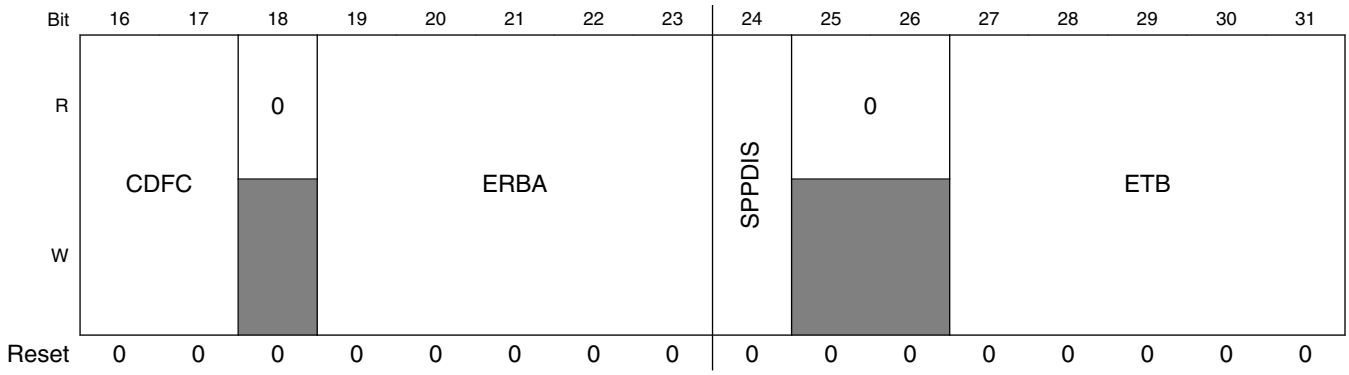
Table 2-7. Entry table base address options

ETB	Entry Table Base Address for CPU Host Address (byte format)	Entry Table Base Address for Microcode Address (word format)
00000	0x000	0x000
00001	0x800	0x200
00010	0x1000	0x400
--------	----------	---------
11110	0xF000	0x3C00
11111	0xF800	0x3E00

3. See T2/T4 channel timing.



2.6.6 eTPU Engine 2 Configuration Register (eTPU_SCR_ECR_ENG2)



This register holds configuration and status fields for engine 2.

NOTE

See Register Reset Values in the chip-specific eTPU information.

Address: 0h base + 18h offset = 18h

* Notes:
- HLTF field: HLTF field reset value is 1 if, after a reset, the eTPU Nexus debug support is on and a breakpoint request is asserted. Otherwise the reset value is 0.
- MDIS field: Reset value is 1.

eTPU_SCR_ECR_ENG2 field descriptions

Field	Description
0 FEND	Force End. FEND assertion terminates any current running thread as if an END instruction have been executed (see Ending Current Thread - END). This bit is self-negating when the thread ends. **NOTE:** Only on rare occasions (e.g., during a long stall, see Microengine Stall) FEND can be read as 1, because it negates as soon as the end begins execution. Writing FEND = 1 is ignored and FEND stays 0 when the microengine is in TST, halted, stopped, or idle (no thread executing). 0 Normal operation. 1 Ends any ongoing thread.
1 MDIS	Module Disable Bit. When MDIS is set, the Engine shuts down its internal clocks, going into Module Disable Mode. TCR1 and TCR2 cease to increment, and input sampling stops. The Engine asserts the stop flag (STF) bit to indicate that it has stopped. However, the BIU continues to run, and the Host can access all registers except for the channel registers (see channel registers starting with eTPU Channel Configuration-Control registers) **NOTE:** The Timebase registers can still be read with MDIS=1, but writes are ineffective and a Bus Error is issued. Global Channel Registers and SDM can be accessed normally. After MDIS is set, even before STF asserts, data read from the channel registers is not meaningful and writes are ineffective, issuing a Bus Error. When the MDIS bit is asserted while the microcode is executing, the eTPU will stop when the thread is complete. Stop completes on the next eTPU clock after the stop condition is valid. **NOTE:** Once MDIS is switched from 1 to 0 or vice versa, it must not write a different value until STF changes accordingly. The MDIS bit is write-protected when VIS=1. See Register Reset Values in the chip-specific eTPU information.

Table continues on the next page...

eTPU_SCR_ECR_ENG2 field descriptions (continued)

Field	Description
	0 eTPU Engine runs. 1 Commands Engine to stop its clocks.
2 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
3 STF	Stop Flag Bit. Each Engine asserts its stop flag (STF) to indicate that it has stopped. Only then the host can assume that the Engine has actually stopped. The eTPU system is fully stopped when the STF bits of both eTPU Engines are asserted. In case of IP-Bus stop, the eTPU system responds by acknowledging stop only after both eTPU 1 and eTPU 2 have been stopped. Engine only stops when any ongoing thread is complete also in this case. Summarizing Engine stop conditions, which STF reflects: STF_1 := (after stop completed) MDIS_1 | device stop request. STF_2 := (after stop completed) MDIS_2 | device stop request. STF_1 and STF_2 mean STF bit from engine 1 and STF bit from engine 2, respectively. See Register Reset Values in the chip-specific eTPU information. 0 Engine is operating. 1 Engine has stopped (after the local MDIS bit has been asserted, or after the IP-Bus stop line has been asserted).
4–7 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
8 HLTF	Halt Mode Flag. If eTPU Engine entered halt state, this flag is asserted. The flag remains asserted while the microengine is in halt state, even during a single-step or forced instruction execution. See Development support features for further details about entering Halt Mode. 0 eTPU Engine is not halted. 1 eTPU Engine is halted.
9–11 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
12 FCSS	Filter Clock Source Selection Speeds up the filter clock source before the prescaler, allowing more input capture resolution at minimum prescaling. **NOTE:** FCSS=1 also makes the channel work on T2/T4 timing mode (see T2/T4 channel timing). 0 Use eTPU clock / 2 as EDF clock source before prescaler. 1 Use eTPU clock as EDF clock source before prescaler
13–15 FPSCK	Filter Prescaler Clock Control.

Table continues on the next page...

eTPU_SCR_ECR_ENG2 field descriptions (continued)

Field	Description
	FPSCK controls the prescaling of the clocks used in digital filters for the channel input signals and TCRCLK input, as shown in the table below. Filtering can be controlled independently by each engine, but all input digital filters in the same engine have same clock prescaling. For more details, see Filter clock prescaler. A new value written to FPSCK only becomes effective when the filter prescaler finishes the current count. **Table 2-8. Filter prescaler clock control** Filter control: 000 → Sample on system clock divided by: 2 001 → 4 010 → 8 011 → 16 100 → 32 101 → 64 110 → 128 111 → 256
16–17 CDFC	Channel Digital Filter Control. These bits select a digital filtering mode for the channels when configured as inputs for improved noise immunity (refer to the table below). The eTPU has three digital filtering modes for the channels which provide programmable trade-off between signal latency and noise immunity (see Enhanced Digital Filter - EDF). Changing CDFC during eTPU normal input channel operation is not recommended since it changes the behavior of the transition detection logic while executing its operation. **Table 2-9. Channel digital filter control** CDFC: 00 → Selected digital filter: TPU2/3 Two Sample Mode: Using the filter clock which is the system clock divided by (2, 4, 8,..., 256) as a sampling clock (selected by FPSCK), comparing two consecutive samples which agree with each other sets the input signal state. This is the default reset state. 01 → eTPU bypass mode: the input signal is taken unfiltered, also making the channels work on T2/T4 timing mode.[3] 10 → eTPU Three Sample Mode: Similar to the TPU2/3 two sample mode, but comparing three consecutive samples which agree with each other sets the input signal state. 11 → eTPU Continuous Mode: Signal need to be stable for the whole filter clock period. This mode compares all the values at the rate of eTPU clock (FCSS=1) or eTPU clock divided by two(FCSS=0), between two consecutive filter clock pulses. Signal needs to be continuously stable for the entire period. If all the values agree with each other, input signal state is updated. 1. See T2/T4 channel timing.
18 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

eTPU_SCR_ECR_ENG2 field descriptions (continued)

Field	Description
19–23 ERBA	Engine Relative Base Address. This field value is concatenated with the AID instruction field in engine relative address mode to form the SDM address (see Engine Relative Addressing Mode).
24 SPPDIS	Schedule Priority Passing Disable. SPPDIS is used to disable the priority passing mechanism of the microengine scheduler (see Primary Scheme - Priority Among Channels on Different Levels). **NOTE:** SPPDIS bit must not be changed while any channel is enabled. 0 Scheduler priority passing mechanism enabled. 1 Scheduler priority passing mechanism disabled.
25–26 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
27–31 ETB	Entry Table Base. The field determines the location of the microcode entry table for the eTPU functions in SCM (see Entry Points). The following table shows the entry table base address options.

Table 2-10. Entry table base address options

ETB	Entry Table Base Address for CPU Host Address (byte format)	Entry Table Base Address for Microcode Address (word format)
00000	0x000	0x000
00001	0x800	0x200
00010	0x1000	0x400
--------	----------	---------
11110	0xF000	0x3C00
11111	0xF800	0x3E00

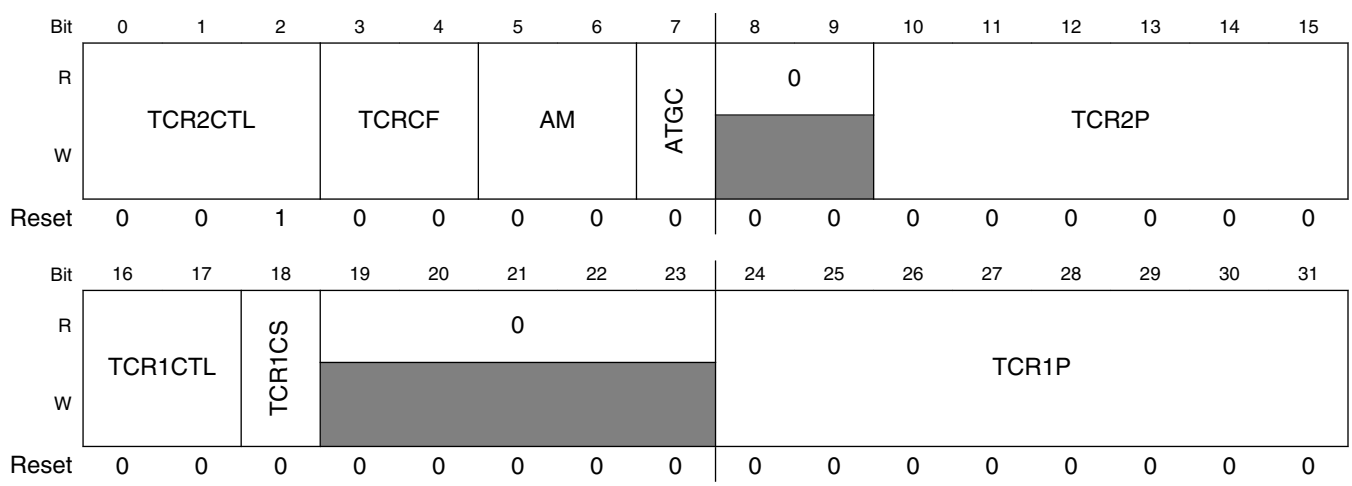
3. See T2/T4 channel timing.

2.7 Timebase memory map and registers

Time Base registers allows configuration and visibility of internally-generated time bases TCR1 and TCR2. There is one of each of these registers for each eTPU Engine.

NOTE

Writes to these registers issue bus error and are ineffective when MDIS=1. Reads are always allowed.



eTPU_TBR memory map

Reserved</td><td>Reserved.

This field is reserved.
This read-only field is reserved and always has the value 0.</td></tr>
<tr><td>10–15
TCR2P</td><td>Timer Count Register 2 Prescaler Control.

These bits are part of the TCR2 clocking system (see Time bases). TCR2 is clocked from the output of a prescaler. The prescaler divides its input by (TCR2P + 1) allowing frequency divisions from 1 to 64. The prescaler input is the eTPU clock divided by 8 (in gated or non-gated clock mode), or Internal Timebase input, or TCRCLK filtered input. This field has no effect on TCR2 in Angle Mode.</td></tr>
<tr><td>16–17
TCR1CTL</td><td>TCR1 Clock/Gate Control.

TCR1CTL is part of the TCR1 clocking system (see Time bases). It determines, together with TCR1CS, the clock source for TCR1. TCR1 can count on detected rising edge of the TCRCLK signal, the eTPU clock, or the eTPU clock divided by 2 (see the table in the TCR1CS bit description). After reset TCRCLK signal is selected.</td></tr>
<tr><td>18
TCR1CS</td><td>TCR1 Clock Source

TCR1CS provides the option to double the TCR1 incrementing speed, using eTPU clock as its clock source instead of eTPU clock / 2.</td></tr>
</table>

Table continues on the next page...

Reserved</td><td>Reserved.

This field is reserved.
This read-only field is reserved and always has the value 0.</td></tr>
<tr><td>24–31
TCR1P</td><td>Timer Count Register 1 Prescaler Control.

TCR1 is clocked from the output of a prescaler. The input to the prescaler is the internal eTPU clock divided by 2, eTPU clock, or the output of TCRCLK filter. The prescaler divides this input by (TCR1P + 1) allowing frequency divisions from 1 up to 256.</td></tr>
</table>

1. TCRCLK edges are not detected by the EAC logic, but they can still be detected by the channel 0 logic if AM=01.
2. This selection must not be used in Angle Mode.

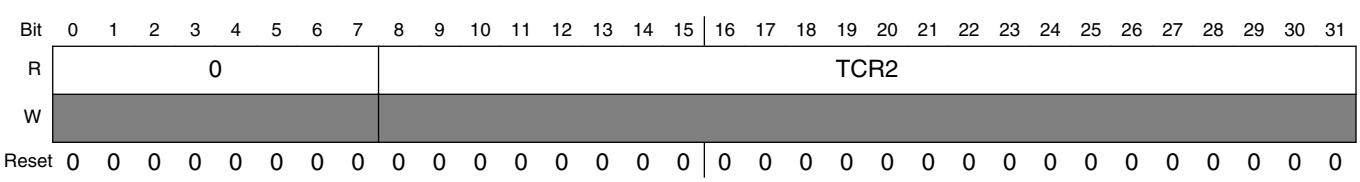
2.7.6 eTPU Engine 2 Time Base 1 (TCR1) Visibility Register (eTPU_TBR_TB1R_ENG2)

This register provides visibility of the TCR1 time base for host read access (see Time bases). This register is read-only. The value of the TCR1 time base shown can be driven by the TCR1 counter or imported from STAC bus, depending on the configuration set in eTPU Engine 2 STAC Configuration Register (eTPU_TBR_STAC_ENG2).

Address: 0h base + 44h offset = 44h



eTPU_TBR_TB1R_ENG2 field descriptions

Field	Description
0–7 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
8–31 TCR1	TCR1 value. TCR1 value used on matches and captures. See Time bases.

2.7.7 eTPU Engine 2 Time Base 2 (TCR2) Visibility Register (eTPU_TBR_TB2R_ENG2)

This register provides visibility of the TCR2 time base for host read access (see Time bases). This register is read-only. The value of the TCR2 time base shown can be driven by the TCR2 counter or imported from the STAC bus, depending on Angle Mode and STAC configurations set in eTPU Engine 2 STAC Configuration Register (eTPU_TBR_STAC_ENG2).

Address: 0h base + 48h offset = 48h

eTPU_TBR_TB2R_ENG2 field descriptions

Field	Description
0–7 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
8–31 TCR2	TCR2 value. TCR2 value used on matches and captures. See Time bases.

2.7.8 eTPU Engine 2 STAC Configuration Register (eTPU_TBR_STAC_ENG2)

This register configures the eTPU STAC bus operation as a STAC Server/Client module (see STAC interface).

Address: 0h base + 4Ch offset = 4Ch

eTPU_TBR_STAC_ENG2 field descriptions

Field	Description
0 REN1	TCR1 Resource Client/Server Operation Enable Bit. This bit enables Client/Server operation to eTPU STAC resources. REN1 enables TCR1 STAC bus operations. 0 Server/Client Operation for TCR1 is disabled. 1 Server/Client Operation for TCR1 is enabled.
1 RSC1	TCR1 Resource Server/Client Assignment Bits. This bit selects the eTPU data resource assignment to be used as Servers or Clients. For Server mode, MCU-dependent value determines the unique server address assigned to each TCR. See the chip-specific

Table continues on the next page...

eTPU_TBR_STAC_ENG2 field descriptions (continued)

Field	Description
	eTPU information for the STAC server IDs. For a Client mode, the SRV1 field determines the Server address to which the Client listens. **NOTE:** Resource identifies any parameter that changes along the time and can be exported / imported from other device. In eTPU context, a resource can be TCR1 or TCR2 (either Time or Angle values). **NOTE:** When TCR1 or TCR2 is configured as a STAC Bus Client (REN2 = 1, RSC2 = 0) the eTPU Angle Clock hardware cannot be used. **NOTE:** RSC1 must not be changed when the REN1 bit is asserted. 0 TCR1 Client operation. 1 TCR1 Server operation.
2–3 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
4–7 SERVER_ID1	STAC ID 1. STAC Server ID= 1 (read-only MCU-dependent values; see the chip-specific eTPU information for the STAC server IDs) used for TCR1 when STAC servers are used.
8–11 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
12–15 SRV1	TCR1 Resource Server. This bit selects the address of the specific STAC Server to which the local TCR1 listens when configured as a STAC Client. SRV1 selects the STAC Server of TCR1.
16 REN2	TCR2 Resource Client/Server Operation Enable Bit. This bit enables Client/Server operation to eTPU STAC resources. REN2 enables TCR2 STAC bus operations. 0 Server/Client Operation for resource 2 is disabled. 1 Server/Client Operation for resource 2 is enabled.
17 RSC2	TCR2 Resource Server/Client Assignment Bits. **NOTE:** Resource identifies any parameter that changes along the time and can be exported / imported from other device. In eTPU context, a resource can be TCR1 or TCR2 (either Time or Angle values). 0 Resource Client operation. 1 Resource Server operation.
18–19 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
20–23 SERVER_ID2	STAC ID 2.

Table continues on the next page...

eTPU_TBR_STAC_ENG2 field descriptions (continued)

Field	Description
	STAC Server ID= 3 (read-only MCU-dependent values; see the chip-specific eTPU information for the STAC server IDs) used for TCR2 when when STAC servers are used.
24–27 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
28–31 SRV2	TCR2 Resource Server. This bit selects the address of the specific STAC Server to which the local TCR2 listens when configured as a STAC Client. SRV2 selects the Red Line STAC Server of TCR2.

2.8 Engine memory map and registers

This section gathers registers that are engine-related, other than eTPU Engine 1 Configuration Register (eTPU_SCR_ECR_ENG1) and eTPU Engine 2 Configuration Register (eTPU_SCR_ECR_ENG2).

eTPU_ER memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
60	eTPU Watchdog Timer Register for Engine 1 (eTPU_ER_WDTR_ENG1)	32	R/W	0000_0000h	2.8.1/123
68	eTPU Idle Register for Engine 1 (eTPU_ER_IDLER_ENG1)	32	R/W	Undefined	2.8.2/124
70	eTPU Watchdog Timer Register for Engine 2 (eTPU_ER_WDTR_ENG2)	32	R/W	0000_0000h	2.8.3/125
78	eTPU Idle Register for Engine 2 (eTPU_ER_IDLER_ENG2)	32	R/W	Undefined	2.8.4/126

2.8.1 eTPU Watchdog Timer Register for Engine 1 (eTPU_ER_WDTR_ENG1)

This register configures the watchdog timer for the engine.

Address: 0h base + 60h offset = 60h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

eTPU_ER_WDTR_ENG1 field descriptions

Field	Description
0–1 WDM	Watchdog Mode. WDM selects the Watchdog operation mode. For more information on the Watchdog operation, see Watchdog). **NOTE:** Before a new mode is configured, all conditions below must apply: 1. All channels must be disabled (CPR =00). 2. No thread must be executing (eTPU Channel Service Status Register for Engine 1 (eTPU_GCR_CSSR_ENG1) reads 0). 3. The watchdog must be disabled (WDM=00). 00 Disabled 01 Reserved 10 Thread length 11 Busy length
2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3 WMO	Watchdog Monitor Operation. This bit enables the monitor operation of the watchdog, inhibiting the thread ending and channel disabling in case of a timeout. The Global Exception occurs on a watchdog timeout, independently of WMO. **NOTE:** WDSn, WDTO1, WDTO2, and the Global Exception always asserts in case of a watchdog timeout, independently of WMO. 0 Force the end of the running thread and disable the service channel in case of a timeout. 1 Do not force the end of the running thread, nor disable the service channel in case of a timeout.
4–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 WDCNT	Watchdog Count.

Table continues on the next page...

eTPU_ER_WDTR_ENG1 field descriptions (continued)

Field	Description
	This field indicates the maximum number of microcycles allowed for a thread (in thread length mode) or a sequence of threads (in busy length mode) before the current running thread is forced to end. For more information on Watchdog operation, see Watchdog. **NOTE:** The TST microcycles are also counted by the watchdog. **NOTE:** Fields WDCNT and WMO must not be changed when the watchdog is enabled.

2.8.2 eTPU Idle Register for Engine 1 (eTPU_ER_IDLER_ENG1)

This register counts the microcycles in which the microengine is idle (see Idle Counter

Address: 0h base + 68h offset = 68h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

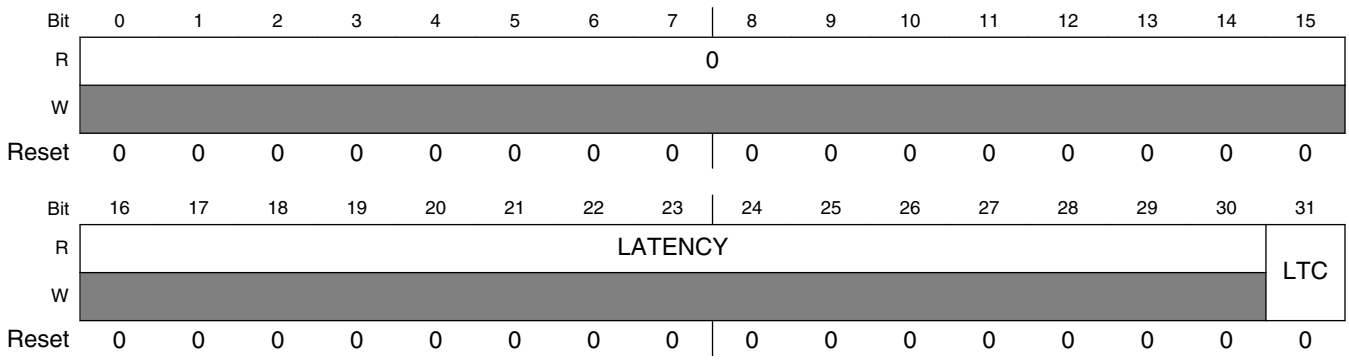
MAXLAT</td><td>Maximum Latency.



This field specifies the maximum latency monitored, in microcycles, before a latency timeout. If MAXLAT=0, the latency keeps on being counted and measured, but the comparison with MAXLAT asserts neither the LTO1/2 fields in eTPU Module Configuration Register (eTPU_SCR_MCR) nor issues a Global Exception. See Latency Monitor for the detailed latency timeout description.

NOTE: MAXLAT must only be changed when the Latency Monitor is in disabled mode.</td></tr>
</table>

2.9.2 eTPU Latency Monitor Measure Register for Engine 1 (eTPU_LMR_LM*n*MR_ENG1)

This register holds the latency measured value.

Address: 0h base + 84h offset + (8d × i), where i=0d to 5d

eTPU_LMR_LM*n*MR_ENG1 field descriptions

Field	Description
0–15 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
16–30 LATENCY	Latency measurement. This read-only field holds the value of the greatest latency measured, in microcycles, since reset or the latest clear. When the value is greater than the maximum specified in MAXLAT and MAXLAT value is not zero, a Global Exception is issued and LTO1 (engine 1) or LTO2 (engine 2) is set. See Latency Monitor for the detailed latency measurement description. **NOTE:** When read, the LATENCY field is concatenated with the LTC bit (LSB) to form a 16-bit value. **NOTE:** Any latency measured above 0xFFFF is captured as 0xFFFF into the LATENCY+LTC field.
31 LTC	Latency measurement clear Writing a 1 to the LTC bit clears the LATENCY field. **NOTE:** When read, the LATENCY field is concatenated with the LTC bit (LSB) to form a 16-bit value. **NOTE:** The LATENCY value is not automatically cleared when the Latency Monitor is disabled. 0 Keep the LATENCY field value. 1 Clear the LATENCY field value.

2.9.3 eTPU Latency Monitor Configuration Register for Engine 2 (eTPU_LMR_LM*n*CR_ENG2)

This register configures the operation of individual latency monitors.

Address: 0h base + C0h offset + (8d × i), where i=0d to 5d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	LMM		0			SRSEL			0			MONCHAN					MAXLAT															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

eTPU_LMR_LM*n*CR_ENG2 field descriptions

Field	Description
0–1 LMM	Latency Monitor Mode. This field selects the operation mode of the latency monitor. See the Latency Monitor section for detailed mode descriptions. **NOTE:** LMM must be in disabled mode to be changed to channel or priority mode. CPR must not be changed while LMM of any Latency Monitor is in priority mode. 00 Disabled mode 01 Channel mode 10 Priority mode 11 Reserved
2–4 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
5–7 SRSEL	Service Request Selection This field selects which service requests are monitored. The SRSEL value has different meanings in channel and priority modes, according to the following table.

Table 2-20. SRSEL - Service Request Selection

SRSEL	Channel Mode	Channel Mode
001	Link SRs monitored only	Low priority monitored
010	Channel SRs monitored only	Medium priority monitored
100	HSRs monitored only	High priority monitored
000	No SRs monitored	Reserved
011	Channel and Link SRs monitored	
101	HSRs and Link SRs monitored	
110	HSRs and Channel SRs monitored	
111	All SRs monitored	

Table continues on the next page...

eTPU_LMR_LM*n*CR_ENG2 field descriptions (continued)

Field	Description
8–10 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
11–15 MONCHAN	Monitored Channel. When the latency monitor is configured for channel mode, this field selects which channel has the latency monitored. MONCHAN has no meaning in priority mode. **NOTE:** MONCHAN must only be changed when the Latency Monitor is in disabled mode.
16–31 MAXLAT	Maximum Latency. This field specifies the maximum latency monitored, in microcycles, before a latency timeout. If MAXLAT=0, the latency keeps on being counted and measured, but the comparison with MAXLAT asserts neither the LTO1/2 fields in eTPU Module Configuration Register (eTPU_SCR_MCR) nor issues a Global Exception. See Latency Monitor for the detailed latency timeout description. **NOTE:** MAXLAT must only be changed when the Latency Monitor is in disabled mode.

2.9.4 eTPU Latency Monitor Measure Register for Engine 2 (eTPU_LMR_LM*n*MR_ENG2)

This register holds the latency measured value.

Address: 0h base + C4h offset + (8d × i), where i=0d to 5d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	LATENCY															LTC
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

eTPU_LMR_LM*n*MR_ENG2 field descriptions

Field	Description
0–15 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
16–30 LATENCY	Latency measurement.

Table continues on the next page...

eTPU_LMR_LM*n*MR_ENG2 field descriptions (continued)

Field	Description
	This read-only field holds the value of the greatest latency measured, in microcycles, since reset or the latest clear. When the value is greater than the maximum specified in MAXLAT and MAXLAT value is not zero, a Global Exception is issued and LTO1 (engine 1) or LTO2 (engine 2) is set. See Latency Monitor for the detailed latency measurement description. **NOTE:** When read, the LATENCY field is concatenated with the LTC bit (LSB) to form a 16-bit value. **NOTE:** Any latency measured above 0xFFFF is captured as 0xFFFF into the LATENCY+LTC field.
31 LTC	Latency measurement clear. Writing a 1 to the LTC bit clears the LATENCY field. **NOTE:** When read, the LATENCY field is concatenated with the LTC bit (LSB) to form a 16-bit value. **NOTE:** The LATENCY value is not automatically cleared when the Latency Monitor is disabled. 0 Keep the LATENCY field value. 1 Clear the LATENCY field value.

2.10 Memory Error Support memory map and registers

eTPU_MESR memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
100	eTPU Memory Error Control Register (eTPU_MESR_MECR)	32	R/W	0000_0000h	2.10.1/134

2.10.1 eTPU Memory Error Control Register (eTPU_MESR_MECR)

This register gathers control bits of both SCM and SDM error detection and correction support.

Address: 0h base + 100h offset = 100h

eTPU_MESR_MECR field descriptions

Field	Description
0 FME	Field Modification Enable. Negation of this bit disables the modification of all fields in the register, except MECIE, DRDIS, CRDIS and FME itself: Write accesses do not cause a bus error, regardless of FME state. 0 Fields cannot be modified during a write access, except MECIE, DRDIS, CRDIS and FME. 1 All fields can be modified during a write access.
1–14 Reserved	Reserved.

Table continues on the next page...

eTPU_MESR_MECR field descriptions (continued)

Field	Description
	This field is reserved. This read-only field is reserved and always has the value 0.
15 MECIE	Memory Error Correction Interrupt Enable. This bit enables the Memory Error Correction Interrupt (see Interrupt types and sources). 0 Memory Error Correction Interrupt disabled. 1 Memory Error Correction Interrupt enabled.
16 HDEIE	Host Data Error Injection Enable This bit enables error injection into the SDM host read path, including CDC transfers. The eTPU Data Error Injection Address Register (eTPU_MESR_DEIAR) specifies the address where the error is injected, while eTPU Data Error Injection Data Pattern Register (eTPU_MESR_DEIDPR) and eTPU Data Error Injection Parity Pattern Register (eTPU_MESR_DEIPPR) define the bit flips on data and parity, respectively. **NOTE:** Data error injection is also performed when data error detection is disabled (DEDD=1). 0 SDM error injection disabled for host reads. 1 SDM error injection enabled for host reads.
17 MDEIE	Microengine(s) Data Error Injection Enable. This bit enables error injection into the SDM microengine read path. The eTPU Data Error Injection Address Register (eTPU_MESR_DEIAR) specifies the address where the error is injected, while eTPU Data Error Injection Data Pattern Register (eTPU_MESR_DEIDPR) and eTPU Data Error Injection Parity Pattern Register (eTPU_MESR_DEIPPR) define the bit flips on data and parity, respectively. **NOTE:** Data error injection is also performed when data error detection is disabled (DEDD=1). 0 SDM error injection disabled for microengine reads. 1 SDM error injection enabled for microengine reads.
18–20 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
21 DTEND	Thread End on Data Non-correctable Error. This bit controls the behavior of the microengine when a non-correctable data error occurs. For more details, see Memory error support. **NOTE:** DTEND must only be changed when the engine is stopped or halted, or when all channels are disabled. 0 Thread continues on non-correctable data read access by the microengine. 1 Thread ends on non-correctable data read access by the microengine.
22 DRDIS	Data Error Report Disable. This bit disables the sampling of SDM error address, data and syndrome into the eTPU Memory Error Support Registers, and eTPU Data Error Report Syndrome Register (eTPU_MESR_DERSR). It does not, however, disable the setting of eTPU Memory Error Status Register (eTPU_MESR_MESR) bits DCERR and DNCERR.

Table continues on the next page...

eTPU_MESR_MECR field descriptions (continued)

Field	Description
	NOTE: To guarantee coherent reading of eTPU Data Error Report Address Register (eTPU_MESR_DERAR), eTPU Data Error Report Data Register (eTPU_MESR_DERDR), and eTPU Data Error Report Syndrome Register (eTPU_MESR_DERSR), DRDIS must be asserted beforehand if SDM concurrent accesses can happen, by host or microengine. After the registers are read, DRDIS may be negated again to allow new samplings. 0 SDM error report sampling enabled. 1 SDM error report sampling disabled.
23 DEDD	Data Error Detection Disable. This bit disables SDM error detection. The disabled state turns ineffective any action due to error detection, including consequently error correction. 0 SDM error detection enabled. 1 SDM error detection disabled.
24 CEIE	Code Error Injection Enable. This bit enables error injection into the SCM read path, either on microengine accesses (see VIS =0) or host accesses (VIS = 1) eTPU Code Error Injection Address Register (eTPU_MESR_CEIAR) specifies the address where the error is injected, while eTPU Code Error Injection Data Pattern Register (eTPU_MESR_CEIDPR) and eTPU Code Error Injection Parity Pattern Register (eTPU_MESR_CEIPPR) define the bit flips on data and parity, respectively. **NOTE:** Code error injection is also performed when code error detection is disabled (CEDD=1). 0 SCM error injection disabled. 1 SCM error injection enabled.
25–28 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
29 CTEND	Thread End on Code Non-correctable Error. This bit controls the behavior of the microengine when a non-correctable code error occurs. For more details, see Memory error support. **NOTE:** CTEND must only be changed when the engine is stopped or halted, or when all channels are disabled. 0 Thread continues on instruction fetch non-correctable error. 1 Thread ends on instruction fetch non-correctable error.
30 CRDIS	Code Error Report Disable. This bit disables the sampling of SCM error address, data and syndrome into the eTPU Code Error Report Address Register (eTPU_MESR_CERAR), eTPU Code Error Report Data Register (eTPU_MESR_CERDR), and eTPU Code Error Report Syndrome Register (eTPU_MESR_CERSR). It does not, however, disable the setting of CCERR and CNCERR in eTPU Memory Error Status Register (eTPU_MESR_MESR).

Table continues on the next page...

eTPU_MESR_MECR field descriptions (continued)

Field	Description
	NOTE: To guarantee coherent reading of eTPU Code Error Report Address Register (eTPU_MESR_CERAR), eTPU Code Error Report Data Register (eTPU_MESR_CERDR), and eTPU Code Error Report Syndrome Register (eTPU_MESR_CERSR), CRDIS must be asserted beforehand if SCM concurrent accesses can happen, by host or microengine. After the registers are read, CRDIS may be negated again to allow new samplings. 0 SCM error report sampling enabled. 1 SCM error report sampling disabled.
31 CEDD	Code Error Detection Disable. This bit disables SCM error detection. The disabled state turns ineffective any action due to error detection, including consequently error correction. 0 SCM error detection enabled. 1 SCM error detection disabled.

2.10.2 eTPU Data Error Injection Address Register (eTPU_MESR_DEIAR)

This register holds the address where error is to be injected into the SDM read data path. The two least significant bits are 0 (read-only), so that the address is always word-aligned.

NOTE

This register must only be modified when HDEIE and MDEIE are both negated.

Address: 0h base + 104h offset = 104h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

eTPU_MESR_DEIAR field descriptions

Field	Description
0–17 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
18–29 INJ_ADDR	Injection Address. INJ_ADDR holds the (word) address where an error is injected into the SDM read data path, as specified by eTPU Data Error Injection Data Pattern Register (eTPU_MESR_DEIDPR) and eTPU Data Error

Table continues on the next page...

eTPU_MESR_DEIAR field descriptions (continued)

Field	Description
	Injection Parity Pattern Register (eTPU_MESR_DEIPPR). For more information on error injection, see Error injection.
30–31 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.

2.10.3 eTPU Data Error Injection Data Pattern Register (eTPU_MESR_DEIDPR)

This register is used to specify the bits in which error is injected into the SDM read data path.

NOTE

This register must only be modified when HDEIE and MDEIE are both negated.

Address: 0h base + 108h offset = 108h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	DFLIP																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

eTPU_MESR_DEIDPR field descriptions

Field	Description
0–31 DFLIP	Data Flip bits. Each bit corresponds to a bit in the actual data read from the SDM address defined in eTPU Data Error Injection Address Register (eTPU_MESR_DEIAR), specifying whether it should be inverted or not. The inversion only occurs if the SDM error injection is enabled by HDEIE and/or MDEIE in eTPU Memory Error Control Register (eTPU_MESR_MECR). For more information on error injection, see Error injection. 0 Read data bit is not inverted. 1 Read data bit is inverted.

2.10.4 eTPU Data Error Injection Parity Pattern Register (eTPU_MESR_DEIPPR)

This register is used to specify the bits in which error is injected into the SDM read parity path.

NOTE

This register must only be modified when HDEIE and MDEIE are both negated.

Address: 0h base + 10Ch offset = 10Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

eTPU_MESR_DEIPPR field descriptions

Field	Description
0–2 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
3–7 PFLIP_19_15	Parity Flip bits. Each bit corresponds to a bit in the actual parity read from the SDM address defined in eTPU Data Error Injection Address Register (eTPU_MESR_DEIAR), specifying whether it should be inverted or not. The inversion only occurs if the SDM error injection is enabled by the HDEIE and/or MDEIE fields in eTPU Memory Error Control Register (eTPU_MESR_MECR). Bits PFLIP[19:15] corresponds to the parity bits for the most significant byte, PFLIP[14:10] to the next most significant byte and so on until PFLIP[4:0] for the least significant byte. For more information on error injection, see Error injection. 0 Parity data bit is not inverted. 1 Parity data bit is inverted.
8–10 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
11–15 PFLIP_14_10	Parity Flip bits. Each bit corresponds to a bit in the actual parity read from the SDM address defined in eTPU Data Error Injection Address Register (eTPU_MESR_DEIAR), specifying whether it should be inverted or not. The inversion only occurs if the SDM error injection is enabled by the HDEIE and/or MDEIE fields in eTPU Memory Error Control Register (eTPU_MESR_MECR). Bits PFLIP[19:15] corresponds to the parity bits for the most significant byte, PFLIP[14:10] to the next most significant byte and so on until PFLIP[4:0] for the least significant byte. For more information on error injection, see Error injection. 0 Parity data bit is not inverted. 1 Parity data bit is inverted.
16–18 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
19–23 PFLIP_9_5	Parity Flip bits. Each bit corresponds to a bit in the actual parity read from the SDM address defined in eTPU Data Error Injection Address Register (eTPU_MESR_DEIAR), specifying whether it should be inverted or not. The inversion only occurs if the SDM error injection is enabled by the HDEIE and/or MDEIE fields in eTPU Memory Error Control Register (eTPU_MESR_MECR). Bits PFLIP[19:15] corresponds to the parity bits for

Table continues on the next page...

eTPU_MESR_DEIPPR field descriptions (continued)

Field	Description
	the most significant byte, PFLIP[14:10] to the next most significant byte and so on until PFLIP[4:0] for the least significant byte. For more information on error injection, see Error injection. 0 Parity data bit is not inverted. 1 Parity data bit is inverted.
24–26 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
27–31 PFLIP_4_0	Parity Flip bits. Each bit corresponds to a bit in the actual parity read from the SDM address defined in eTPU Data Error Injection Address Register (eTPU_MESR_DEIAR), specifying whether it should be inverted or not. The inversion only occurs if the SDM error injection is enabled by the HDEIE and/or MDEIE fields in eTPU Memory Error Control Register (eTPU_MESR_MECR). Bits PFLIP[19:15] corresponds to the parity bits for the most significant byte, PFLIP[14:10] to the next most significant byte and so on until PFLIP[4:0] for the least significant byte. For more information on error injection, see Error injection. 0 Parity data bit is not inverted. 1 Parity data bit is inverted.

2.10.5 eTPU Data Error Report Address Register (eTPU_MESR_DERAR)

This register holds the address where the last non-correctable error was detected from the SDM It also captures the address of the last correctable error detected, as long as DNCERR is 0. The two least significant bits are 0 (read-only), so that the address is always word-aligned.

Address: 0h base + 110h offset = 110h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	ERR_ACC		0	ERR_CHANNEL					0							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R	0		ERR_ADDR												0	
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

eTPU_MESR_DERAR field descriptions

Field	Description
0–1 ERR_ACC	Error Access Source Indication. This two-bit field indicates the source of the access when the error occurred. 00 Host - direct access 01 Engine 1 10 Engine 2 11 CDC
2 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
3–7 ERR_CHANNEL	Error Channel Access Indication. This field holds the number of the channel being serviced (not necessarily CHAN) when the error occurred. Its content is meaningful only when the field ERR_ACC indicates Engine 1 or Engine 2.
8–17 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
18–29 ERR_ADDR	Error Address. ERR_ADDR holds the (word) address where the last captured SDM read error was detected. The last captured error is a non-correctable one if DNCERR =1, or a correctable one if DNCERR =0 and DCERR =1. The field is meaningless if both DNCERR and DCERR are 0. For more information on error detection, see Memory error support.
30–31 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.

2.10.6 eTPU Data Error Report Data Register (eTPU_MESR_DERDR)

This register holds the data read with the last non-correctable error detected from the SDM. It also captures the data of the last correctable error read detection, as long as DNCERR is 0. In both cases, the data is captured after the error correction logic. The data is meaningless if both DNCERR and DCERR are 0. For more information on error detection, see Memory error support.

NOTE

Data is sampled before the error correction logic.

Address: 0h base + 114h offset = 114h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

eTPU_MESR_DERSR field descriptions

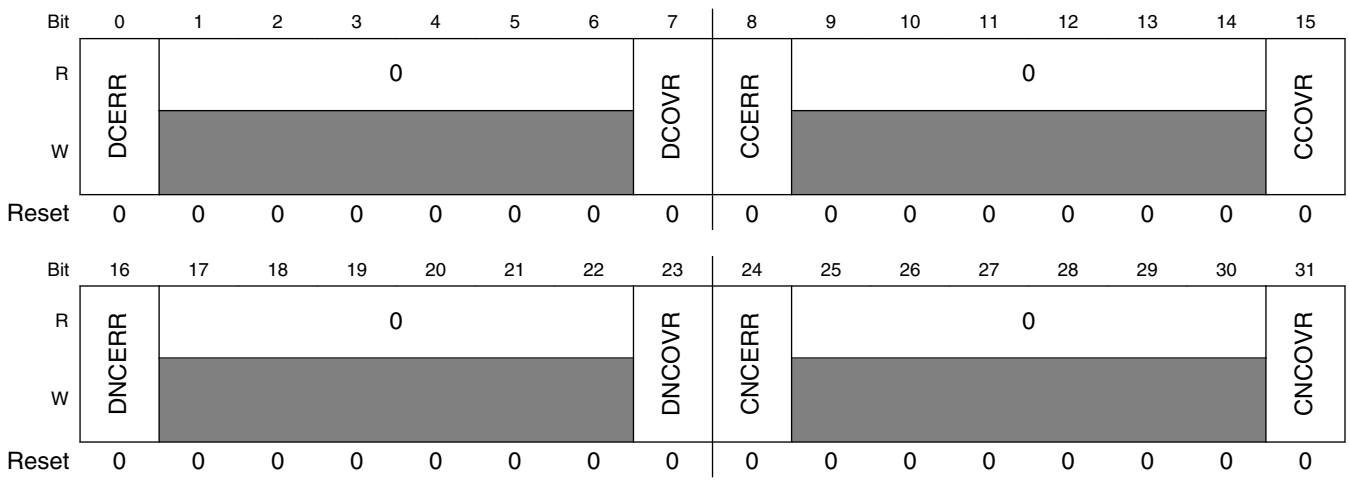
Field	Description
0 BE3	Byte Enable 3. Each BE bit corresponds to a report byte in a 32-bit aligned data word. BE3 corresponds to the most significant one. BE qualifies the error report for its respective byte. 0 Byte was not selected for read, therefore its respective error report fields are not meaningful. 1 Byte was selected for read, and the error report for the respective byte is meaningful.
1–2 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
3–7 SYND3	Error Syndrome 3. SYND3 holds the syndrome of an error detected in the SDM read data path, as defined in Error Correction Code (ECC) and syndrome definition. The field is meaningless if both DNCERR and DCERR are 0. For more information on error detection, see Memory error support.

Table continues on the next page...

eTPU_MESR_DERSR field descriptions (continued)

Field	Description
	NOTE: Syndrome fields which have their respective BE bits negated are not meaningful.
8 BE2	Byte Enable 2. Each BE bit corresponds to a report byte in a 32-bit aligned data word. BE3 corresponds to the most significant one. BE qualifies the error report for its respective byte. 0 Byte was not selected for read, therefore its respective error report fields are not meaningful. 1 Byte was selected for read, and the error report for the respective byte is meaningful.
9–10 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
11–15 SYND2	Error Syndrome 2. SYND2 holds the syndrome of an error detected in the SDM read data path, as defined in the “Error Correction Code (ECC) and Syndrome Definition”section. The field is meaningless if both DNCERR and DCERR are 0. For more information on error detection, see Memory error support. **NOTE:** Syndrome fields which have their respective BE bits negated are not meaningful.
16 BE1	Byte Enable 1. Each BE bit corresponds to a report byte in a 32-bit aligned data word. BE3 corresponds to the most significant one. BE qualifies the error report for its respective byte. 0 Byte was not selected for read, therefore its respective error report fields are not meaningful. 1 Byte was selected for read, and the error report for the respective byte is meaningful.
17–18 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
19–23 SYND1	Error Syndrome 1. SYND1 holds the syndrome of an error detected in the SDM read data path, as defined in the “Error Correction Code (ECC) and Syndrome Definition”section. The field is meaningless if both DNCERR and DCERR are 0. For more information on error detection, see Memory error support. **NOTE:** Syndrome fields which have their respective BE bits negated are not meaningful.
24 BE0	Byte Enable 0. Each BE bit corresponds to a report byte in a 32-bit aligned data word. BE3 corresponds to the most significant one. BE qualifies the error report for its respective byte. 0 Byte was not selected for read, therefore its respective error report fields are not meaningful. 1 Byte was selected for read, and the error report for the respective byte is meaningful.
25–26 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
27–31 SYND0	Error Syndrome 0.

Table continues on the next page...



eTPU_MESR_DERSR field descriptions (continued)

Field	Description
	SYND0 holds the syndrome of an error detected in the SDM read data path, as defined in the “Error Correction Code (ECC) and Syndrome Definition”section. The field is meaningless if both DNCERR and DCERR are 0. For more information on error detection, see Memory error support. **NOTE:** Syndrome fields which have their respective BE bits negated are not meaningful.

2.10.8 eTPU Memory Error Status Register (eTPU_MESR_MESR)

This register gathers status bits of both SCM and SDM error detection and correction support.

Address: 0h base + 120h offset = 120h

eTPU_MESR_MESR field descriptions

Field	Description
0 DCERR	Data Correctable Error flag. When read: 0.....No SDM correctable error occurred. 1.....An SDM correctable error occurred. Writing 1 to this bit clears the DCERR status flag. DCERR asserts even if DNCERR is asserted beforehand, but in this case the address and data of the erroneous access is not captured (see Memory Error Support memory map and registers and following sections). DCERR is cleared by writing a 1 to it. Assertion of this bit can also assert the Memory Error Correction Interrupt (see Interrupt types and sources). **NOTE:** A correctable error is not considered for flagging if accompanied of a non-correctable one. Therefore, if both correctable and non-correctable data errors occur on the same access (in distinct bytes), the DNCERR flag asserts, but not the DCERR flag.

Table continues on the next page...

eTPU_MESR_MESR field descriptions (continued)

Field	Description
	0 Do not clear DCERR flag. 1 Clears DCERR flag
1–6 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
7 DCOVR	Data Correctable Overrun flag. Writing 1 to this bit clears the DCOVR status flag. 0 Data correctable error occurred while DCOVR = 1. 1 No data correctable error occurred while DCOVR = 1. DCOVR asserts when an SDM correctable error occurs and the DCERR flag is already asserted. Assertion of this bit causes no interrupt. **NOTE:** A correctable error is not considered for flagging if accompanied by a non-correctable one. Therefore, if both correctable and non-correctable data errors occur on the same access (in distinct bytes), the DCOVR does not assert, even if DCERR is asserted. The DNCOVR flag, on the other hand, asserts if DNCERR is asserted.
8 CCERR	Code Error flag. When read: 0.....No SCM correctable error occurred. 1.....An SCM correctable error occurred. When written: 0.....Do not clear CCERR flag. 1.....Clears CCERR flag. The CCERR flag asserts even if CNCERR is asserted beforehand, but in this case the address and data of the erroneous access is not captured (see eTPU Code Error Report Address Register (eTPU_MESR_CERAR) and the following sections). CCERR is cleared by writing a 1 at the same position. Assertion of this bit can also assert the Memory Error Correction Interrupt (see Interrupt types and sources).
9–14 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
15 CCOVR	Code Correctable Overrun flag This bit asserts when an SCM correctable error occurs and the CCERR flag is already asserted. Assertion of this bit causes no interrupt. When read: 0.....No SCM correctable error overrun occurred. 1.....An SCM correctable error overrun occurred. Writing 1 to this bit clears the CCOVR status flag: 0 Do not clear CCOVR flag. 1 Clear CCOVR flag.

Table continues on the next page...

eTPU_MESR_MESR field descriptions (continued)

Field	Description
16 DNCERR	Data Non-Correctable Error flag DNCERR flags a non-correctable error. When read: 0.....No SDM non-correctable error occurred. 1.....An SDM non-correctable error occurred; registers eTPU Global Channel Registers are not updated by correctable error detections. DNCERR must be cleared (by writing a 1 to it) to allow correctable error updates to eTPU Data Error Report Address Register (eTPU_MESR_DERAR) and eTPU Data Error Report Data Register (eTPU_MESR_DERDR). 0 Do not clear DNCERR flag. 1 Clear DNCERR flag.
17–22 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
23 DNCOVR	Data Non-Correctable Overrun flag. DNCOVR asserts when an SDM non-correctable error occurs and the DNCERR flag is already asserted. Assertion of this bit causes no interrupt. When read: 0.....No SDM non-correctable error overrun occurred. 1.....An SDM non-correctable error overrun occurred. DNCOVR is cleared by writing a 1 to it. 0 Do not clear DNCOVR flag. 1 Clear DNCOVR flag.
24 CNCERR	Code Non-Correctable Error flag CNCERR flags a non-correctable error: When read: 0.....An SCM non-correctable error occurred; the eTPU Global Channel Registers are not updated by correctable error detections. 1....an SCM non-correctable error occurred; eTPU Code Error Report Address Register (eTPU_MESR_CERAR) and eTPU Code Error Report Data Register (eTPU_MESR_CERDR) are not updated by correctable error detections. CNCERR must be cleared to allow correctable error updates to eTPU Code Error Report Address Register (eTPU_MESR_CERAR) and eTPU Code Error Report Data Register (eTPU_MESR_CERDR). CNCERR is cleared by writing a 1 to it. 0 Do not clear CNCERR flag. 1 Clear CNCERR flag.
25–30 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

eTPU_MESR_MESR field descriptions (continued)

Field	Description
31 CNCOVR	Code Non-Correctable Overrun flag. CNCOVR asserts when an SCM non-correctable error occurs and the CNCERR flag is already asserted. Assertion of this bit causes no interrupt. When read: 0.....an SCM non-correctable error overrun occurred. 1.....An SCM non-correctable error overrun occurred. When written: 0 Do not clear CNCOVR flag. 1 Clear CNCOVR flag.

2.10.9 eTPU Code Error Injection Address Register (eTPU_MESR_CEIAR)

This register holds the address where error is to be injected into the SCM read data path. The two least significant bits are 0 (read-only), so that the address is always word-aligned.

NOTE

This register must only be modified when CEIE is negated.

Address: 0h base + 124h offset = 124h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0																INJ_ADDR														0	
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

eTPU_MESR_CEIAR field descriptions

Field	Description
0–15 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
16–29 INJ_ADDR	Injection Address. INJ_ADDR holds the (word) address where an error is injected in the SCM read data path, as specified by eTPU Code Error Injection Data Pattern Register (eTPU_MESR_CEIDPR) and eTPU Code Error Injection Parity Pattern Register (eTPU_MESR_CEIPPR). For more information on error injection, see Error injection.
30–31 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.

2.10.10 eTPU Code Error Injection Data Pattern Register (eTPU_MESR_CEIDPR)

This register is used to specify the bits in which error is injected into the SCM read data path.

NOTE

This register must only be modified when CEIE is negated.

Address: 0h base + 128h offset = 128h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	DFLIP																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

eTPU_MESR_CEIDPR field descriptions

Field	Description
0–31 DFLIP	Data Flip bits. Each bit corresponds to a bit in the actual data read from the SCM address defined in eTPU Code Error Injection Address Register (eTPU_MESR_CEIAR), specifying whether it should be inverted or not. The inversion only occurs if the SCM error injection is enabled by CEIE. For more information on error injection, see Error injection. 0 Read data bit is not inverted. 1 Read data bit is inverted.

2.10.11 eTPU Code Error Injection Parity Pattern Register (eTPU_MESR_CEIPPR)

This register is used to specify the bits in which error is injected into the SCM read parity path.

NOTE

This register must only be modified when CEIE is negated.

Address: 0h base + 12Ch offset = 12Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0																									PFLIP						
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

eTPU_MESR_CEIPPR field descriptions

Field	Description
0–24 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
25–31 PFLIP	Parity Flip bits. Each bit corresponds to a bit in the actual parity/code read from the SCM address defined in eTPU Code Error Injection Address Register (eTPU_MESR_CEIAR), specifying whether it should be inverted or not. The inversion only occurs if the SCM error injection is enabled by CEIE. For more information on error injection, see Error injection. 0 Parity data bit is not inverted. 1 Parity data bit is inverted.

2.10.12 eTPU Code Error Report Address Register (eTPU_MESR_CERAR)

This register holds the address where the last non-correctable error was detected from the SCM. It also captures the address of the last correctable error detected, as long as CNCERR is 0. The two least significant bits are 0 (read-only), so that the address is always word-aligned.

Address: 0h base + 130h offset = 130h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	ERR_ACC		0	ERR_CHANNEL					0							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	ERR_ADDR														0	
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

eTPU_MESR_CERAR field descriptions

Field	Description
0–1 ERR_ACC	Error Access Source Indication. This two-bit field indicates the source of the access when the error occurred. 00 Host 01 Engine 1

Table continues on the next page...

eTPU_MESR_CERAR field descriptions (continued)

Field	Description
	10 Engine 2 11 MISC
2 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
3–7 ERR_CHANNEL	Error Channel Access Indication. This field holds the number of the channel being serviced (not necessarily CHAN) when the error occurred. Its content is meaningful only when the field ERR_ACC indicates Engine 1 or Engine 2.
8–15 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
16–29 ERR_ADDR	Error Address. ERR_ADDR holds the (word) address where the last captured SCM read error was detected. The last captured error is a non-correctable one if CNCERR = 1, or a correctable one if CNCERR = 0 and CCERR = 1. The field is meaningless if both CNCERR and CCERR are 0. For more information on error detection, see Memory error support.
30–31 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.

2.10.13 eTPU Code Error Report Data Register (eTPU_MESR_CERDR)

This register holds the data read with the last non-correctable error detected from the SCM. It also captures the data of the last correctable error read detection, as long as CNCERR is 0. In both cases, the data is captured after the error correction logic. The data may be meaningless if both CNCERR and CCERR are 0. For more information on error detection, see Memory error support.

NOTE

CODE is sampled before the error correction logic.

Address: 0h base + 134h offset = 134h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

eTPU_MESR_CERDR field descriptions

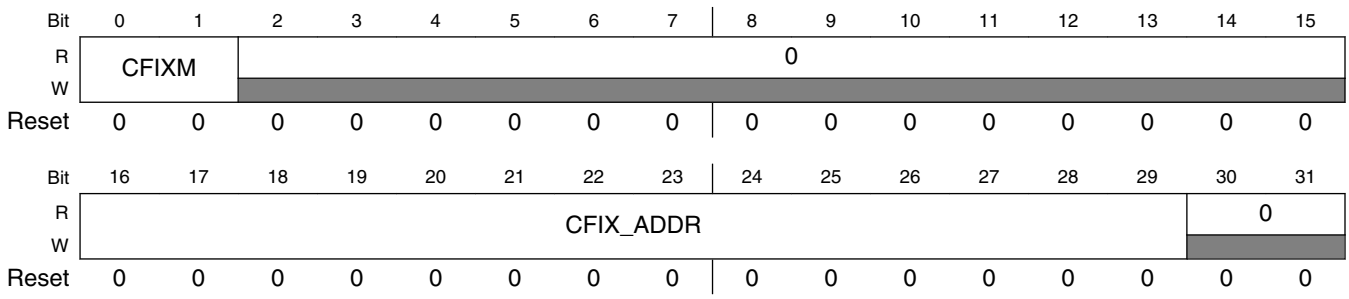
Field	Description
0–31 CODE	CODE[31-0].

2.10.14 eTPU Code Error Report Syndrome Register (eTPU_MESR_CERSR)

This register holds the syndrome and global parity read with the last non-correctable error detected from the SCM. It also captures the syndrome of the last correctable error read detection, as long as CNCERR is 0.

Address: 0h base + 138h offset = 138h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0																									SYND						
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0



eTPU_MESR_CERSR field descriptions

Field	Description
0–24 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
25–31 SYND	Error Syndrome. SYND holds the syndrome of an error detected in the SCM read data path, as defined in Error Correction Code (ECC) and syndrome definition. The field is meaningless if both CNCERR and CCERR are 0. For more information on error detection, see Memory error support.

2.10.15 eTPU Code Error Fix Register (eTPU_MESR_CEFR)

This register is used to fix single-bit error in a specified SCM position. The fix is done automatically, concurrently with code execution, by the MISC logic (see Error fixing).

Address: 0h base + 13Ch offset = 13Ch

eTPU_MESR_CEFR field descriptions

Field	Description
0–1 CFIXM	Code Fix Mode. This field specifies the SCM MISC fix logic operation mode as shown in the table below. **NOTE:** The CFIXM field can only be changed to/from disabled mode. **Table 2-21. CFIXM - Code Fix Mode** Value / Mode / Description: 00 / Disabled / SCM error fix disabled. 01 / Reserved / Reserved value, must not be used. 10 / Reserved / Reserved value, must not be used. 11 / Automatic / The MISC logic rewrites the code word value read (already fixed by the error correction mechanism) into the same address whenever it finds a correctable error.
2–15 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
16–29 CFIX_ADDR	Code Fix Address. This field is used for hardware debug purposes. CFIX_ADDR may change its contents and must not be written in automatic mode. For more information on error detection and correction, see Memory error support.
30–31 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.

2.11 Global Channel memory map and registers

The registers in this section group, by type, the interrupt status and enable bits from all the channels. This organization eases management of all channels or groups of channels by a single interrupt handler routine. These bits, except the service and watchdog status, are mirrored in the individual channel registers, grouped by channel.

eTPU_GCR memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
200	eTPU Channel Interrupt Status Register for Engine 1 (eTPU_GCR_CISR_ENG1)	32	R/W	0000_0000h	2.11.1/154
204	eTPU Channel Interrupt Status Register for Engine 2 (eTPU_GCR_CISR_ENG2)	32	R/W	0000_0000h	2.11.2/154
210	eTPU Channel Data Transfer Request Status Register for Engine 1 (eTPU_GCR_CDTRSR_ENG1)	32	R/W	0000_0000h	2.11.3/155
214	eTPU Channel Data Transfer Request Status Register for Engine 2 (eTPU_GCR_CDTRSR_ENG2)	32	R/W	0000_0000h	2.11.4/156

264	eTPU Watchdog Status Register for Engine 2 (eTPU_GCR_WDSR_ENG2)	32	R/W	0000_0000h	2.11.14/162
280	eTPU Channel Pending Service Status Register for Engine 1 (eTPU_GCR_CPSSR_ENG1)	32	R	0000_0000h	2.11.15/162
284	eTPU Channel Pending Service Status Register for Engine 2 (eTPU_GCR_CPSSR_ENG2)	32	R	0000_0000h	2.11.16/163
290	eTPU Channel Service Status Register for Engine 1 (eTPU_GCR_CSSR_ENG1)	32	R	0000_0000h	2.11.17/164
294	eTPU Channel Service Status Register for Engine 2 (eTPU_GCR_CSSR_ENG2)	32	R	0000_0000h	2.11.18/164

2.11.1 eTPU Channel Interrupt Status Register for Engine 1 (eTPU_GCR_CISR_ENG1)

This register groups the host interrupt status from all channels.These bits are mirrored from the Channel Status Control register (see eTPU Channel n Status Control Register for Engine 1 (eTPU_CCCR_C*n*SCR_ENG1)) and the Host must write 1 to clear a status bit.

For details about interrupts, see Interrupts and data transfer requests.

Address: 0h base + 200h offset = 200h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

eTPU_GCR_CISR_ENG1 field descriptions

Field	Description
0–31 CISn	Channel n Interrupt Status. When read, each bit: 0.....Indicates that channel n has no pending interrupt to the CPU. 1.....Indicates that channel n has a pending interrupt to the CPU. When written: 0.....Keep interrupt status bit unaltered. 1.....Clear interrupt status bit.

2.11.2 eTPU Channel Interrupt Status Register for Engine 2 (eTPU_GCR_CISR_ENG2)

This register groups the host interrupt status from all channels.These bits are mirrored from the Channel Status Control register (see eTPU Channel n Status Control Register for Engine 2 (eTPU_CCCR_C*n*SCR_ENG2)) and the Host must write 1 to clear a status bit.

For details about interrupts, see Interrupts and data transfer requests.

Address: 0h base + 204h offset = 204h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

eTPU_GCR_CISR_ENG2 field descriptions

Field	Description
0–31 CISn	Channel n Interrupt Status. When read, each bit: 0.....Indicates that channel n has no pending interrupt to the CPU. 1.....Indicates that channel n has a pending interrupt to the CPU. When written: 0.....Keep interrupt status bit unaltered. 1.....Clear interrupt status bit.

2.11.3 eTPU Channel Data Transfer Request Status Register for Engine 1 (eTPU_GCR_CDTRSR_ENG1)

This register groups data transfer request status from all channels. Their bits are mirrored from the Channel Status Control registers (see eTPU Channel n Status Control Register for Engine 1 (eTPU_CCCR_C*n*SCR_ENG1)) and Host must write 1 to clear a status bit.

For details about interrupts, see Interrupts and data transfer requests.

Address: 0h base + 210h offset = 210h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

eTPU_GCR_CDTRSR_ENG1 field descriptions

Field	Description
0–31 DTRSn	Channel n Data Transfer Request Status. These bits mimic the corresponding eTPU DMA requests. DTRSn can be cleared by software writing a 1 to it or by the assertion of corresponding DMA completion acknowledge line. When read: 0.....Indicates that channel n has no pending data transfer request. 1.....Indicates that channel x has a pending data transfer request. When written: 0.....Keep status bit unaltered. 1.....Clear status bit.

2.11.4 eTPU Channel Data Transfer Request Status Register for Engine 2 (eTPU_GCR_CDTRSR_ENG2)

This register groups data transfer request status from all channels.These bits are mirrored from the Channel Status Control registers (see eTPU Channel n Status Control Register for Engine 2 (eTPU_CCCR_C*n*SCR_ENG2)) and Host must write 1 to clear a status bit.

For details about interrupts, see Interrupts and data transfer requests.

Address: 0h base + 214h offset = 214h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

eTPU_GCR_CDTRSR_ENG2 field descriptions

Field	Description
0–31 DTRSn	Channel n Data Transfer Request Status. These bits mimic the corresponding eTPU DMA requests. DTRSn can be cleared by software writing a 1 to it or by the assertion of corresponding DMA completion acknowledge line. When read: 0.....Indicates that channel n has no pending data transfer request. 1.....Indicates that channel x has a pending data transfer request. When written: 0.....Keep status bit unaltered. 1.....Clear status bit.

2.11.5 eTPU Channel Interrupt Overflow Status Register for Engine 1 (eTPU_GCR_CIOSR_ENG1)

This register groups the interrupt overflow status from all channels. These bits are mirrored from the Channel Status Control registers (see eTPU Channel n Status Control Register for Engine 1 (eTPU_CCCR_C*n*SCR_ENG1)) and the Host must write 1 to clear a status bit.

For details about interrupts, see Interrupts and data transfer requests.

eTPU_GCR_CPSSR_ENG2 field descriptions

Field	Description
0–31 SRn	Pending Service Request n. Indicates a pending Service Request for channel n. Pending SR status is a logic OR of all service requests pending: if only HSR is active, SRn clears only at the end of the thread. SRn clear due to the other request sources is microcode dependent. **NOTE:** The pending service status bit for a channel is 1 when a Service Request is pending, even if the Channel is disabled (CPRn = 0). **NOTE:** There can be a delay of one clock between writing HSR greater than 0 in eTPU Channel n Host Service Request Register for Engine 2 (eTPU_CCCR_C*n*HSRR_ENG2) of a channel and its respective bit being asserted in eTPU_GCR_CPSSR_ENG2. 0 No Service Request pending for channel n. 1 Pending Service Request for channel n.

2.11.17 eTPU Channel Service Status Register for Engine 1 (eTPU_GCR_CSSR_ENG1)

This register holds the current channel service status on whether it is being serviced or not (see Functions and threads). Only one bit may be asserted in this register at a given time. When no channel is being serviced, the register read value is 0x0000_0000. This register is read-only and can be read during normal eTPU operation for monitoring the scheduler activity.

NOTE

Channel Service Status does not always reflect decoding of the CHAN register (see CHAN Register), since the latter can be changed by the service thread microcode.

Address: 0h base + 290h offset = 290h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

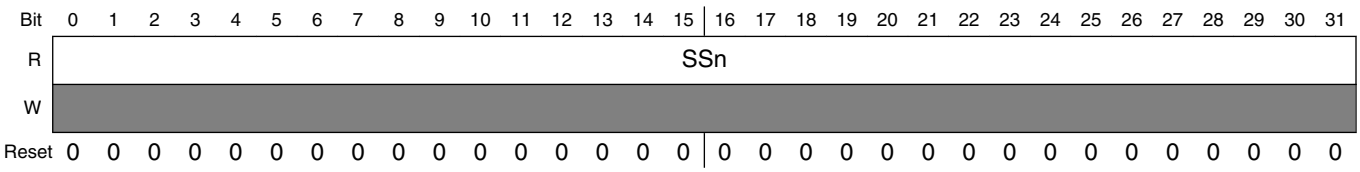
eTPU_GCR_CSSR_ENG1 field descriptions

Field	Description
0–31 SSn	Service Status n. Indicates that channel n is currently being serviced. It is updated at the 1st microcycle of a Time Slot Transition (see Time Slot Transition), or when the microengine ends the thread. 0 Channel n is not currently being serviced. 1 channel n is currently being serviced.



2.11.18 eTPU Channel Service Status Register for Engine 2 (eTPU_GCR_CSSR_ENG2)

This register holds the current channel service status on whether it is being serviced or not (see Functions and threads). Only one bit may be asserted in this register at a given time. When no channel is being serviced, the register read value is 0x0000_0000. This read-only register can be read during normal eTPU operation for monitoring the scheduler activity.

NOTE

Channel Service Status does not always reflect decoding of the CHAN register (see CHAN Register), since the latter can be changed by the service thread microcode.

Address: 0h base + 294h offset = 294h

eTPU_GCR_CSSR_ENG2 field descriptions

Field	Description
0–31 SSn	Service Status n. Indicates that channel n is currently being serviced. It is updated at the 1st microcycle of a Time Slot Transition (see Time Slot Transition), or when the microengine ends the thread. 0 Channel n is not currently being serviced. 1 channel n is currently being serviced.

2.12 Channel Configuration Control memory map and registers

Each channel has a group of 3 registers used to control, configure and check status of that channel as shown in the following table. This organization eases individual channel management.

Table 2-22. Channel registers structure

Channel offset	Register name
0x00	eTPU_CCCR_C*n*CR_ENG*m* - eTPU Channel Configuration Register
0x04	eTPU_CCCR_C*n*SCR_ENG*m* - eTPU Channel Status/Control Register
0x08	eTPU_CCCR_C*n*HSRR_ENG*m* - eTPU Channel Host Service Request Register
0x0C	Reserved

One contiguous area is used to map all channel registers of each eTPU engine as shown in the following table.

Table 2-23. Channel registers mMap

Offset	Registers structure
0x400	eTPU 1 Channel 0 Registers Structure
0x410	eTPU 1 Channel 1 Registers Structure
0x420	eTPU 1 Channel 2 Registers Structure
0x430	-----
0x5E0	eTPU 1 Channel 30 Registers Structure
0x5F0	eTPU 1 Channel 31 Registers Structure
0x600	RESERVED
0x800	eTPU 2 Channel 0 Registers Structure
0x810	eTPU 2 Channel 1 Registers Structure
0x820	-----
0x9E0	eTPU 2 Channel 30 Registers Structure
0x9F0	eTPU 2 Channel 31 Registers Structure
0xA00	RESERVED

There are 64 structures defined, one for each available channel in the eTPU System (32 for each Engine). The base address for the structure presented can be calculated by using the following equation:

Channel_Register_Base = eTPU_Engine_Channel_Base + (channel_number * 0x10), where:

- eTPU_Engine_Channel_Base = eTPU_Base + 0x400 for Engine 1.
- eTPU_Engine_Channel_Base = eTPU_Base + 0x800 for Engine 2.

eTPU_CCCR_C*n*CR_ENG1 field descriptions

Field	Description
0 CIE	Channel Interrupt Enable (see Channel Interrupt and Data Transfer Requests). This bit is mirrored from eTPU Channel Interrupt Enable Register for Engine 1 (eTPU_GCR_CIER_ENG1). 0 Disable interrupt for this channel. 1 Enable interrupt for this channel.
1 DTRE	Channel Data Transfer Request Enable (see Interrupts and data transfer requests). This bit is mirrored from eTPU Channel Data Transfer Request Enable Register for Engine 1 (eTPU_GCR_CDTRER_ENG1). 0 Disable data transfer request for this channel. 1 Enable data transfer request for this channel.
2–3 CPR	Channel Priority. This field defines the priority level for the channel, used by the Hardware Scheduler (see Scheduler). 00 Disabled 01 Low 10 Middle 11 High
4 T4DIS	T4 channel action Disable. This bit forces the channel to work on T2 timing mode, regardless of the FCSS and CDFC fields in eTPU Engine 1 Configuration Register (eTPU_SCR_ECR_ENG1), or of the TCR1CS field in eTPU Engine 1 Time Base Configuration Register (eTPU_TBR_TBCR_ENG1). For more details, see Channel timing modes. 0 Channel works either in T2 or T2/T4 timing modes, depending on the TCR1CS field in eTPU Engine 1 Time Base Configuration Register (eTPU_TBR_TBCR_ENG1) and the FCSS and CDFC fields in eTPU Engine 1 Configuration Register (eTPU_SCR_ECR_ENG1). 1 Channel works in T2 timing mode, regardless of the TCR1CS field in eTPU Engine 1 Time Base Configuration Register (eTPU_TBR_TBCR_ENG1) or the FCSS and CDFC fields in eTPU Engine 1 Configuration Register (eTPU_SCR_ECR_ENG1).
5 SSMAE	Shared Subsystem Microengine Access Enable. This bit enables the microengine access to the Shared Subsystem Area (see Shared Subsystems support). When this bit is negated, DIOB address values pointing to the Shared Subsystem Area actually access SDM mirrors, in legacy mode. **NOTE:** SSMAE value must only be changed when the engine is either stopped or halted. 0 An SDM mirror is accessed when the Shared Subsystem Area is addressed by the microengine. 1 Enables microengine access to the Shared Subsystem Area.
6 ETPD	Entry Table Pin Direction. This bit selects which channel signal, input or output, is used in the Entry Point selection. The ETPD value has to be compatible with the function chosen for the channel, selected in the field CFS. For details about Entry Table and condition encoding schemes, see Entry Points.

Table continues on the next page...

eTPU_CCCR_C*n*CR_ENG1 field descriptions (continued)

Field	Description
	0 Use PSTI for Entry Point selection. 1 Use PSTO for Entry Point selection.
7 ETCS	Entry Table Condition Select. This bit determines the channel condition encoding scheme that selects, according to channel conditions, the Entry Point to be taken in an Entry Table. ETCS value has to be compatible with the function chosen for the channel, selected in field CFS. Two condition encoding schemes are available. For details about Entry Table and condition encoding schemes, see Entry Points. 0 Select Standard Entry Table Condition encoding scheme. 1 Select Alternate Entry Table Condition encoding scheme.
8–10 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
11–15 CFS	Channel Function Select. This field defines the function to be performed by the channel (see Functions and threads). The Function assigned to the channel has to be compatible with the channel condition encoding scheme, selected by field ETCS.
16 ODIS	Output Disable. This bit enables the channel to have its output forced to the value opposite to OPOL when the output disable input signal corresponding to the channel group that it belongs is active (see eTPU channel output disable signals). 0 Turns off the output disable feature for the channel. 1 Turns on the output disable feature for the channel.
17 OPOL	Output Polarity. Determines the output signal polarity. The activation of the output disable signal forces, when enabled by the ODIS bit, the channel output signal to the opposite of this polarity. 0 Output active low (output disable drives output to high). 1 output active high (output disable drives output to low).
18–20 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
21–31 CPBA	Channel n Parameter Base Address. The value of this field times 8 specifies the SDM parameter base host (byte) address for channel n (2-parameter granularity; see SDM organization). As seen by the Host, the channel parameter base (byte) address is (without parameter sign extension) eTPU_Base + 0x8000 + CPBA * 8 or (with parameter sign extension), eTPU_Base + 0xC000 + CPBA*8.

2.12.2 eTPU Channel n Status Control Register for Engine 1 (eTPU_CCCR_C*n*SCR_ENG1)

This register gathers the interrupt status bits of the channel and the Function Mode definition (read-write). Bits CIS, CIOS and DTRS for each channel can be also accessed from eTPU Channel Interrupt Status Register for Engine 1 (eTPU_GCR_CISR_ENG1), eTPU Channel Interrupt Overflow Status Register for Engine 1 (eTPU_GCR_CIOSR_ENG1) and eTPU Channel Data Transfer Request Status Register for Engine 1 (eTPU_GCR_CDTRSR_ENG1). Host must write 1 to clear a status bit.

Address: 0h base + 404h offset + (16d × i), where i=0d to 31d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

eTPU_CCCR_C*n*SCR_ENG1 field descriptions

Field	Description
0 CIS	Channel Interrupt Status. These bits are mirrored in eTPU Channel Interrupt Status Register for Engine 1 (eTPU_GCR_CISR_ENG1). Also, see Channel Interrupt and Data Transfer Requests. When read: 0.....Channel has no pending interrupt to the Host CPU. 1.....Channel has a pending interrupt to the Host CPU. When written: 0.....Keep interrupt status bit unaltered.

Table continues on the next page...

eTPU_CCCR_C*n*SCR_ENG1 field descriptions (continued)

Field	Description
	1.....Clear interrupt status bit.
1 CIOS	Channel Interrupt Overflow Status. These bits are mirrored in eTPU Channel Interrupt Overflow Status Register for Engine 1 (eTPU_GCR_CIOSR_ENG1). Also, see Interrupt and Data Transfer Request overflow. When read: 0.....Interrupt overflow negated for this channel. 1.....Interrupt overflow asserted for this channel. When written: 0.....Keep status bit unaltered. 1.....Clear status bit.
2–7 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
8 DTRS	Data Transfer Request Status. These bits are mirrored in eTPU Channel Data Transfer Request Status Register for Engine 1 (eTPU_GCR_CDTRSR_ENG1). Also, see Channel Interrupt and Data Transfer Requests. When read: 0.....Channel has no pending data transfer request. 1.....Channel has a pending data transfer request. When written: 0.....Keep status bit unaltered. 1.....Clear status bit.
9 DTROS	Data Transfer Request Overflow Status. These bits are mirrored in eTPU Channel Data Transfer Request Overflow Status Register for Engine 1 (eTPU_GCR_CDTROSR_ENG1). Also, see Interrupt and Data Transfer Request overflow. When read: 0.....Data transfer request overflow negated for this channel. 1.....Data transfer request overflow asserted for this channel. When written: 0.....Keep status bit unaltered. 1.....Clear status bit.
10–15 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
16 IPS	Channel Input Pin State. This bit shows the current value of the filtered channel input signal state.
17 OPS	Channel Output Pin State.

Table continues on the next page...

eTPU_CCCR_C*n*SCR_ENG1 field descriptions (continued)

Field	Description
	This bit shows the current value driven in the channel output signal, including the effect of the external output disable feature (see eTPU channel output disable signals). If the channel input and output signals are connected to the same pad, OPS reflects the value driven to the pad (if OBE=1). This is not necessarily the actual pad value, which drives the value in the bit IPS.
18 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
19–29 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
30–31 FM	Channel Function Mode. Each function uses this field for a specific configuration. These bits can be tested by microengine code (see Conditional/unconditional branch). These bits are equivalent to the TPU/TPU2/TPU3 Host Sequence (HSQ) bits.

2.12.3 eTPU Channel n Host Service Request Register for Engine 1 (eTPU_CCCR_C*n*HSRR_ENG1)

This register is used by the Host to issue service requests to the channel.

Address: 0h base + 408h offset + (16d × i), where i=0d to 31d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0																													HSR		
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

eTPU_CCCR_C*n*HSRR_ENG1 field descriptions

Field	Description
0–28 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
29–31 HSR	Host Service Request This field is used by the Host CPU to request service to the channel (see Host Service Requests). HSR value turns to 000 automatically at the end of microengine service for that channel, but only if the thread started due to an HSR. Host should write HSR greater than 0 only when HSR=0. Writing HSR=000 withdraws a pending request if scheduler did not begin to resolve the Entry Point yet, but it does not abort the service thread from that point on. For more details, see Entry Points and Host Service Requests. 000 No Host Service Request pending.

Table continues on the next page...

Field	Description
0–28 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
29–31 HSR	Host Service Request This field is used by the Host CPU to request service to the channel (see Host Service Requests). HSR value turns to 000 automatically at the end of microengine service for that channel, but only if the thread started due to an HSR. Host should write HSR greater than 0 only when HSR=0. Writing HSR=000 withdraws a pending request if scheduler did not begin to resolve the Entry Point yet, but it does not abort the service thread from that point on. For more details, see Entry Points and Host Service Requests. 000 No Host Service Request pending.

2.13 Shared Subsystem Integration memory map and registers

Shared Subsystems Integration Registers configure aspects of how the shared modules interface with the eTPU. There is one integration register for each subsystem unit, which can be, depending on the specific subsystem, a whole IP module, a sub-module, or a channel within a module. For more details, see Shared Subsystems support.

eTPU_SSIR memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page

eTPU_SSIR_ETPUSSSIR*n* field descriptions

Field	Description
0–23 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
24–25 LENG	Link Engine. LENG specifies the engine that receives a Link Service Request when an interrupt is issued by the Shared Unit, or disables Shared Unit linking. The channel that receives the Link Service Request is specified in the LCHAN field. 00 Shared Unit Link Service Request disabled 01 Engine 1 receives Shared Unit Link Service Request 10 Engine 2 receives Shared Unit Link Service Request 11 Reserved
26 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
27–31 LCHAN	Link Channel. LCHAN specifies the channel linked when an interrupt is issued by the Shared Unit, if enabled in the LENG field. The field is meaningless if LENG disables Shared Unit linking. For more information on Link Service Requests, see Channel Link.

2.14 Functional description

2.14.1 Functions and threads

eTPU processing is event-driven, in the sense that eTPU microcode only runs to service a request from an event. Service Requests may result from the occurrence of any of the following events:

- Host CPU writing a non-zero value to the channel HSR (Host Service Request) field in eTPU Channel n Host Service Request Register for Engine 1 (eTPU_CCCR_C*n*HSRR_ENG1) and eTPU Channel n Host Service Request Register for Engine 2 (eTPU_CCCR_C*n*HSRR_ENG2).
- Occurrence of a time base match, an input signal transition, or a specific combination of them (depending on the Channel Mode currently configured).
- A Link Service Request.

A given event is always associated to only one Channel:

- There is one HSR register field for each Channel
- Each signal is associated with only one Channel, which has its own Match registers and independent mode configuration.
- Each Link Service Request can have only one Channel as a target.

Service Request processing is done by a set of microengine routines. A set of related routines that implement a specific channel application is called a **Function**. One or more Functions reside on SCM, limited only by the SCM space available, size of microcode Functions and the number of entry points available. Each Engine can be controlled by up to 32 Functions at a time.

A Function can be assigned to several channels, but only one Function can be assigned to a given Channel at a time. This is defined by the Host through the Channel Configuration Registers (see Channel Configuration Control memory map and registers).

The term **Thread** will be used hereafter to refer to a service routine of a Function, or its execution. A Thread is constructed of a specific number of microinstructions, typically the code necessary to calculate the next phase of waveform to be input to, or output from, a given channel. Once a Thread begins, its execution cannot be interrupted. A Thread normally finishes when an END microinstruction is executed.

A given Thread is selected and called by the Scheduler depending on the following:

- the type of event that generated the service request.

- the Function assigned to the target channel.
- target channel pin state.
- the state of the channel logic.
- the priority assigned to the target channel, relative to the priorities of other channels with pending service requests

The mechanism to select a thread based on the channel Function and type of event is described in the Entry Points.

The priority mechanism that determines the order of Thread execution amongst pending service requests is described in Scheduler.

2.14.1.1 Entry Points

2.14.1.1.1 Entry Table

Each Thread has its **Entry Point**, which contains the SCM address of its first instruction, besides other information. For a complete Entry Point description, see Entry Point format.

Once the Scheduler chooses a channel among pending Service Requests, the Entry Point is taken from an **Entry Table**, based on the Function assigned for the channel and other conditions. Entry Table layout is shown in the following figure.

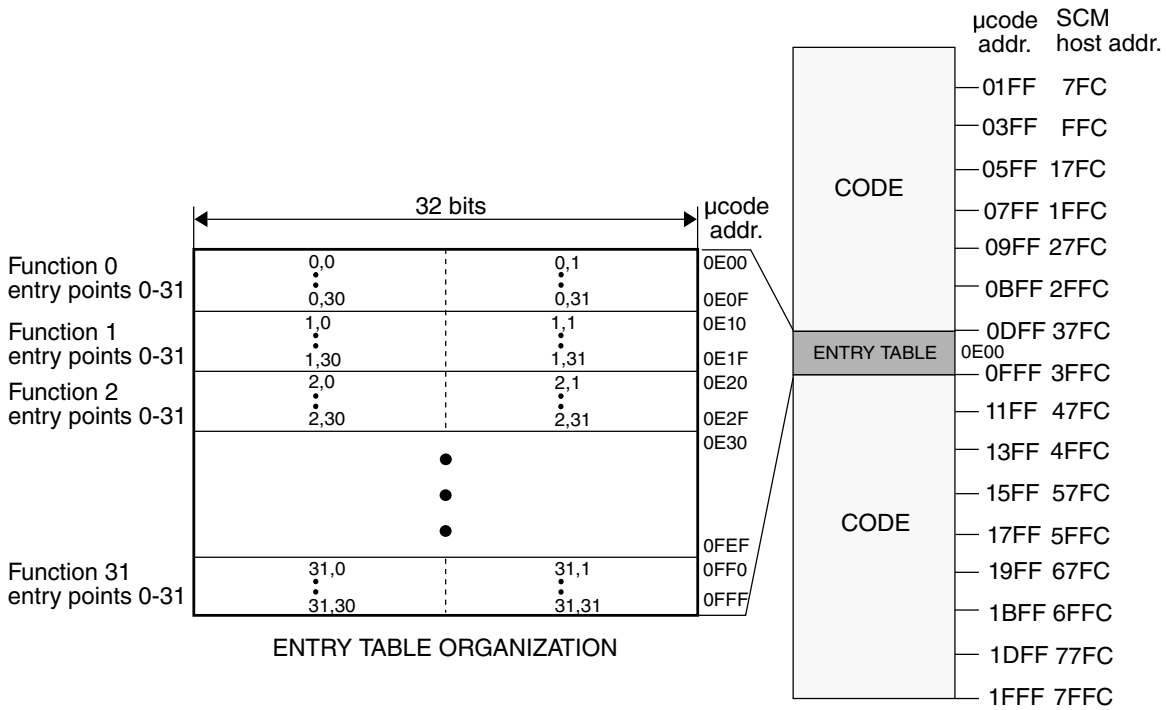

Figure 2-3. Entry Table

The Entry Table is organized by Functions. Each Function can have up to 32 Entry Points of 16 bits each, corresponding to 32 possible Threads per Function. Each Entry Point location in the table corresponds to a combination of events and channel states (see Entry Point address generation). A single Thread can be associated to more than one combination, having its Entry Point repeated in the table. Each 32-bit word in the Entry Table holds two Entry Points.

Note that the Entry Table can be placed in any SCM address multiple of the Entry Table size, determined by the ETB field in eTPU Engine 1 Configuration Register (eTPU_SCR_ECR_ENG1) and eTPU Engine 2 Configuration Register (eTPU_SCR_ECR_ENG2). However, it is recommended to place the Entry Table at the start of the SCM to get continuous code memory and to ease the eventual migration of the code from larger parts down to smaller ones without rearranging the binary image, but this is not a restriction. Unused Entry Points may be used for microcode, so this organization extends the microcode continuous area to the unused area of the Entry Table. For this purpose, Function numbers should be selected from 0 up to 31. If, for example, only 8 functions are implemented, only the Entry Table locations for Functions 0 to 7 are used, and the Entry Table locations for functions 8 to 31 can be used as microinstruction memory (adding extra continuous 1536 bytes for microprogram usage).

One way of implementing different sets of Functions is having more than one Entry Table, and configuring the eTPU with the appropriate one for the application by changing the ETB field in eTPU Engine 1 Configuration Register (eTPU_SCR_ECR_ENG1) and eTPU Engine 2 Configuration Register (eTPU_SCR_ECR_ENG2). Note that the Engines can use different Entry Tables, with or without the same set of Functions.

2.14.1.1.2 Entry Point address generation

The Entry Point address within the Entry Table is determined by the Function assigned to the Channel, the state of the Channel, the type of event, and the condition encoding scheme. Together with the Entry Table base address, they form the Entry Point Address at the SCM, as shown in the following figure.

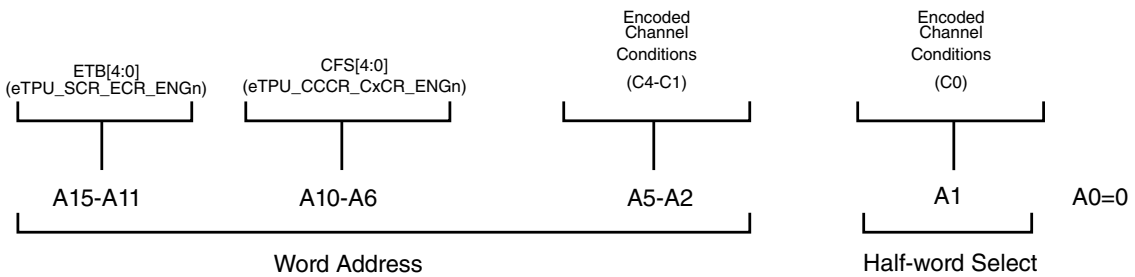

Figure 2-4. Entry Point Address (host address offset)

The type of event and channel state are coded in the Encoded Channel Conditions field C4-C0, according to one of two encoding schemes:

- Standard Entry Table Condition encoding scheme, shown in Table 2-24, which privileges Host Service Requests.
- Alternate Entry Table Condition encoding scheme, shown in Table 2-25, which focus on other events and state decoding.

The events that take part on condition encoding generate a Service Request, and have four origins:

1. Match Recognition (caused by greater/equal match, or equal-only, between the value TCR1/2 and the value stored in the channel match registers). eTPU channels support single and double match in various modes of match recognition; see Match Recognition.
2. Transition Detect Service Request (channel input signal transition detection of a selected edge). The eTPU channels support single and double transition, which together with the double match options provide various modes of transition detection; see Transition detection and Time Base Capture.

3. Channel Linking Service Request (microcode writing the channel number to the LINK register). Link service request allows one channel to activate another (see Channel Link). Links may also come from Shared Subsystem units (see Shared Subsystems support).
4. Host Service Request (Host writes a non-zero value to the HSR bits of the channel; see Host Service Requests).

Note

Even if a Transition or Match Service Request is inhibited (by channel mode/state or SRI), the Transition Detection and Match Recognition are taken into account for condition encoding. That is, the MRLA/B and TDLA/B flags are used, not their respective Service Requests.

Columns Host Request Bits, Link Request, MatchA/TransB, and MatchB/TransA determine the type of event. A non-zero value in these columns represents the recognition of the event, while "x" indicates that its recognition is irrelevant. Values 1 and 0 mean that event was recognized or not, respectively. Note that Match and Transition events may occur and not be recognized, and in this case it assumes value 0 for the condition encoding. The recognition of such an occurred event depends on the channel mode assigned and other conditions, as described in Enhanced Channels.

The **Host Service Request Bits** column refers to the value written by the Host CPU to the Host Service Request Registers (eTPU Channel n Host Service Request Register for Engine 1 (eTPU_CCCR_C*n*HSRR_ENG1) and eTPU Channel n Host Service Request Register for Engine 2 (eTPU_CCCR_C*n*HSRR_ENG2)) of the Channel being serviced. Note that the bits on this row are coded (3-bit representation). If the value of HSR is not zero, then the Host actually requested service.

The **Link Request** column refers to the occurrence of a Channel Link or SSS Link requests.

The **MatchA/TransB** column refers to the recognition of either a Match event specified by MatchA channel register or the detection of a channel input signal event specified by the IPACB configuration register (see Pin Control Registers).

The **MatchB/TransA** column refers to the recognition of either a Match event specified by MatchB channel register or the detection of a channel input signal event specified by the IPACA configuration register (see Pin Control Registers).

For the channel input signal, MatchA and MatchB provide double timeout conditions which depend on the channel mode programming (see Channel Modes). If the channel is used for output only, there are no transition detections, so the MatchB/TransA column

represents only Match B, and MatchA/TransB column the Match A. In this case Match A and Match B are separated to give better state resolution in double match output functions. For more information about channel requests refer to Enhanced Channels.

Besides those events, the following channel state conditions help to determine the Entry Point:

1. Channel Flags 0 and 1: these are channel-internal flags (not in SDM) associated with a channel. Their values are set by microcode (see Channel flags operations).
2. Input Pin state or Output Flip Flop: the state (0 or 1) of the channel input signal after the Enhanced Filter (see Enhanced Digital Filter - EDF), or the state driven to the output signal. Which one (input or output) is used is selected by the ETPD field in eTPU Channel n Configuration Register for Engine 1 (eTPU_CCCR_C*n*CR_ENG1) and eTPU Channel n Configuration Register for Engine 2 (eTPU_CCCR_C*n*CR_ENG2).

The two Entry Table Condition encoding schemes combine events and state conditions differently, as detailed in the following sections.

2.14.1.1.3 Standard condition encoding scheme

In this scheme, shown in the following table, all 7 HSR combinations are used and other event type columns are marked "x" when HSR is non-zero, indicating that Host Service Request has priority over any other type of event. However, when an HSR service thread is called (entry numbers 0 to 9), other events may also have been recognized, and it is microcode responsibility to check them.

When HSR is 0, i.e., Host did not issue a Service Request to the channel, the other event conditions, the input signal state and channel flags determine the Entry Point. Note that channel flag 1 does not influence the encoding in this scheme.

Table 2-24. Standard channel condition encoding scheme

No.	Encoded channel conditions [C4-C0]	Host Service Request bits	Link request	MatchA/ TransB	MatchB/ TransA	In/output pin state[1]	Channel Flag1	Channel Flag0

Host Service Request

1. The ETPD field in CCR_ENG1 and CCR_ENG2 selects between input and output pin state.

2.14.1.1.4 Alternate condition encoding scheme

This scheme is shown in the following table. Because the HSR bits cannot be tested by microcode, only three distinct Host Service Request can be used:

1. HSR=010 or 011, which are coded into the same Entry Points (0 to 3)
2. HSR=100, 101 or 001, which are all coded into Entry Point 4

3. HSR=110 or 111, which are both coded into Entry Point 5

The remaining Entry Points use both channel flags for better state decoding, making this scheme better suited for Functions which need more states and/or faster state decoding, without needing many HSRs.

Table 2-25. Alternate channel condition encoding scheme

No.	Encoded channel conditions [C4-C0]	Host Service Request bits	Link request	MatchA/ TransB	MatchB/ TransA	In/Output pin state[1]	Channel Flag1	Channel Flag0

		Host Service Request						

1. The ETPD field in CCR_ENG1 and CCR_ENG2 selects between input and output pin state.

2.14.1.1.5 Entry Point format

Entry Point information includes a Preload-Parameter selection field, a Match Enable field, and the first microcode address of the thread. The Entry Point format is illustrated in the following figure.

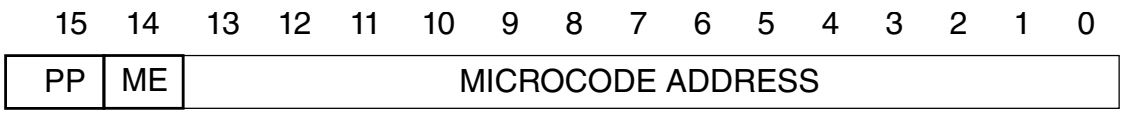

Figure 2-5. Entry Point format

PP - Preload Parameter

PP indicates which pair of channel parameters are loaded into registers P and DIOB from the SDM prior to the execution of a thread. Preloading occurs during the time-slot transition period (see Time Slot Transition).

1 = microengine register P is preloaded from parameter 2 and DIOB from parameter 3.

0 = microengine register P is preloaded from parameter 0 and DIOB from parameter 1.

The parameter numbers are offsets from the channel parameter base address. For more info, see Parameter Access.

ME - Match Enable

ME specifies whether match event recognitions are enabled or disabled for the thread associated with the entry point during the thread execution. If they are disabled, a match recognition can only occur after channel service. For more details refer to Match Recognition.

1 = Matches are enabled during the thread.

0 = Matches are disabled during the thread.

The disabling of Match A/B recognition by MEF is dependent on IPACA/B configuration on the serviced channel (see Pin Control Registers). If IPACA=1xx, Match A is not disabled by ME=0. Likewise, IPACB=1xx overrides the effect of ME on Match B to "always on" If IPACA/B=0xx, Match A/B is disabled for two microcycles during TST (see Time Slot Transition) and is re-enabled when Entry Point is loaded, if ME=1. Note that if the comparator is in equal-only mode and the time base reaches the value of the Match register during the time that recognition is disabled (beginning of TST, plus whole thread if ME=0), the match recognition is lost. If the comparator is in greater-equal mode, the match event may be recognized after the disabling period if it satisfies the "greater-than" condition.

MICROCODE ADDRESS - Starting Microcode Address

This field specifies the microcode address on which the thread is to begin execution.

2.14.1.2 Time Slot Transition

The Time Slot Transition period (also called TST for short) is the interval between the servicing of two channels, during which all Channel-specific context is loaded for the new serviced Channel. The primary tasks completed during this period include:

- Set MEF for the TST wait-states, if any.
- Reset MEF for the first two microcycles (after eventual wait-states).
- Update of the CHAN register with the number of the new channel to be serviced.
- Parallel update of ERTA and ERTB from CaptureA and CaptureB registers of the new serviced channel.
- Sampling of the branch conditions of the new channel to be serviced into the branch logic (this means flags TDLA/B, MRLA/B, LSR, FM[1], FM[0], and PSS). The branch conditions are coherent with the timebase capture values sampled into ERTA/B (if MRLA/B, TDLA/B are set at the same time of the sampling, either both old flag state and capture values are sampled, or both new values are sampled).
- Formation of the entry point address.
- Copy the ME bit in the Entry Point into MEF.
- Access to the entry point location and getting the first microinstruction address.
- Preload of two parameters from the SDM into P (32 bits) and DIOB (24 bits).
- Fetch the first instruction of the thread to be executed for the new channel.
- Preset the RAR register value (see RAR Register).

The preload operation is 32-bit wide for P and 24-bit wide for DIOB. The P register is loaded with all the 32-bit parameter. The DIOB register is loaded with the lower 24-bits of the parameter. The microcode can switch at any time to access the lower 24-bits, upper byte, or all the 32-bits of any parameter in the SDM. Preload of P-DIOB pair of parameters is atomic with respect to Host and CDC accesses, and so are coherent with their dual-parameter coherent transfers. For more details see Parameter sharing and coherency.

No instructions are executed at the Engine where the time slot transition period occurs, but the other Engine can execute normally. Match A/B is unconditionally disabled on the first two TST microcycles, if IPACA/B=0xx (respectively). During the rest of time slot transition, match recognition can be disabled or not, depending on IPACA/B field and ME. See Match Recognition .

Time Slot Transition takes a minimum of 3 microcycles (6 eTPU clocks), which may be extended due to SDM arbitration wait-states for the first preload access (see SDM arbitration). When no wait-states are received (Figure 2-6), DIOB is preloaded twice, one for each PP value, and the correct value remains in DIOB when the Entry Point is loaded. Figure 2-7 and Figure 2-8 show the timing for one and two wait-states, respectively.

Registers B, C, D and SR are not altered by TST and keep their values from the previous thread. The values of registers A, MACL and MACH are not guaranteed at the thread start.

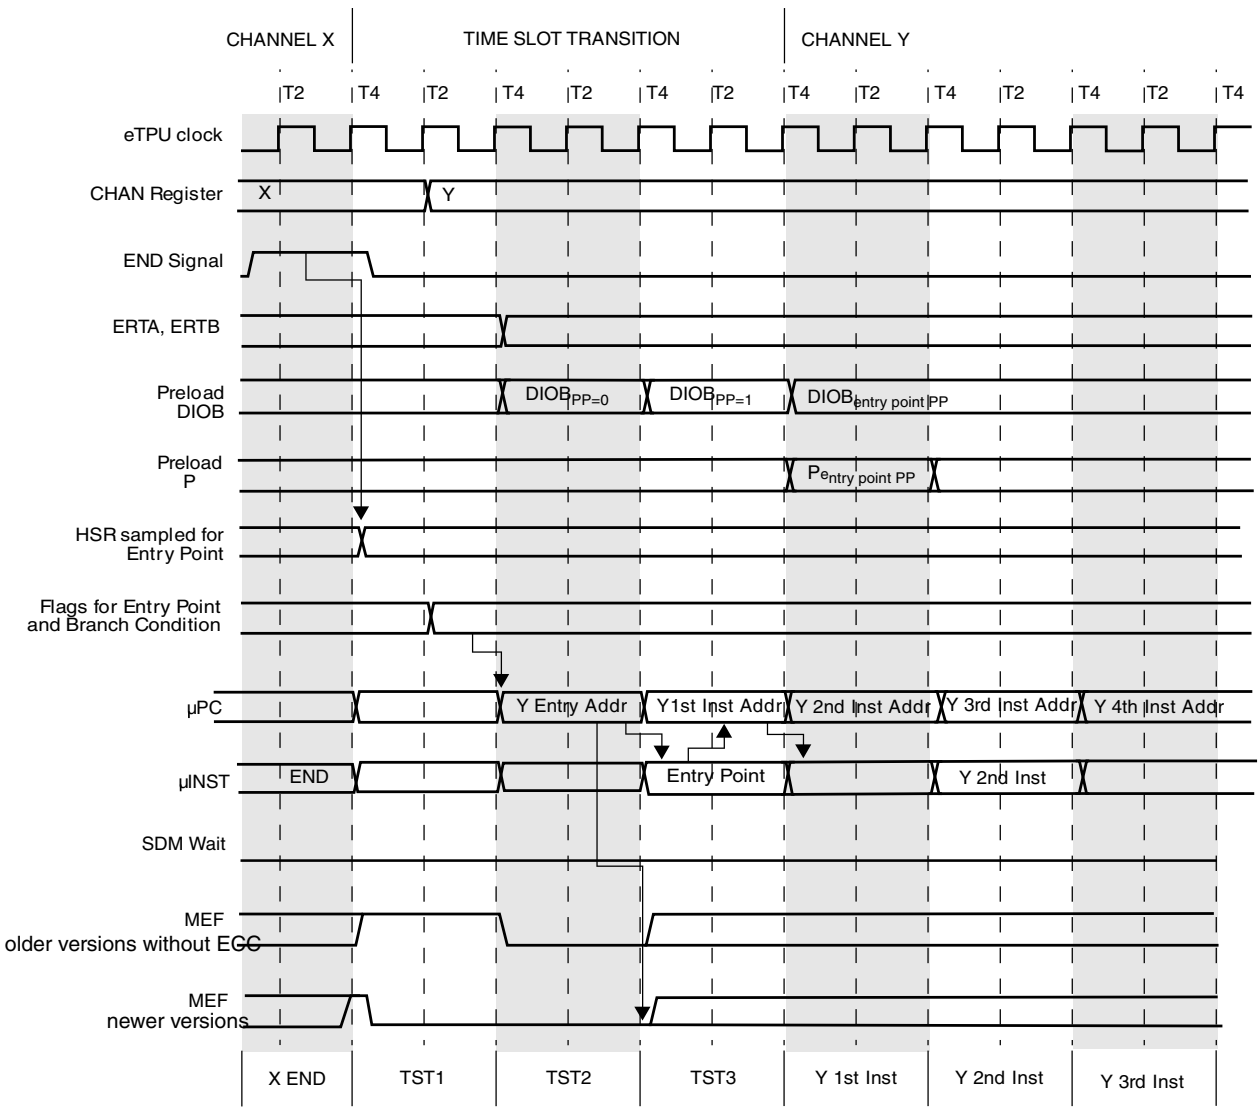

Figure 2-6. TST Timing - No Wait-states

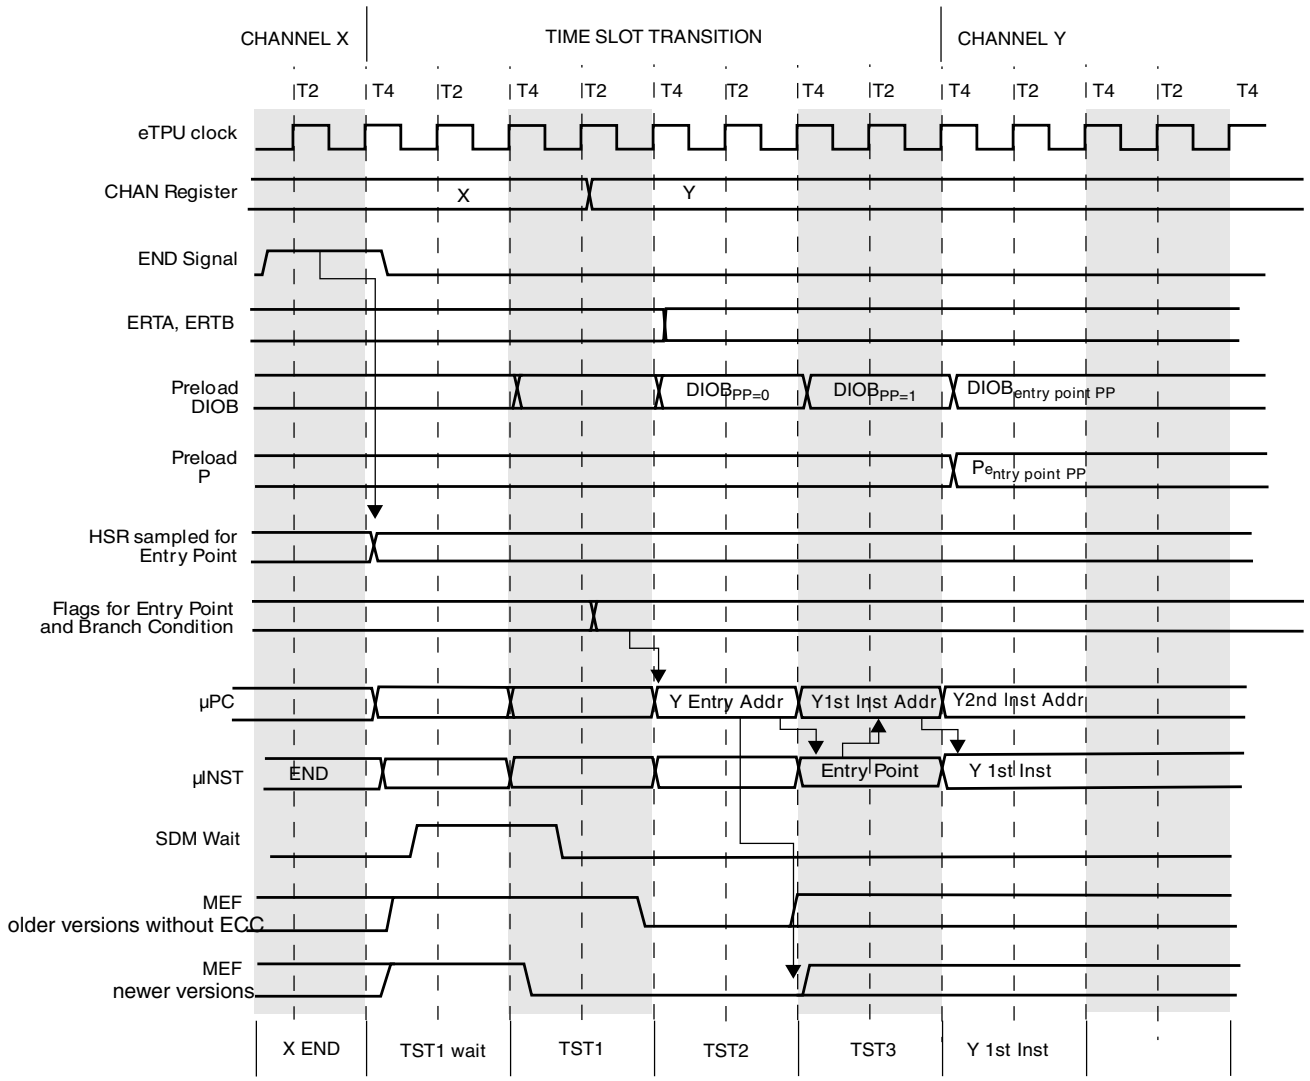

Figure 2-7. TST Timing - 1 Wait-State

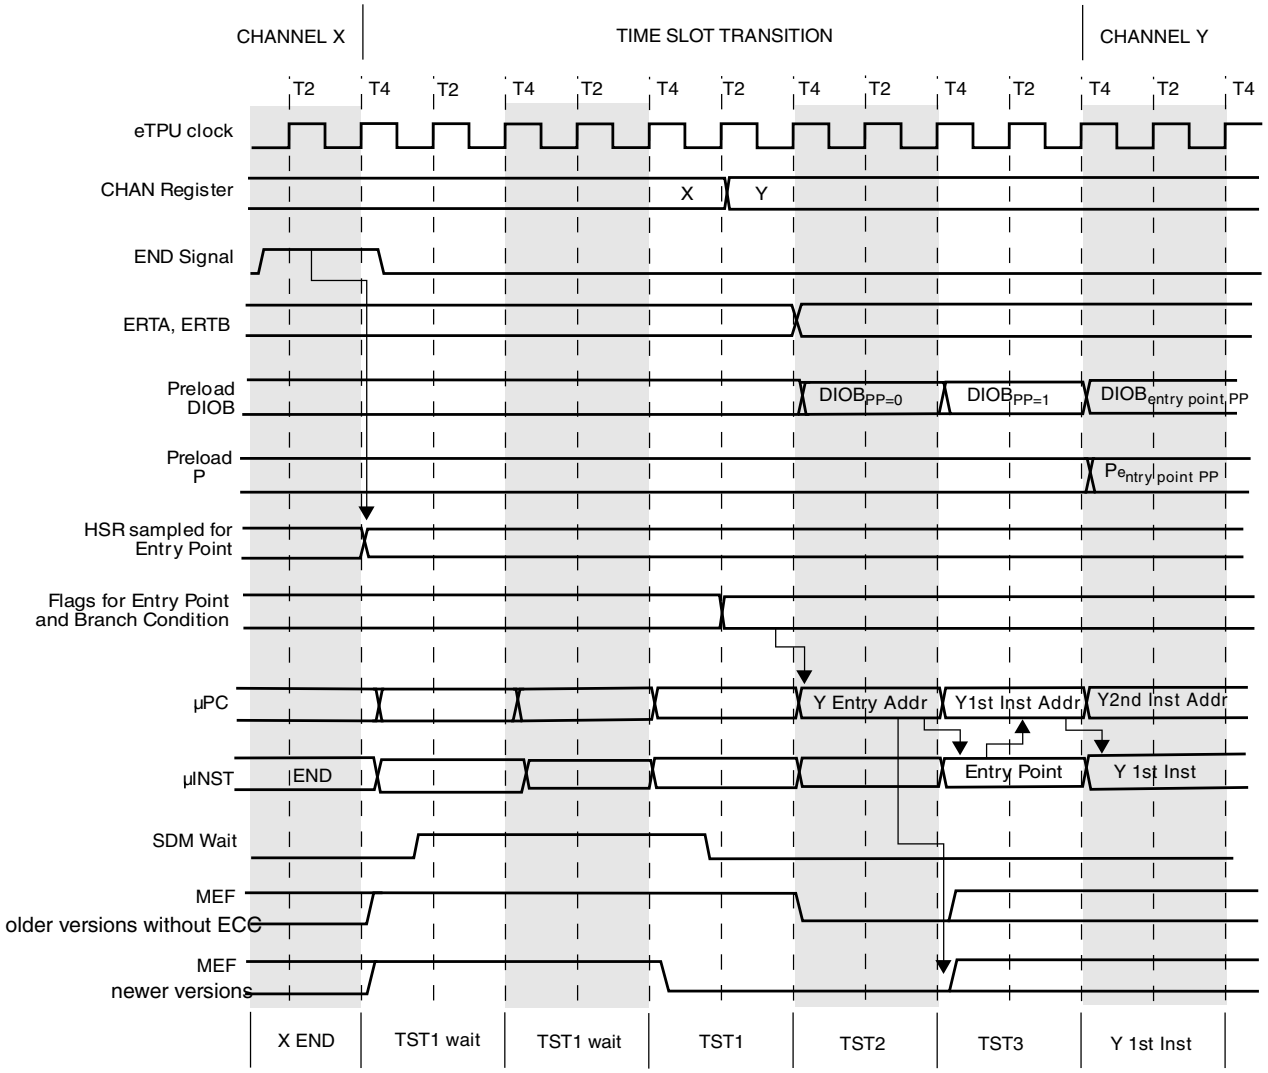

Figure 2-8. TST Timing - 2 Wait-states

For more information on Channel-specific registers and flags, refer to Enhanced Channels. For more information on P, ERTA/B and DIOB registers refer to Registers.

2.14.1.2.1 Thread gap

The MEF timing has changed from previous eTPU/eTPU2 versions, now being reset for two microcycles from the start of TST. Therefore, two consecutive threads with ME=0 serving the same channel could block any match until the end of the second thread (see Figure 2-6). This could cause latency problems and also break compatibility with legacy code, so the thread transition logic was modified to introduce a one-microcycle gap between consecutive threads servicing the same channel, as shown in the following figure. During the gap MEF is set to one, regardless of the previous or the next entry point ME field. The thread gap is inserted only between threads serving the same channel.

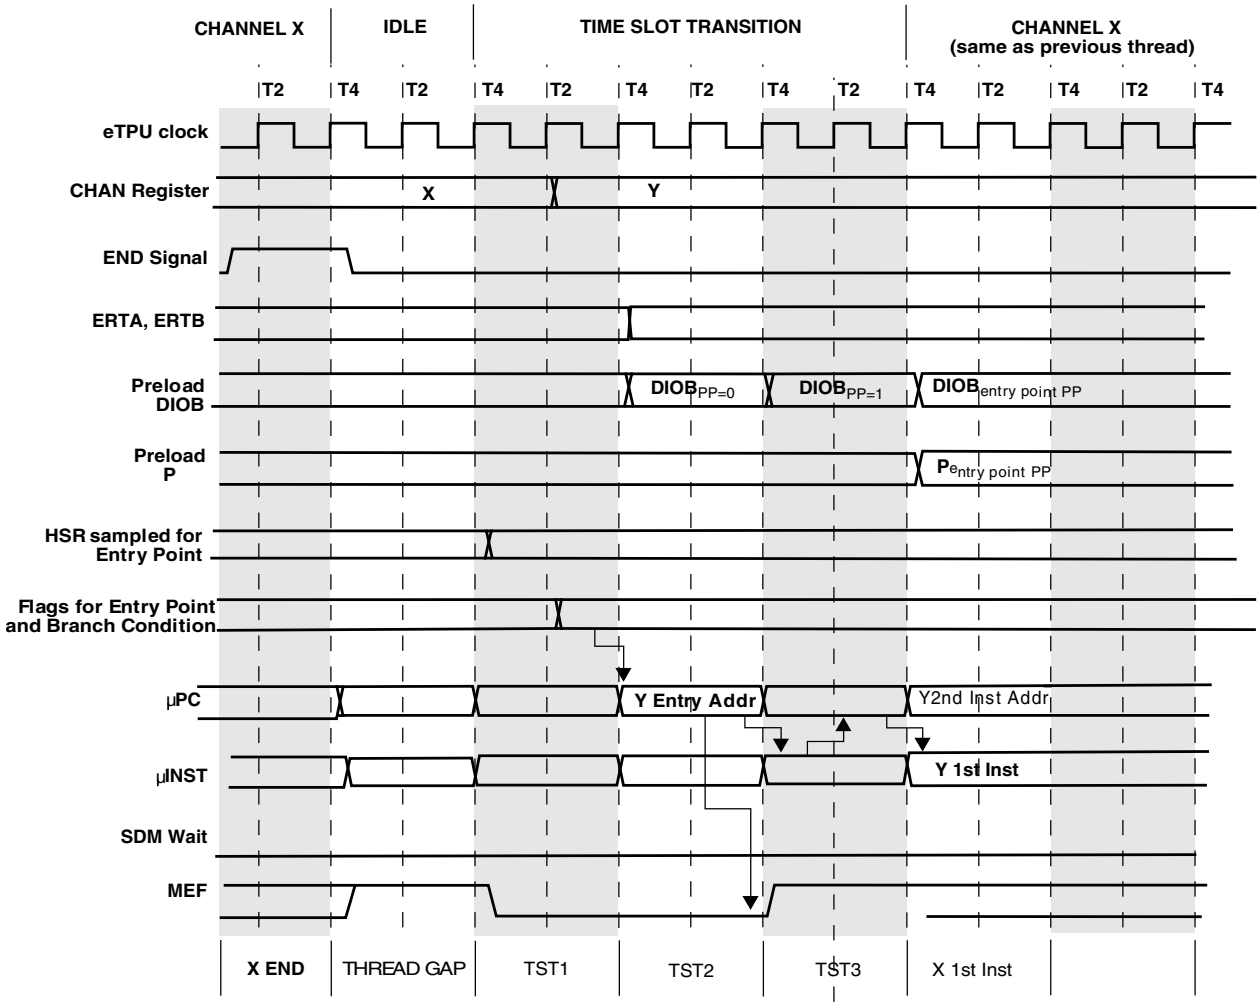

Figure 2-9. Thread gap

2.14.1.3 Thread ending

Threads can finish by either:

- an instruction with the END field active (see Ending Current Thread - END).
- a forced END by host writing to the FEND field in eTPU Engine 1 Configuration Register (eTPU_SCR_ECR_ENG1) and eTPU Engine 2 Configuration Register (eTPU_SCR_ECR_ENG2).
- a forced END caused by Watchdog timeout (see Watchdog).
- a forced END caused by a non-correctable memory error (see Memory error support).

2.14.1.4 Watchdog

Each engine has a watchdog mechanism to prevent a thread or a sequence of threads from running too long, impacting the latency of the other channel services. The watchdog is configured through eTPU Watchdog Timer Register for Engine 1 (eTPU_ER_WDTR_ENG1) and eTPU Watchdog Timer Register for Engine 2 (eTPU_ER_WDTR_ENG2). When the watchdog is enabled, an internal counter increments on each microcycle when a thread is executing. If the count is greater than the value specified in the WDCNT field in eTPU Watchdog Timer Register for Engine 1 (eTPU_ER_WDTR_ENG1) and eTPU Watchdog Timer Register for Engine 2 (eTPU_ER_WDTR_ENG2) and a thread is still executing, the watchdog:

1. If the WMO field in eTPU Watchdog Timer Register for Engine 1 (eTPU_ER_WDTR_ENG1) and eTPU Watchdog Timer Register for Engine 2 (eTPU_ER_WDTR_ENG2) is negated, forces an END of the thread, allowing other channels to be serviced
2. Sets the WDS status bit of the serviced channel in eTPU Watchdog Status Register for Engine 1 (eTPU_GCR_WDSR_ENG1) and eTPU Watchdog Status Register for Engine 2 (eTPU_GCR_WDSR_ENG2).
3. If the WMO field in eTPU Watchdog Timer Register for Engine 1 (eTPU_ER_WDTR_ENG1) and eTPU Watchdog Timer Register for Engine 2 (eTPU_ER_WDTR_ENG2) is negated, the channel is disabled, not initiating any thread until its WDS bit is cleared (however, its CPR field in eTPU Channel n Configuration Register for Engine 1 (eTPU_CCCR_C*n*CR_ENG1) and eTPU Channel n Configuration Register for Engine 2 (eTPU_CCCR_C*n*CR_ENG2) is not changed).
4. Issues a Global Exception and sets WDTO1 (engine 1) or WDTO2 (engine 2), regardless of the WMO bit state.

If the WMO field in eTPU Watchdog Timer Register for Engine 1 (eTPU_ER_WDTR_ENG1) and eTPU Watchdog Timer Register for Engine 2 (eTPU_ER_WDTR_ENG2) is asserted, the watchdog can be used to monitor the execution time threshold of a thread or thread sequence without interfering with the eTPU code execution.

The watchdog can be configured in one of the following modes, defining how the internal watchdog count is reset:

- **Thread Length Mode**: the watchdog count is reset at the end of each thread.
- **Busy Length Mode**: the watchdog count is reset when the microengine goes idle. A sequence of threads, one right after another, keeps the count running. The counter is also reinitialized when a thread is forced to end, so that a new count begins if another TST initiates at the following microcycle.

The following applies to the watchdog mechanism:

- microcycles during TST and SDM access wait-states (on TST or instruction execution) are counted.
- if the watchdog count equals WDCNT in the last microinstruction (with SDM wait-states or not) of a thread servicing a channel, its WDS bit is not set.
- if the watchdog count expires (gets greater than WDCNT) during the TST, the thread is forced end on its first instruction.
- the watchdog count does not wrap, so that a thread (in thread length mode) or a thread sequence (in busy length mode) that lasts for more than the maximum value of WDCNT does get a forced end.

Note

Watchdog must not be enabled when the microengine enters halt mode.

The counter does not run when the engine is stopped, and resets when the watchdog is disabled.

2.14.2 Host interface

2.14.2.1 System configuration

System Configuration Registers are described in System Configuration memory map and registers. Detailed explanation of the configured functionalities is found throughout Functional description and a specification for the initial configuration sequence is found in Configuration sequence.

2.14.2.2 Interrupts and data transfer requests

2.14.2.2.1 Interrupt types and sources

Each one of the eTPU channels can be a source of two requests: **Channel Interrupt** request and **Data Transfer Request**. Channel Interrupts are targeted to a Host CPU. Data Transfer Requests may be targeted to a data transfer module (for example, a DMA controller). Interrupt and Data Transfer registers are used by the Host to enable interrupts and data transfer requests, indicate their status and service them. Interrupt and Data Transfer requests have the same sets of registers and external signals, and are handled in the same way. They differ only by the fact that Data Transfer Requests are also cleared by the assertion of respective DMA completion acknowledge line.

Note

Interrupt and Data Transfer requests can be cleared even when Engines are in Module Disable Mode, through the Global Channel Registers, and also DMA completion for Data Transfer requests.

Channel Interrupts and Data Transfer Requests can only be issued by eTPU microcode, through one of the Channel Control instruction fields (see Channel Interrupt and Data Transfer Requests).

Both Channel Interrupt and Data Transfer requests can be individually enabled for each channel.

eTPU Interrupt and Data Transfer Registers are mirrored in two organizations: grouped by Channel and grouped by type (interrupt status, interrupt enable, data transfer status, data transfer enable). This allows either "channel-oriented" or "bundled channel" Host interrupt service schemes, or a combination of them. For a detailed description, refer to the Channel Register Layout and Global Channel Registers sections.

eTPU can also assert a **Global Exception** interrupt indicating a global illegal state. There are six possible sources for a Global Exception:

- Execution of an illegal instruction by the microengine (see Illegal instructions). This Global Exception source is flagged by ILF1 and ILF2.
- An SCM signature mismatch detected by the Multiple Input Signature Calculator - MISC. See SCM Test - Multiple Input Signature Calculator. This source is flagged by SCMMISF.

- Microcode request, through microinstruction field CIRC (see Channel Interrupt and Data Transfer Requests). This Global Exception source is flagged by MGE1 (Engine 1) and MGE2 (Engine 2). The cause of this illegal state is application-dependent. The microcode may write an error code into the SDM to indicate the cause of the exception, for instance.
- A Watchdog timeout, flagged by WDTO1 and WDTO2 (see Watchdog).
- An SDM or SCM non-correctable error on a microengine or host access, flagged by SDMERR and SCMERR, respectively (see Memory error support).
- The latency measured by any of either engine's Latency Monitors is greater than the specified maximum, flagged by LTO1 (Engine 1) and LTO2 (Engine 2) (see Latency Monitor).

Global Exceptions cannot be directly disabled within eTPU, except by disabling its sources (Memory Error, SSS, MISC and microcode), and it is cleared by writing 1 to GEC. Clearing Global Exception clears all Global Exception source status bits (ILF1, ILF2, SCMMISF, MGE1, MGE2, SCMERR, SDMERR). If GEC is written 1 at the same time any of the sources issues a Global Exception, both the interrupt and the status bit of that source remains asserted. The assertion of Global Exception by one of the sources above does not prevent the others from asserting it too, so any number of them, in any combination, can be flagged.

Note

There can be a race between the clear of a Global Exception and occurrence of a new set condition, such that the set happens just before the clear and cannot be sensed by the Host. Therefore, Global Exception cannot be used as a normal interrupt source. It should only be used for emergency procedures.

Memory Error Correction support (see Memory error support) has a distinct interrupt source, which can activate on any correctable error occurrence, either to SCM or SDM accesses, but does not activate on non-correctable errors (which assert Global Exception instead). Memory Error Correction interrupt assert when it is enabled through MECIE (see eTPU Memory Error Status Register (eTPU_MESR_MESR)) and either DCERR or CCERR in eTPU Memory Error Status Register (eTPU_MESR_MESR) is asserted. The interrupt is negated when both DCERR and CCERR are negated, or MECIE is negated.

2.14.2.2.2 Interrupt and Data Transfer Request overflow

If a Channel Interrupt was issued, its status bit is still set, and microcode issues another Channel Interrupt, the Interrupt Overflow status bit is set for that channel. Interrupt Overflow status can be checked by the Host in the CIOS field of eTPU Channel n Status Control Register for Engine 1 (eTPU_CCCR_C*n*SCR_ENG1) and eTPU Channel n Status Control Register for Engine 2 (eTPU_CCCR_C*n*SCR_ENG2), mirrored in eTPU Channel Interrupt Overflow Status Register for Engine 1 (eTPU_GCR_CIOSR_ENG1) and eTPU Channel Interrupt Overflow Status Register for Engine 2 (eTPU_GCR_CIOSR_ENG2). Interrupt Overflow status is not cleared automatically when Interrupt Status is cleared. The same mechanism and respective registers (eTPU Channel Data Transfer Request Overflow Status Register for Engine 1 (eTPU_GCR_CDTROSR_ENG1) and eTPU Channel Data Transfer Request Overflow Status Register for Engine 2 (eTPU_GCR_CDTROSR_ENG2)) are available for Data Transfer Requests.

If interrupt is set and cleared at the same time, set prevails and overflow is not altered (keeps the same state as it was before, asserted or not).

Global Exception has no overflow status.

2.14.2.3 Parameter Access

2.14.2.3.1 Parameter Access Widths

From the Host side the SDM address space is mapped in bytes, and each 32-bit parameter occupies 4 contiguous, aligned bytes. The Host can read/write the SDM by 8-, 16-, or 32-bit accesses in aligned addresses.

In 32-bit access, Host can access all 32 bits or only the lower 24 bits with an automatic sign extension (see Parameter Sign Extension area).

2.14.2.3.2 Parameter Addresses and Endianness

To access parameter number xxx, eTPU Microengine(s) would select address xxx. The Host would add *(xxx*4)* to the SDM base address to access the same parameter. For example, parameter 0x101 is seen by the Host in *(SDM base address +0x404)* . An example of SDM memory map is shown in Figure 2-10 . The Host can access the SDM with a 32-bit-wide bus cycle to a four-byte aligned address, 16-bit-wide bus cycle to a two-byte aligned address, or 8-bit wide bus cycle to any byte address.

The address of the 24-bit parameters and the most significant byte depends on the endianness of the MCU. For more details, see the Endianness.

2.14.2.3.3 Parameter concurrency

Host accesses to parameters may occur in parallel with eTPU Microengine accesses. Readings taken from a group of parameters while they are being simultaneously updated may lack coherency. eTPU provides mechanisms to ensure parameter coherency in accesses from both Host side and Microengine side, including the use of a coherent dual-parameter transfer mechanism, described in detail on Parameter sharing and coherency.

2.14.2.3.4 Parameter Sign Extension area

The SDM address space to the Host is mirrored in a Parameter Sign Extension (PSE) area (see Table 2-3). Accesses from the Host to the PSE area differ from accesses to the standard SDM address space as follows:

- **Writes**: the most significant byte of the parameters is not written, and the SDM retains the old byte value, regardless of the Host access size.
- **Reads**: the most significant bit of the 24-bit parameter (that is, the MSB of the second most significant 32-bit parameter byte) is repeated in the 8 most significant bits of the read value on all 32-bit reads and most significant 16- and 8-bit reads.

The same parameters written in the standard SDM address space are read from the PSE area with the same offsets, and vice-versa. See Table 2-117 for a reference of the address offsets in big and little endian machines.

This feature reliefs the Host from extending the signal of 24-bit eTPU parameters before calculations, and from read-modify-write accesses to modify 24-bit parameters at the SDM.

2.14.2.4 SDM organization

The SDM internal partition for channel allocation is dynamic and programmed in the Channel Registers (see eTPU Channel n Configuration Register for Engine 1 (eTPU_CCCR_C*n*CR_ENG1) and eTPU Channel n Configuration Register for Engine 2 (eTPU_CCCR_C*n*CR_ENG2)).

The Host application is responsible for allocating a different parameter base address to each channel during the initial eTPU configuration, and to allocate enough parameters for the selected Function, with no unintentional overlapping between parameters of different functions.

Besides channel parameters, global areas may have to be allocated for parameters that are shared by more than one channel, in one or both Engines. Also, temporary parameter areas should be reserved to be used by the coherent parameter transfer mechanisms described in Parameter sharing and coherency, if necessary. An SDM organization example is shown in the following figure.

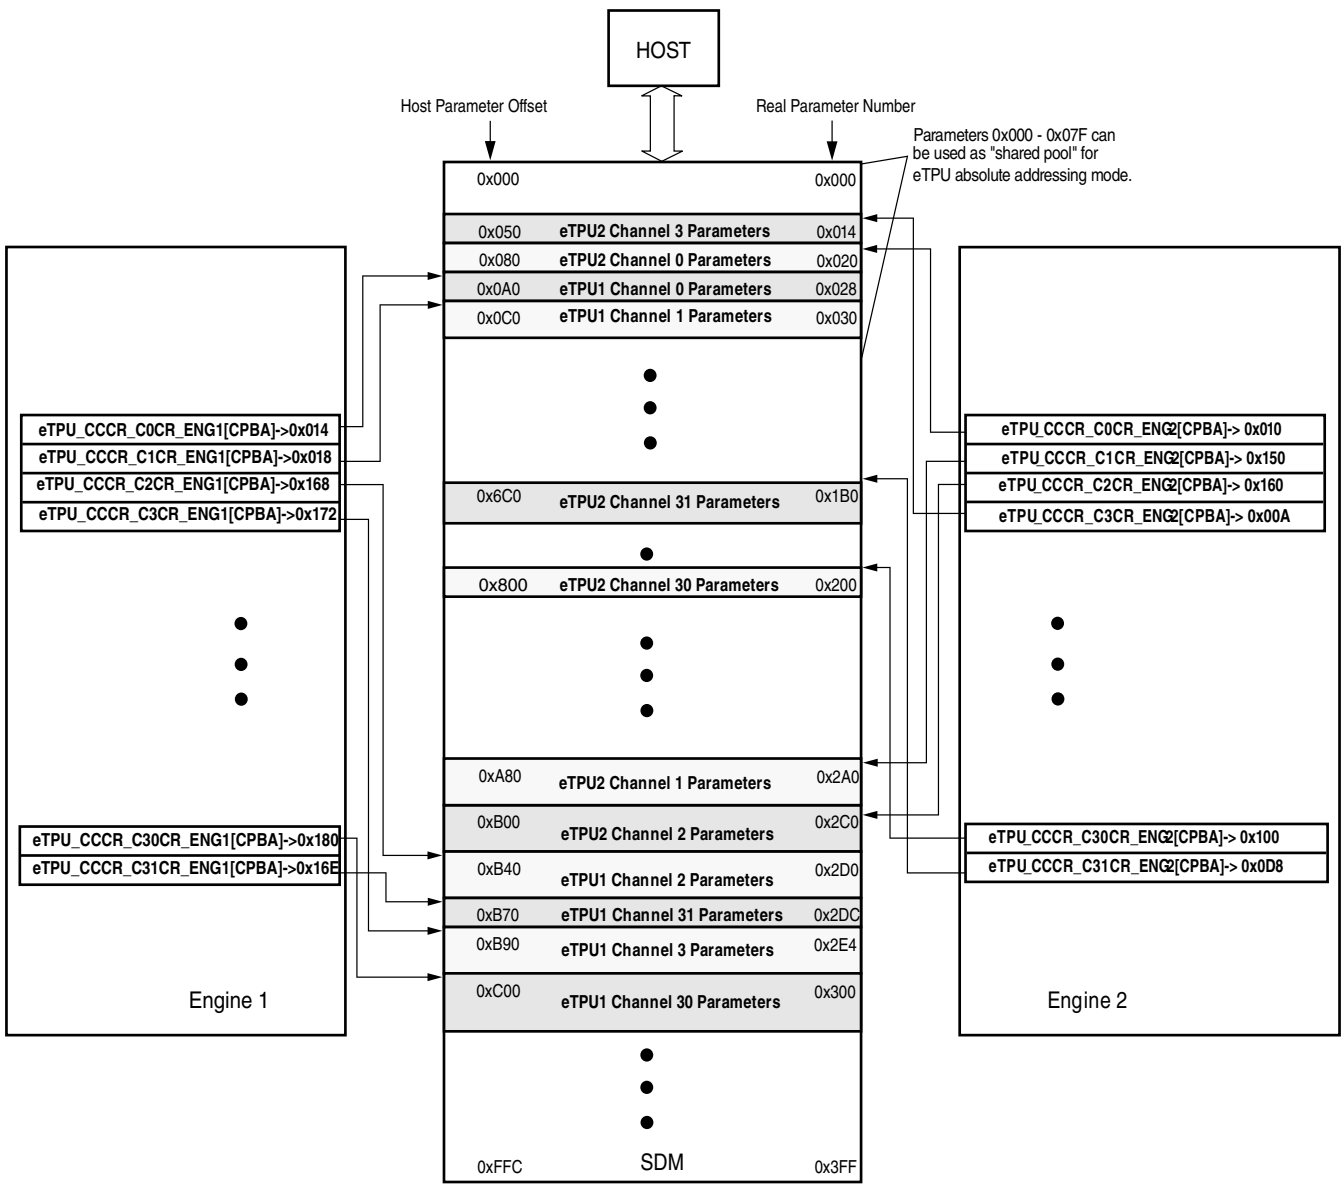

Figure 2-10. SDM Organization Example (4 KB)

Single-engine eTPU or dual eTPU system may require less parameters than the maximum number provided by the SDM. Since the SDM partition is fully dynamic, there is no limitation of fixed channel addresses, and the reduced array can be fully utilized.

2.14.2.5 Host Service Requests

Host CPU can request immediate service from a channel by writing a non-zero value to the Host Service Request register field - HSR (see eTPU Channel n Host Service Request Register for Engine 1 (eTPU_CCCR_C*n*HSRR_ENG1) and eTPU Channel n Host Service Request Register for Engine 2 (eTPU_CCCR_C*n*HSRR_ENG2)). There is one HSR field for each channel, so that writing to it generates a Service Request to the respective channel only. A zero value in HSR means no Host Service Request is pending for the channel.

HSR value turns to 000 automatically at the end of microengine service for that channel, but only if the thread started due to an HSR.

The meaning of a non-zero HSR value depends on the Function assigned for the channel. These bits are part of the conditions which select the Function entry point, and cannot be tested by microcode. For more details, refer to Entry Points.

If Host writes HSR=000 when a thread for the same channel is already running, the thread runs until the end and is not aborted. If Host writes HSR>000 when an HSR thread for the same channel is already running, HSR value resets at the end of the thread, and no new HSR will be pending. If HSR is written before its value is resolved by the scheduler during TST, the entry point will obey the new HSR value, and if this new value is 000, no service thread is executed for the HSR.

The scheduling of HSRs is completely asynchronous with Host accesses, and there is no race-free manner to change an HSR value before service thread execution, so generally the safe way is: write HSR>0 only when HSR=0. Error recovery or emergency host procedures may require one to the safely abort service and reset channel state when an HSR is already pending or executing. In these cases, the procedure below should be followed:

1. Disable the channel, writing CPR=00 in eTPU Channel n Configuration Register for Engine 1 (eTPU_CCCR_C*n*CR_ENG1) and eTPU Channel n Configuration Register for Engine 2 (eTPU_CCCR_C*n*CR_ENG2). That will prevent any pending HSR to be serviced.
2. Check if the channel is currently being serviced, reading its service status bit in eTPU Channel Service Status Register for Engine 1 (eTPU_GCR_CSSR_ENG1) and eTPU Channel Service Status Register for Engine 2 (eTPU_GCR_CSSR_ENG2). If

it is, wait for the time necessary to finish the service pending, or check again until HSR == 0, or channel service bit in eTPU Channel Service Status Register for Engine 1 (eTPU_GCR_CSSR_ENG1) and eTPU Channel Service Status Register for Engine 2 (eTPU_GCR_CSSR_ENG2) is cleared.

3. Write HSR with the error recover value. This value should, possibly combined with other host-defined flags in SDM or FM bits, initiate a channel reset or error recovery procedure.
4. Re-enable the channel, writing CPR value > 0 in eTPU Channel n Configuration Register for Engine 1 (eTPU_CCCR_C*n*CR_ENG1) and eTPU Channel n Configuration Register for Engine 2 (eTPU_CCCR_C*n*CR_ENG2).

2.14.2.6 SCM access

Only Host can access SCM as data. Depending on the specific device, SCM may be implemented as a RAM or ROM. This determines Host accesses to the SCM as shown below.

2.14.2.6.1 SCM RAM implementations

When SCM is implemented as RAM, the Host may read or write to SCM by setting VIS =1. If VIS=0 and Host tries to access SCM space, a bus error is issued, writes are ineffective and read data is meaningless. Both Engines must be stopped or halted to set VIS=1.

Note

It is necessary to turn VIS bit on to set software breakpoints (see Software breakpoints).

2.14.2.6.2 SCM low power

SCM turns off its internal clocks when both Engines are stopped (STF field in eTPU Engine 1 Configuration Register (eTPU_SCR_ECR_ENG1) and eTPU Engine 2 Configuration Register (eTPU_SCR_ECR_ENG2) asserted), VIS, and MISC is not enabled (SCMMISEN=0). The SCM clocks are automatically turned on if either one of the STF bits is negated or VIS turns to 1, or SCMMISEN turns to 1.

SCM clocks are not turned off if any of the Engines is not stopped, even if they are both halted.

The conditions for SCM Clocks and MISC activation are summarized in the following table.

Table 2-26. SCM clocks and MISC activation

STF in eTPU_SCR_ECR_ENG1	STF in eTPU_SCR_ECR_ENG2	VIS in eTPU_SCR_MCR	SCMMISEN in eTPU_SCR_MCR	SCM clocks	MISC
0	x	0[1]	1	On	On
0	x	0[1]	0	On	off
x	0	0[1]	1	On	On
x	0	0[1]	0	On	off
1	1	0	0	off	off
1	1	0	1	On	On
1[2]	1[2]	1	0	On	off
1[2]	1[2]	1	1	On	off[3]
0	0	x	0	On	off
0	0	x	1	On	On

1. VIS cannot be written 1 if eTPU_SCR_ECR_ENG1[STF]=0 or eTPU_SCR_ECR_ENG2[STF]=0, and both HLTF bits are 0.
2. If VIS=1, neither MDIS can be written 0 nor the Engine leaves Stop Mode, regardless of device stop request .
3. MISC resets and stays so when VIS=1, restarting automatically when VIS goes 0 if SCMMISEN=1.

2.14.2.6.3 SCM Off-range data

When read accesses are made, either by the Host or by a microengine, to addresses above the limit corresponding to SCMSIZE, the value read comes from eTPU SCM Off-range Data Register (eTPU_SCR_SCMOFFDATAR). The Host can program the register at initialization with an opcode value with operations that try to protect or recover the system from runaway code, for instance: terminate the thread, clear channel flags, disable match and transition service requests, issue an interrupt, jump to an error recovery procedure[12] . Writes to unimplemented addresses do not return error and can write on unspecified mirror addresses, so they should be avoided.

2.14.2.7 Bus error conditions

Follows a summary of the possible causes of bus errors on host accesses to the eTPU memory space:

- Read or write access to the SCM with VIS =0.

12. Only part of these suggested operations can be parallelized in a single instruction, see Microinstruction formats.

- Read or write access to the channel registers with eTPU_SCR_ECR_ENG*n* bits MDIS=1, or bit STF=1 (see eTPU Engine 1 Configuration Register (eTPU_SCR_ECR_ENG1) and eTPU Engine 2 Configuration Register (eTPU_SCR_ECR_ENG2)).
- Write access to the Time Base Registers with eTPU_SCR_ECR_ENG*n* bits MDIS=1, or bit STF=1 (see eTPU Engine 1 Configuration Register (eTPU_SCR_ECR_ENG1) and eTPU Engine 2 Configuration Register (eTPU_SCR_ECR_ENG2)).
- Non-correctable errors in the SCM on reads of any size or writes less than 32-bits wide when CEDD =0.
- Non-correctable errors in the SDM on reads when DEDD =0.
- Accesses to the Shared Subsystem Area, when propagating a bus error issued by the attached subsystem.

2.14.3 Scheduler

Every Function is composed of one or more Threads. A Thread consists of a group of instructions that, once begins execution, cannot be interrupted by host or channel events. Each active channel intents to be serviced, being granted time for Thread execution. Since one microengine handles several channels operating concurrently, the Function threads must be executed serially.

The task of the Scheduler is to recognize and prioritize the channels needing service and to grant execution time to each channel. The time given to an individual Thread for execution or service is called a **Time Slot**. The duration of a time slot is determined by the number of instructions executed in the Thread plus SDM wait-states received, and varies in length.

At any time, an arbitrary number of channels can require service. To request service, channel logic, eTPU microcode or Host application notifies the Scheduler by issuing a Service Request.

2.14.3.1 Channel enabling and priority assignment

Every channel is assigned one of three priority levels - high, middle, or low - by the Host CPU, through the Channel Configuration Register field CPR (seeeTPU Channel n Configuration Register for Engine 1 (eTPU_CCCR_C*n*CR_ENG1) and eTPU Channel n

Configuration Register for Engine 2 (eTPU_CCCR_C*n*CR_ENG2)). These registers are also used to disable the channel, which is equivalent to assigning it a "null" priority. In this case, the Scheduler does not grant any of its Service Requests.

It is possible to change the channel priority level or disable it dynamically. If the Host disables a channel when it is currently being serviced, channel service thread will complete. This means that it is possible for the output level of a channel signal to change, or a Host interrupt occur, even after its priority register was written to "null". For instance, if an output transition is scheduled, the transition will occur even after the channel is disabled.

Service requests previously pending or that occur while a channel is disabled remain asserted while the channel is disabled, and are serviced if the channel is enabled again, in due time determined by the priority scheme and concurrent requests from other channels. Channels are disabled after reset, and it is recommended to configure a Host Service Request for initialization of a channel before that channel is enabled to active priority (see Initialization/application information).

2.14.3.2 Channel priority schemes

The Scheduler holds a Service Grant register with one bit for each channel. Once the Scheduler grants a time slot to channel, the Service Grant bit for that channel is asserted in the Service Grant register. When the Service Grant bit of a channel is set, the channel may request new service but is not serviced again before its Service Grant bit is cleared.

When all channels in a same priority level are serviced, their Service Grant bits are cleared at the end of the thread, one eTPU clock before the next serviced channel is calculated, according to the scheme below[13] :

- Clear all grant bits of priority High if all channels of that priority that are requesting have their grant bits in 1.
- Clear all grant bits of priority Medium if all channels of that priority that are requesting have their grant bits in 1.
- Clear all grant bits of priority Low if all channels of that priority that are requesting have their grant bits in 1.
- Clear all grant bits of disabled channels.

13. Grant bits are also cleared in the next clock, when the service channel is chosen, or when the microengine is idle, using the same scheme.

This scheme assures that no channel is left with its grant bit forever asserted (preventing it from being serviced again), even if the channel priorities are reassigned during the execution.

Priority level is determined based on the maximum latency desired for each channel. A channel having a Function that requires the most frequent or more immediate service should be allocated a high priority level.

The eTPU employs a **primary** and a **secondary priority scheme**. These two schemes ensure frequent servicing of high-demand Functions and ensure a minimum time allocation to all channels requesting service, regardless of their priority level. The primary scheme prioritizes requesting channels that have different priority levels; the secondary scheme prioritizes requesting channels that have the same priority level.

Initially, a channel requests service and is granted a time slot by the Scheduler: Service Grant bit is asserted. If only high-level channels constantly receive service first because of their priority level, middle- and low-level channels would only be serviced by default, i.e., if no high-level channels request service. To ensure that each priority level receives an opportunity for servicing, every time slot has a fixed priority level that the Scheduler honors first. Divided into sets of seven, time slots are numbered from one to seven. The figure below illustrates the numbered time slots in sets of seven (fields A and B) and identifies their assigned default priority level. The high level has more time slots than the middle and low levels. Out of every seven time slots available, four are assigned to honor high-level channels first, two are assigned to honor middle-level channels first, and one is assigned to honor low-level channels first. Only one request (in each Engine) is serviced per time slot. When no channel requests service and the microengine is idle the priority scheme is initialized to time slot one, to prevent priority inversion on the next request[14].

14. Priority inversion would occur in the following situation: no channel is requesting service, and the current time slot is primarily assigned to a low-priority channel. If the Scheduler was not reset to time slot one and two channels requested service at the same time, one with high priority and the other with low priority, the channel to be serviced would be the low-priority channel.

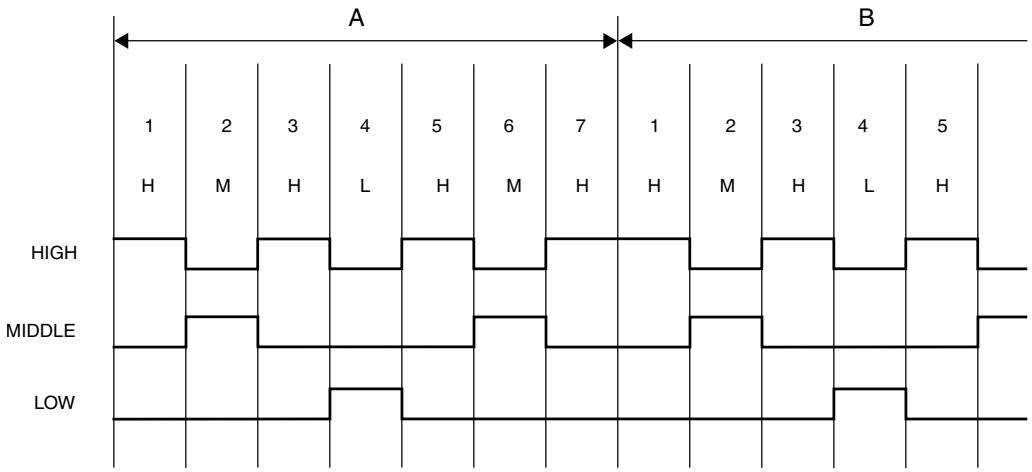

Figure 2-11. Time Slot Priority levels

2.14.3.2.1 Primary Scheme - Priority Among Channels on Different Levels

Although time slot priority assignment is fixed, the servicing priority is not. The primary scheme acknowledges the priority level assigned to a time slot, granting service first to a channel having the same priority. In Channel priority schemes, time slot one has a high-level assignment; therefore, a high-level channel requesting service is recognized first. However, if no high-level channel requests service, the Scheduler recognizes a requesting middle-level channel. If this level has no request, the Scheduler continues to the low-level. If no requests occur, the Scheduler truncates the seven state cycle and starts a new cycle at time slot one, waiting for the first request. Granting service to a different-level channel is called priority passing. The order of passing always gives the highest priority to the assigned level, and the second priority to the higher of the remaining requesting priority levels as shown in the following table.

Table 2-27. Priority Passing

Assigned Priority Level	Next Priority Level	Next Priority Level
High	Middle	Low
Middle	High	Low
Low	High	Middle

When priority is passed to another level, that level is serviced and the fixed-priority-level sequence is resumed with the next time slot.

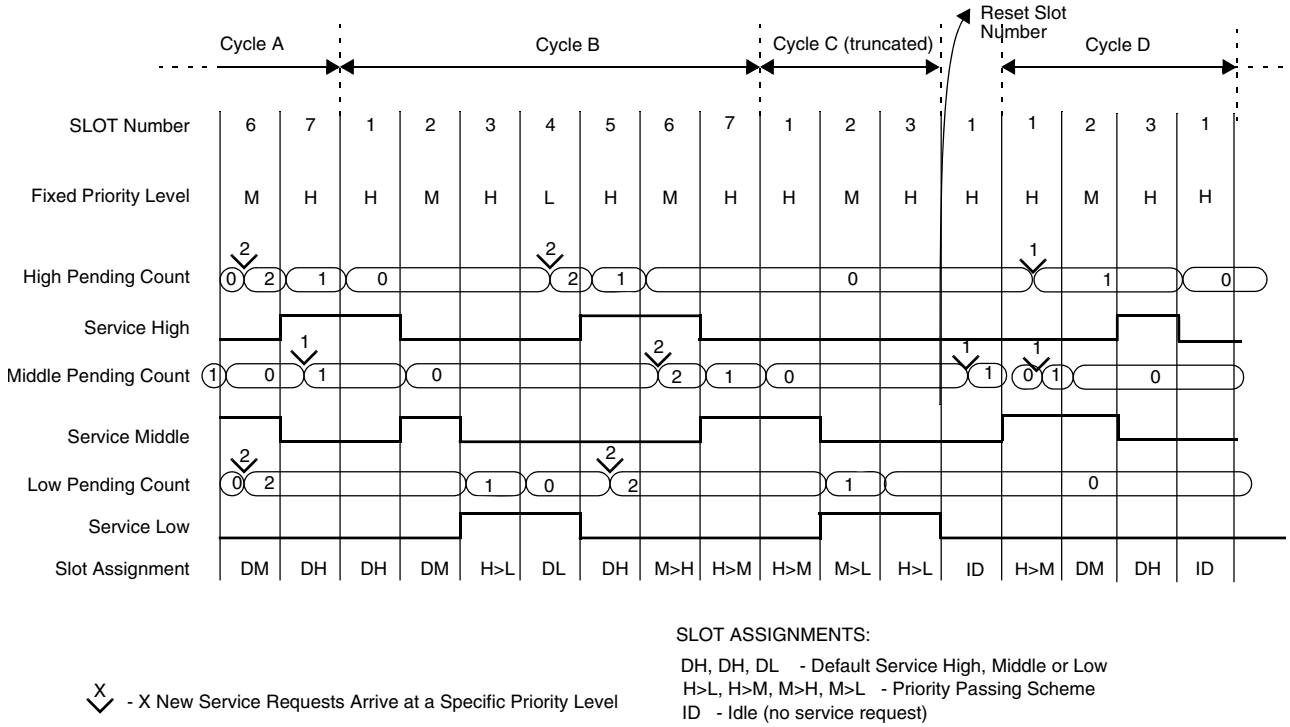

Figure 2-12. Priority Passing Example

Examples of priority passing are shown in the above figure. Each cycle contains seven time slots (or less if no service request exist). In cycle B, no high-level or middle-level service requests are present before time slot three which is assigned by default to high-level priority. Thus, time slot three is passed to the low level. In cycle B there are also no middle-level service requests before time slot six, so it passes the priority to a requesting high-level channel. During time slot six no more high level requests are left, but two new middle-level requests arrive, and there are also three low level pending service requests. Thus, time slot seven of cycle B and time slot one of cycle C are passed to the middle-level which is the next priority level after high. Time slots two and three of cycle C are passed to the low level which contains the three remaining channel service requests. At time slot three of cycle C the last low level request is serviced, and the Scheduler passes to idle state. At this point the cycle C is truncated and the Scheduler passes to time slot one of cycle D.

2.14.3.2.2 Priority passing disabling

The priority passing scheme allows a case where a high priority channel looses to a lower priority one right after another lower priority has been serviced, exemplified in the Cycle D on Figure 2-12. A middle priority channel wins time slot 1 due to priority passing from high to middle. While it is being serviced, two new service requests arrive, one high and one middle priority. The high priority request looses to the middle one on next time slot 2 by default priority assignment.

This priority inversion can be avoided by setting the SPPDIS field in the eTPU_SCR_ECR_ENG*n* registers (see eTPU Engine 1 Configuration Register (eTPU_SCR_ECR_ENG1) and eTPU Engine 2 Configuration Register (eTPU_SCR_ECR_ENG2)), which disables the priority passing mechanism. When priority passing is disabled, at the end of the thread the slot number is incremented until a time slot that matches the priority of one of the requesting channel(s). The time slot advance takes no extra clocks. If no channel requests service, the time slot counter stays at time slot 1. The priority selection scheme with disabled priority passing is summarized in the following table.

Table 2-28. Priority Passing Disabling

At the endof time slot	servicing priority	if any request of priority	service it on time slot	else if any request of priority	service it on time slot	else if any request of priority	service it on time slot
1	High	Medium	2	High	3	Low	4
2	Medium	High	3	Low	4	Medium	6
3	High	Low	4	High	5	Medium	6
4	Low	High	5	Medium	6	Low	4
5	High	Medium	6	High	7	Low	4
6	Medium	High	7	Medium	2	Low	4
7	High	High	1	Medium	2	Low	4

An example of the priority passing disabling scheme is illustrated in the figure below. The sequence of service requests is the same as in the example of Figure 2-12, and although the time slot incrementing differs, the priorities granted are the same for cycle B. Cycle C has one of the low priority channels serviced before the second middle one. Cycle D, however, no longer has the priority inversion.

In cycle B, after the time slot 2 only a low priority request remains, so the time slot count advances directly to 4, which has a low priority assigned. Time slot keeps on 4 for the next service, as only a low priority request remains also, and only time slot 4 is assigned to low. Two high priority services contend for the next time slot 5 (assigned to High). The second high priority channel is serviced on the next time slot, jumped to 7 because there is no middle request, ending cycle B. Cycle C starts with time slot 2, as there are no high priority requests and two middle and two low ones. After the first middle service, time slot count skips 3 assigned to high (no high requests), and services a low priority channel on time slot 4. It follows the same scheme until there are no other requests and cycle C is truncated, resetting the time slot counter to 1.

Cycle D begins with a middle request, jumping to time slot 2. During this service two requests arrive, one high and one middle. Unlike what happened with priority passing, the next serviced is the high priority channel, as the time slot increments to 3. The second middle priority channel request in cycle D is finally serviced next, on time slot 6.

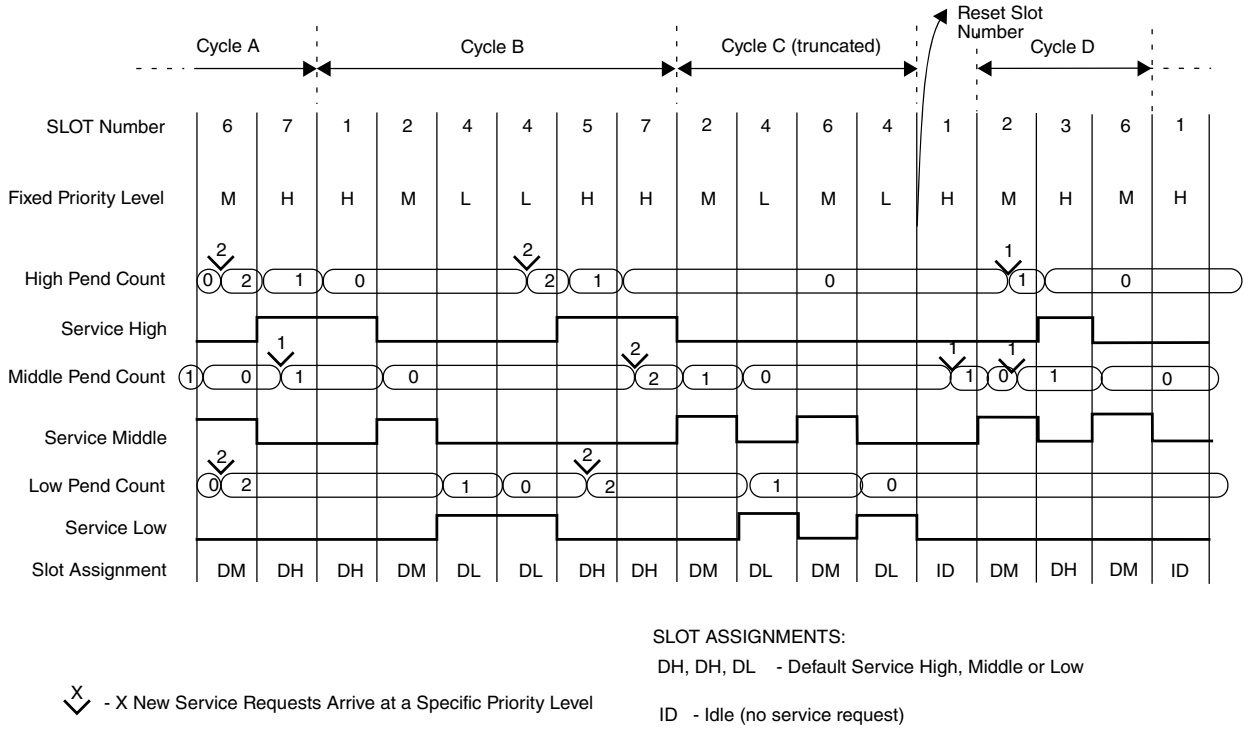

Figure 2-13. Priority Passing Disabling Example

2.14.3.2.3 Secondary Scheme - Priority Among Channels on the Same Level

Because channels can randomly request service, channels having the same priority level will inevitably request service simultaneously. A secondary scheme prioritizes these requests. The Scheduler services channels on each of the three priority levels, beginning with the lowest numbered channel on that level.

2.14.3.2.4 Priority Scheme Example

The overall priority scheme simultaneously incorporates both primary and secondary schemes. Combining both schemes in the following example conveys their correlation.

1. One high-priority and one low priority channels request service, while the Scheduler is in time slot one. Having its service request bit asserted, a single high-level channel is granted the time slot, which has high-level priority (primary scheme) and its service grant bit is asserted. At the end of the thread, the service grant bit is negated (no more requests of high priority level channels).

2. The Scheduler proceeds to time slot two, which has middle-level priority; however, no middle-level channel is requesting service. Priority is passed to the high level, but no high-level channel is requesting service; therefore, priority is passed again, and service is granted to the single requesting low-level channel. Once serviced, this channel's grant bit is negated (no more low-level requests).
3. The Scheduler resumes with the fixed-priority sequence on time slot three; however, no channels are requesting service. The Scheduler returns to time slot one, waiting for requests.
4. Two high-level and two middle-level channels simultaneously request service. Being in time slot one which is assigned high priority, the Scheduler finds the lowest numbered high-level channel (secondary scheme) and selects it for service. This channel's service grant bit is asserted.
5. The Scheduler continues to time slot two, which has middle priority (primary scheme), and allocates the slot to the lowest numbered middle-level channel requesting service (secondary scheme). The Scheduler notes the still unserviced middle-level channel and proceeds to time slot three.
6. Time slot three is allocated for high priority. The slot is allocated to the remaining unserviced high-priority channel, and the channel's service grant bit is asserted. The Scheduler checks again at the end of the thread. All service grant bits of high-level requested channels are asserted; therefore, all high-priority channels that requested have been allocated execution time. Under this condition, all service grant bits of the high-level serviced channels are negated. The Scheduler proceeds to time slot four.
7. Time slot four is allocated for low-priority channel; however, no low-level channel is requesting service. Priority is passed to the high level, but no high-level channel is requesting service; therefore, priority is passed again, and service is granted to the remaining middle-level channel which requests service. This channel's service grant bit is asserted. The Scheduler checks again at the end of the thread. All grant bits of middle-level requested channels are asserted; therefore, all middle-priority channels have been allocated execution time. Under this condition, all service grant bits of the middle-level serviced channels are negated. The Scheduler proceeds to time slot five. Meanwhile a low priority channel requests service.
8. Time slot five is allocated for high-priority channels, but there are no more requests from high-priority or middle priority channels. The single low-level channel which required service is granted time slot five. Once serviced, the channel's service grant bit is asserted. Next, the service grant bit is negated (no more requests of low priority level channels).

9. The Scheduler resumes with the fixed-priority sequence on time slot six; however, no channels are requesting service. The Scheduler returns to time slot one and waits for requests.

2.14.3.3 Time slot latency

Latency is the amount of time between a service request and the beginning of service on that channel. The following factors affect latency:

- Number of active channels
- Number of channels on a priority level
- Number of available time slots on a priority level
- Number of microcycles required to execute a thread of a Function
- Number of SDM accesses during execution of a Function thread
- eTPU clock frequency

Each time slot may require a different number of microcycles, depending on the thread of a Function to be executed. This variation is shown in the figure below.

For more details on latency evaluation, see Estimating Worst Case Latency.

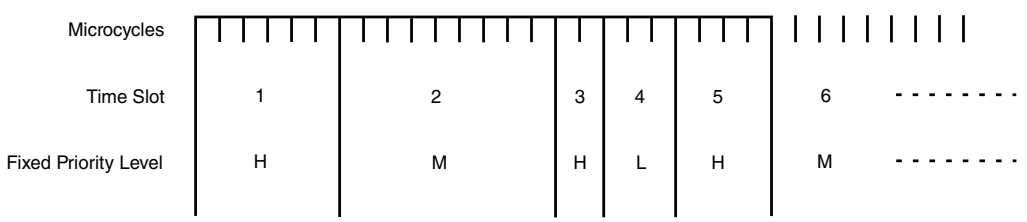

Figure 2-14. Time-slot variation

2.14.4 Parameter sharing and coherency

SDM can be concurrently accessed by Host and Microengines (two in a Dual eTPU Engine system). In general, there is no guaranteed order by which a group of parameters is accessed, which may lead to a lack of internal consistency if two or more related parameters are read when only part of them is updated.

eTPU provides mechanisms to guarantee parameter coherency. The most generic mechanisms for Host-eTPU coherency, suitable for any number of parameters, are:

- the use of Transfer Service Thread mechanism.
- the mailbox (or "software semaphore") mechanism.

These mechanisms, described in Multiple parameter coherency methods, use microcode to transfer parameters from temporary buffers in SDM to their definitive locations (or vice-versa). These methods have the disadvantage of wasting processing and code memory resources.

eTPU also provides a **Coherent Dual-parameter Controller - CDC** - mechanism. It is used by Host to coherently transfer pairs of parameters from/to a parameter buffer located on SDM to/from the locations on SDM where parameters are accessed directly by the channels. Coherency is guaranteed by SDM access arbitration. Although limited to two parameters only, it has lower latency and wastes no microengine resources[15]. CDC usage is described in Coherent Dual-parameter Controller (CDC).

For parameters shared by both Engines, eTPU provides **Hardware Semaphores**. Coherency is assured given the semaphores are used to prevent concurrent access to the changing parameters. Microengine can request semaphores using specific microinstructions (see Semaphore Operations). Hardware Semaphores are described in detail in Hardware Semaphores.

Neither Host nor CDC have access to the hardware semaphores, but they can be combined with microcode transfer mechanisms if Host must coherently access parameters which are also shared by both Engines.

In order to ensure coherent access to a group of parameters by two or more contenders, **each contender must have atomic access** to the shared parameters. Atomicity conditions are discussed in Host side atomic access and Microengine Side Atomic Accesses.

2.14.4.1 Host side atomic access

Host side atomic accesses can be achieved by either of following ways:

- For one parameter, the SDM should be accessed by 32-bit-wide data transfers to ensure coherency

15. A microengine access to the SDM in the moment CDC is performing the transfer may suffer a maximum of two wait-states.

- For two parameters only, using the Coherent Dual Parameter Controller.
- Indirectly, for any number of parameters, by requesting microcode to coherently access SDM in its behalf. The host side atomicity problem becomes, then, a microengine side atomicity problem. Some methods that use this approach to achieve coherency are described in Multiple parameter coherency methods.

2.14.4.2 Microengine Side Atomic Accesses

2.14.4.2.1 Microengine Single Parameter Atomicity

SDM should be accessed by 32-bit-wide data transfers to ensure atomicity for 32-bit parameters. This applies either to Host-Microengine coherency or Microengine-Microengine coherency in a dual eTPU Engine system.

2.14.4.2.2 Microengine Dual Parameter Atomicity

Microengine has the ability to access two parameters coherently in back-to-back accesses, at random addresses: once it accesses SDM, it has priority over Host for another access in the next microcycle (see SDM arbitration). Note that it applies **only to Microengine-Host** coherency. For Microengine-Microengine coherency in a dual eTPU Engine system, one must use Hardware Semaphores (see Hardware Semaphores).

Microengine dual back-to-back accesses are guaranteed to be atomic in relation to Host slave accesses or Coherent Dual-parameter Controller, regardless of semaphore usage: Host or CDC accesses cannot break-up a back-to-back Microengine access, neither Microengine can break a CDC transfer, due to the SDM arbitration mechanism described in SDM arbitration.

Atomicity is not guaranteed if microengine enters halt state in the middle of a back-to-back access (see Microengine Halt State): Host can access SDM while microengine is halted in the middle of a back-to-back access.

2.14.4.2.3 Microengine Side Multiple Atomicity

Hardware Semaphores must be used for Microengine-Microengine coherency (more than 1 parameter) since two or more accesses from one Microengine are not atomic with respect to the other.

For multiple Microengine-Host coherency, the software methods described in Multiple parameter coherency methods, or similar ones, must be used. Some of these methods rely on the fact that parameter access of a thread is atomic in relation to another thread in the same Engine, since a thread cannot be suspended (preempted).

For 1 parameter coherent access, or dual parameter coherency between only one Microengine and Host, the alternatives shown in previous sections apply.

2.14.4.3 Coherent Dual-parameter Controller (CDC)

Dual-parameter coherency is supported by a Coherent Dual-parameter Controller hardware (CDC), which contends with microengine for SDM access. CDC atomically transfers, upon Host's command, two parameters from one area of the SDM to another. One area is a temporary (buffer) area, where the two parameters are directly read or written by the Host. This temporary area has to begin in an SDM address multiple of 2 words, and the two parameters must be sequential. The other area is the channel parameter area where the microcode normally accesses the parameters, usually with the channel relative address mode (see SDM Addressing Modes). In this area, the parameters transferred by CDC don't have to be sequential. A transfer from the temporary area to the channel area, when the Host sends data to the channel, is called a **write transfer**. Inversely, in a **read transfer** the parameters are copied from the channel area to the temporary area (channel to Host).

Coherency is guaranteed by the SDM access contention rules implemented in the SDM arbiter (see SDM arbitration). CDC transfers are coherent in respect to the two Engines, so the target parameters in the channel area may be shared by channels on them both. During CDC operation, the Host may suffer from 3 up to 11 eTPU clocks wait states[16], and the Microengine(s) may suffer up to 2 microcycle wait-states[17]. CDC accesses are atomic with respect to Microengine(s) accesses to the SDM. Even when neither engine is in TST, CDC may suffer up to 4 eTPU clock internal wait-states from SDM arbiter, meaning 9 slave wait-states to Host, so that it does not break atomic back-to-back accesses from microengine(s). CDC also cannot break TST preload accesses. Host can initiate CDC back-to-back transfers: there is no need of idle slave cycles between two transfers.

16. The maximum number of Host wait states on CDC occurs when both microengines overlap their TSTs, delayed 3 eTPU clocks from each other.
17. One microcycle takes two eTPU clocks. Microengines get wait-states in multiples of microcycles, while Host and CDC wait-states are multiples of eTPU clocks.

Note

SDM memory error detection and correction does not affect the number of wait-states to host due to CDC (see Memory error support).

CDC can be used to atomically fix SDM soft errors. For more details, see Error fixing.

2.14.4.3.1 CDC programming

The Coherent Dual-parameter Controller Register (see eTPU Coherent Dual-Parameter Controller Register (eTPU_SCR_CDCR)) is used to configure and initiate CDC transfers between the temporary area and channel parameter area. Host asserts STS bit in order to start the data transfer. CDC then contends for the SDM and starts the transfer. When the data transfer is complete, STS returns to 0. Host receives wait-states for writing STS=1 while CDC contends for SDM and during the transfer. The write access ends when CDC finishes the transfer. Host receives wait-states during the CDC transfer. If Host writes eTPU Coherent Dual-Parameter Controller Register (eTPU_SCR_CDCR) with STS=0 or does not write the STS byte, the CDC transfer does not occur. CDC programming can be summarized as follows:

1. If it is a write transfer, i.e., from Host to channel, write the two parameters into temporary area.
2. Write STS =1 and the remaining CDC programming parameters: parameter width (32 or 24 bits, field PWIDTH), transfer direction (read or write, field WR), temporary parameter area base address (field PBBASE), and the absolute addresses of the parameters to be transferred (concatenation of the fields CTBASE and PARM0/1).
3. If it is a read transfer -- that is, from channel to host -- read the two parameters from the temporary area into Host memory/registers.

2.14.4.4 Hardware Semaphores

eTPU provides Hardware Semaphores accessible by the Microengine only. It is the responsibility of the application to ensure proper use of the semaphores (i.e., agree upon a specific semaphore and use it properly, to ensure coherency).

The eTPU microinstruction set has support for locking and freeing the semaphores, described in Semaphore Operations, and this is the only way to access them.

There are four semaphores available, which reduces the amount of collisions by assigning unrelated data transfers to different semaphores. Semaphores are used for parameters which can be shared by channels in different Engines, and for Engine-to-Engine synchronization. Semaphores are also the only way to ensure coherent access to parameters shared between the two Microengines.

Attempting to lock one semaphore (even not successfully) frees the other locked by the same Engine, ensuring one can lock just one semaphore at a time. That prevents deadlock conditions between the two Engines.

Microcode END command or Engine being in idle state (no thread executing) automatically releases all semaphores from one Engine side, even if a semaphore lock is done in parallel. However, it is recommended to write the microcode in a way which locks semaphores for the shortest required period, and frees them without waiting for the END command, to improve the performance of the other microengine. Semaphores are free after reset. An Engine can only free a sempaphore locked by itself.

Semaphore lock requests are always **non-blocking**, in the sense that they do not suspend the requester in case the semaphore is already locked. The semaphore status after the lock request - indicating if it was successfully locked or not - must be tested through the SMLCK microengine branch condition (see Branch conditions).

2.14.4.5 SDM arbitration

Up to four entities can access SDM:

- Two Microengines (in a dual eTPU Engine system)
- The Coherent Dual-parameter Controller (CDC)
- The Host CPU (direct memory-mapped access)

The following rules specify the access priorities for contended access. They keep compatibility with the TPU3 dual parameter access atomicity, but only between the microengine and CDC (not Host accesses through slave bus).

1. Microengine accesses from the two eTPU Engines are interleaved between each other, but not with Host or CDC accesses;
2. The eTPU microengine(s) gives priority for SDM accesses to either the Host CPU or the CDC under any of the following conditions:
    a. The microengine has completed accessing the second parameter in a back-to-back SDM access[18].

b. The SDM was not accessed during the last arbitration slot for the microengine and the host does not loose the access to the other engine in the current arbitration slot[19]

c. CDC is transferring data, after its first (read) access. Note that the CDC can be in middle of a data transfer of another pair of parameters, unrelated to the ones that microengine tries to access.

3. The eTPU microengine takes priority for SDM accesses under either of the following conditions:

a. the Host CPU or CDC has done a data transfer during the last access arbitration slot for the engine[19]. Also, the Host CPU does not hold a pending access against the other eTPU microengine.

b. the microengine is arbitrating for the access of its second parameter in a back-to-back access[1]. All pairs of back-to-back parameter accesses are coherent with respect to Host and CDC (not to the other microengine).

The direction (read or write) of any individual access by Host or microengine is irrelevant to the arbitration. The use of Normal or PSE SDM area by the Host is also irrelevant to the arbitration.

The first parameter preloading in a TST is considered first access by the arbiter, regardless of any access made at the END microinstruction of the previous thread, that is, the last access of a thread and the first preload are never considered a back-to-back access. On the other hand, the TST preload accesses are considered back-to-back and are, therefore, atomic with respect to Host or CDC.

Note

The Zero SDM operation (see Zero SDM Operation) is considered an SDM access for arbitration purposes both on writes and reads; the fact that read SDM data is discarded is irrelevant for arbitration.

18. If microengine tries to access the SDM in the following microcycles, the third and fourth consecutive accesses are considered the first and second of a new back-to-back dual access.

19. The microengine access slot is between its own T4 and T2 edges (see Microcycle and I/O timing).

2.14.5 Enhanced Channels

Enhanced Channels comprise hardware support for input digital signal processing and output signal generation. Each Channel is associated with one input and one output signal. Enhanced Channel logic is combined with Function microcode (and optionally Angle Mode logic) to implement Channel I/O functionality.

eTPU's Enhanced Channels are capable of **dual action**, meaning that each channel logic can handle two events at different times and/or cause two separated actions - these actions and events can be mutually dependent (with the first either blocking or enabling the other), or both independent, depending on the programmed **Channel Mode**.

Each Enhanced Channel contains event logic containing two **Event Register sets**, each set supporting one input and/or output action, the pair implementing dual action support. Each Event Register set contains two 24 bit registers: Match and Capture. The **Match register** holds the pending match value which is compared against one of the two time bases by an equal-only/greater-equal comparator. The **Capture register** captures one of the two time bases as a result of a Match or Transition detection. Service Requests are issued on particular combination of match and capture events, defined by the selected Channel Mode.

In the context of the eTPU channels, a **Match** is a comparison between a time base value and a channel Match register. If those two values are coincident, or the time base value is greater than the value of the Match register, a **Match Event occurs**. Depending on the channel mode of operation and current state of the channel logic, the match event may be recognized, i.e., change the state of the channel, or be ignored. A match event recognized by the channel logic is called a **Match Recognition**. Match Recognitions can cause, also depending on Channel Mode and current state, the channel to request service, configuring a **Match Service Request**.

eTPU uses two kinds of comparator to assert a Match Event: an **Equal comparator**, in which both the Match Register and the value of the selected time base must match exactly, and a **Greater-Equal comparator**. The Greater-Equal comparator considers any time base value between the range [N : N+0x800000-1] as a valid match against the value of N in the Match Register, even when the value N+0x800000-1 wraps around the point of origin (0x0). See the following figure for an illustration of the matching values on a Greater-Equal comparator.

The second source of events for the eTPU channel is a **Transition** detected at the corresponding channel's input signal. Two distinct Transition detections can be programmed individually for each channel, allowing recognition of all possible combinations of edge detection. It is also possible to check the sampled state of an input

signal upon the occurrence of a Match: the sampling of the expected value is treated as a Transition, even if the input signal did not necessarily toggled at the time of the Match, or at any time at all.

Like Match Events, **Transitions Events** may or not be recognized by the channel logic. When they are, a **Transition Detection** occurs. As well as Match Recognitions, Transition Detections can issue a Channel Service Request, depending on Channel Mode and current state.

Transition Detections and Match Recognitions are sometimes simply called Transitions and Matches throughout this document, for short.

Input and output signals can be processed separately by the channel logic and microcode, and can also be combined such that Matches and Transitions are used to cause **output signal actions**. The output signals can also be directly controlled by microcode. Many event combinations are allowed for a channel, given the possibility of configuring pairs of matches and transitions for the dual action logic, where each event is able to block or enable the next one. There is a full set of Channel Modes described in Channel Modes, exploring all the capabilities mentioned here.

Each channel has its own set of registers and flags. They are selected, and made accessible to the Microengine, according to the value written into the microengine **CHAN Register** that points to the desired channel . Every time the CHAN register is written, even if with the same previous value, a channel is selected and its flags and registers are updated. For further detail, see the Channel Selection Register-CHAN topic in the General Channel Registers section .

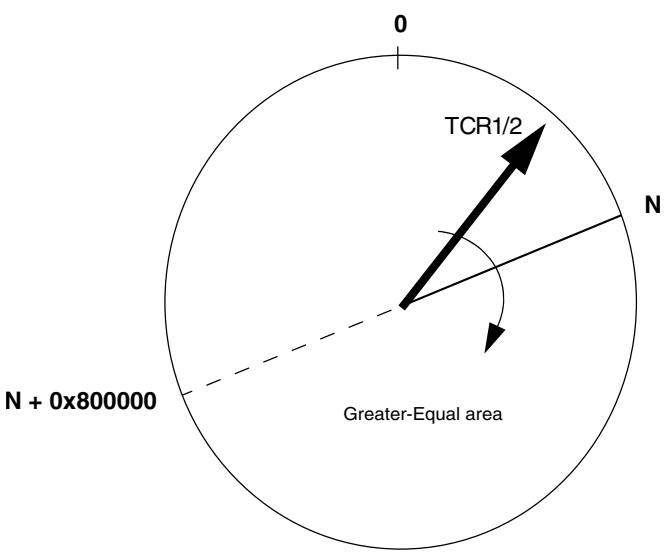

Figure 2-15. Greater-Equal Comparator

Beyond the request of services due to the signal and timing internal to each channel, one eTPU channel microcode can explicitly request service from another channel through the microengine **LINK Register**. A microcode write to the LINK Register asserts a service request to the channel whose number matches the contents of LINK. See Channel Link for a complete description of this mechanism.

These service requests originated in the eTPU Enhanced Channels (either time base match, input signal transition, or link service request) result in a call to the corresponding channel service routine, which is the sequence of microinstructions that is called a **Thread**. For further detail, see Functions and threads.

In addition to Event Logic, each Channel has an Output Buffer Enable signal, controlled by microcode, and an Enhanced Digital Filter, which eliminates spurious glitches on input pin signal. See the chip-specific eTPU information for how the Output Buffer Enable signal is controlled.

A high level diagram of Channel logic and registers is shown in the following figure.

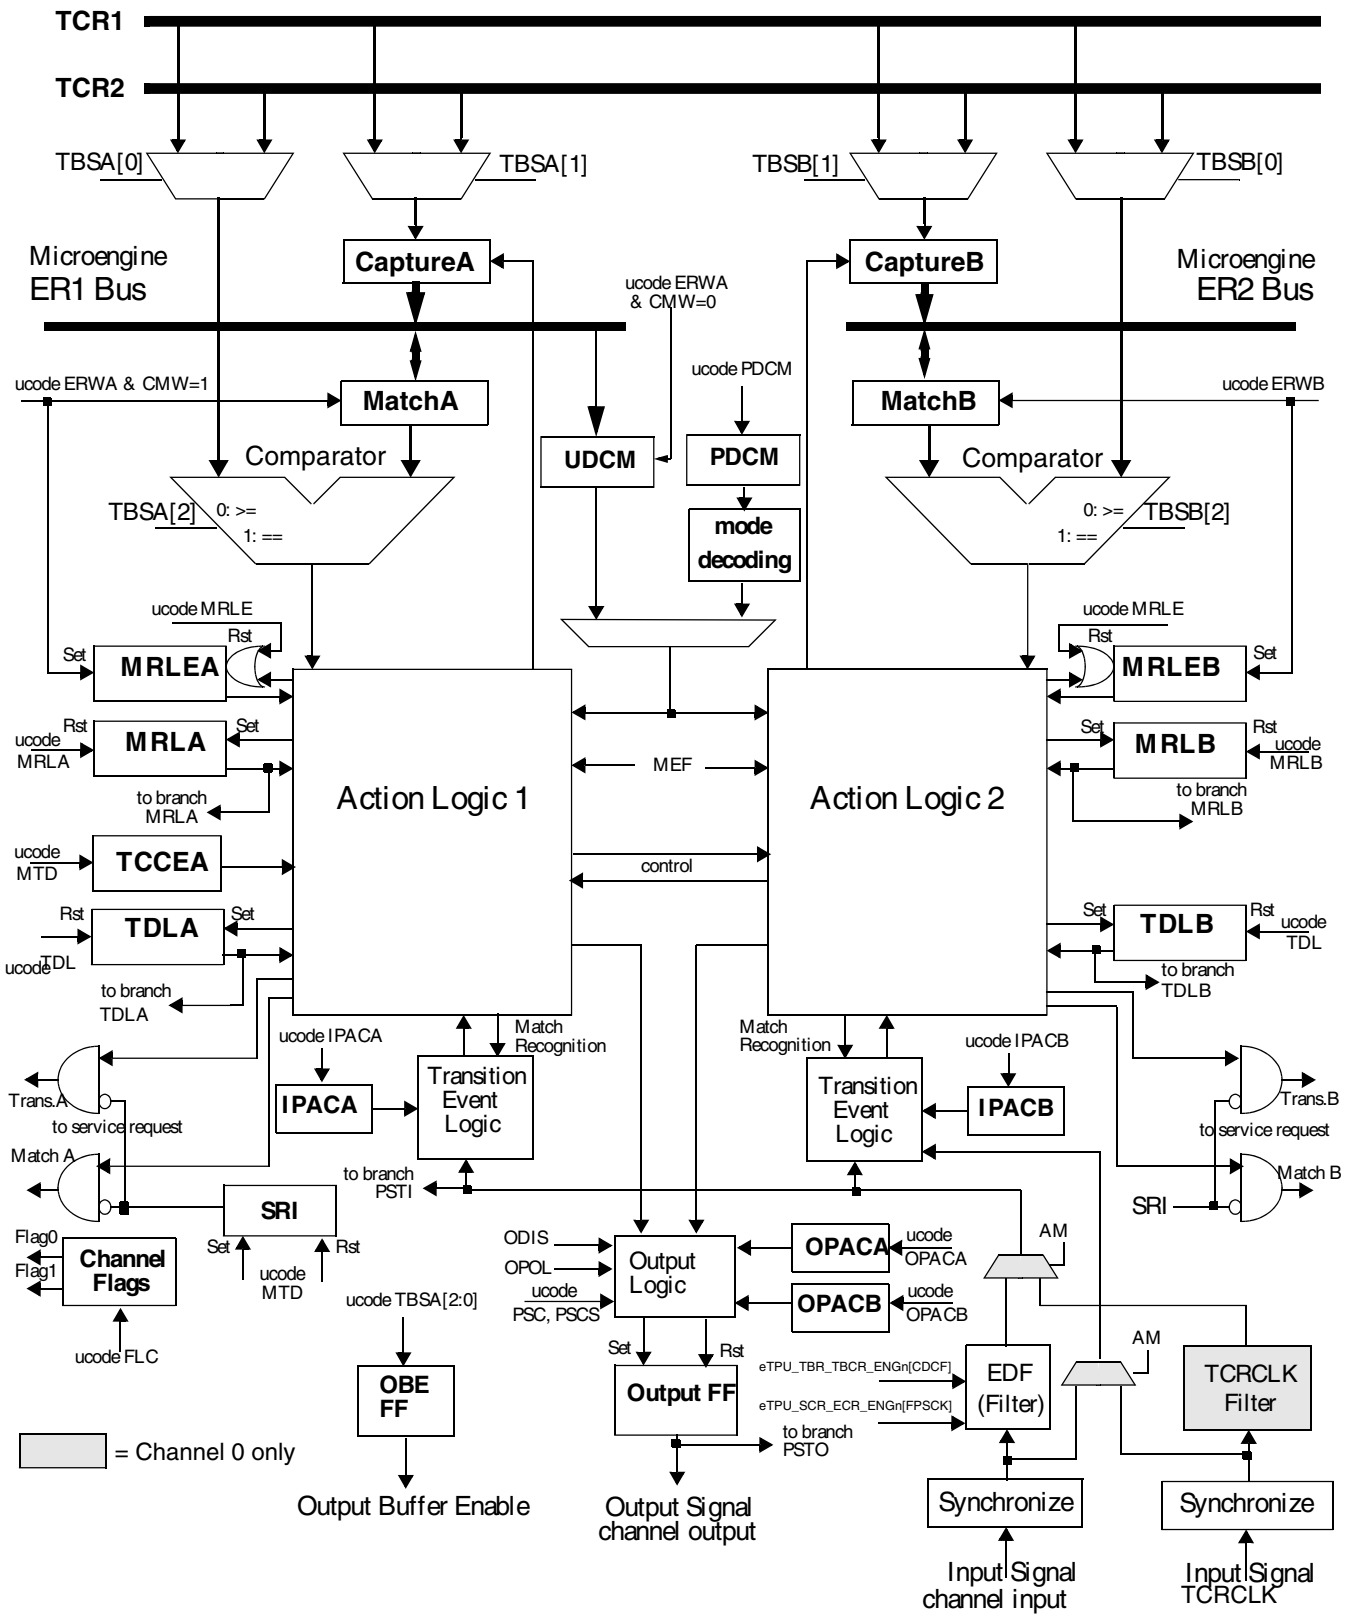

Figure 2-16. Channel logic block diagram

2.14.5.1 Channel registers and flags

Channel configuration and control registers can be divided in the following groups:

- **Host Configuration and Control registers**, which define channel Function and parameter allocation in SDM, input signal filtering, manage Host interrupts, and are used for Host Service Requests; they can only be accessed by Host, except for the Function Mode bits which can be also tested by microcode.
- **Event Registers**, which can only be accessed by eTPU Microengine, through dedicated Channel Control microinstruction operations (see Channel Control and Configuration Microoperations); these registers are directly used to implement channel functionality, and include channel event status latches which can be directly tested by Microengine branch instructions.
- **Pin Control registers**, which basically define pin state and transition polarity (but not input signal filtering); they are accessible only by dedicated Channel Control microinstruction operations.
- **Link registers**, which implement the channel link mechanism that allows one channel to request service to another one; they are accessible only by microinstruction operations.
- **General Channel registers**: CHAN, SRI, Flag0/1, PDCM, UDCM.

Most of those registers are channel exclusive, i.e., there is one copy of them for each channel. Microcode can access registers from only one channel at a time. The Channel Selection (CHAN) register (see Channel Selection Register - CHAN), accessible only by microcode, defines the channel whose registers are being accessed, with exception of link register and function mode. CHAN register assumes the value of the channel to be serviced at the beginning of TST.

The Service Request Inhibit - SRI - register controls the generation of Service Requests on matches and transitions, also affecting channel logic behavior. For a full description see SRI - Match/Transition Service Request Inhibit Latch. Flag0/1 are used to select channel service threads based on channel software state. See Flag1,Flag0 - Channel "state resolution" flags for more details.

Host Configuration and Control registers are described in Channel Configuration Control memory map and registers.

Time Base configuration is common to all channels, and described in Time bases. Time Base selection for matches and captures, however, is individual to each channel, and is part of the Event Registers.

Link registers are described in Channel Link.

The following sections describe the Event Registers and Pin Control registers.

2.14.5.1.1 ER - Event Registers

Each channel contains two identical Event Register sets, named ERA and ERB, corresponding to the two actions supported. Each Event Register set contains:

- a 24-bit Match register (Match A or Match B), which holds a match value. This value is compared against the selected match time base (TCR1 or TCR2).
- a 24-bit Capture register (CaptureA or CaptureB), which samples the selected capture time base (TCR1 or TCR2)
- a Time Base Selection register (TBSA or TBSB)
- a Match Recognition status flag (or latch) (MRLA or MRLB)
- a Match Recognition Enable latch (MRLEA or MRLEB)
- a Transition Detection flag (or latch) (TDLA or TDLB)
- a Transition Continuous Capture enable (TCCEA only)

ERA and ERB are associated with the first and second events in double action modes, not necessarily in that order. The order of Match events associated with ERA and ERB depends on the programmed channel mode, the MatchA and MatchB values, and the timebases selected by TBSA and TBSB. Similarly, the order of Transition events associated with ERA and ERB depends on the programmed channel mode, and the transition detection selected by IPACA and IPACB.

These registers are directly or indirectly accessed by the microcode. TBSA and TBSB registers are defined in TBSA and TBSB - Time Base Selection Registers. The other registers are explained in Match Recognition and Transition detection and Time Base Capture.

Access to the Event Registers is qualified by the channel currently selected by the microengine (i.e., the channel value currently in the CHAN register). During the channel transition period (automatic CHAN assignment), or whenever CHAN is written by microcode, Capture values of the new selected channel are sampled into Microengine registers ERTA and ERTB, therefore becoming visible to the microcode. At the same time, updated values of MRLA, MRLB, TDLA and TDLB are sampled into the branch logic, making the register values and the flags coherent with respect to each other and with the thread selected by the Scheduler. [20]

20. The thread selected is determined by the Entry Point which, in turn, is determined partially by the channel latches. See Entry Point address generation.

Note

The Function Mode bits are also sampled from the Host interface on Time Slot Transition, so that they remain constant to microengine even when Host changes them.

During service, the microcode can access updated values of the Event Registers of any channel by writing the channel number to CHAN. Writing CHAN with the same value (CHAN := CHAN) updates ERTA and ERTB with the new captured values, the branch logic with updated MRLA/B and TDLA/B flags. Writing CHAN with a different value does the same with the values from the newly selected channel.

Match values are also accessed through ERTA and ERTB Microengine registers, which are copied to/from the channel MatchA and MatchB registers by specific microinstruction operations.

Microcode writes to the flags and selections (MRLA/B, TDLA/B and TBSA/B) are immediately effective to the channel. The MRLA/B and TDLA/B branch conditions are also immediately reset when their correspondent flags are reset by microcode. Match registers are indirectly written by microcode through ERTA/B. MRLEA/B is unconditionally asserted when respective Match register is updated from ERTA/B, and its negation is immediate.

The following table summarizes Event Registers accesses.

Table 2-29. Event Registers microcode accesses

Register	Access type	Sampled from channel	Update to channel	Microcode fields[1]	Reset value[2]
CaptureA, CaptureB	read through ERTA/B	to ERTA/B on CHAN assignment	no	T2ABD	n.a.
MatchA, MatchB	read and write through ERTA/B	to ERTA/B by microcode	from ERTA/B by microcode	ERWA, CMW, ERWB, T4ABS	n.a.
MRLEA, MRLEB	write to 0 (negate) directly; write to 1 (assert) upon MatchA/B update from ERTA/B	no	immediate	MRLE, ERWA, ERWB	0, 0
TBSA, TBSB	write only	no	immediate	TBSA, TBSB	000, 000
MRLA, MRLB	flag test on branch, write to 0 (negate) only	on CHAN assignment	immediate	BCC (test) MRLA, MRLB (reset)	0, 0
TDLA, TDLB	flag test on branch, write to 0 (negate) only	on CHAN assignment	immediate	BCC (test) TDL (reset)	0, 0
TCCEA	write only	no	immediate	MTD	0

1. See Microinstruction Set.
2. n.a. means that value of the register is undetermined after reset.

2.14.5.1.1.1 MatchA and MatchB Registers

MatchA and MatchB registers hold a match value to be compared against the selected channel time base. A match value can only be written into the Match register by microcode, through ERTA/B microengine registers (see Write Channel Match and UDCM Registers). Microcode can also read the Match register as a special T4ABS source operation, when T4ABS=0101, and the source for T4ABS is selected from the second register set. In this operation, MatchA/B registers are copied into ERTA/B registers (see Selecting sources and destination). For more information on time base matches, see Match Recognition.

2.14.5.1.1.2 CaptureA and CaptureB Registers

CaptureA and CaptureB registers capture the selected channel time base. CaptureA/B registers cannot be directly written or read by microcode. During the Time Slot Transition (TST) or during CHAN assignment, CaptureA/B registers are copied into ERTA/B microengine registers. For more information, see Transition detection and Time Base Capture.

2.14.5.1.1.3 TBSA and TBSB - Time Base Selection Registers

TBSA/B are 3-bit registers which have the following effect on channel configuration:

- Selection of the timebase (TCR1 or TCR2) to be compared against the match values in MatchA and/or MatchB registers.
- Selection of the timebase (TCR1 or TCR2) to be captured in the CaptureA and/or CaptureB registers by a match or transition detection event.
- Selection of comparator mode to be used with MatchA and MatchB registers: equal-only or greater-equal.

After reset TBSA/B are 000. The following table shows values of TBSA and TBSB for configuration selection. Note that the time base selection for capture is independent of the time base selected for matches.

Table 2-30. TBSA/B Programming States

TBS bit	2	1	0
bit value	Comparator selection	Capture time base selection	Match time base selection
0	greater or equal	TCR1	TCR1
1	equal-only	TCR2	TCR2

TBSA/B are written through the microcode fields TBSA/B (see Comparator and Time Base Selection). Note that microcode field TBSA is also used to control the OBE pin control register (see Pin Control Registers), which is separate from the TBSA register.

2.14.5.1.1.4 MRLA/B - Match Recognition Latches

See MRLA/B - Match Recognition Latches.

2.14.5.1.1.5 MRLEA/B - Match Recognition Latch Enable

See MRLEA/B - Match Recognition Latch Enable.

2.14.5.1.1.6 TDLA/B - Transition Detection Latch

See TDLA/B - Transition Detect Latches.

2.14.5.1.1.7 TCCEA - Transition Continuous Capture Enable

See TCCEA - Transition Continuous Capture Enable.

2.14.5.1.2 Pin Control Registers

Pin Control Registers are replicated one per channel, accessed only by microcode and qualified by the CHAN register in the same way as Event Registers.

The following table lists Pin Control Registers, explained in following subsections, and their accesses.

Table 2-31. Pin Control Registers microcode accesses

Register	Access type	Sampled from channel	Update to channel	Microcode fields[1]	Reset value
IPACA, IPACB	write only	no	immediate	IPACA, IPACB	000,000
OPACA, OPACB	write only	no	immediate	OPACA, OPACB	000,000
PSTI	flag test on branch	no	no	BCC	0

Table continues on the next page...

Table 2-31. Pin Control Registers microcode accesses (continued)

Register	Access type	Sampled from channel	Update to channel	Microcode fields[1]	Reset value
PSTO	flag test on branch, write	no	immediate	BCC (test) PSC, PSCS (set)	0
OBE[2]	write only	no	immediate	TBSA values 1000,1001	0 (negated)
PSS	flag test on branch	on CHAN assignment	no	BCC	n.a.[3]
PRSS	flag test on branch	on CHAN assignment	no	BCC	n.a.[4]

1. See Microinstruction Set.
2. Although this register exists for code compatibility reasons, OBE functionality is not available on this chip.
3. PSS is PSTI or PSTO sampled on CHAN assignments and at thread start.
4. PRSS is PSTI sampled on channel service request.

2.14.5.1.2.1 IPACA/B and OPACA/B - Input and Output Pin Action Control Registers

These registers determine the transition detections and output pin actions which takes place due to match or transition events. Each field is three bit wide. After reset, the IPACA/B and OPACA/B registers are set to 000. IPACA and IPACB registers are mutually independent and have identical encoding, and so do OPACA and OPACB. The table below shows IPAC and OPAC encoding. Note that transition detections are independent from the output actions, but some options of output actions are triggered by transition detections. Output actions can also be triggered by Matches. For a detailed definition of Transition Detections, see Transition detection and Time Base Capture.

IPACA/B define the Transition events treated by channel logic. Although the name "transition" is generically used for the transition detections, IPAC options 100 and 101 do not really detect transitions: they actually sample the state of the input signal at the occurrence of the corresponding Match (Match A used for IPACA, Match B used for IPACB).

Table 2-32. IPACA/B and OPACA/B Encoding

Value	IPAC meaning	OPAC meaning
000	Do not detect transitions	Do not change output signal
001	Detect rising edge only	Match[1] sets output signal high
010	Detect falling edge only	Match[1] sets output signal low
011	Detect either edge	Match[1] toggles output signal
100	Detect input signal = 0 on Match[1]	Transition sets output signal low
101	Detect input signal = 1 on Match[1]	Transition detection sets output signal high

Table continues on the next page...

Table 2-32. IPACA/B and OPACA/B Encoding (continued)

Value	IPAC meaning	OPAC meaning
110	reserved	Transition detection toggles output signal
111	n.a.[2]	n.a.[2]

1. Match A is used for IPACA/OPACA, and Match B for IPACB/OPACB.
2. On the microinstruction fields IPACA/B and OPACA/B this value is neutral, meaning that IPAC/OPAC register values are not changed.

2.14.5.1.2.2 Output Pin Control Logic and Pin State Output Register - PSTO

The output signal control logic uses OPACA/B, the Pre-defined Channel Mode (PDCM) and the User Defined Channel Mode (UDCM), and the microcode Pin State Control (PSC and PSCS) fields. It is responsible for setting the Pin State Output (PSTO) register to the specified logic value required by microcode, by input events, or by Match A and/or Match B events. The PSTO register stores the driven pin state determined by the Pin Control logic. The Output Buffer Enable signal, if used at MCU integration, must be set by microcode (using TBSA field) to make the pad propagate the PSTO register output to the actual pin.

PSTO register output also goes to the microengine branch logic, enabling branching on the driven pin state. PSTO is set to 0 on reset.

The PSC and PSCS microcode fields are used for setting the PSTO register to a fixed value, or to the value specified by the OPACA or OPACB microcode field, as shown in the following table.

Table 2-33. PSC and PSCS encoding

PSC	Output pin action
00	Force pin state according to OPACA (PSCS=0) or OPACB (PSCS=1).
01	Force pin high.
10	Force pin low.
11	Do not change pin state.

See Channel Control and Configuration Microoperations for details.

On occurrence of match recognitions or transition detections, the pin control logic sets PSTO value according to the event number (Match A/Transition A or Match B/Transition B) and the contents of OPACA/IPACA or OPACB/IPACB registers. There are cases in which two match or transition events may occur at the same time, each of them trying to force a different pin action. The resolution of the selected match event which sets the

value depends on the Pre-defined Channel Mode (PDCM) register and the User Defined Channel Mode (UDCM). For details refer to Match/Transition Pin Action Conflict Resolution.

2.14.5.1.2.3 PSTI and PSS - Pin State Input and Pin Sampled State Registers

During the time slot transition period, or whenever the CHAN register is written by microcode, the filtered[21] input signal PSTI or output signal PSTO (selected by the ETPD field in eTPU Channel n Configuration Register for Engine 1 (eTPU_CCCR_C*n*CR_ENG1) and eTPU Channel n Configuration Register for Engine 2 (eTPU_CCCR_C*n*CR_ENG2)) is sampled into the branch logic as the PSS flag (see Table 2-100). The microcode can then branch on either the currently driven (PSTO) or input (PSTI) pin state, or on sampled pin state (PSS, which is stable as long as CHAN does not change).

Note

If a transition occurs simultaneously (after the filter) with the CHAN assignment, PSS samples the new pin value. Therefore, if TDLA/B is cleared simultaneously with the assignment CHAN := CHAN, the occurrence of a transition at this very moment can still be tested with PSS.

2.14.5.1.2.4 PRSS - Pin Request Service Sample

Channel logic can, depending on its state and programmed mode, request service to the eTPU microengine (see Functions and threads). When the channel logic issues a service request, the filtered input signal PSTI is sampled into an internal channel flag PRSS. There is one such PRSS flag for each channel (see Pin Control registers). Channel PRSS keeps its value until all its service request sources are cleared and until a new channel service request rises.

Note

Only channel service requests update PRSS: it is updated neither by host service requests (HSRs) nor by link service requests. Moreover, a channel service request updates PRSS even if the channel is disabled (its CPR set to 0, see (xref to eTPU Channel n Configuration Register for Engine 1 (eTPU_CCCR_C*n*CR_ENG1) and eTPU Channel n Configuration Register for Engine 2 (eTPU_CCCR_C*n*CR_ENG2)).

21. The filter can be bypassed.

The channel PRSS flag is sampled into the branch logic as the PRSS flag (see Table 2-100) during the time slot transition period, or whenever the CHAN register is written by microcode.

2.14.5.1.3 General Channel registers

These registers control other aspects of channel logic. Except for CHAN, they are unique per channel. The following table summarizes the registers and access options.

Table 2-34. General Channel registers microcode access

Register	Access type	Sampled from channel	Update to channel	Microcode fields[1]	Reset value
CHAN	read/write	n.a.[2]	n.a.[2]	T4ABS, T4BBS, T2ABD	defaults to serviced channel at thread start
PDCM	write only	no	immediate	PDCM	1100 (sm_st)
UDCM	write only	no	from ERTA by microcode	CMW, ERWA	parameter value defined at integration
SRI	write only	no	immediate	MTD	1
Flag1, Flag0	branch flag test, write	no	immediate	BCC,FLC	0, 0

1. See Microinstruction Set.
2. CHAN is common to all channels in the Engine.

2.14.5.1.3.1 Channel Selection Register - CHAN

CHAN is the register that holds the number of the channel that qualifies the context of most Channel Registers, including Pin Control and ER accesses, and is common to all channels in a same Engine.

When a thread starts to be executed, the contents of CHAN register is automatically updated on Time Slot transition to the number of the channel to be serviced. Serviced channel is constant during channel servicing, but the selected channel can be changed any time by microengine writing into CHAN register.

Some microinstructions are affected by the serviced channel instead of CHAN. These are:

- Conditional branch using LSR (see LINK Register) or Function Mode (see eTPU Channel n Status Control Register for Engine 1 (eTPU_CCCR_C*n*SCR_ENG1) and eTPU Channel n Status Control Register for Engine 2 (eTPU_CCCR_C*n*SCR_ENG2)).
- Negate channel flag LSR, Interrupt CPU and Data Transfer Request (see Channel Interrupt and Data Transfer Requests).

When CHAN register is written, accesses are qualified by the new CHAN register value from the instruction following CHAN assignment on, except CaptureA/B sampling into ERTA/B and Match register writing from ERTA/B (see CHAN assignment, Read Match and ERWA/B).

Writing CHAN (including with the same value, CHAN:= CHAN) updates ERTA and ERTB with the new captured values, the branch logic with updated MRLA/B and TDLA/B flags.

The following table shows the commands, flags and registers selected by the CHAN register value.

Table 2-35. CHAN-selected features

Feature used	Selected by CHAN
Channel-relative SDM access	YES
Branch using PSS, PRSS, PSTI and PSTO channel flags	YES
Branch using MRLA/B, TDLA/B, Flag0/1[1]	YES
Branch on all other conditions[2]	no
ERTA/B Value	YES
Configure (selected) channel	YES
Channel commands applied to: MRLA/B, TDLA/B, TBSA/B, IPACA/B,OPACA/B, PSC, PSCS, OBE, PDCM, MRLE, Flag0/1	YES
Channel command: set/reset SRI	YES
Channel command: write to Match registers (ERWA/B)	YES[3]
Channel command: read Match registers into ERTA/B	YES
Clear LSR	no
Channel interrupts and data transfer requests (CIRC)	optionally

1. In TPU, these conditions retained the old values.
2. See Branch Operations
3. If write Match (ERWA/B) occurs at the same time of a CHAN assignment, the channel which is target of the write is the one selected by the new CHAN value. See CHAN assignment, Read Match and ERWA/B.

2.14.5.1.3.2 PDCM - Predefined Channel Mode

PDCM determines the channel mode assigned to the channel. Channel mode defines much of the channel logic behavior, specially how matches blocks and enables transitions and vice-versa, as well as occurrence of time base captures and service requests based on matches and transitions. For a complete description see Channel Modes.

PDCM is a 4-bit register set by the microcode field of the same name (see Predefined Channel Modes), and cannot be read or tested in branch instructions. The table below relates the PDCM value with channel modes. The second column specifies the mnemonic used to reference the mode, introduced in Channel Modes Overview . There is one PDCM for each channel, initialized with 1100 on reset.

PDCM is also used to select the User Programmable Channel Mode. If this selection is made, the channel behavior is defined by the settings of the UDCM register (see UDCM - User Defined Channel Mode).

Table 2-36. PDCM encoding

PDCM	Channel mode
0000	em_b_st
0001	em_b_dt
0010	em_nb_st
0011	em_nb_dt
0100	m2_st
0101	m2_dt
0110	bm_st
0111	bm_dt
1000	m2_o_st
1001	m2_o_dt
1010	User Defined Channel Mode
1011	reserved
1100	sm_st[1]
1101	sm_dt
1110	sm_st_e
1111	n.a.[2]

1. This is the reset value, also compatible with TPU channel behavior.
2. This value is used as a neutral (do not change) value in the PDCM microinstruction field.

2.14.5.1.3.3 UDCM - User Defined Channel Mode

UDCM holds the control signals that define the channel logic behavior in terms of Match and Transition blocking and enabling, captures and service requests triggered by events. The register layout is defined in the figure below. The individual fields are defined in Channel Mode Logic and Event Flags. There is one UDCM register for each channel, which can be independently programmed.

UDCM can only be written into the Match register by microcode, through ERTA/B microengine registers (see Write Channel Match and UDCM Registers).

13	12	11	10	9	8	7	6	5	4	3	2	1	0
MSR		MCAP	M1ET	M1EM2	M1BM2	M2BM1	M2BT	T1BM1	T2BM1	TBM2	T1ET2	TSR	TCAP

Figure 2-17. UDCM Register

2.14.5.1.3.4 SRI - Match/Transition Service Request Inhibit Latch

SRI blocks channel service requests due to the assertion of MRLA/B and/or TDLA/B. SRI does not affect recognition of Link Service Requests or Host Service Requests, neither MRLA/B or TDLA/B microcode branch tests nor Entry Table selection[22] . SRI is asserted during reset and is controlled by microcode field MTD.

To unburden the microengine, SRI asserted configures a channel "dumb" regarding the servicing of match and capture channel service requests. Even with SRI=1, TDLA/B and MRLA/B can still be asserted, and the level specified by the OPAC (Output Pin Action Control) registers will be output to the pin.

2.14.5.1.3.5 Flag1,Flag0 - Channel "state resolution" flags

Each channel has a pair of flags, simply called Flag0 and Flag1, that can be set/reset by microcode through microinstruction field FLC. FLC sets/resets Flag0/1 of the channel selected by CHAN. These flags can be tested by microcode, and are also used to resolve the microcode entry point for the channel service (see Entry Points"). Flag0 and Flag1 are, so, typically used for fast state resolution. FLC microinstruction field also allows Flag1,Flag0 to be copied from selected bits of P register high byte, which is also meant to be used to hold application state. Flag0 and Flag1 are both zero out of reset.

22. In TPU, SRI also blocked TDL and MDL branches and enabled any transition to capture time base.

2.14.5.2 Match Recognition

The match operation is performed every microcycle by comparing the channel MatchA and MatchB registers against the value of the TCR bus specified for each match. TCR1 or TCR2 bus is selected according to TBSA and TBSB fields. Both results have effect on the next clock cycle (see Microcycle and I/O timing).

A Match A/B event is qualified by a set of match enabling conditions to the Match Recognition Registers MRLA/B. To recognize the match, the following match enabling conditions are required:

- For IPACA/B=0xx, Match Enable Flag (MEF), qualified by the channel currently being serviced must be asserted. For IPACA/B =1xx, Match A/B is always enabled (even during Time Slot Transition - TST), regardless the state of the Match Enable Flag (MEF). See MEF - Match Enable Flag for the conditions of MEF assertion.
- Match Recognition Latch Enable 1/2 (MRLEA/B) is asserted. A match event recognition may only occur if its corresponding MRLEA/B bit is set, which only happens upon a write to a channel match register by the microcode, copied from ERTA/B. MRLEA/B is negated when the respective match occurs or, in some double match channel modes, when a match for the other Match register occurs. It ensures that the greater-equal comparison will not cause additional matches[23] .
- In selected modes (see Channel Modes), the particular conditions of MRL and TDL flags of the other event, i.e:
  - MRLA, TDLA enable or block MRLB;
  - MRLB, TDLB enable or block MRLA.
- The respective MRL is negated.
- In selected modes (see Channel Modes), the state of its respective TDL flag.

If the Match A and/or Match B conditions are met, the channel immediately forces the pin state if specified by the appropriate OPACA/B registers (Output Pin Action Control 1/2) and, in some cases, by IPACA/B registers. Refer to IPACA/B and OPACA/B - Input and Output Pin Action Control Registers.

If both Match A and Match B events occur at the same time, with conflicting pin actions, the priority over the pin action is mode dependent. For further details on pin action resolution refer to Match/Transition Pin Action Conflict Resolution.

23. Microcode can also negate MRLEA/B.

2.14.5.2.1 MRLA/B - Match Recognition Latches

MRLA/B indicate the recognition of a match event detected by the comparator. They can be asserted either on T2 or T4 (see Microcycle and I/O timing). Assertion of MRLA/B issues a match Service Request in specific channel modes, depending on previous events and state of SRI. After reset MRLA and MRLB are both negated.

When MRLA or MRLB is asserted, it may change the output signal level according to the Input and Output Pin Action Control registers (refer to IPACA/B and OPACA/B - Input and Output Pin Action Control Registers). Assertion of MRLA/B causes a capture of one or two time bases, according to the selected mode capturing scheme (see Transition detection and Time Base Capture)

A match recognition is self-blocking, regardless of Channel Mode: once MRLA (MRLB) has been asserted, it negates its associated MRLEA (MRLEB) register, preventing future match recognitions, until the associated match register is rewritten by microcode. The microcode has to enable new matches by updating the new match value in the MatchA (MatchB) register[24] . In addition, assertion of MRLA/B can block its twin MRLB/A, depending on the channel mode. In some double match blocking channel modes, Match A/B event blocks the occurrence of Match B/A in a "first win" scheme.

It is the transition from 0 to 1 in MRL that causes the Match actions, except the service request: apart from MRLEA/B negation(s) and service request, no action due to a Match occurs if MRL was already set to 1, even if the other MRL assert conditions are satisfied. However, if a Match and a microoperation negating its corresponding MRL occur at the same time, MRL negation by microcode overrides its assertion, but any dependable captures and pin action occurs anyway (if MRL was already negated before), and also the negation of MRLE(s) (the respective one and, in some channel modes, the other, regardless of MRL state before). Note that MRLE must have been set before (by writing a new Match value).

2.14.5.2.2 MEF - Match Enable Flag

MEF is a one-bit latch that is unique for all channels in an Engine.

MEF can selectively enable assertion of MRLA/B, depending on the IPACA/B field. For IPACA/B=0xx, MEF=1 enables assertion of MRLA/B for the scheduled channel during service. For IPACA/B=1xx, Match A/B is always enabled, regardless the state of the MEF, but it still depends on the other Match recognition conditions. Matches of channels not being serviced are never disabled by MEF.

24. Before that, microcode should also negate MRLA (MRLB), otherwise an old match may be recognized by the scheduler and serviced as a new one

MEF is not accessible by Microengine or Host. MEF is negated for two microcycles in the beginning of the time slot transition period. After two microcycles (plus wait-states) into TST, the ME bit in the entry point is copied to MEF to allow selective enabling of MRL for each thread (refer to Time Slot Transition). MEF is asserted unconditionally soon after a thread ends.

If a channel service needs to postpone a programmed match, MEF assures that microcode wins the race against match event after time slot transition (only for IPAC=0xx).

Note that a match event may be lost during the periods when MEF is negated only if:

- the match comparator is configured for "equal-only" behavior, and
- IPACA/B=0xx, and
- TCR increments at the rate of eTPU clock divided by 2 or faster.

When the comparator is configured as "greater-equal", the match event that occurred when MEF was negated may be recognized after MEF is asserted again, due to the "greater than" condition.

2.14.5.2.3 MRLEA/B - Match Recognition Latch Enable

MRLEA/B is negated upon the assertion of its respective MRLA/B. In blocking match channel modes it may also be negated together with the assertion of the twin MRLB/A. The MRLEA/B bits ensure that data captured due to the first match event will not be overwritten when MRLA/B is negated: due to greater-equal comparison, the match condition continues to be true, but should not cause another capture event.

In addition to negation by local match event, the microcode can negate both MRLEA and MRLEB, to block pending matches, and also MRLA/B, individually. This action will prevent future match events from the selected channel.

Writing the MatchA/B registers by microcode to schedule the next match values sets MRLEA and/or MRLEB and enables new matches. This setting overrides the MRLE negation conditions due to channel logic or microcode (see Channel Modes). By combining write to Match A/B with MRLEA/B negation microinstructions, the microcode can negate one MRLE while asserting the other.

Note

If the MRLE negation conditions continue after writing MatchA/B registers, the respective MRLE does not keep asserted. For instance, if MRL=1 and a match is programmed for a time value in the past during a thread with ME=1, then

MRLE will be cleared soon after MatchA/B is written, even though a match does not occur (because MRL was already asserted, neither captures nor pin toggles occur).

When the match register is updated (with MRLE already asserted before) and field MRLA/B = 1 (no clear, see Clear Transition/Match Event Registers) and MRLA/B flag is zero, the eTPU behaves exactly as the TPU, that is: a match that comes concurrently with the rewrite of the match register, matching the old value, sets the MRL, as if the setting of the MRLE due to match register write had precedence over its clear by the match at that moment. After this simultaneous operation, the MRLE value stays at 1, and the captured time base value, if any, reflects the match value.

When the match register is updated (with MRLE already asserted before) and field MRLA/B = 0 (clear MRL, see Clear Transition/Match Event Registers) and MRLA/B flag is zero, the match captures will occur, the MRLA/B flag will keep negated, and MRLE will stay asserted. Special care must be taken when a match is reprogrammed on a channel running at T2/T4 timing, please see the details in the “T2/T4 Channel Timing” section.

2.14.5.3 Transition detection and Time Base Capture

Time Base Capture(s) occur when the value of a specified TCR is sampled into the CaptureA and/or CaptureB register. TBSA[1] and TBSB[1] select which TCR will be captured in CaptureA and CaptureB, respectively.

A capture event may occur due to either of the following events:

- The assertion condition of Match Recognition Latch (MRL), even if MRL is simultaneously negated by microcode
- The assertion condition of Transition Detection Latch (TDL), even if TDL is simultaneously negated by microcode.
- Any Transition Event specified by IPACA if both the Transition Detection Latch TDLA and Transition Continuous Capture Enable TCCEA are asserted.

A capture event occurs together with the assertion of MRL or TDL either on T2 or T4 positive edges, and captures the time-base value that caused the match, even if TCR1/2 increments concurrently with the assertion (see Microcycle and I/O timing)[25] . MRLA/B and TDLA may, depending on the channel mode, inhibit the capture of the second event's TCR into CaptureA/B. As a general rule, values captured by signal transitions are not overwritten by values captured by match events.

25. In TPU3, when TCR1 was counting at maximum rate of eTPU clock divided by 2, the next value was captured.

When the enable bit TCCEA is asserted, captures due to Transition Events also occur after TDLA is asserted. Those captures happen on transition events specified by IPACA, and the TCR value is saved into CaptureA register only.

The capturing scheme is defined by the Channel Mode programmed at register PDCM, or at register UDCM when User Defined Channel Mode is selected . For more information on mode-dependent capture schemes refer to Channel Modes.

2.14.5.3.1 TDLA/B - Transition Detect Latches

TDLA/B indicate detection of specific transition occurrences on a channel input signal. TDLA and TDLB assertion causes service request in single and double transition predefined modes, respectively. TDLB assertion does not cause Service Request in single transition predefined modes, and TDLA assertion does not cause Service request in double transition predefined modes. In single transition channel predefined modes TDLB can be asserted on the second transition, but does not generate Service Request. Yet on predefined modes, TDLB assertion is enabled only if TDLA is asserted to detect an ordered input signal double transition. All the restrictions above, however, may be overridden by using the User Defined Channel Mode. The IPACA and IPACB registers indicate the programmed edges of the first and second detected transition, respectively.

The sampling of a determined value (0 or 1) on the input signal due the occurrence of a Match is also treated as a "transition", depending on IPACA/B programming (see IPACA/B and OPACA/B - Input and Output Pin Action Control Registers). When using a channel mode where the transition1 is initially blocked and IPACA is programmed to detect such "transitions", the occurrence of a Match A only unblocks the transition after the sampling. It means that the transition on the first Match (IPACA configurations 100 and 101) is not effective on predefined modes where Transition A is enabled by Match A (m2_st, m2_dt, m2_o_st and m2_o_dt) or user-defined modes with UDCM bit M1ET asserted . A Transition A can still happen after the Match A, however, if MatchA register is reprogrammed without clearing MRLA.

TDLA/B assertion conditions initiates a capture event of one or both selected TCR buses. TDLA or TDLB transition event generates a Service Request, depending on channel mode, previous events and the state of SRI. For more information on service request scheme refer to Entry Point address generation" and Channel Modes.

Assertion of TDLA/B occurs on either T2 or T4 positive edges. The capture event occurs on the same clock, and captures the time base value present when TDLA/B was asserted[1] . TDLA and TDLB are negated during reset and may also be negated independently by microcode. TDLA/B is reset by no way other than reset and microcode.

It is the transition from 0 to 1 in TDL that causes the Transition actions: even if TDL assert conditions are satisfied, no action due to a Transition occurs if TDL was already set to 1. However, if a Transition and a microoperation negating TDLs occur at the same time and TDL was already negated, TDL negation by microcode overrides its assertion, but any dependable captures and pin action occurs anyway.

2.14.5.3.2 TCCEA - Transition Continuous Capture Enable

TCCEA enables capture from transitions after the TDLA flag is set. TCCEA is negated on reset, so that a capture occurs only when TDLA asserts. TCCEA can be set and reset by microcode only, through the instruction field MTD (see Disable Match and Transition Service Requests). It can only be set together with inhibiting of the channel service requests (SRI = 1)[26].

When TCCEA is asserted, the transition events specified by IPACA that occur after TDLA is set also cause captures, into the CaptureA register only. However, output actions related to transition events are still blocked by TDLA.

2.14.5.4 Channel Modes

The Enhanced Channels support various modes of operation combining Match A/B recognition and transition detection events which set MRLA/B and TDLA/B. The channel mode is individually set for each channel by eTPU microcode, through the PDCM register (see PDCM - Predefined Channel Mode). The PDCM register selects among a set of 13 predefined channel modes, and also a user-defined channel mode.

The order in which events occur, combined with assigned channel mode, establish which following event detections are inhibited and/or enabled, as well as the actions taken: Time Base capture, flag setting (MRLA/B, TDLA/B), match disabling (MRLEA/B), output signal transition, and Service Request. Those channel mode characteristics are fixed in the predefined modes, but can be individually programmed in the user-defined channel mode.

A generic description of channel modes from the usage point of view can be found in Channel Modes Overview . Each mode is named with a mnemonic acronym for terse reference. The individual programmed attributes of the user-programmable channel mode are also described.

26. TCCEA provides compatibility with TPU when service request is inhibited.

The modes are used differently for input and output signals, as explained in Predefined Channel Modes on Input Signal Processing and Channel Modes on Output Signal Generation. Modes also allow combining input processing and output generation in a single channel, as exemplified in Combining Input and Output Signals.

Channel Mode Logic and Event Flags shows a structural definition of channel logic and its relation to channel modes. A dynamic, event-oriented view of each channel mode can be found in Channel Mode Summary.

2.14.5.4.1 Channel Mode Logic and Event Flags

Figure 2-18 shows a more detailed diagram of channel mode logic. The logic shown here is not necessarily identical to the actual channel logic implementation, but is equivalent with respect to conditions for event blocking, enabling, capture, and service requests.

Signals MSR, TSR, MCAP, TCAP, M1ET, M1EM2, M1BM2, M2BM1, M2BT, T1BM1, T2BM1, TBM2 and T1ET2 are decoded from programmed channel mode PDCM in predefined modes, and come directly from the UDCM register when user-defined mode is selected:

- TSR (1 bit) defines Service Requests issued by Transitions, as shown in Table 2-38.
- MSR (2 bits) defines Service Requests issued by Matches, as shown in Table 2-37.
- TCAP (1 bit) defines time base captures caused by Transitions, as shown in Table 2-38
- MCAP (1bit) defines time base captures caused by Matches, as shown in Table 2-39.
- M1ET, M1EM2, M1BM2, M2BM1, M2BT, T1BM1, T2BM1, TBM2, T1ET2 (1 bit each) define Match and Transition reciprocal blocking and enabling, as well as Transition ordering, as shown in Table 2-40 and Table 2-41.

Table 2-42 shows the decoded values of those control signals for each predefined channel mode. The first column shows the mnemonic reference for the predefined channel modes described in the following sections.

Changing PDCM or the UDCM when user mode is selected may set or reset any of the channel flags, or issue captures and service requests, so it is advisable to switch channel modes only in a quiescent channel state, with channel flags MRLEA/B, TDLA/B, MRLA/B cleared. Furthermore, an event flag asserted in one mode may keep asserted after the mode programming change, even if the flag is impossible to be set in the new mode.

Table 2-37. MSR signals - Match Service Requests

value	MSR
00	issue no Service Requests on Matches
01	issue Service Request on Match B only
10	issue Service Request on 2nd[1] Match
11	issue Service Request on both Matches

1. 2nd Match means the Match that happens after the 1st Match in time, either Match A or Match B.

Table 2-38. TCAP and TSR signals - Transition Captures and Service Requests

value	TCAP	TSR
0	1st[1] Transition captures Time Bases corresponding to Transition A and Transition B[2] Transition A captures corresponding Time Base if it is the second transition; Transition B captures corresponding Time Base if it is the second transition.	issue Service Request on the 1st[1] Transition
1	Transition A captures corresponding Time Base. Transition B captures corresponding Time Base.	issue Service Request on the 2nd[3] Transition

1. 1st Transition means the Transition that happens first in time, either Transition A or Transition B.
2. Match capture(s) never overwrites a Transition capture. Transition captures can always overwrite a Match capture.
3. 2nd Transition means the Transition that happens second in time, either Transition A or Transition B

Table 2-39. MCAP signal - Match Capture

value	MCAP
0	Match A captures corresponding Time Base; Match B captures corresponding Time Base
1	either Match captures Time Bases corresponding to Match A and Match B[1]

1. Match capture(s) never overwrites a Transition capture. Transition captures can always overwrite a Match capture.

Table 2-40. TBM2 signal - Transition Blocks Match B

value	TBM2
0	Transition A Blocks Match B
1	Transition B Blocks Match B

Table 2-41. M1ET, M1EM2, M1BM2, M2BM1, M2BT signals

signal	active value meaning
M1ET (Match A Enable Transitions)	Transitions are initially blocked, and Match A enables Transitions
M1EM2	Match B is initially blocked[1],

Table continues on the next page...

Table 2-41. M1ET, M1EM2, M1BM2, M2BM1, M2BT signals (continued)

signal	active value meaning
(Match A Enables Match B)	and Match A enables Match B
M1BM2[2] (Match A Blocks Match B)	Match B is initially enabled[1], and Match A blocks Match B[3]
M2BM1[2] (Match B Blocks Match A)	Match A is initially enabled,and Match B blocks Match A[3]
M2BT (Match B Blocks Transitions)	Match B blocks Transitions
T1BM1 (Transition A Blocks Match A)	Transition A blocks Match A
T2BM1 (Transition B Blocks Match A)	Transition B blocks Match A
T1ET2 (Transition A Enables Transition B)	Transition B is initially blocked, and Transition A enables Transition B

1. The initial condition of M1EM2 prevails over M1BM2, while M1BM2 blocking prevails over M1EM2 enabling, so that Match B stays always blocked when both M1BM2 and M1EM2 are active. This combination is used in single-match modes (sm_*).
2. Blocking of one Match by the other is done through MRLEs.
3. Matches always block themselves by resetting their own MRLEs (Match A always blocks Match A, Match B always blocks Match B)

Table 2-42. Predefined Channel Mode control signals decoding

Predefined Mode	MSR	MCAP	M1ET	M1EM2	M1BM2	M2BM1	M2BT	T1BM1	T2BM1	TBM2[1]	T1ET2	TSR[1]	TCAP[1]
em_nb_st	11	0	off	off	off	off	off	On	off	0	On	0	0
em_nb_dt	11	0	off	off	off	off	off	On	off	1	On	1	1

sm_dt[2]	11	1	off	On	On	On	off	off	On	1	On	1	1
sm_st_e[3]	11	0	off	On	On	On	off	On	off	0	On	0	0

1. signals TSR, TCAP and TBM2 replace the signal DTM used in previous eTPU versions.
2. bm_dt and sm_dt are exceptions in the match blocking logic by transitions. See Both Match Request Modes (bm_st, bm_dt) and Single Match Modes (sm_st, sm_dt).
3. sm_st_e is an exception in the capture scheme. See Single Match Enhanced Mode (sm_st_e).

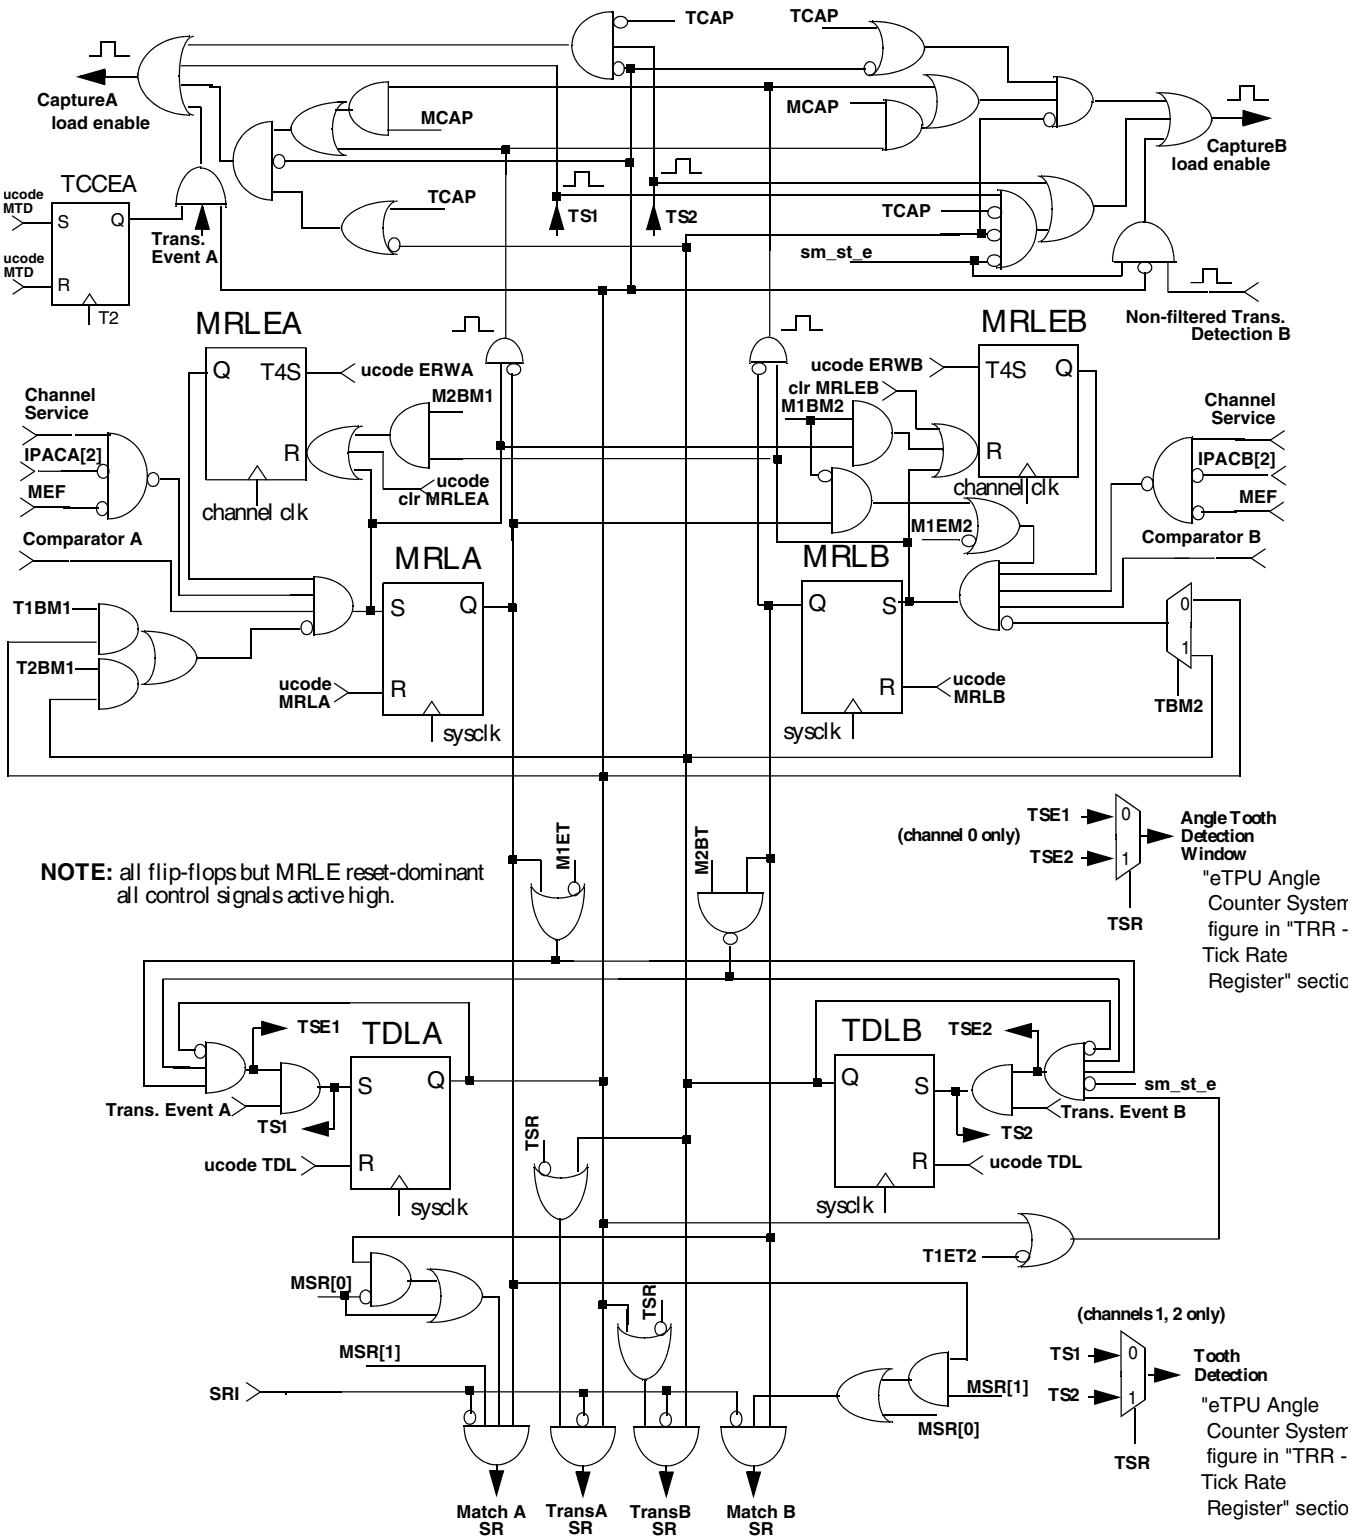

Figure 2-18. Channel Mode Logic and Event Flags

2.14.5.4.2 Channel Modes Overview

The predefined channel modes are divided, according to the way they treat transitions, in two basic modes:

- **Single Transition Modes** (mnemonic suffix **_st**): in these modes the first transition (flagged in TDLA) issues a service request, and captures both time bases (selected by TBSA[1] and TBSB[1]) except on sm_st_e. The second transition (flagged in TDLB) does not issue a service request, but it captures time base selected by TBSB[1], except on sm_st_e.
- **Double Transition Modes** (mnemonic suffix **_dt**): in these modes the second transition (flagged in TDLB) issues a service request, and each transition captures its own selected time base (Transition A and Transition B capture time bases selected by TBSA[1] and TBSB[1], respectively).

In predefined modes, Transition B is always (but not only) enabled by Transition A, so that transitions are always ordered: TDLA is set on the first transition and TDLB on the second. Unordered transitions are possible with user-defined mode, when UDCM bit T1ET2=0. Matches are generally not ordered, except on specific ordered match modes m2_o_st and m2_o_dt. Match capture(s) never overwrites a Transition capture, while Transition captures can always overwrite a Match capture, either in predefined or user-defined modes.

The following general rules apply to both predefined and user-defined modes:

- Blocking of one Match by the other, when it occurs, is done through MRLEs.
- Matches always block themselves by resetting their own MRLEs (Match A always blocks Match A, Match B always blocks Match B).

Predefined modes differ mostly by the way matches affects and are affected by other matches and transitions, as explained in next sections. However, some general rules on Match blocking apply:

- Match B is blocked by first transition (TDLA) in single transition modes, and by second transition (TDLB) in double transition modes.
- Both Matches are blocked by first transition in single transition modes.

Note

The rules above and in following sections may be overruled by the state of the channel latches if they are set/reset by microcode or if channel mode is changed. Care must be taken

to change channel modes, and is advisable to reset channel flags MRLA/B, TDLA/B and MRLEA/B before writing PDCM, or to UDCM when user-defined mode is selected.

2.14.5.4.2.1 Either Match, Blocking Modes (em_b_st, em_b_dt)

In these modes the first match recognition that occurs blocks the other match recognition and generates a service request. They end up with one service request for two programmed match recognitions where only the first match recognition has an actual effect. If both match recognitions occur at the same time, both MRLA and MRLB are set, before the mutual blocking takes effect. The associated logic is shown in the following figure.

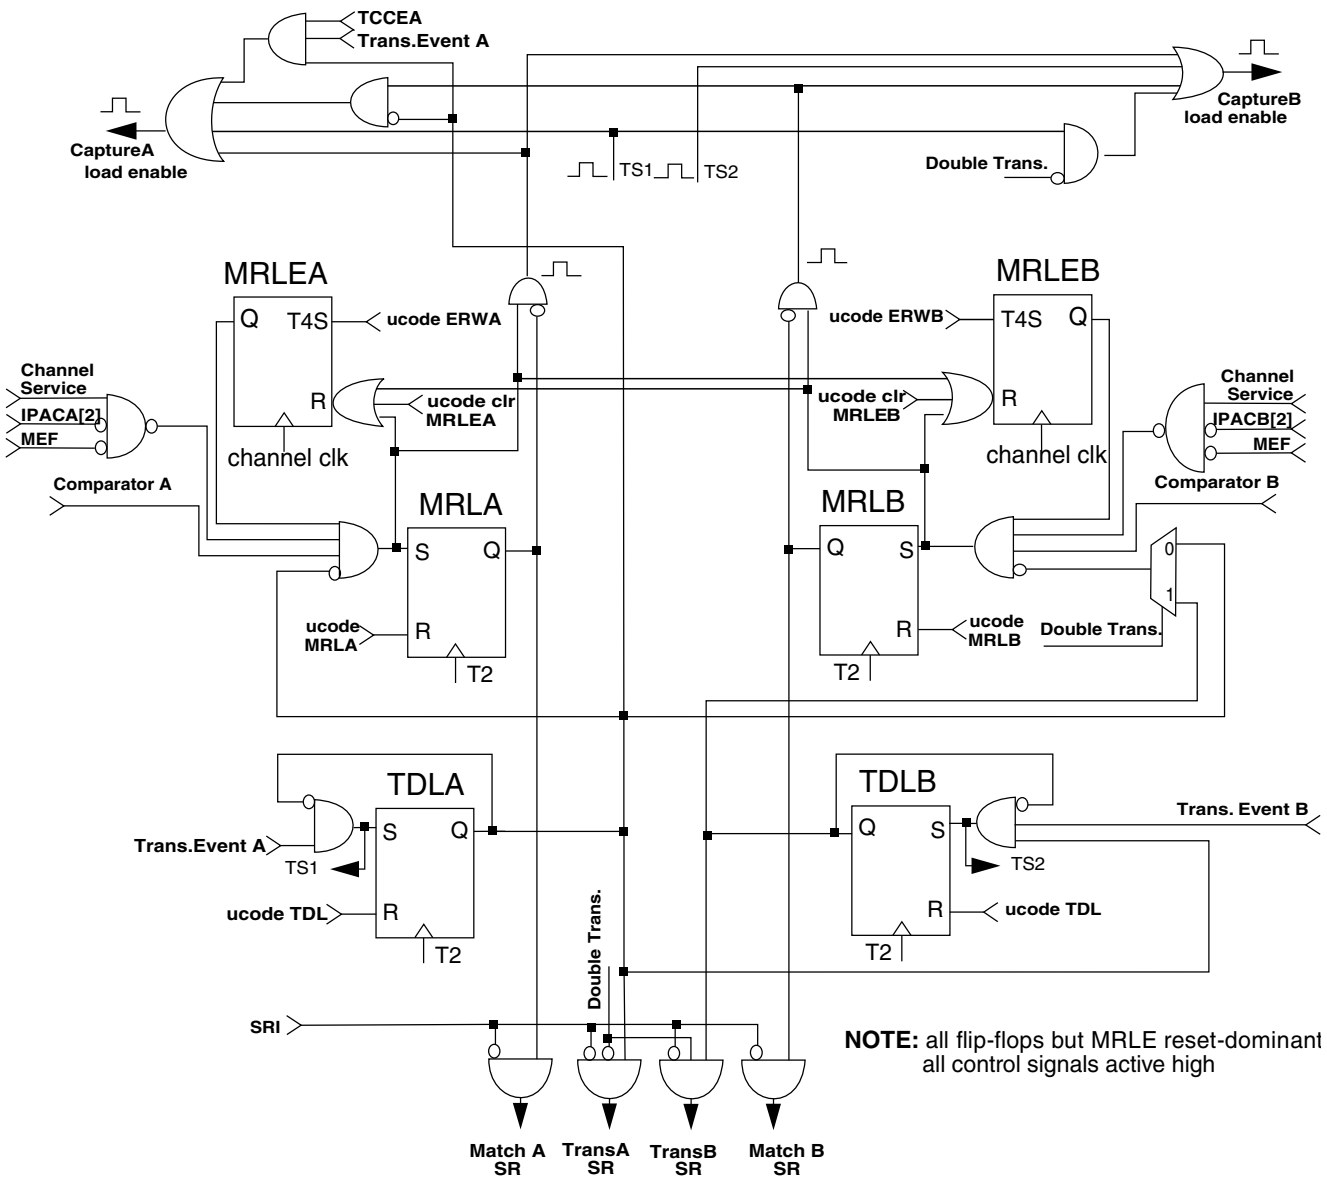

Figure 2-19. Either Match, Blocking Modes (em_b_st, em_b_dt)

2.14.5.4.2.2 Either Match, Non Blocking Modes (em_nb_st, em_nb_dt)

In these modes both match recognitions are independent and each of them generates service request. Each match recognition captures its related time base and does not block the other. The associated logic is shown in the following figure.

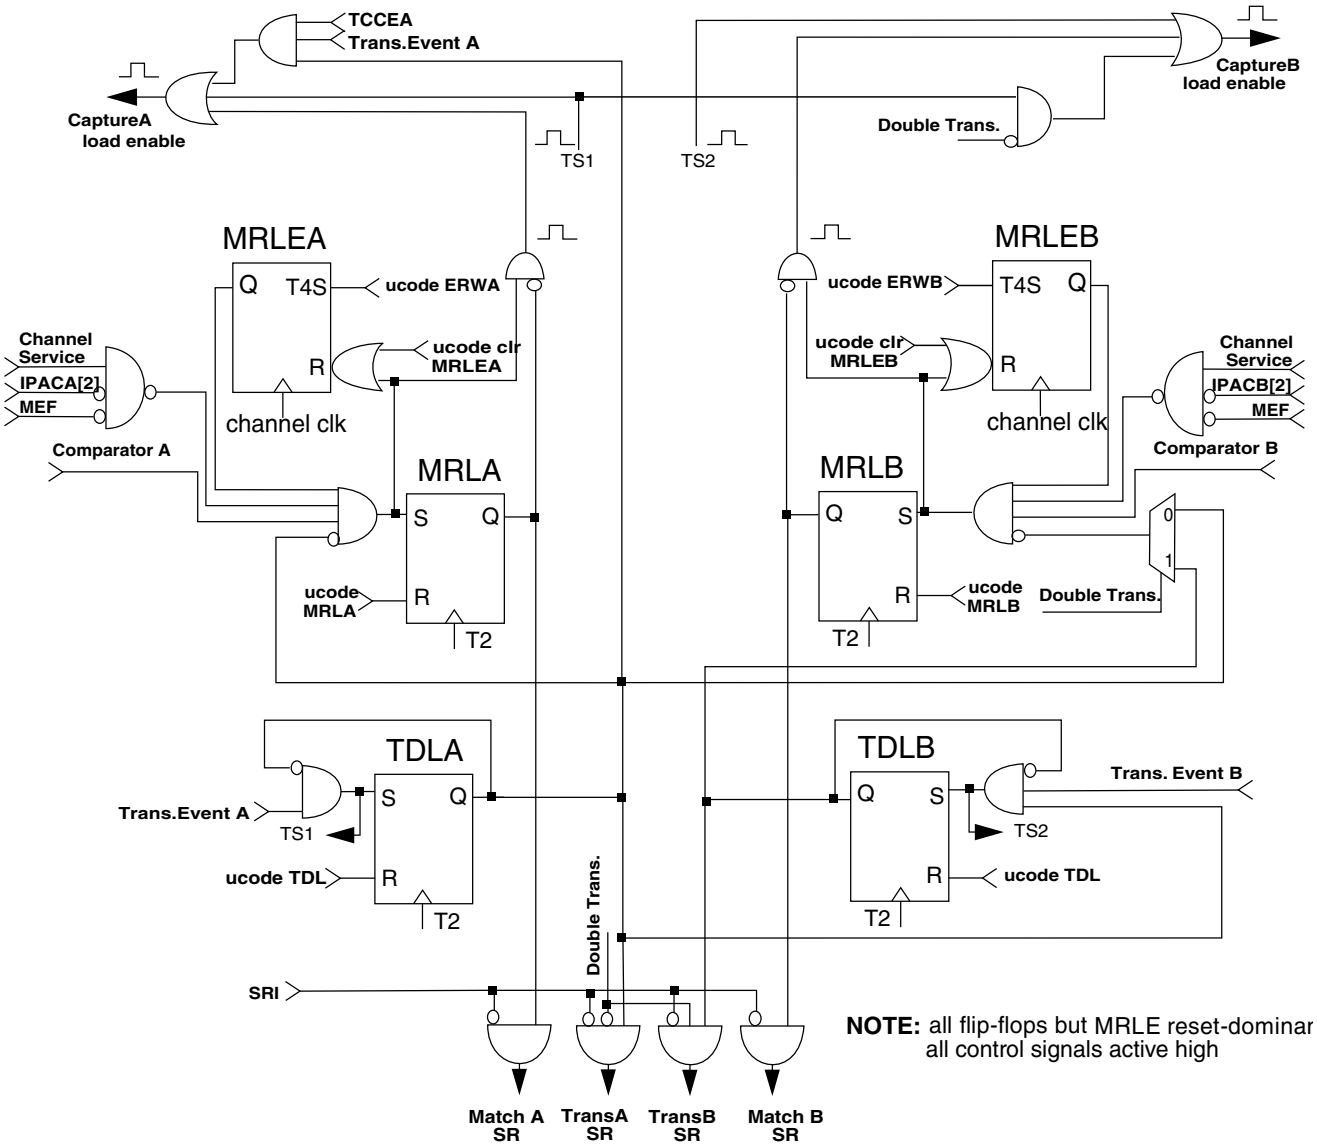

Figure 2-20. Either Match, Non Blocking Modes (em_nb_st, em_nb_dt)

2.14.5.4.2.3 Match B Request Modes (m2_st, m2_dt)

In these modes transitions are initially blocked, and are enabled by Match A. Match B recognition generates the match service request and disables Match A recognition. Each match recognition captures its own programmed timebase. In case of simultaneous match

recognition, both MRLA and MRLB are set, and OPACB register has priority over OPACA for selecting the pin action. The associated logic is shown in the following figure.

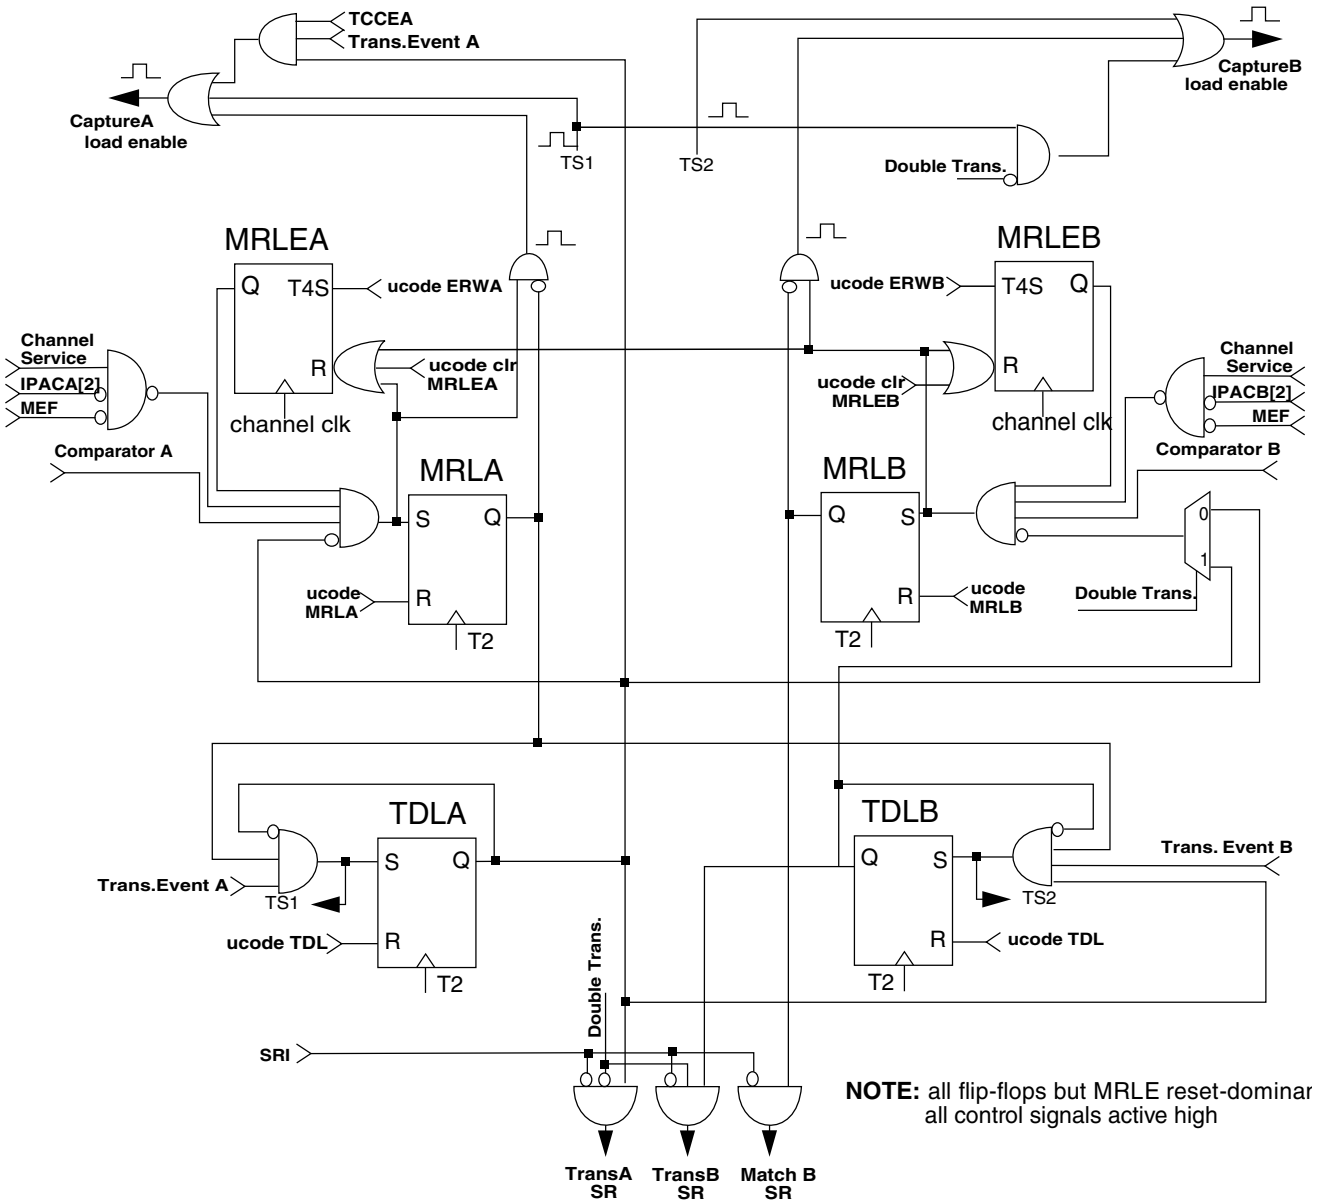

Figure 2-21. Match B Request Modes (m2_st, m2_dt)

2.14.5.4.2.4 Both Match Request Modes (bm_st, bm_dt)

In these modes, match service request is generated only after both match recognitions occurred. By definition this is a non-blocking match mode: match recognitions do not block each other, implementing a last-served scheme. Unlike other double transition

modes, bm_dt blocks Match A with Transition B (not with Transition A), so that the second transition blocks both matches. The associated logic is shown in the following figure.

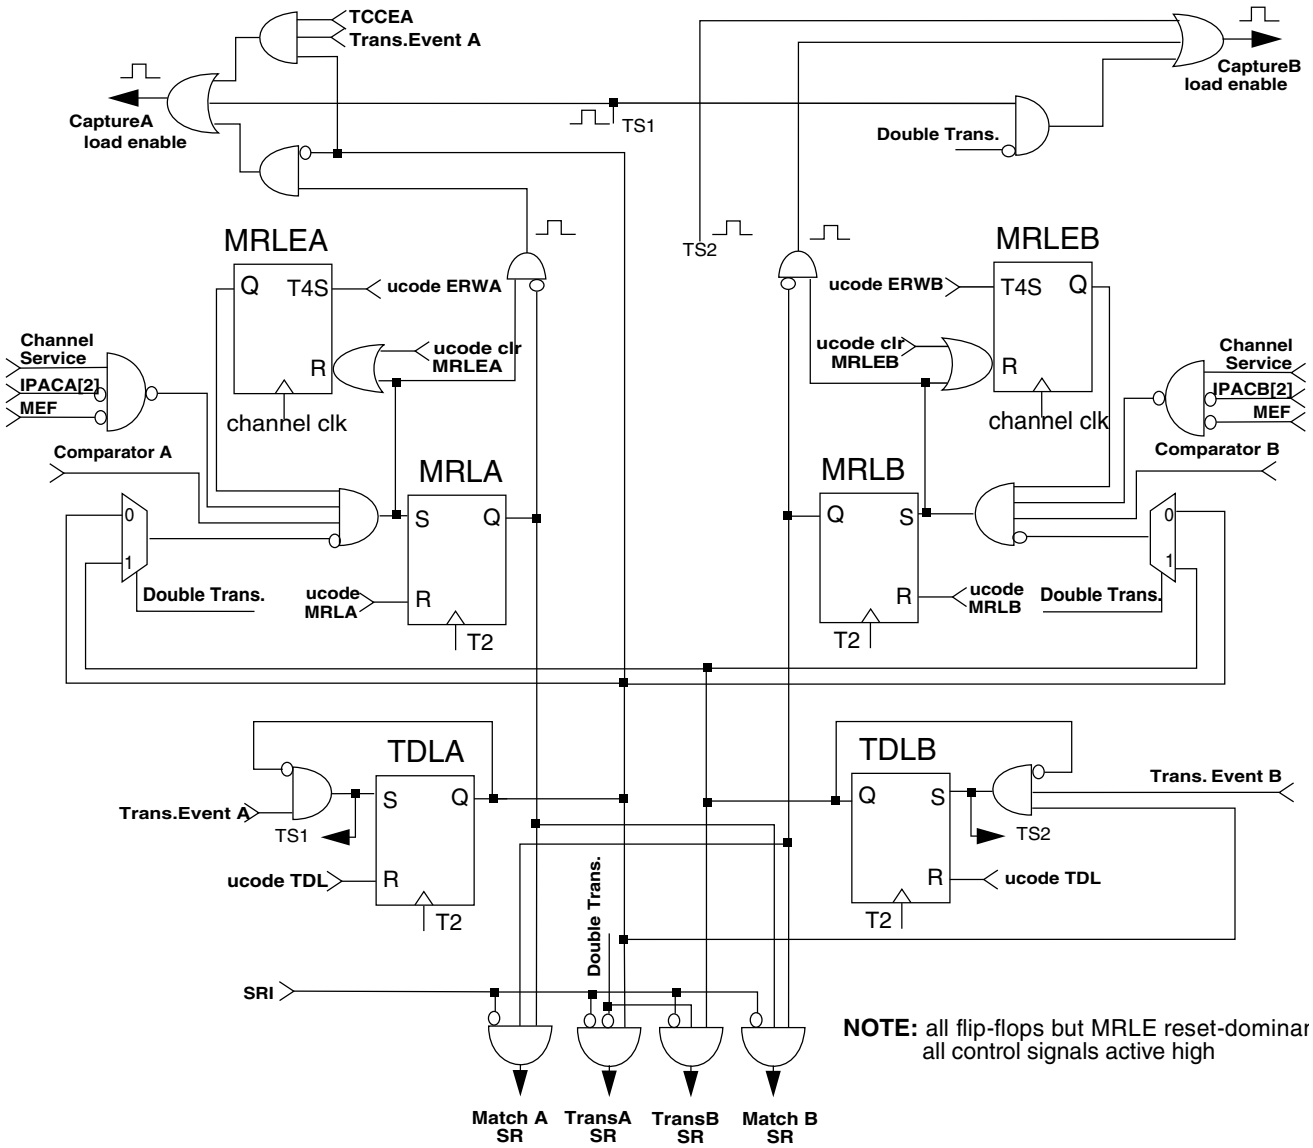

Figure 2-22. Both Match Request Modes (bm_st, bm_dt)

2.14.5.4.2.5 Ordered Modes with Match B Request (m2_o_st, m2_o_dt)

These are ordered match modes on which Match A recognition must precede Match B recognition (ordered 1->2). Match A asserts MRLA and enables Match B and transitions. Match B asserts MRLB, generates a match service request, and blocks both transitions. The associated logic is shown in the following figure.

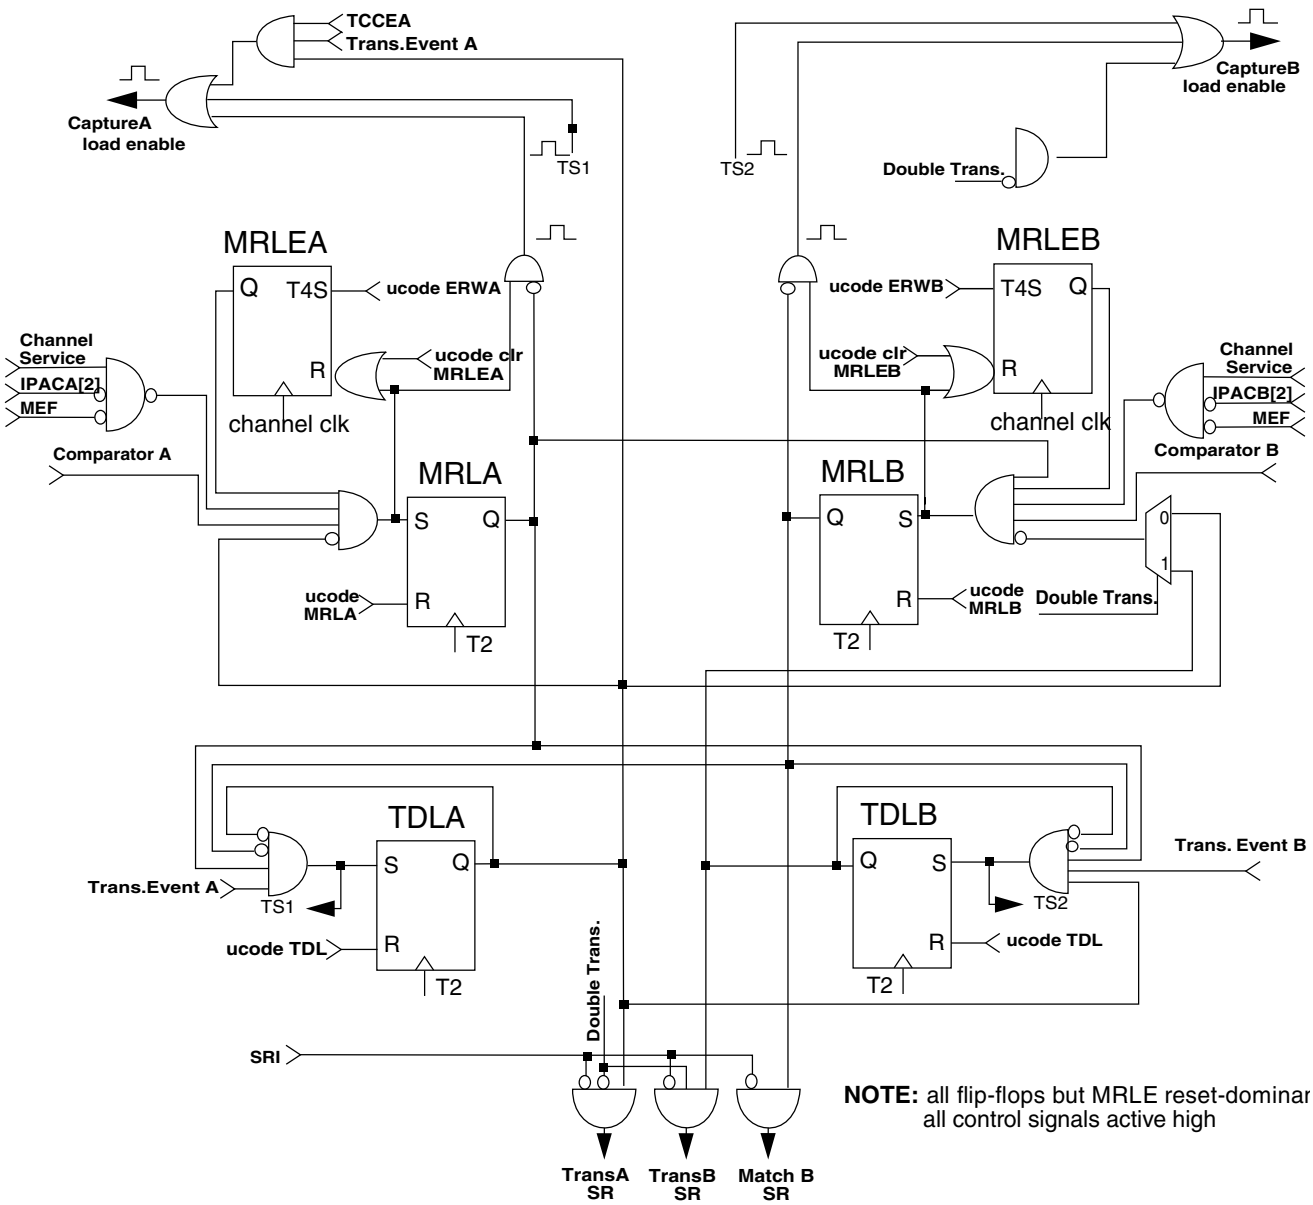

Figure 2-23. Ordered Modes with Match B Request (m2_o_st, m2_o_dt)

2.14.5.4.2.6 Single Match Modes (sm_st, sm_dt)

Single match modes support single or double transition with single match recognition. MRLB is never set, and MRLEB has no effect. The associated logic is shown in the following figure.

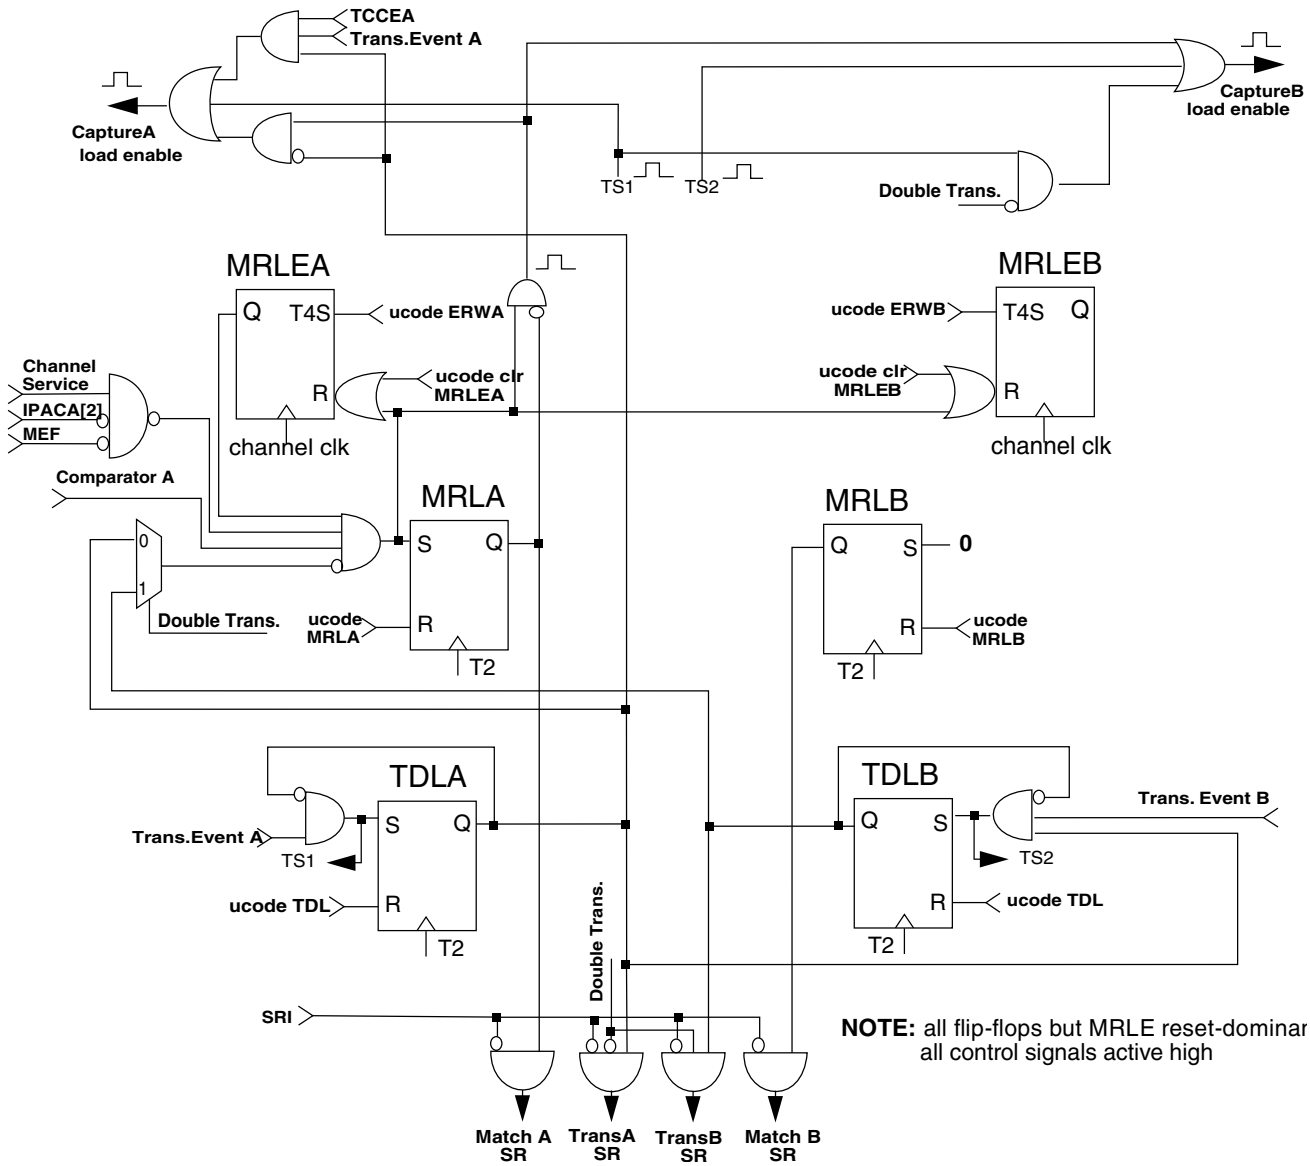

Figure 2-24. Single Match Modes (sm_st, sm_dt)

2.14.5.4.2.7 Single Match Enhanced Mode (sm_st_e)

This is an enhanced single transition and single capture mode, which provides non-filtered input captures in addition to the single capture, allowing one to measure the delay of the digital filter. In an output channel, it has the same functionality of sm_st (captures both time bases at once due to a match recognition). The associated logic is shown in the following figure.

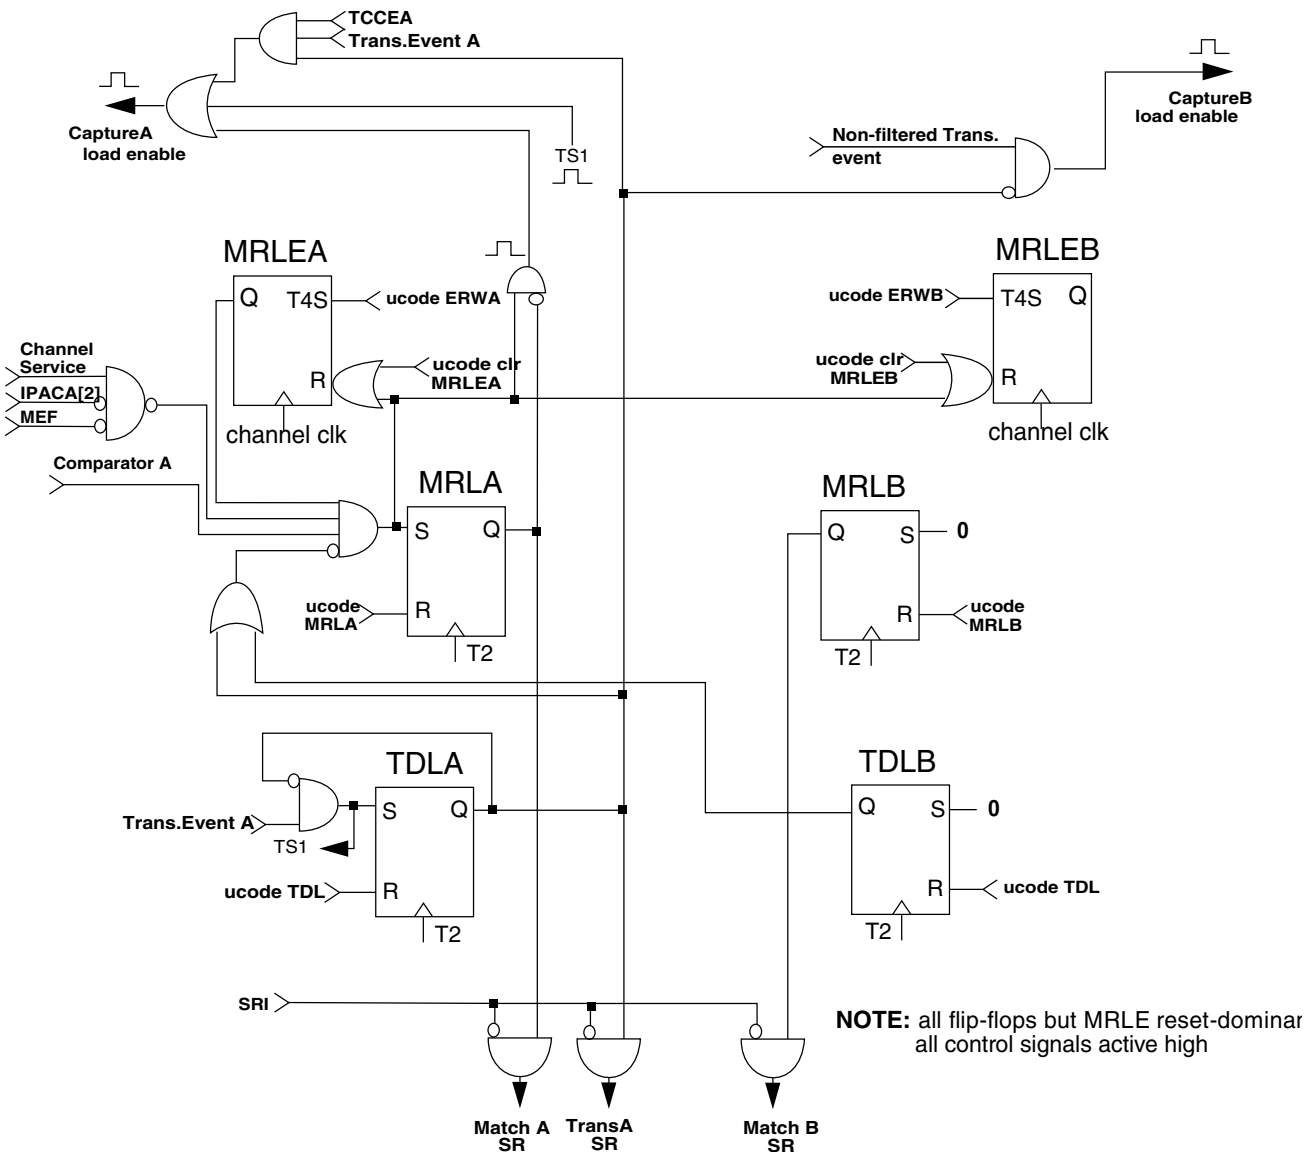

Figure 2-25. Single Match Enhanced Mode (sm_st_e)

2.14.5.4.3 Predefined Channel Modes on Input Signal Processing

When processing an input signal, the predefined channel modes can be classified in the following primary mode groups:

- Single Transition, Single Match: em_b_st, sm_st, sm_st_e
- Single Transition, Double Match: em_nb_st, bm_st, m2_st, m2_o_st
- Double Transition, Single Match: em_b_dt, sm_dt
- Double Transition, Double Match: em_nb_dt, bm_dt, m2_dt, m2_o_dt

In single transition modes, TDLA assertion may capture both time bases at once, while in double transition modes each transition captures its related time base in its related capture register.

Double transition is always ordered, i.e TDLB is enabled by TDLA and generates the service request.

The channel logic supports various input modes with combinations of single/double transition and single/double match, explained in the following subsections.

2.14.5.4.3.1 Either Match, Blocking, Single Transition (em_b_st)

On an input signal, this mode provides double timeout mechanism on a programmed transition edge with two timebases. The signal transition blocks both pending matches, indicating that no timeout condition occurred. The two match recognitions block each other, giving good separation in the entry table as to which match recognition caused the first timeout condition, and generating only one service request. Either match performs timebase captures which do not overwrite captures by transitions.

2.14.5.4.3.2 Either Match, Blocking, Double Transition (em_b_dt)

In double transition mode each transition is related to one match recognition. TDLA assertion captures its related timebase, blocks Match A and enables TDLB. TDLB assertion blocks Match B, captures its related timebase and generates a service request. Match recognitions block each other, so if there is a match timeout condition on TDLA, only one match service request is generated. This mode is good for qualifying two signal transitions by match timeout mechanisms, with one service request. Note that although TDLA assertion does not block Match B recognition, the value captured in CaptureA by TDLA assertion is not overwritten by this recognition. The second transition blocks Match B. Either match performs timebase captures which do not overwrite captures by transitions.

2.14.5.4.3.3 Either Match, Non Blocking, Single Transition (em_nb_st)

On an input signal, this is a double timeout mechanism of independent match recognitions of two different timebases. The match recognitions do not block each other, such that the microcode can check if one or two match recognitions occurred before their related signal transition. The signal transition detection (by IPACA) asserts TDLA, blocks both matches, captures both time bases and generates a transition service request, indicating that none of the two timeout conditions occurred. Any combination can be easily resolved by microcode (for example, signal transition after Match A and before Match B, or signal transition after both Match A and Match B).

Another possible use of this mode is allocating one match recognition for transition timeout and the other for another non-critical timed task, adding functionality to a single channel. Since the transition detection blocks both match recognitions, the match recognition of the other timed task is based on the fact that the comparator checks greater-equal conditions. It may be delayed if it occurs in the period between the signal transition detection (which blocks it) and the time TDLA is negated by microcode. If matches are enabled during the service, the same code can check if the match recognition of the timed task occurred in this period, by negating TDLA and writing to the CHAN register its own value (in order to update the MRLA flag in the branch logic).

2.14.5.4.3.4 Either Match, Non Blocking, Double Transition (em_nb_dt)

In this mode each transition is related to one match recognition, and the match recognitions are independent of each other. This mode can be used to give independent timeout conditions for the first and the second signal transition recognitions, and call service in any case of any timeout condition.

The first transition detection programmed in IPACA sets TDLA, captures its related timebase, blocks Match A recognition and enables TDLB assertion. The second transition detection programmed in IPACB sets TDLB, blocks Match B recognition, captures its related timebase and generates a service request. Any match recognition that occurs captures its related time base and generates a match service request, independent on the other match recognition.

2.14.5.4.3.5 Match B Request, Single Transition (m2_st)

On an input signal, this mode provides an open window filter for a single signal transition. MRLA assertion opens the window, and enables transition detection on TDLA from this time on. MRLB assertion blocks Match A (by negating MRLEA), providing conditional window opening, because transitions are indirectly blocked. It also generates service request, but if it happens after Match A it does not block transitions, providing a non-blocking timeout mechanism for the estimated signal transition time (typically it indicates a missing transition, or mis-prediction of the transition time).

Transitions can be detected from the microcycle following MRLA assertion. The Transition A detection asserts TDLA, blocks both matches, captures both timebases and generates service request.

Using this mode, the channel can replace software open window filtering of qualified transitions with the channel hardware window. The window opening and timeout can be scheduled for any of the two time bases or combination of them. Typically, Match A will be used to open a prediction window, and Match B will be used as a timeout condition

which does not close the prediction window. This configuration improves noise immunity from early signal transitions, and reduces the probability for blocking late signal transitions due to timeout mis-prediction.

Using these conditions, the microcode can easily resolve the state:

- If TDLA and MRLA are asserted and MRLB negated, signal transition is in the expected range.
- If MRLA and MRLB are both asserted, and TDLA is asserted, the signal transition had a timeout condition due to Match B mis-prediction.
- If MRLB is asserted and TDLA negated, a timeout condition occurred, and the expected signal transition had not occurred yet.
- If MRLA is negated and MRLB is asserted, the conditional window did not open at all (for example: a time window is open only after a specific angle, otherwise it is not opened).

2.14.5.4.3.6 Match B Request, Double Transition (m2_dt)

This mode is used as an open window filter for two signal transitions. In this case the Match A recognition opens the window (unless Match B recognition occurred first), and Match B recognition blocks Match A and generates a match service request. It is similar to m2_st, but in this case, it is the second transition that blocks Match B. MRLB assertion is a global timeout condition for the two pulses. Like m2_st, MRLB can conditionally eliminate the window from opening.

Using the TDLA, TDLB, MRLA and MRLB conditions, the microcode can easily resolve the state, in a similar manner as m2_st, with additional information on the second transition (TDLB).

2.14.5.4.3.7 Both Match Request, Single Transition (bm_st)

On an input signal, this is a double timeout mechanism on two different time bases. Both match recognitions must occur before the signal transition to generate a match timeout service request. Assertion of TDLA blocks both Match A and Match B recognitions, and captures both time bases, indicating there was no double timeout condition from both time bases.

Using the same timebase implements two timeout conditions, the first only sets its related MRL and the second generates a service request. Using these flags allows the microcode to check if one or both match recognitions precede the signal transition.

2.14.5.4.3.8 Both Match Request, Double Transition (bm_dt)

In this mode the first transition detection does not block matches, since both match recognitions are required to generate a match service request. The second transition detection asserts TDLB, blocks Match A and Match B, captures its related timebase and generates transition service request. In this mode, a Match A recognition which occurs after the assertion of TDLA does not capture a new value in CaptureA, to preserve the actual signal transition time. Assertion of TDLA, however, always captures its related timebase.

This mode allows putting a double match timeout condition on the second transition. Typically, a pulse trailing edge timing can be checked against two time bases, to indicate if the pulse has not ended when both MRLA and MRLB are asserted. When a transition service request is generated by TDLB assertion, the state of MRLA and MRLB indicates which timeout condition occurred, if any.

2.14.5.4.3.9 Ordered Mode with Match B Request, Single Transition (m2_o_st)

On an input channel, this mode provides a closing window filter for a single signal transition. Match A assertion captures its programmed time base in CaptureA, opens the filter window (enables assertion of TDLA), and enables assertion of MRLB. Match B recognition captures its related timebase, closes the window (disables assertion of TDLA) and generates a service request. Due to Match A and Match B ordering, the window is opened for at least one microcycle. Match B recognition indicates a window timeout condition which blocks late signal transitions, outside the prediction window. Transition detection blocks both matches, indicating the transition occurred inside the estimated window. Transitions can be detected from the microcycle following MRLA assertion until the microcycle on which MRLB is asserted. When TDLA is asserted inside the window range it disables both matches, captures both time bases and generates a transition service request.

Using this mode, the channel can replace software window filtering of qualified transitions with the channel hardware window. The window opening and closing time can be scheduled for any of the two time bases or a combination of them.

2.14.5.4.3.10 Ordered Mode with Match B Request, Double Transition (m2_o_dt)

In this mode the channel logic implements a window filter for two detected signal transitions. MRLA assertion captures its related timebase and enables the assertion of both TDLA and TDLB. MRLB assertion captures its related timebase and disables the assertion of both TDLA and TDLB. Transitions can be detected from the microcycle following MRLA assertion until the microcycle on which MRLB is asserted. The first

signal transition (following MRLA assertion) asserts TDLA, captures its related timebase and enables assertion of TDLB. The second signal transition detection asserts TDLB, blocks Match B, captures its related timebase and generates the service request.

If both signal transitions occur inside the scheduled window, Match B recognition is blocked. If one or both signal transitions do not occur inside the scheduled window, Match B recognition generates a match service request and blocks further transition detections. The microcode can resolve the state using MRLA, MRLB, TDLA and TDLB, which affect the entry point selection.

2.14.5.4.3.11 Single Match Enhanced Mode (sm_st_e)

This is an enhanced single transition and single match channel mode which provides timing information of the digital filter delay.

The CaptureA register captures the timebase selected by TBSA due to transition detection specified by IPACA or match recognition, as in sm_st mode. Initially, the CaptureB register continuously captures the unfiltered IPACB-selected signal transitions from the digital filter input, directly from the signal synchronizer. When an IPACA-qualified, filtered transition detection occurs, TDLA is set, MRLA assertion is blocked, and, in addition, captures into CaptureB are also blocked. On service, CaptureA and CaptureB (copied into ERTA and ERTB) holds the time of the qualified transition detection (ERTA), and the time of the last signal transition at the input of the digital filter (ERTB). Subtracting the time in ERTB from the time in ERTA provides the delay of the digital filter.

In a quiet environment, the two captures provide the accurate delay of the digital filter in granularity of two eTPU clocks. In a noisy environment, false transitions may be detected at the input of the digital filter due to the noise, and the delay measurement may be reduced, especially if IPACB selects both edge detection. The microcode can do sanity checks on this value to recognize noise effects (for example: calculated delay is less than the minimum delay of the digital filter).

Note

In Channel 0, if eTPU_TBR_TBCR_ENG*n*[AM]=01 (Angle Mode), the unfiltered input comes from TCRCLK input and the filtered input comes from the TCRCLK filter output. The edge is selected by IPACA/B, and is independent of the edge selection by eTPU_TBR_TBCR_ENG*n*[TCR2CTL].

2.14.5.4.3.12 Single Match, Single Transition (sm_st)

In this mode the channel logic is functionally back-compatible to a TPU3 single action channel, but a match or transition detection captures at once both timebases. The mode recognizes a single transition with single match timeout. Either TDLA or MRLA generates service request and captures both timebases. Assertion of TDLA blocks future assertions of MRLA.

2.14.5.4.3.13 Single Match, Double Transition (sm_dt)

In this mode, the first transition detection asserts TDLA, captures a timebase in CaptureA and enables TDLB. The second signal transition asserts TDLB, blocks Match A, captures a timebase in CaptureB and generates a service request.

Match A (before TDLB) captures into CaptureB the timebase selected by TBSA, in order not to overwrite the captured value of TDLA.

This mode is used for scheduling one timeout condition on two input signal transitions (pulse timeout).

2.14.5.4.4 Channel Modes on Output Signal Generation

Since channel logic can generate output signal transitions based on Matches, the channel can be viewed as working in the following primary mode groups for signal generation:

- Single Match: em_b_st, sm_st, sm_st_e, em_b_dt, sm_dt
- Double Match: em_nb_st, bm_st, m2_st, m2_o_st, em_nb_dt, bm_dt, m2_dt, m2_o_dt

The channel logic supports various match channel modes with single/double match, as explained in the following subsections.

2.14.5.4.4.1 Either Match, Blocking Modes (em_b_st, em_b_dt)

On an output signal these modes are useful when using two different time bases to set a required signal transition. The first match condition which is met sets a required pin action, captures both time bases, blocks any effects of the other recognition, and generates a service request. Because the first match recognition blocks the other, the microcode can get good separation in the function entry table as to which match caused the timeout first, and both time bases are captured, enabling the microcode to compare one timebase to the other at the moment of the match recognition. These modes can be used for:

- Scheduling a required pin action to the first match recognition of two different time bases.
- Canceling a programmed pin action scheduled on one time base by match on another timebase (as a consequence of Table 2-43). Microcode has to set the OPAC register of the canceling match to no-action and the OPAC register of the other match to the required pin action which may be blocked. If Match A is the canceling match, it blocks the pin action also in case of two matches at the same time, since it has priority in this case. If Match B is the canceling match, it does not block the pin action in case of two matches at the same time.

2.14.5.4.4.2 Either Match, Non Blocking Modes (em_nb_st, em_nb_dt)

On an output signal these modes are useful in combination with the ME bit set on the entry point, to define an interlaced operation. For example, each match recognition can set a pin action, and the second pin action is not sensitive to microcode latency (ME bit asserted). Example for usage is PWM interlaced function on which the latency is determined by the period and not the duty cycle.

Another possibility is using one match for pin actions and the other match for an unrelated timed task without pin action (double the functionality of a single channel).

2.14.5.4.4.3 Match B Request Modes (m2_st, m2_dt)

On an output signal, these modes can generate narrow pulses or do conditional pin actions. A conditional pin action means that the pin state is changed only if the match recognitions occurred in the correct order, since the Match B recognition which generates the service request also has priority over the pin action and blocks future Match A recognitions.

Setting OPACA to a desired pin action and OPACB to no-action, and using different time bases for Match A and Match B defines a conditional OPACA pin action which can be blocked by Match B recognition. For example, setting Match A on time and Match B on angle can limit the pin action to a maximum angle value.

When pulses are generated, the service is requested at the trailing edge of the pulse, after MRLB is asserted.

2.14.5.4.4.4 Both Match Request Modes (bm_st, bm_dt)

On an output signal, each match recognition can affect the pin state, and capture its programmed time base. This way the pin action can be programmed separately for both match recognitions. For example, both match recognitions can negate the signal, and

service request is generated after both conditions are met. This mechanism can set two conditions to do a required pin action, and the first recognition changes the signal, but service is called only after both conditions occur.

When using the same time base, these modes can generate narrow pulses in any required order. For example, in a PWM function, when duty cycle is below 50% the function can get service on the low time and program the pulse to the required duty cycle of the high time. When duty cycle is equal or above 50%, the function can get service on the high time and program a negative pulse with the width of the required low time. To switch between the two states the function can program once the same transition time to MatchA and Match B with a required pin action, and on the next service program double match for the new state.

Another usage is generating a required pin action on one programmed time and service request later on another time, after the second match recognition occurs, or capturing some timebase on one time and generating a required signal transition and service request later.

2.14.5.4.4.5 Ordered Modes with Match B Request (m2_o_st, m2_o_dt)

The order of the match recognitions imply that OPACA register programmed pin action always precede the OPACB register pin action. Setting OPACA to no-action, based on the greater-equal comparator, enables using Match A on one time base to delay the signal effect of Match B on the other time base. This method implements a conditional pulse extension or conditional delay on signal transition.

These modes can also be used for deferred pulse generation with microcode service request after its trailing edge (if Match A condition comes after Match B condition). Another option is having Match A recognition associated with output pin actions and Match B recognition for a timed microcode task which has to be scheduled at a programmed time which may be delayed by the Match A pin action.

2.14.5.4.4.6 Single Match Modes (sm_st, sm_dt, sm_st_e)

There is no difference between plain and enhanced Single Match modes on an output signal.

In this mode the channel logic is functionally back-compatible to a TPU3 single match output channel. Match A recognition generates service request and sets the pin state according to OPACA register. It captures at once the timebase selected by TBSA in CaptureA and the timebase selected by TBSB in CaptureB.

2.14.5.4.4.7 Match/Transition Pin Action Conflict Resolution

In output signals, matches and/or transitions automatically cause pin actions defined by the OPACA/B and/or IPACA/B channel control registers (see Pin Control Registers). Simultaneous matches/transitions may be associated with different, possibly contradictory, pin actions. These conflicts are resolved according to the table below.

If an OPACA/B=000 (no action) prevails over non-zero OPAC according to the table below, then if Match A/Transition A and Match B/Transition B occur simultaneously, no output pin action occurs, that is: a match on the action logic with OPAC=000 inhibits simultaneous actions of the other OPAC, if prevailing according to the following table. That also applies when output actions are caused by inputs (OPAC=1xx).

Table 2-43. Simultaneous Match Pin Action Priority

Channel Mode	Priority
em_nb_st / em_nb_dt	OPACA
em_b_st / em_b_dt	OPACA
bm_st / bm_dt	OPACA
m2_st / m2_dt	OPACB
m2_o_st / m2_o_dt	in these modes there is no possibility of simultaneous matches
user-defined	OPACB if M2BM1 = 1 and M1BM2 = 0, OPACA otherwise

2.14.5.4.5 Combining Input and Output Signals

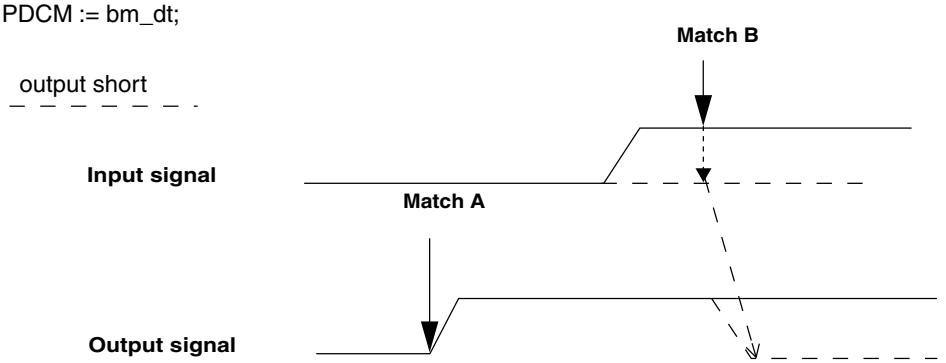
The processing of input signal can be combined with output signal generation. A detected input transition can trigger an output signal edge, even without microcode intervention, by using OPAC options 1xx.

The channel set-up examples below show these two capabilities combined (see the figure below).

The **first example** implements a fast (no microcode intervention) short-circuit protection feedback mechanism for driving high-current output devices. The signal after the high-current driver feeds back to the channel input. The input signal is normally delayed from the output signal by the device turn-on delay. After the channel output turns on, the channel logic must check if the driver output (connected to the channel input) follows the driven value after the maximum device turn-on delay. If it does not, the driver output is probably shorted, and the channel output must be turned off immediately to avoid damaging the device.

Match A causes the output to be driven high (for simplicity the output and input signals are shown as positive logic). It also causes a transition A, because IPACA=100 and the input is still low. Match B occurs after the expected driver delay, and causes a service request. If the output is shorted, a Transition B occurs on Match B because IPACB=100. This will cause the output to go low immediately, because OPACB=100.

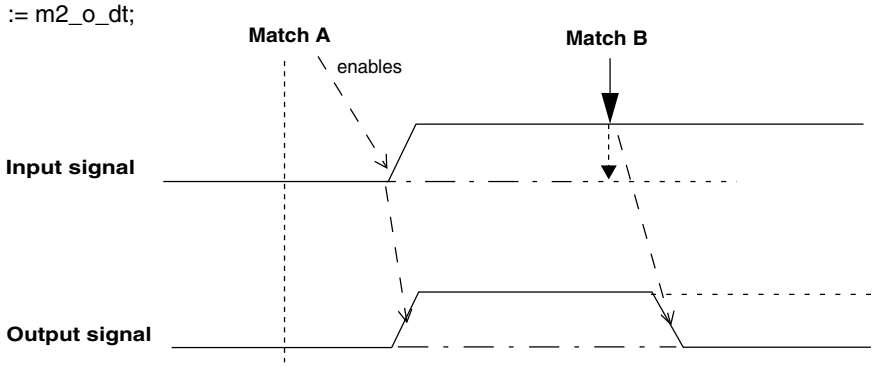
In the **second example**, an output pulse is generated from an input transition without microcode intervention. Match A opens a window for transitions and also enables Match B. A rising edge on input sets output high. On Match B the window closes, and input signal is checked: if sampled high, the output resets; otherwise it stays high.



In the **third example**, a pulse is generated depending on the value sampled on the input signal at a predetermined time. Match A samples the input signal, causing a Transition. Low level on input sets output low, otherwise it stays high. Match B sets output high. In both cases a service request is issued (microcode intervention), at the beginning and at the end of the pulse (Match B), if required (SRI := 0).

Note

When IPAC = 1xx, a match event can cause simultaneously a Match recognition and a Transition detection. Depending on the Channel Mode, these Match and Transition may have conflicting effects on other Transition/Match blocking or enabling. In these cases, blocking always prevails over enabling, effective on the next microcycle.



Example 1: Short-circuit protection feedback

IPACA := 100; OPACA := 001; MatchA := output activate time;
IPACB := 100; OPACB := 100; MatchB := MatchA + max. high-current driver turn-on delay;
PDCM := bm_dt;

Example 2: Pulse generation on windowed input transition

IPACA := 001; OPACA := 101; MatchA := window open time;
IPACB := 101; OPACB := 100; MatchB := window close time, input sampling;
PDCM := m2_o_dt;

Example 3: Pulse generation on input sampling

IPACA := 100; OPACA := 100; MatchA := window open time,input sampling;
IPACB := 000; OPACB := 001; MatchB := window close time = MatchA + pulse width;
PDCM := em_nb_dt;

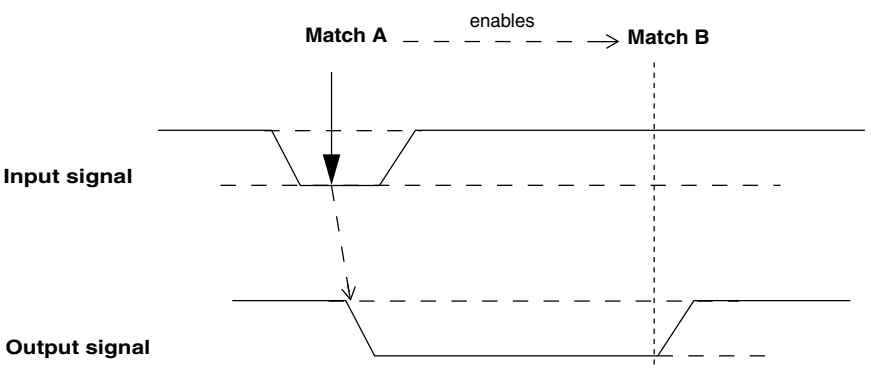


Figure 2-26. Input/Output combination

2.14.5.5 Channel Link

A channel can issue service requests to other channels through microcode, by assigning to the write-only microengine register LINK (refer to LINK Register) a value which specifies the target channel of the Link Service Request, as shown in the figure below.

Writing to the LINK register issues a link request to the target channel, setting its LSR flag. Each channel has its own LSR flag, which can be tested as a microcode branch condition (see Conditional/unconditional branch) and reset through the microcode field LSR (see Clear Link Service Request). The link branch condition samples, at the TST start, the value used to calculate the Entry Point.

Writing LINK with another channel target value in the same thread issues a Link Service Request to the new target, without negating the service request to the former one. This allows a channel to issue service requests to any number of channels, including itself. Neither LINK nor LSR microengine accesses are qualified by the CHAN register, i.e., they always access the serviced channel LINK and LSR, regardless of the value written in CHAN.

Channels can also receive link service requests from the Shared Subsystem Units (see Shared Subsystems support). These links are set by the interrupt signals from the shared subsystem and are level-sensitive, that is, they keep on requesting link service as long as the interrupt is active. Therefore, it is not enough to clear the link service request through the LSR instruction field: one must clear beforehand the respective shared subsystem unit interrupt source.

If microcode executes an instruction with field LSR=0 (clear Link Service Request), the link branch condition is cleared. However, the link service request itself is cleared only if no link from other channel was received by the serviced channel during the same thread[27] . Note that this applies only to links that come from the other engine or the same channel: if only Shared Subsystem link was received during the thread, the link service is also cleared with field LSR=0. If microengine clears LSR of its channel and, simultaneously, Link Service Request is issued to the current serviced channel, the branch condition is cleared but the link service request remains pending.

Engine Selection		Reserved[1]	Channel Number				

NOTES:
1 reserved bit must be written 0.

Figure 2-27. Microengine LINK Register

27. That can only happen if the link service request came from the other Engine, or from the serviced channel itself.

A channel can issue Link Service Requests to channels in any of two Engines, determined by the LINK register field Engine Selection (2 bits), as shown in the following table. In a Single Engine eTPU, Link is ignored when sent to the other engine, or engine 2.

Table 2-44. LINK Engine Selection

Engine Selection	Description
00	this Engine
01	Engine 1
10[1]	Engine 2
11[1]	the other Engine

1. ignored in Single Engine eTPU.

There is no explicit hardware mechanism to allow the thread to identify the link service request source, but it can be done by a software protocol using SDM parameters. All links are negated on reset.

2.14.5.6 Enhanced Digital Filter - EDF

The EDF eliminates passing of signal transitions which are caused by noise. Its purpose is to eliminate false transition service requests caused by noise pulses which are shorter than a programmed width.

See the chip-specific eTPU information for connections between eTPU and input glitch filters.

The EDF has three modes of operations, selected by the CDFC field in eTPU Engine 1 Configuration Register (eTPU_SCR_ECR_ENG1) and eTPU Engine 2 Configuration Register (eTPU_SCR_ECR_ENG2). These modes offer selections of trade-off between noise immunity and signal latency. CDFC also allows the filter to be bypassed. Table 2-45 gives an example of minimum detected signal pulse and maximum filtered noise pulse in the three EDF operation modes. In Angle Mode, if AM=01, the EDF in channel 0 is replaced with the digital filter and synchronizer of the TCRCLK signal. In this mode, channel 0 works in combination with the Angle Counter logic, and their operation is fully synchronized.

Following subsections provide the functional description of the eTPU channel digital filter.

2.14.5.6.1 Two-Sample mode

In this mode the EDF works like the TPU2/3 digital filter. It uses the filter clock which is the eTPU clock divided by (2, 4, 8,.., 256) as a sampling clock. The filter clock is selected by the FPSCK field ineTPU Engine 1 Configuration Register (eTPU_SCR_ECR_ENG1) and eTPU Engine 2 Configuration Register (eTPU_SCR_ECR_ENG2). The EDF compares two consecutive samples. If both samples have the same value, the input signal state is updated. Note that when the FPSCK field selects the eTPU clock divided by two, the EDF works like the TPU1 four-clock digital filter.

2.14.5.6.2 Three-Sample mode

In this mode, like in the TPU2/3 mode, the EDF uses the filter clock as a sampling clock. The EDF compares three consecutive samples. If all three samples have the same value, the input signal state is updated.

The Three-Sample mode gives more signal latency than the Two-Sample mode, but also better noise immunity and better ratio between minimum detected signal pulse to maximum filtered noise pulse. When a certain filter clock frequency is selected for Two-sample mode, double filter clock frequency can be selected to get better latency in Three-sample mode.

2.14.5.6.3 Continuous mode

In this mode the EDF compares all the values sampled at the rate of eTPU clock divided by two, between two consecutive filter clock pulses. If the signal is continuously stable for the entire digital filter clock period (i.e all the samples have the same signal value), the input signal state is updated.

This method gives the same latency and the same ratio between minimum detected signal pulse to maximum filtered noise pulse, as the Two-Sample mode, as long as there is no noise. Each sampled noise delays the signal transition detection by at least a whole digital filter clock period.

The Continuous mode gives the best noise immunity by comparing multiple samples of the noise. On the other hand, when a short noise pulse appears in the middle of the filter clock period at the same time of a real signal transition, the Continuous mode may reject a real signal transition and delay the response to the first filter clock period in which the signal is continuously stable. This may add to the latency and also to the minimum detected signal pulse in a noisy environment.

2.14.5.6.4 Bypass Mode

In bypass mode the signal that feeds the edge detection comes directly from the output of the synchronizer, not filtered. Bypass mode automatically makes the channel logic work in T2/T4 timing mode (see Channel timing modes).

2.14.5.6.5 Filter clock prescaler

Each channel configured as an input has an associated synchronizer followed by a digital filter connected to the signal that samples signal transitions. After reset, the digital filter filters out high and low pulse widths smaller than the period of two eTPU clocks with eTPU_SCR_ECR_ENG*n* field FCSS=0, or 1 eTPU clock with FCSS=1 (see eTPU Engine 1 Configuration Register (eTPU_SCR_ECR_ENG1) and eTPU Engine 2 Configuration Register (eTPU_SCR_ECR_ENG2)), preventing these transitions from being input to the transition detect logic. For FPSCK=0 and FCSS=0, the synchronizer and digital filter are guaranteed to pass pulses that are as wide as or wider than four eTPU clocks, meaning a minimum period of 8 eTPU clocks. These figures are halved by setting FCSS=1. By changing the FPSCK field in eTPU Engine 1 Configuration Register (eTPU_SCR_ECR_ENG1) and eTPU Engine 2 Configuration Register (eTPU_SCR_ECR_ENG2) the user can select a lower clock rate for the filter signal to define wider valid pulses and filter out wider noise pulses. The filter prescaler clock control is a division of the eTPU clock. To guarantee pulse detection by the digital filter, the pulse must cover at least the stated number of samples at the filter clock rate. For example, a two sample digital filter must sample two points in the pulse to detect it. The table below shows the minimum guaranteed detected pulse width and the maximum filtered noise pulse width. The table refers only to the digital filter operation. The external pulses may have to be wider (to ensure detection) or narrower (to ensure filtering) depending on the rise/fall delay differences in the MCU receivers and internal logic. Delays introduced by synchronizer, filter and edge detection logic are explained in Input/Output Signal Delays.

The TCRCLK signal also has a synchronizer and a filter. The FCSS bit has no influence on the clock prescaler of the TCRCLK filter, which works like the channel filter with FCSS=0.

Table 2-45. Pulse widths and delays

Filter control (FPSCK)		Filter clock period[1]	Min. width guaranteed detected / max. width filtered (min. filter delay / max. filter delay)[1]	
FCSS = 0	FCSS = 1		Two-Sample or Continuous mode	Three-Sample or Integrator[2] mode
not avail.	000	1	2 / 1 (2 / 3)	3 / 2 (3 / 4)
000[3]	001	2	4 / 2 (3 / 3)	6 / 4 (5 / 5)

Table continues on the next page...

Table 2-45. Pulse widths and delays (continued)

Filter control (FPSCK)		Filter clock period[1]	Min. width guaranteed detected / max. width filtered (min. filter delay / max. filter delay)[1]	
FCSS = 0	FCSS = 1		Two-Sample or Continuous mode	Three-Sample or Integrator[2] mode
001	010	4	8 / 4 (5 / 7)	12 / 8 (9 / 11)
010	011	8	16 / 8 (9 / 15)	24 / 16 (17 / 23)
011	100	16	32 / 16 (17 / 31)	48 / 32 (33 / 47)
100	101	32	64 / 32 (33 / 63)	96 / 64 (65 / 95)
101	110	64	128 / 64 (65 / 127)	192 / 128 (129 / 191)
110	111	128	256 / 128 (129 / 255)	384 / 256 (257 / 383)
111	not avail.	256	512 / 256 (257 / 511)	768 / 512 (513 / 767)

1. This table shows pulse widths and delays in number of periods of the eTPU clock.
2. Integrator mode is available for TCRCLK filtering only, see TCRCLK digital filter.
3. These delays also apply to the TCRCLK filter when TCRCF selects eTPU clock/2 as filter clock.

Note

The TCRCLK filter is clocked as if FCSS=0, always dividing eTPU clock /2 using FPSCK, regardless of the FCSS field.

2.14.5.7 Channel timing modes

Channels can work on two different timing schemes, defining the period of channel clocking, tied to T2 and T4 microengine phases, as explained in subsections below. Microengine T2 and T4 phases are shown in Microcycle and I/O timing.

2.14.5.7.1 T2 channel timing

In T2 timing mode the channel event state can only be updated every two eTPU clocks (see Figure 2-55). Pin state, TDLs, MRLs and Capture registers are updated on the microengine's T2 clock phase. MRLE clears also happen on T2, but MRLE setting occurs on T4, together with the Match register write by microcode (see Write Channel Match and UDCM Registers).

Channels work in T2 timing mode when either the T4DIS field in eTPU Channel n Configuration Register for Engine 1 (eTPU_CCCR_C*n*CR_ENG1) and eTPU Channel n Configuration Register for Engine 2 (eTPU_CCCR_C*n*CR_ENG2) is 1 or all the following conditions are true:

- The TCR1CS field in eTPU Engine 1 Time Base Configuration Register (eTPU_TBR_TBCR_ENG1) and eTPU Engine 2 Time Base Configuration Register (eTPU_TBR_TBCR_ENG2) is 0.
- The Enhanced Digital Filter is not configured as bypass (see Enhanced Digital Filter - EDF).
- The FCSS field in eTPU Engine 1 Configuration Register (eTPU_SCR_ECR_ENG1) and eTPU Engine 2 Configuration Register (eTPU_SCR_ECR_ENG2) is 0 (see Filter clock prescaler).

2.14.5.7.2 T2/T4 channel timing

In T2/T4 timing mode the channel event state can be updated on any eTPU clock (see Figure 2-56). Pin state, TDLs, MRLs, MRLEs, and Capture registers are updated either on microengine's T2 or T4 clock phases. MRLE clears can happen on T2 or T4, but MRLE setting occurs on T4 only, together with the Match register write by microcode (see Write Channel Match and UDCM Registers).

Channels work in T2/T4 timing mode when the T4DIS field in eTPU Channel n Configuration Register for Engine 1 (eTPU_CCCR_C*n*CR_ENG1) and eTPU Channel n Configuration Register for Engine 2 (eTPU_CCCR_C*n*CR_ENG2) is 0 and either one the following conditions are true:

- The TCR1CS field in eTPU Engine 1 Time Base Configuration Register (eTPU_TBR_TBCR_ENG1) and eTPU Engine 2 Time Base Configuration Register (eTPU_TBR_TBCR_ENG2) is 1.
- The Enhanced Digital Filter is configured as bypass (see Enhanced Digital Filter - EDF).
- The FCSS field in eTPU Engine 1 Configuration Register (eTPU_SCR_ECR_ENG1) and eTPU Engine 2 Configuration Register (eTPU_SCR_ECR_ENG2) (see Filter clock prescaler).

T2/T4 timing mode demands special care on channel microcode that reprograms a match in a thread with matches enabled (entry point ME=1, see the “Entry Points” section). When the match register is written and the MRLA/B flag(s) is(are) cleared in the same instruction, a match can occur after MRLA/B is cleared, together with the set of respective MRLE. In this case, both MRL and MRLE will be set, and a match service request will occur if enabled. However, the match happened on the old match value, not on the new (reprogrammed) one. In order to prevent this ambiguity to the code that services the match, it is advisable to clear the MRLE (besides MRL) together with the

match reprogramming, avoiding the match on the old value to occur while the new match value is being written. The set of the MRLE due to match reprogramming prevails over the MRLE clear, thus allowing the new programmed match to occur in the future.

A similar case occurs when a match is blocked by a transition, the blocking TDL is cleared and the blocked match is reprogrammed at the same instruction: in T2/T4 timing mode: a match can occur on the old match value. The solution is the same as the case above, that is, clear the respective MRLE in the same instruction.

2.14.6 Time bases

Each eTPU engine has two Time Counter Registers, TCR1 and TCR2. They provide 24-bit time bases, shared by all 32 channels. Any channel can use both time bases to:

- Match channel's internal registers MatchA or MatchB;
- Capture time base value to channel's internal registers, CaptureA and/or CaptureB, when a match recognition or an Input transition detection occurs. For more information on channel events refer to Enhanced Channels.

The TCR1 and TCR2 counters are accessible by the microcode for read and write operations. Its current value is used for getting the current time, and the captured values are used for channel relative time calculations of future events. When they are written at the same time they are incremented from any clock source, the written value prevails.

TCR1 with eTPU_TBR_TBCR_ENG*n*[TCR1CS]=0 and TCR2 values are updated in T2 and read in T4 (see Microcycle and I/O timing). TCR1 can also work at full-speed eTPU clock, and so be updated on both T2 and T4, when eTPU_TBR_TBCR_ENG*n*[TCR1CS]=1. Both TCR1 and TCR2 values can be imported from or exported to the STAC bus. When their values are imported (STAC Clients), these registers are written from the STAC bus and can only be read by microcode.

The TCR2 counters between the two Engines are out of phase by 1 eTPU clock, even when Time Bases are shared between them through STAC. It also applies to TCR1 counters if eTPU_TBR_TBCR_ENG*n*[TCR1CS]=0, but they can be in phase otherwise.

2.14.6.1 Timer Count Register 1 - TCR1

TCR1 can be used in the following modes:

- Internally Clocked Mode

- Externally Clocked Mode
- STAC Bus Client Mode

The host program can read TCR1 time base through eTPU Engine 1 Time Base 1 (TCR1) Visibility Register (eTPU_TBR_TB1R_ENG1) and eTPU Engine 2 Time Base 1 (TCR1) Visibility Register (eTPU_TBR_TB1R_ENG2).

The TCR1 bus runs through all the local engine channels. In channels which select TCR1 as MatchA and/or MatchB source, when its value is greater or equal to the programmed match value, a Match A and/or Match B event occurs on that channel. A recognized match event sets its related Match Recognition Latch 1 or 2, and according to the Predefined Channel Modes (PDCM) it may generate a channel service request. For details on eTPU channels see Enhanced Channels.

2.14.6.1.1 Externally Clocked Mode

TCR1 can be driven externally by the TCRCLK input, after the digital filter. The TCR1 clock source is configured by the TCR1CTL bit, as shown in the following figure. For more information on clock source selection, see eTPU Engine 1 Time Base Configuration Register (eTPU_TBR_TBCR_ENG1) and eTPU Engine 2 Time Base Configuration Register (eTPU_TBR_TBCR_ENG2).

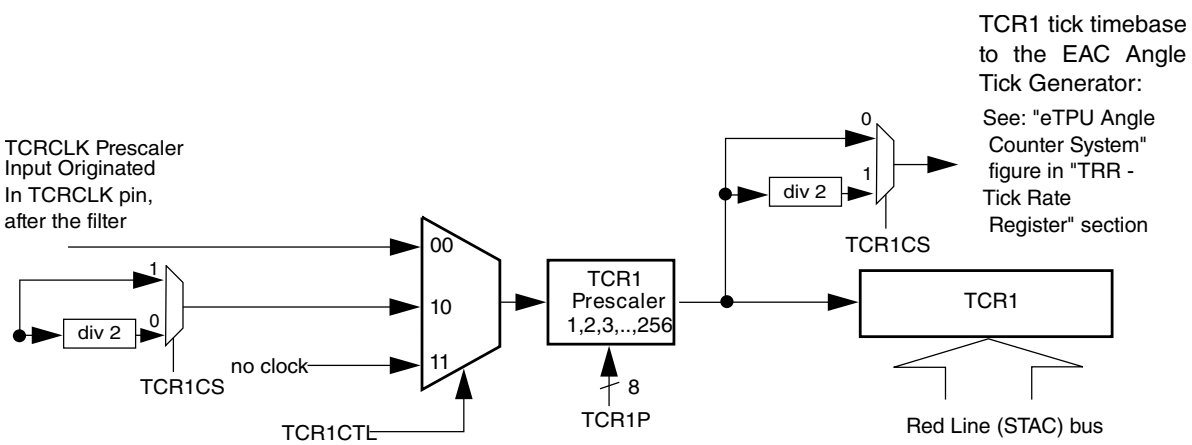

Figure 2-28. TCR1 clock selection

2.14.6.1.2 Internally Clocked Mode

TCR1 can be driven by the eTPU clock or eTPU clock divided by 2, before the prescaler. TCR1CTL can also be used to freeze TCR1 clock independently of TCR2 (unlike GTBE).

2.14.6.1.3 TCR1 clock prescaling

Any clock source selected by TCR1CTL is prescaled by a factor of 1 to 256, selected by the TCR1P field in eTPU Engine 1 Time Base Configuration Register (eTPU_TBR_TBCR_ENG1) and eTPU Engine 2 Time Base Configuration Register (eTPU_TBR_TBCR_ENG2). For more information on prescaler configuration see eTPU Engine 1 Time Base Configuration Register (eTPU_TBR_TBCR_ENG1) and eTPU Engine 2 Time Base Configuration Register (eTPU_TBR_TBCR_ENG2). The TCR1 Prescaler resets when the eTPU GTBE input is negated. After reset, it starts counting up to TCR1P when the eTPU GTBE input is asserted. When TCR1 increments (the eTPU GTBE input = 1), the prescaler starts a new count and the new TCR1P becomes effective. When TCR1 is written by microcode, the prescaler is reloaded with TCR1P and it becomes effective, if the eTPU GTBE input is asserted.

2.14.6.1.4 STAC Bus Client Mode

In this mode the TCR1 register is continuously updated from the STAC bus, and the clock selection and prescaling logic becomes ineffective. It is not writable by the microcode, and when read, it reflects the STAC bus imported value. The use of EAC is not allowed in client mode. This mode is configured through eTPU Engine 1 STAC Configuration Register (eTPU_TBR_STAC_ENG1) and eTPU Engine 2 STAC Configuration Register (eTPU_TBR_STAC_ENG2).

2.14.6.1.5 STAC Bus Server Mode

TCR1 bus can be exported to the STAC bus as a server, providing time information to other peripherals. This mode is configured through eTPU Engine 1 STAC Configuration Register (eTPU_TBR_STAC_ENG1) and eTPU Engine 2 STAC Configuration Register (eTPU_TBR_STAC_ENG2).

2.14.6.2 Timer Count Register 2 - TCR2

The TCR2 is a 24-bit counter which can be used in the following modes:

- Pin Transition Mode: Count the rise, fall or both transitions of TCRCLK signal.
- Angle Clock Mode: Count internal tooth angle in combination with the eTPU Angle Counter (EAC) hardware which implements an Angle PLL, and generates angle information to the channels. This mode is targeted for angle based applications.
- STAC (STAC) Bus Client Mode: TCR2 is driven by an external source (see STAC Bus Client mode).

- Gated Mode: Count with rate derived from the eTPU clock divided by eight. The TCRCLK signal is used to gate this count, enabling pulse accumulator operations.
- Internally Clocked Modes: TCR2 is driven by internal clock, with count rate of eTPU clock divided by eight.

All clock sources pass through a prescaler. In addition, the TCR2 count can be originated from the EAC which is a hardware angle clock and angle counter. Figure 2-29 shows the diagram for TCR2 clock control. When TCR2 is not driven by the EAC or STAC, the eTPU_TBR_TBCR_ENG*n*[TCR2CTL] field selects the clock source, also allowing TCR2 to be frozen independently of TCR1 (see eTPU Engine 1 Time Base Configuration Register (eTPU_TBR_TBCR_ENG1) and eTPU Engine 2 Time Base Configuration Register (eTPU_TBR_TBCR_ENG2)). When in Angle Mode, TCR2CTL selects the TCRCLK edge sensitivity.

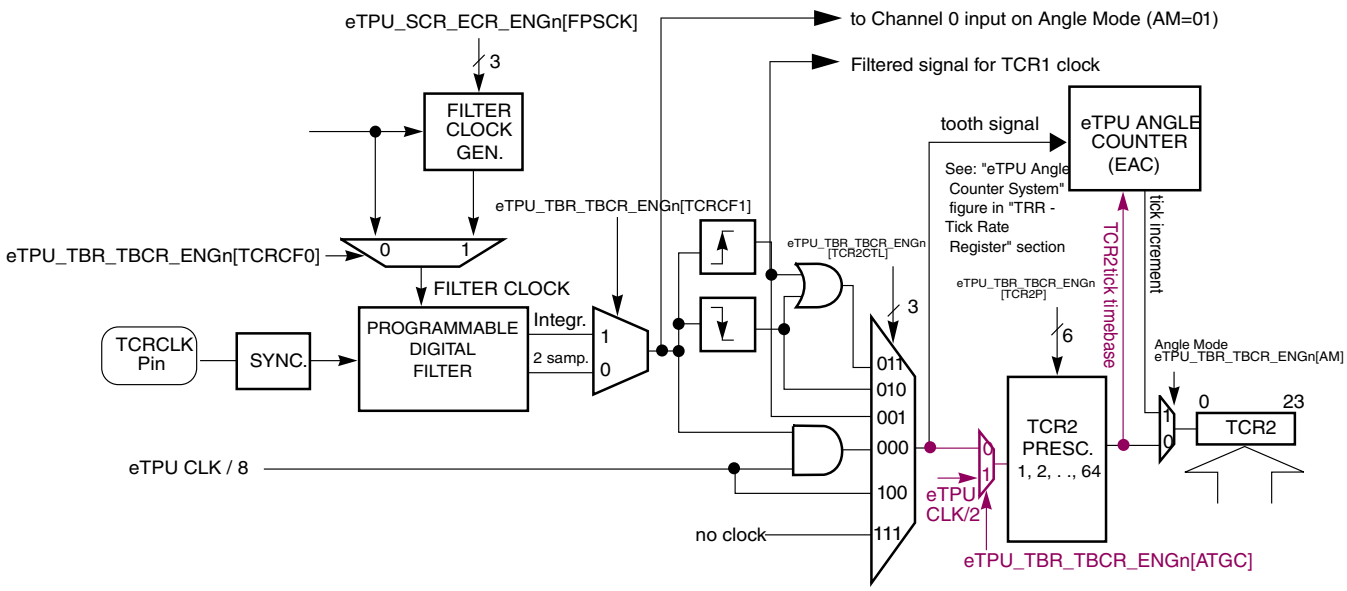

Figure 2-29. TCR2 clock control

The TCRCLK signal input is passed through a synchronizer and a programmable digital filter. In Angle Mode with AM=01, synchronizer and filter are also used in Channel 0, replacing its input synchronizer and filter, to get the same timing in the EAC and Channel 0. The TCRCLK synchronizer is an improved filter that provides best latency while maintaining proper noise filtering (see the field TCRCF in eTPU Engine 1 Time Base Configuration Register (eTPU_TBR_TBCR_ENG1))

The TCR2 bus runs through all the local engine channels. It transitions on clock T2 (see Microcycle and I/O timing). In channels which select TCR2 as MatchA and/or MatchB source, TCR2 value is compared against MatchA and/or MatchB registers. A recognized

match event sets its related Match Recognition Latch 1 or 2, and according to the Predefined Channel Modes (PDCM) it may generate a channel service request. For details on eTPU channels see Enhanced Channels.

The TCR2 counter is accessible by the microcode for read and write operations. Its current value is used for getting the current counter value (representing signal transitions, time or angle), and the captured values are used for channel relative count calculations of future events. The TCR2 value is readable to the host through eTPU Engine 1 Time Base 2 (TCR2) Visibility Register (eTPU_TBR_TB2R_ENG1) and eTPU Engine 2 Time Base 2 (TCR2) Visibility Register (eTPU_TBR_TB2R_ENG2). When the TCR2 bus value is imported from the STAC bus (STAC client mode), TCR2 is not writable by the microcode, and read access from the microcode or from the host reflect the imported TCR2 value.

2.14.6.2.1 TCR2 clock prescaling

Except in Angle Mode, any clock source selected by TCR2CTL is prescaled by a factor of 1 to 64, selected by eTPU_TBR_TBCR_ENG*n*[TCR2P]. For more information on prescaler configuration, see eTPU Engine 1 Time Base Configuration Register (eTPU_TBR_TBCR_ENG1) and eTPU Engine 2 Time Base Configuration Register (eTPU_TBR_TBCR_ENG2). The TCR2 Prescaler resets when the eTPU GTBE input is negated. After reset, it starts counting up to TCR2P when the eTPU GTBE input is asserted. When TCR2 increments (the eTPU GTBE input = 1), the prescaler starts a new count and the new TCR2P becomes effective. When TCR2 is written by microcode, the prescaler is reloaded with TCR2P and it becomes effective, if the eTPU GTBE input is asserted.

The counter that divides the eTPU clock by 8 before the prescaler also resets when the eTPU GTBE input is negated, or when TCR2 is written by microcode.

In Angle Mode the TCR2 prescaler is not used to directly increment TCR2, but can be used, selected by programming eTPU_TBR_TBCR_ENG*n*[ATGC]=1, as a clock source for the EAC generation of the angle ticks which increments TCR2. In this case, the TCR2 prescaler input is eTPU clock/2, independently of TCR2CTL. See Generating the angle ticks for details.

2.14.6.2.2 TCR2 Gated mode

TCR2 Gated mode is selected in the eTPU_TBR_TBCR_ENG*n*[TCR2CTL] field. In this mode the TCRCLK signal enables or disables transfer of the eTPU clock divided by 8 to the TCR2 prescaler. By programming the prescaler, TCR2 can run at rates from eTPU clock divided by eight down to eTPU clock divided by 512, in steps of eight eTPU clock

divisions. For more information, see eTPU Engine 1 Time Base Configuration Register (eTPU_TBR_TBCR_ENG1) and eTPU Engine 2 Time Base Configuration Register (eTPU_TBR_TBCR_ENG2).

2.14.6.2.3 TCR2 Signal Transition modes

These modes are selected when eTPU_TBR_TBCR_ENG*n*[TCR2CTL] is set to rise, fall or "rise-and-fall". In these modes the TCRCLK signal is the TCR2 clock source, and its maximum transition rate depends on the TCRCLK digital filter mode of operation. The TCRCLK digital filter can be programmed to use the eTPU clock divided by two, or use the same filter clock of the channels, controlled by eTPU_TBR_TBCR_ENG*n*[TCRCF]. It contains an up-down counter which operates as a digital integrator, optimizing signal latency in the selected mode and clock rate.

When eTPU clock divided by two is selected, the synchronizer and the digital filter are guaranteed to pass pulses that are wider than four eTPU clocks (two filter clocks). Otherwise the TCRCLK is filtered with the same filter clock as the channel input signals. For details on TCRCLK and channels digital filter control, see eTPU Engine 1 Time Base Configuration Register (eTPU_TBR_TBCR_ENG1), eTPU Engine 2 Time Base Configuration Register (eTPU_TBR_TBCR_ENG2), and Enhanced Digital Filter - EDF.

2.14.6.2.4 STAC Bus Client mode

In this mode the TCR2 register is continuously updated from the STAC bus, and the clock selection and prescaling logic becomes ineffective. It is not write accessible for the microcode, and when read, it reflects the STAC bus imported value. The use of EAC is not allowed in client mode. This mode is configured throughTPU Engine 1 STAC Configuration Register (eTPU_TBR_STAC_ENG1) and eTPU Engine 2 STAC Configuration Register (eTPU_TBR_STAC_ENG2).

2.14.6.2.5 STAC Bus Server mode

When TCR2 bus is exported to the STAC bus as a server, it can provide either time or angle bus to other peripherals, according to its operation mode. This mode is configured through eTPU Engine 1 STAC Configuration Register (eTPU_TBR_STAC_ENG1) and eTPU Engine 2 STAC Configuration Register (eTPU_TBR_STAC_ENG2). To provide sequential update of the STAC clients, the Angle tick rate must not be faster than the STAC programmed update rate. This requirement puts a limitation on the angle clock count rate on high rate mode. In this case the Angle and Angle Fraction accumulator (see Angle Tick Generator and Figure 2-35) are advanced at rate of eTPU clock divided by eight. Therefore, the STAC update rate for the Angle Bus must not be slower than eight eTPU clocks.

2.14.6.2.6 TCR2 bus in Angle Clock mode

In this mode the TCR2 counter operates as part of the eTPU Angle Counter (EAC). The TCR2 bus value reflects this angle representation in which it counts Angle Ticks. Angle Mode is selected when eTPU_TBR_TBCR_ENG*n*[AM]=1.

Note that when TCR2 works in Angle Mode, it does not count directly from the TCR2 clock input which indicates tooth signal transition. Its Angle counter is controlled by the Count Control and High Rate logic (see Count Control and High Rate Logic), which provides the interpolated pin position, and handle cases of missing tooth, acceleration, de-acceleration and mechanical corrections.

The EAC uses the TCRCLK signal to get the tooth transition indications. The eTPU_TBR_TBCR_ENG*n*[TCR2CTL] field has to be set for the appropriate tooth edge detection rise, fall, "rise-and-fall" or none. TCR2 count clock comes from the EAC control and not directly from the physical tooth. This way the EAC control processes the signal transitions and handles missing teeth and flywheel mechanical corrections. Note that when TCR2CTL selects "none" for tooth edge selection, the TCR2 is not necessarily frozen, but can still be incremented by the EAC logic.

In Angle Mode, eTPU channel 0, 1 or 2 operation is combined with the EAC operation. When channel 0 is selected for EAC operation, the TCRCLK digital filter is used both by the EAC and by channel 0 to get full synchronization between the two logics.

The eTPU Angle Counter (EAC) logic runs continuously and updates the TCR2 Angle counter, eliminating the microcode latency in updating the TCR2 value.

2.14.6.3 STAC interface

Both time bases TCR1 and TCR2 can be shared between the Engines and with other blocks in the same MCU. Each one of both eTPU engines can drive their time bases to the STAC (Shared Time and Count) bus, acting as a server, while any other block can capture the value into its resources and behave like a client. For further reference about the STAC bus operation see eTPU Engine 1 STAC Configuration Register (eTPU_TBR_STAC_ENG1) and eTPU Engine 2 STAC Configuration Register (eTPU_TBR_STAC_ENG2).

The eTPU can export to the STAC bus or import from the STAC bus the following internal resources:

- TCR1: Can be exported to or imported from the STAC bus. TCR1 can only be imported from STAC bus when the engine is not in Angle Mode. When TCR1 is imported from the STAC bus, it becomes read-only for the microcode and reflects the imported values. For details, see Timer Count Register 1 - TCR1.
- TCR2: Can be exported to or imported from the STAC bus. TCR2 can only be imported from the STAC bus when engine is not in Angle Mode. When TCR2 is imported from the STAC bus, it becomes read-only for the microcode, and reflects the imported values. When exported to the STAC bus, TCR2 can work in either Angle Mode or as a free running counter associated with the TCRCLK signal. For details, see EAC - eTPU Angle Counter.

Proper configuration of the following bits is necessary to determine what can drive the STAC bus: eTPU_TBR_TBCR_ENG*n*[AM] and eTPU_TBR_STAC_ENG*n*[REN2, RSC2], according to the following table.

Table 2-46. STAC bus and host read sources

AM (eTPU_TBR_TBCR_ENG*n*)	REN2, RSC2 (eTPU_TBR_STAC_ENG*n*)	TCR2 bus source (Host read of eTPU_TBR_TB2R_ENG*n*)	STAC bus driver
00	0× (disabled)	TCR2/Time	×
01, 10 or 11	0× (disabled)	TCR2/Angle	×
00	11 (Server)	TCR2/Time	TCR2/Time
01, 10 or 11	11 (Server)	TCR2/Angle	TCR2/Angle
01, 10 or 11	10 (Client)	not allowed[1]	

1. STAC client configuration in Angle Mode is also not allowed for TCR1.

Note that Angle Mode is not available for STAC bus clients: configuring both at the same time brings unspecified results and must be avoided. When TCR2 is a stand-alone counter or a STAC Bus server, the same value that is driven to the internal TCR2 bus is also exported to the STAC bus (either Time Count or Angle).

STAC bus configuration is provided by the eTPU_TBR_STAC_ENG*n* fields REN1/2 and RSC1/2. REN1/2 enable the STAC interface to interact with the resource (either TCR1 or TCR2 bus). RSC1/2 configure the resource (either TCR1 or TCR2 bus) as Server or Client.

Each time base / angle count resource from each engine receives a unique 4-bit hard-wired address that identifies it as a potential server. This address is used by the STAC Controller to coordinate which resource will drive the bus at a given STAC time-slot. For any time-slot there is a server driving the bus upon selection of the STAC Controller, and there may be a client linked to that server by the eTPU_TBR_STAC_ENG*n* fields bits SRV1/2 on each Engine. When the server address on the Red Line STAC bus matches

the value in SRV1/2, the client will load the STAC information into the appropriate resource. For information on eTPU STAC Bus configuration, see eTPU Engine 1 STAC Configuration Register (eTPU_TBR_STAC_ENG1) and eTPU Engine 2 STAC Configuration Register (eTPU_TBR_STAC_ENG2).

The eTPU does not include a STAC Controller module, which is instantiated once in the system integration.

Note

Setting a timebase as client of itself is not allowed.

2.14.6.4 GTBE - Global Time Base Enable

GTBE enables time bases in both engines, allowing them to be started synchronously. GTBE is divided in two block interface signals: the eTPU GTBE output and the eTPU GTBE input. GTBE bit sets the eTPU GTBE output , and the eTPU GTBE input enables time bases to start. The eTPU GTBE output signal can be used by MCU integration for synchronization between eTPU time bases and time bases from other modules. If GTBE must enable only the eTPU time bases, the eTPU GTBE output is simply connected to the eTPU GTBE input. These two cases are shown in the figure below. Synchronization logic can be as simple as an OR logic gate.

Once the eTPU GTBE input transitions to 1, the Engine 1 Time Bases start 1 eTPU clock earlier than Time Bases in Engine 2, except when TCRCLK is selected as clock source or TCR1 when eTPU_TBR_TBCR_ENG*n*[TCR1CS]=1 . This happens independently of prescaler values as long as they are the same for both engines, because the prescalers also freeze when the eTPU GTBE input = 0. Microcode can always write to TCR1/2 registers, with either value of the eTPU GTBE input.

NOTE

The timebase prescalers are reset when the GTBE input is negated.

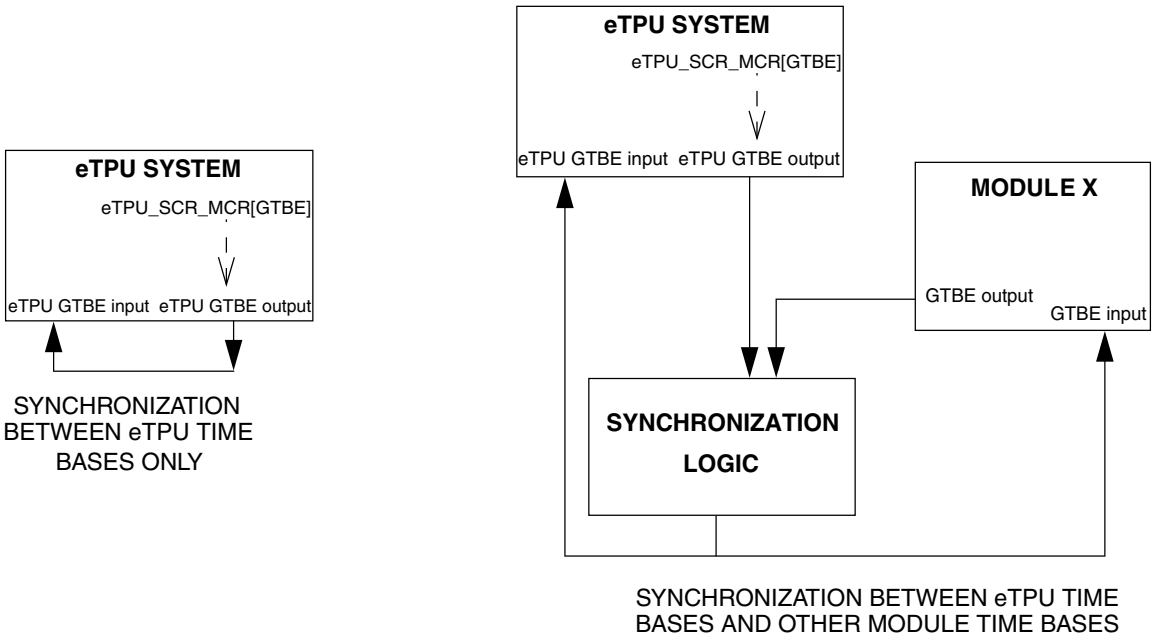

Figure 2-30. Time base synchronization

2.14.6.5 TCRCLK digital filter

The TCRCLK signal has an improved integrating digital filter with a 2-bit up-down counter. The counter counts up to 3 when a high signal level is detected, or down to 0 when a low level is detected. The signal state is updated to one when the counter stops at 3, or zero when the counter stops at 0. The eTPU_TBR_TBCR_ENG*n*[TCRCF] field (see eTPU Engine 1 Time Base Configuration Register (eTPU_TBR_TBCR_ENG1) and eTPU Engine 2 Time Base Configuration Register (eTPU_TBR_TBCR_ENG2)) determines whether the TCRCLK signal input (after a synchronizer) is filtered with the same filter clock as the channel input signals (see Enhanced Digital Filter - EDF) or uses the eTPU clock divided by 2, and also whether the TCRCLK digital filter works in integrator mode or the same two sample mode as the channel filters (see Table 2-30).

The TCRCLK filter delay and prescaling determines the minimum detectable TCRCLK pulse widths and, therefore, its maximum frequency, as shown in Filter clock prescaler and Table 2-45 . The TCRCLK signal delay from the module input to TCR1/TCR2 incrementing or detection in the EAC logic is explained in Input/Output Signal Delays.

2.14.7 EAC - eTPU Angle Counter

2.14.7.1 General

The EAC logic contains a mechanism which follows the flywheel angle, based on the tooth rate. This hardware works in combination with the TCRCLK signal, the TCR2 counter and Channel 0, 1 or 2 (depending on the eTPU_TBR_TBCR_ENG*n*[AM] field) to generate angle information on the TCR2 bus which is passed to all the local engine channels. The EAC helps to implement a digital angle PLL (see Figure 2-34), which combines hardware with microcode processing at channel 0, 1 or 2. The angle measurement is based on history knowledge of the tooth period, for predicting the period of the next tooth. The tooth period is partitioned into a programmable number of **Angle Ticks**. The eTPU application will use the divider in the MAC/Divide unit to calculate an integer and a fraction part of the angle tick such that the full tooth period gets the correct programmed number of angle ticks with no accumulated error.

Each single tooth can be divided in angle ticks, up to 1024. In a 60 teeth flywheel, 128 Angle Ticks per tooth provide resolution of ~0.05 degrees per tick, which meets the accuracy requirement of 0.1 degrees in current automotive applications.

The measurement of one tooth in angle ticks is independent on engine RPM; it is the tooth period itself (and the corresponding tick period) that is re-calculated for each new tooth, based on the difference between the estimated tooth and the actual detection.

For these applications, one of the eTPU channels 0, 1 or 2 is dedicated to service the physical tooth detection. Channel 0 shares the same filtered input as the TCRCLK signal to get the same timing as the EAC. The TCRCLK edge detection is selected by the eTPU_TBR_TBCR_ENG*n*[TCR2CTL] field for the EAC, and by IPACA/B on channel 0, which must be set to detect the same edge(s). When channels 1 or 2 are selected to work with the EAC, IPACA/B is used to select the tooth signal edge detection for both the channel and the EAC, and the tooth signal that feeds the EAC is the same filtered input which feeds the channel.

Channel 0, 1 or 2 generates the signal transition service request, and can also be used for generation of a window filter on this transition, to qualify TCR2 clocks. For this purpose, the selected channel should be configured with double match window filtering mode (refer to Channel Modes). Depending on the channel mode set for the channel, Match A recognition opens the window, and Match B recognition may close it or leave it open. See Angle Logic and Channel Modes for details. Match B also generates a time-out service request. Its input signal transition comes from the tooth. The window can be defined by microcode to open at a predefined point inside the tooth period, and stay open for a desired percentage to the tooth period. The window can be measured in angle or time This method improves the noise immunity by allowing transition detection only on an expected period, a feature which was software responsibility in previous TPU versions.

The EAC supports deceleration, acceleration, last tooth and missing tooth scenarios. The large range of angle ticks per tooth can be used to cover longer tick counts caused by one or more missing teeth, or to provide extra resolution for future application requirements. In case of a missing tooth, the EAC can be configured to insert a dummy tooth or to simply measure a longer tooth.

Figure 2-35 shows the block diagram of the Angle Counter system. TCR1 or TCR2 prescaler is used as a time base which measures the tooth period and is used for partitioning the period to angle ticks.

2.14.7.2 Angle Mode registers

In Angle Mode, the registers described below control eTPU angle operations. They are accessible only by microengine as source and destination registers in microinstructions. When eTPU is not in angle mode (eTPU_TBR_TBCR_ENG*n*[AM] field is negated), all Angle Mode registers can be used as general purpose registers.

2.14.7.2.1 TPR - Tooth Program Register

TPR provides configuration for the Angle Counter circuit. In this register, the microcode can properly adjust the tooth count (controlling last tooth, missing teeth, dummy tooth insertion, halt until tooth detection) and the number of angle ticks per tooth (field TICKS). Note that this register is sampled into a temporary register in the EAC logic when the High Rate Mode is detected (see High Rate Mode (Acceleration) and TPR Buffering), which means that changes to this register may take effect only for the next tooth.

See Count Control and High Rate Logic and to Special Cases of Missing Teeth and Last Tooth until Handling False Tooth Detection for a detailed explanation about the use of this register. The figure below provides a detailed description of TPR register.

Several conflict issues on TPR writes are explained in Special TPR write cases.

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	LAST	MISSCNT [1:0]		IPH	HOLD	MISS CNT [2]	TICKS									
RESET:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 2-31. TPR

LAST —Last Tooth Indication

Asserted by microcode and negated when a tooth is detected or inserted via IPH.

Table continues on the next page...

1 = Last Tooth - reset TCR2 Counter at the end of the tooth tick count (after physical tooth or IPH=1) when MISSCNT=0.

0 = Not Last Tooth.

If the tooth is detected or inserted before the tooth tick count completes (going High Rate mode, see High Rate Mode (Acceleration)), LAST resets immediately, but TCR2 resets only when the tooth count completes and MISSCNT=0.

MISSCNT — Missing Tooth Counter

Decremented on each estimated tooth, stops at zero. Used for generation of up to 7 "Dummy Teeth" whenever it holds a non-zero value.

If the tooth is detected or inserted before the missing tooth tick count completes (going High Rate mode, see High Rate Mode (Acceleration)), MISSCNT resets immediately, but missing teeth count continues in High Rate mode (see TPR Buffering).

IPH — Insert Physical Tooth

This bit generates a dummy physical tooth which has the same effect as a real physical tooth, and resets itself subsequently. If EAC is in Halt mode, it switches back to Normal mode[1]. If EAC is in Normal Mode, it switches to High Rate Mode. If Angle Logic is frozen by HOLD=1 (see below), it returns to the state it was at the freezing moment.

1 = Insert dummy physical tooth.

0 = No Operation.

Note: IPH reads as 1 in the next microinstruction after it is asserted, negating subsequently. However, it can be set twice in two consecutive microinstructions to generate two teeth and make the EAC go from Halt to Normal to High Rate Mode.

HOLD — Force EAC Hold

This bit forces the EAC to halt its operation in a special EAC freeze mode until a new physical tooth (a real one or emulated with IPH=1) is detected. Assertion of this bit immediately freezes the EAC in the middle of the tooth period. When a new physical tooth is detected, the bit is automatically negated by the EAC. The HOLD bit can be used for synchronizing the EAC tooth count, in case that a false physical tooth is detected due to noise.

1 = Force EAC to halt until detection of a physical tooth.

0 = Normal Operation.

TICKS — Angle Ticks Number in the Current Tooth

This field defines the number of angle ticks in the current physical tooth. It partitions the tooth period to the required number of angle ticks. The actual number of angle ticks in a tooth is (TICKS+1).

Note: In High Rate mode (see High Rate Mode (Acceleration)), TPR writes are immediately effective only for bits IPH and HOLD. All other fields changes are "buffered" and become effective when EAC leaves High Rate mode. See also Special TPR write cases.

Note: Bits LAST, IPH and HOLD must not be asserted all at once

1. Missing a physical tooth naturally causes EAC to get into Halt mode.

2.14.7.2.2 TCR2 - Timer Counter 2

In Angle Mode, TCR2 (see the following figure) counts angle ticks instead of time.

	23	22	21	20	19	18	17	16
R W	Angle Tick Counter[23:16]							
RESET:	0	0	0	0	0	0	0	0

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	Angle Tick Counter[15:0]															
RESET:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 2-32. TCR2 in Angle Mode

This 24-bit free-running counter is used to generate an accumulated Angle Fraction value. It is updated by the Angle Tick Generator - refer to Angle Tick Generator for more details. Refer to Count Control and High Rate Logic for a detailed explanation about the use of this register in Angle Mode.

TCR2 provides continuous count of the angle in units of angle ticks. The Angle Tick Counter in TCR2 can be reset due to "Last Tooth" microcode indication. TCR2 Prescaling is disregarded in Angle Mode: physical tooth detection is done by EAC regardless of the value set in TCR2P.

2.14.7.2.3 TRR - Tick Rate Register

The exact period of the Angle Tick is programmed in the Tick Rate Register (see the figure below) by microcode. The TRR time unit depends on eTPU_TBR_TBCR_ENG*n*[ATGC] (see Figure 2-35):

- if ATGC=0, the TRR time unit is the period of TCR1 clocks taken as eTPU clocks divided by 2*(TCR1P + 1), even if TCR1CS=1 (see eTPU Engine 1 Time Base Configuration Register (eTPU_TBR_TBCR_ENG1) and eTPU Engine 2 Time Base Configuration Register (eTPU_TBR_TBCR_ENG2)) .
- if ATGC=1, the TRR time unit is given by the eTPU clock divided by 2*(TCR2P+1), using the TCR2 prescaler fed by eTPU clock/2 (independently of TCR1CS).

See Calculating the Angle Tick Period Integer and Fraction for a complete description about the mechanism to calculate the value to be written into this register.

	23	22	21	20	19	18	17	16
R W	INTEGER[14:7]							
RESET:	0	0	0	0	0	0	0	0

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	INTEGER[6:0]							FRACTION								
RESET:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 2-33. TRR

INTEGER — The integer part of TCR1/TCR2 clocks in one Angle Tick.

This number, decremented by one, works as a down-counter preload value. A value of INTEGER=0 represents an integer of 32768. A new value written is reloaded into the counter (becoming effective) when a new tick starts or a tooth is detected or inserted via IPH.

FRACTION — Nine-bit fractional part of TCR1/TCR2 clocks in one angle tick.

The FRACTION value is accumulated in the EAC Fraction Accumulator, and whenever the result overflows (i.e., the accumulated fraction added up to an integer), the Tick Prescaler is halted for one TRR time unit.

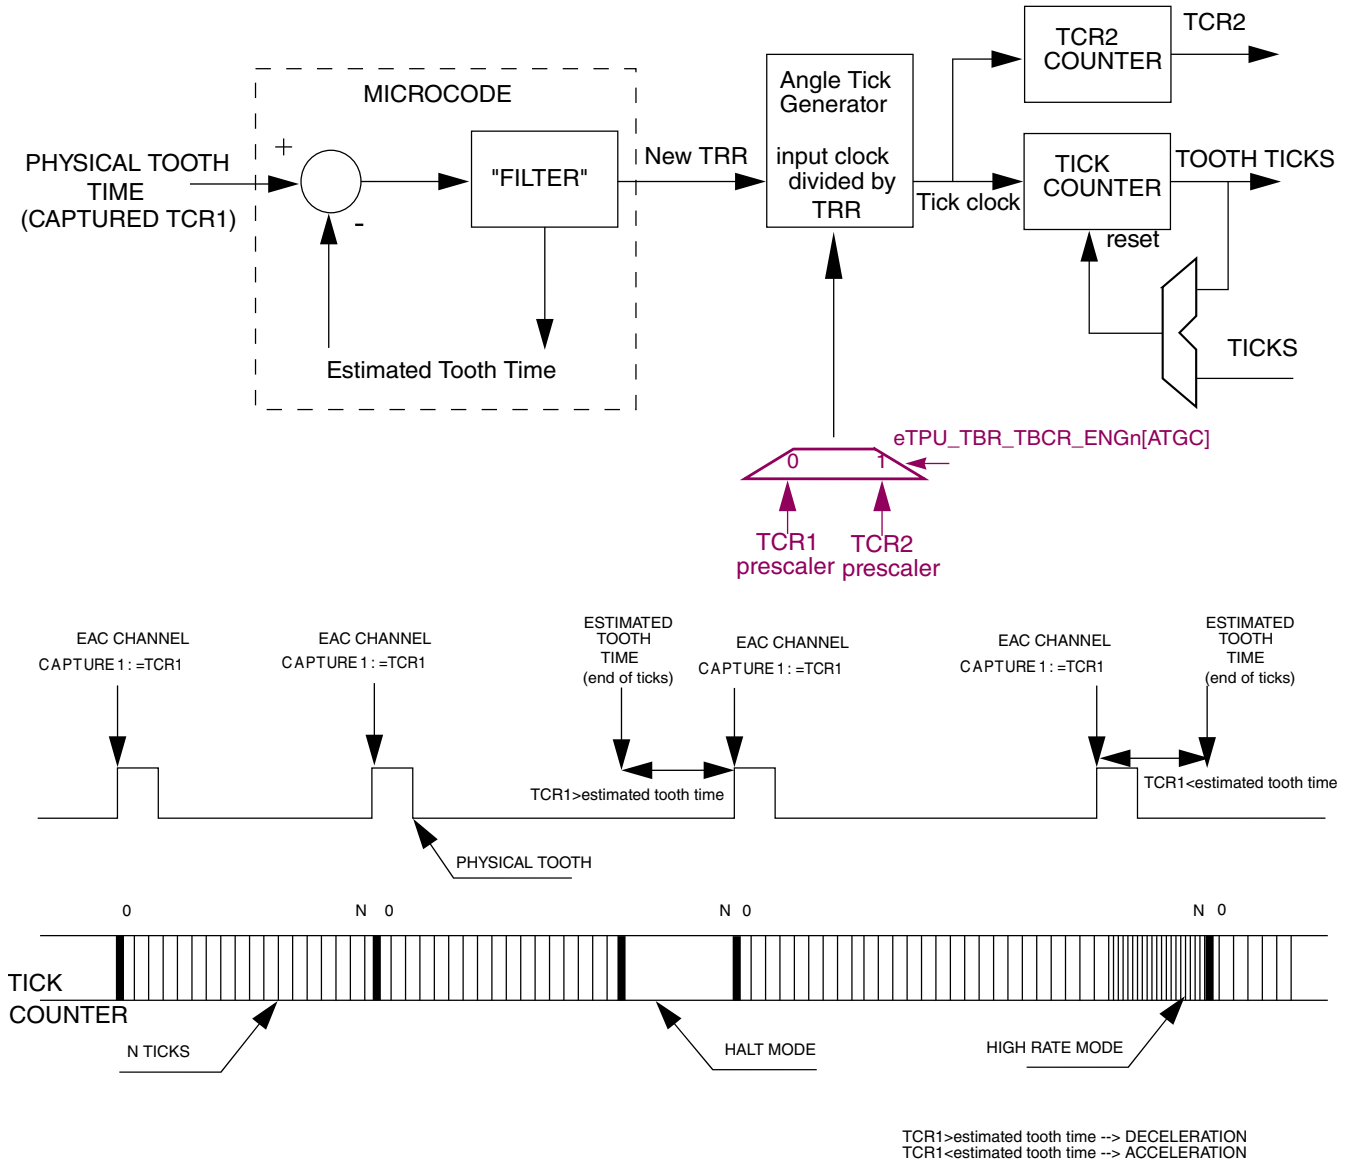

Figure 2-34. EAC "PLL"

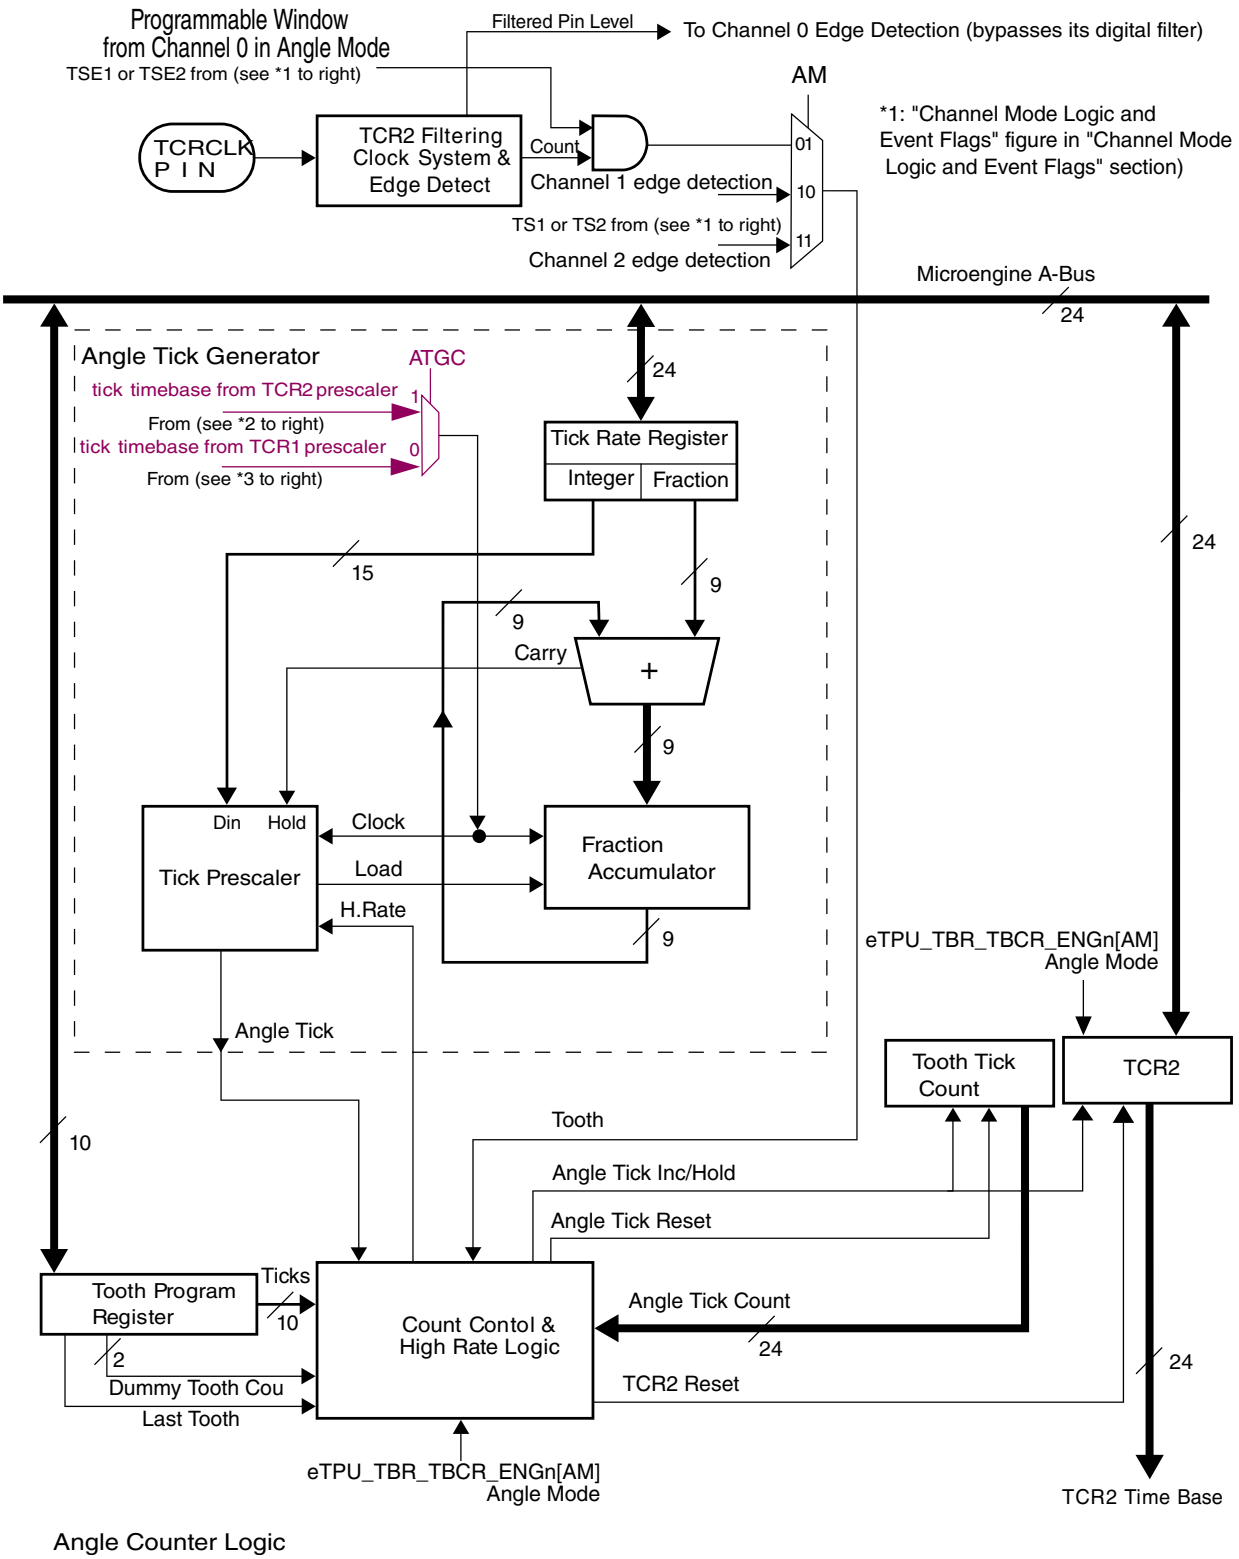

Figure 2-35. eTPU angle counter system

2.14.7.3 Acceleration and Deceleration

Acceleration and deceleration affect the new tooth period relative to the known period of the last tooth. Changes in tooth period may be extreme at very low engine RPM (such as cold start and warm start). The worst case of tooth period changes is caused during missing teeth, since there is more time for changes in angular velocity to be unnoticed by the EAC hardware. For example, on cold start (~20 RPM) there may be extreme acceleration: the ratio between a known tooth period before two missing teeth and the new tooth period after the missing teeth can be very high (up to a factor of 75). Acceleration and deceleration effects from tooth to tooth are less extreme as the engine climbs to high RPM.

In case of deceleration, the estimated tooth period ends before the actual tooth detection arrives. In this case, the EAC hardware waits at the end of the current tooth period, when it is said to be in **Halt mode**, until the real tooth indication is received, then continues with normal operation (**Normal mode**). See Figure 2-34.

In case of acceleration, the actual tooth period is shorter than the estimated tooth period. As a result, a new physical tooth indication arrives before the end of the estimated tooth period. In this case the EAC closes the gap on **High Rate mode** by counting on eTPU clock divided by eight to the end of the tooth, advances to the next tooth, and switches back to normal operation mode. See Figure 2-34.

The reason that the EAC does not jump directly to the next tooth is the need to provide sequential angle count throughout the whole tooth period, for channels or external STAC clients (if TCR2 is a STAC server) which compare angle in "equal" mode. These peripherals must get all the valid angle values in a sequential manner, to avoid missing angle matches.

TCR2 advancing from one tooth to another is a continuous count, and can be optionally reset at the end of the tooth. An estimated tooth is generated after the Tooth Tick Counter reaches the TICKS programmed value.

The EAC works continuously and switches automatically between Normal, Halt and High Rate modes. It relies on the microcode to calculate the estimated tooth period on every tooth, and to update the correct angle tick and tooth parameters in the EAC control registers. On high RPM, tooth period changes are reduced from tooth to tooth, and the EAC may follow the angle with good accuracy for several teeth without microcode intervention.

The EAC handles missing teeth by insertion of "dummy" teeth, or by enlarging the expected tooth period. It is a good practice to locate the flywheel missing teeth in non-critical angles, since a missing tooth may increase the angle measurement error (acceleration and deceleration is detected late).

2.14.7.4 Angle Tick Generator

The Angle Tick Generator is responsible for generating a programmed number of angle ticks in the tooth period. It generates the ticks in an average rate which ensures completion of the correct number of angle counts in the estimated period of the tooth, since the count of one tooth in angle ticks is independent on engine RPM. The main output of the Angle Tick Generator is the tick clock that feeds TCR2 in Angle Mode, as well as the internal Tooth Tick Counter (see Figure 2-35). The Tooth Tick Counter counts ticks within a tooth, from 0 up to TICKS, is controlled by the Angle Tick Generator logic and cannot be accessed by microcode. Refer to Figure 2-36 for a generic presentation of the angle tick count and the measurement of a single tooth period.

2.14.7.4.1 Calculating the Angle Tick Period Integer and Fraction

On each tooth the microcode has to update the exact period of a single angle tick used for counting the internal angle in the tooth. The period of an angle tick is determined by the EAC configuration, see Generating the angle ticks for details.

The microcode can use the eTPU MAC Divider unit (see MAC and Divide Unit (MDU)) to divide the tooth period by the number of angle ticks per tooth, which is stored in the TICKS field of TPR (refer to Angle Mode registers). This division yields the integer part of the angle tick period and the remainder. Dividing again the remainder shifted left nine positions, by the number of angle ticks per tooth translates the remainder to a 9-bit fraction. The microcode concatenates the 15-bit integer and the 9-bit fraction to a 24-bit value and writes it to TRR. The new rate is effective immediately after the next Angle Tick is generated by the Angle Tick Generator[28].

For high RPM, note that shifting the tooth period value nine positions to the left prior to the first divide operation would calculate, in one operation, the integer and the fraction. For example: On 60 teeth flywheel running at 1000 RPM, tooth period is 1 msec. If TCR1/TCR2 counts @25 MHz, it counts 25,000 times in a tooth, which can be represented by 15 bits. Therefore the tooth period can be shifted nine positions to the left prior to divide operation, and be represented with 24 bits.

Using shift left nine positions and one divide operation would get the result in MACL register (in MDU) which holds the integer and nine bits of the fraction:

```
Angle_Tick_Rate {Integer[14:0], Fraction[8:0]} = (ToothPeriod <<9) / Ticks
TRR = Angle_Tick_Rate {Integer[14:0], Fraction[8:0]}
```

28. In High-rate mode, the tick keeps being updated at the rate of eTPU clock/8 until it goes back to Normal mode, when the new TRR value is used.

NOTE

In the pseudocode above, the tooth period (ToothPeriod) is not, in general, the value of estimated tooth time. It is obtained by microcode by subtracting TCR1 values between two teeth detections, converted to TCR2 periods if ATGC=1. Its comparison with the estimated tooth time indicates acceleration (if minor) or deceleration (if greater) to the microcode.

On low RPM the initial tooth period, measured in TCR1/TCR2 counts, may be too big to be shifted nine positions to the left. For lower RPM (for example 500 RPM) the tooth period cannot be represented by 15 bits, and shifting it nine positions to the left would lose the MSB. In this case, two divide operations are required as follows: first divide the Tooth Period by the number of TICKS - the integer is stored in MACL and remainder in MACH. MACL is saved in another register. MACH is shifted 9 positions to the left and divided again by TICKS. In parallel with the second divide, the register which saved the original MACL is shifted left 9 positions. After the divide MACL contains the 9 bits fraction and the other register contains the 15-bit integer, shifted left nine times. The logical OR of the two registers is written to the TRR:

```
Angle_Tick_Rate {Integer[14:0]} = (ToothPeriod) / Ticks
Remainder[9:0]                  = ToothPeriod) mod Ticks
Angle_Tick_Rate {Fraction[8:0]} = (Remainder[9:0] << 9) / Ticks
TRR = Angle_Tick_Rate {Integer[14:0], Fraction[8:0]} = (Integer[14:0] << 9) | Fraction[8:0]
```

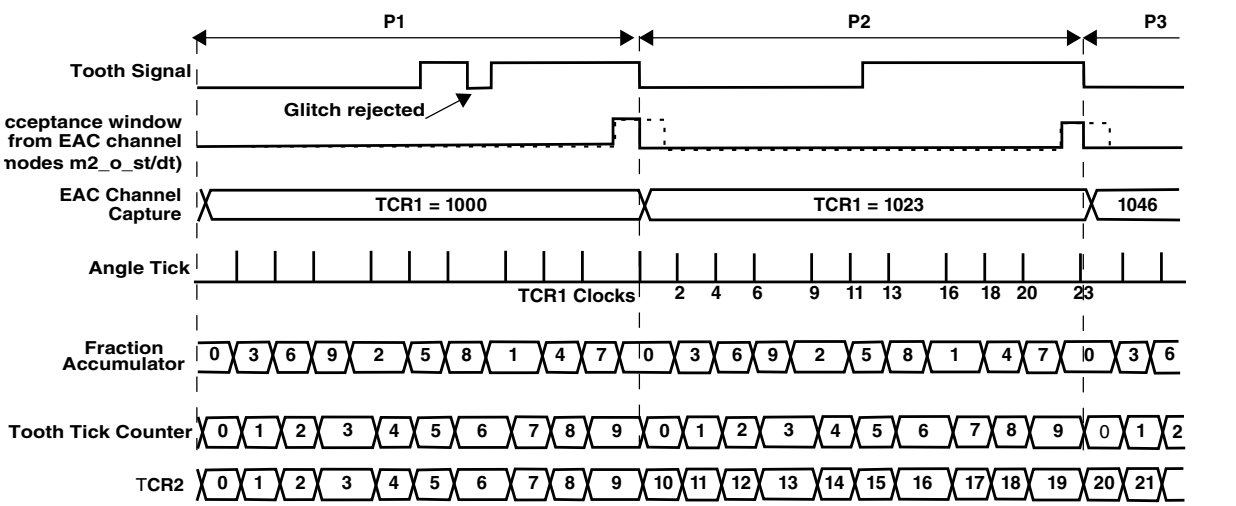

Figure 2-36. Angle Ticks Generation

2.14.7.4.2 Generating the angle ticks

The integer part of TRR is preloaded to a prescaler, which counts in time intervals as follows (see Figure 2-35):

- If eTPU_TBR_TBCR_ENG*n*[ATGC]=0, one unit of TCR1 clock period (if TCR1CS=0) or twice the TCR1 clock period (if TCR1CS=1)[29], that is, eTPU clock period*2*(TCR1P+1) (independently of TCR1CS).
- If ATGC=1, two units of the eTPU clock period multiplied by the TCR2 prescaler factor, that is, eTPU clock period*2*(TCR2P+1).

When the down counter reaches zero, it generates an angle tick pulse to the Angle Counter Logic and a Load pulse to the Fraction Accumulator. It is then preloaded with most updated TRR integer part. Due to the Load pulse, the 9-bit fraction is accumulated in a 9-bit Fraction Accumulator. If a fraction overflow condition occurs (the 9-bit adder asserts carry out), the accumulator saves the lower 9 bits of the addition result, which is the remaining fractional part. The carry out bit indicates an accumulated integer "one" which means that the angle tick is early by one input clock. It halts the prescaler operation for one input clock to compensate the accumulated error generated by the integer prescaler. As a result, the average angle tick period takes into account both the integer and the fraction parts. The accuracy depends on the bit count of the fraction. Using 9-bit fraction part while the width of the field TICKS in register TPR is 10 bits provides accuracy of two LSB on a full scale (TICKS=1023) or one LSB on lower scale (TICKS<=511).

When the Tick Prescaler gets High Rate mode indication from the Angle Counter Logic, it generates angle ticks at a rate of eTPU clock divided by eight. In this case it does not generate Load pulses to the Fraction Accumulator, ignores its "hold" input and preloads internally to a fixed period of eight eTPU clocks. When High Rate mode is entered, the prescaler is preloaded to a period of eight eTPU clocks before its first angle tick generation, ensuring separation of at least eight eTPU clocks between the last Normal mode angle tick and the first High Rate mode angle tick. The fraction accumulator resets when the tick count advances to the next tooth, or when TRR is written by the microcode.

2.14.7.5 Count Control and High Rate Logic

The Count Control and High Rate Logic controls TCR2 operation in Angle Mode, using the angle ticks generated by the Angle Tick Generator. Count Control logic is responsible for advancing, holding and resetting the TCR2 and Tooth Tick Counter in the proper timing, such that the TCR2 time base will reflect the correct estimated angle. This logic also includes the Tooth Program Register (TPR, see Angle Mode registers for more information).

29. The EAC logic overall runs at a rate of eTPU clock divided by 2, therefore the tick generator takes the halved TCR1 clock when TCR1CS=1 and ATGC=0.

The Count Control and High Rate Logic handles deceleration, acceleration, missing teeth and last tooth. On High Rate (acceleration) it ensures that the angle bus scans all valid angle values in a rate which can be traced by the STAC bus. This operation enables external STAC clients (if TCR2 is a STAC server) or channels working in "equal-only" comparator mode to match the TCR2 exported angle information in "equal" mode, in an exact match.

Because the eTPU channels are capable of capturing either TCR1 or TCR2 due to signal transition, the microcode can get either the angle or time of the physical pin transition. Since the EAC channel (0, 1 or 2) is connected to the physical tooth, the microcode can get the EAC error in angle domain (tooth appears at the wrong angle) or time domain (physical tooth captured time into the EAC channel, relative to the estimated tooth time). Note that in angle mode, the transition detect logic of the channel 0, if selected as the EAC channel, is fed from the digital filter of the TCRCLK signal, and not from the channel 0 internal digital filter. This ensures synchronous operation of channel 0 and the EAC hardware.

Another feature of the eTPU channel, when working in Single Match And Single Transition Enhanced Mode (refer to Single Match Enhanced Mode (sm_st_e)), is capturing a single time base due to signal transition before and after the digital filter. This option allows subtracting the digital filter delay to get accurate signal transition timing on the channel. This way, the TCRCLK signal may be programmed with a slow and reliable digital filter, and get accurate time measurement of the digital filter delay.

To assert the end of the estimated tooth period the Count Control and High Rate logic compares the TICKS field in TPR (refer to Angle Mode registers) with the current value of the tooth tick counter. When the Tooth Tick value is greater or equal to TICKS, it determines the end of the estimated tooth period. On acceleration this event occurs during High Rate mode operation, after the arrival of a physical tooth. In deceleration, this event occurs during Normal Mode, before the arrival of a physical tooth. On constant angular velocity, this event appears together with the arrival of a physical tooth.

The following sections describe the operation of the Counter Control and High Rate logic.

2.14.7.5.1 Normal Mode

In Normal mode the Counter Control logic advances TCR2 and the Tooth Tick counter as if the engine has a constant speed during the tooth period. It receives the angle ticks from the Angle Tick Generator in an average rate which is determined by the Tooth Rate Register (TRR). This is the reset mode.

When the Tooth Tick Counter is about to reach the last value effectively stored in TPR field TICKS plus one, the hardware detects the end of the estimated tooth period. If the physical tooth and the estimated tooth arrive at the same time the EAC stays in Normal mode, the Tooth Tick Counter is reset, and TCR2 is incremented (depending on TPR bits LAST and MISSCNT). If the physical tooth and the estimated tooth do not arrive at the same time, either acceleration or deceleration is detected, and the EAC switches to the proper mode. See the figure below for a detailed diagram of Normal Mode behavior.

The microcode which services the EAC channel physical tooth transition may update TRR according to various conditions to give the best estimation of the current tooth period, according to the previous tooth period and other engine parameters.

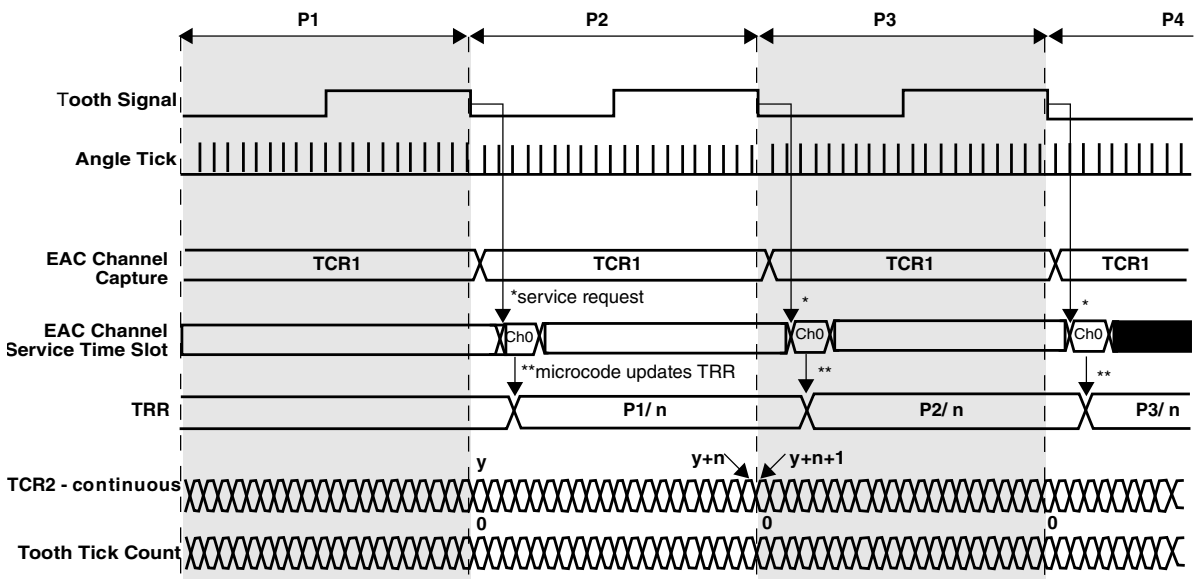

Figure 2-37. Normal Mode

2.14.7.5.2 Halt Mode (Deceleration)

In case of deceleration, the Tooth Tick Counter reaches the TICKS value before the arrival of the next tooth. The Count Control logic does not reset neither advances TCR2 and Tooth Tick Counters. The Count Control logic halts TCR2 and Tooth Tick Counters at the end of the tooth, waiting for the physical tooth to arrive.

When the physical tooth is detected the EAC switches back to Normal Mode and releases TCR2 to count the angle ticks of the new tooth, also resetting the Tooth Tick Counter. Only then TCR2 may wrap to 0, if TPR bit LAST is asserted. See the figure below for a detailed diagram of Halt Mode behavior.

The microcode service caused by the physical tooth determines the deceleration, calculates the new tooth period and Angle Tick period and updates TRR. This operation slows the angle tick rate generated by the Angle Tick Generator on-the-fly, to the rate required for the new tooth period.

Since the microcode service is initiated by the physical tooth edge, microcode latency may introduce a small angle error caused by using the TRR value of the previous tooth at the beginning of the current tooth. On high RPM, deceleration is relatively small but the microcode latency may take a significant percentage of the tooth period. On low RPM microcode service latency takes little percentage of the tooth period, but there may be cases of extreme acceleration and deceleration. The microcode latency can be calculated knowing TCR1 value during the service time, and TCR1 value captured in the EAC channel due to the physical tooth pin transition. The duration of the Halt mode is obtained using the estimated tooth time.

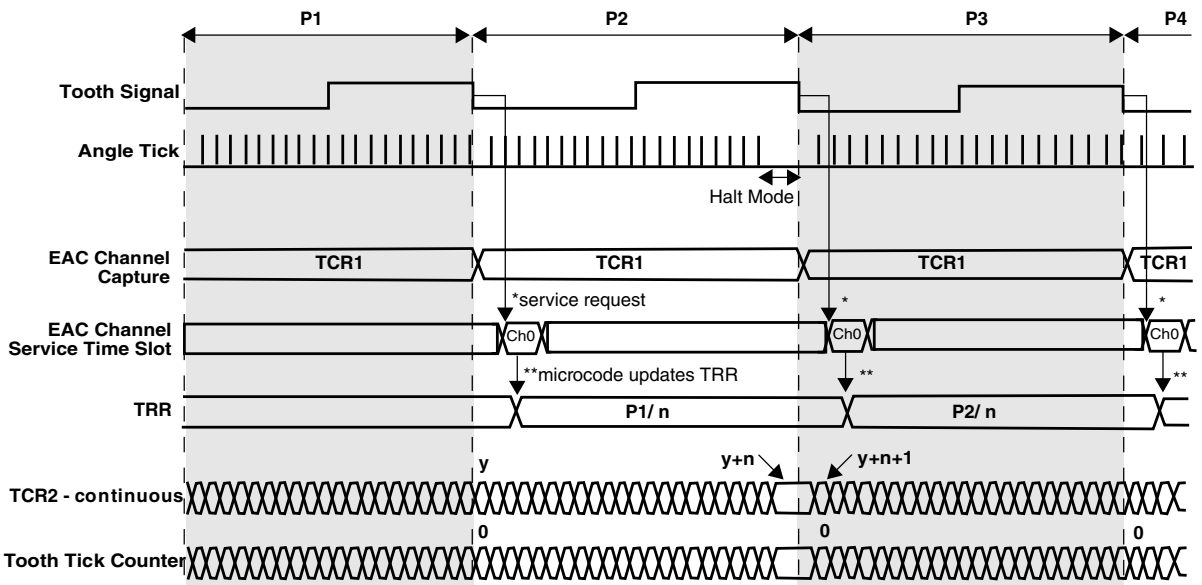

Figure 2-38. Halt Mode - Deceleration

2.14.7.5.3 High Rate Mode (Acceleration)

In case of acceleration, the next tooth arrives before the Tooth Tick Counter reaches the TICKS value. In this case the High Rate logic is responsible for closing the gap and advancing the tooth on the correct timing. The High Rate mode operates as follows:

- When the acceleration is detected (physical tooth arrives before the Tooth Tick Counter reaches the TICKS value), the Count Control and High Rate logic switches to High Rate mode in which both the Tooth Tick Counter and TCR2 count at rate of

eTPU clock divided by eight, until the Tooth Tick Counter reaches the current TICKS value. To ensure correct operation, the TICKS value is sampled in the logic at the beginning of the mode.

- At this point, which represents the estimated tooth edge, the logic resets the Tooth Tick Counter and advances TCR2 (or resets it if LAST is asserted and MISSCNT = 0).
- The control logic switches back to Normal Mode, using the most updated TRR value as input to the Angle Tick Generator. The logic samples the updated TICKS value for the tooth estimation, last tooth indication and number of missing teeth from TPR.

In High Rate mode the angle ticks are provided at high speed until the end of the current tooth. This operation is required to scan all the valid angle values of the current tooth, in a rate which is not too high for the STAC bus continuous update, but much higher than the rate dictated by TRR.

EAC channel microcode, which services the physical tooth transition detection, can start its service either before High Rate mode operation is complete (the Tooth Tick Counter has not reached the TICKS value) or after the EAC switched back to Normal mode. Any physical teeth received while the EAC is in High Rate Mode does not alter the immediate EAC state, but it is still detected by the EAC channel logic and can, therefore, alter future EAC behavior (for instance, closing the tooth detection window - see Angle Logic and Channel Modes).

At the beginning of High Rate mode operation, the TPR value is preloaded into a temporary register in the Counter Control Logic, used for scanning all the valid values to the end of the current tooth, with its appropriate LAST and MISSCNT attributes. While the EAC is in High Rate mode operation, the effect of microcode update of TPR fields LAST, MISSCNT and TICKS is delayed to the next estimated tooth, after the High Rate mode operation is complete (see Special TPR write cases). This is because the current physical tooth represents the next estimated tooth. If the microcode updates this field after High Rate mode operation is complete, the current physical tooth and estimated tooth are the same, and the effect is immediate. Either in High-Rate mode or not, the value read by microengine is the same written, even if not yet effective, until the EAC resets LAST and/or IPH, or decrements MISSCNT. Typically the microcode service may occur during the High Rate mode on extreme acceleration situation at low RPM. Therefore, the microcode operations are always related to the real physical tooth. From the above it can be seen that the microcode updates of the TICKS field in TPR affect the end time of the current physical tooth. For correct operation, this field should be updated before the Tooth Tick Counter has reached either the old or the new TICKS value.

During High Rate mode operation, TRR is ignored and the Angle Tick Generator uses eTPU clock divided by eight. Therefore, the TRR update by microcode will take effect only after the EAC switches back to Normal mode. If microcode service occurs after the Tooth Tick Counter has been reset, the EAC is already back in Normal mode, and some angle ticks may have been counted at the rate of the previous tooth. In this case the new TRR value will have immediate effect on the angle tick period, and the microcode should take into consideration the delay from the physical tooth to the estimated tooth in calculation of the next tooth period. See the figure below for a detailed diagram of High Rate Mode behavior.

An angle error may be introduced by the duration of the High Rate mode. Also, the scheduler latency may introduce a small accumulated error by using TRR value of the previous estimated tooth at the beginning of the current tooth. After the estimated tooth has advanced, the duration of the High Rate mode operation is the actual delay from the physical tooth edge to the estimated tooth edge. This delay can be obtained by comparing the estimated tooth time with the EAC channel capture register which captured TCR1 on the physical pin transition.

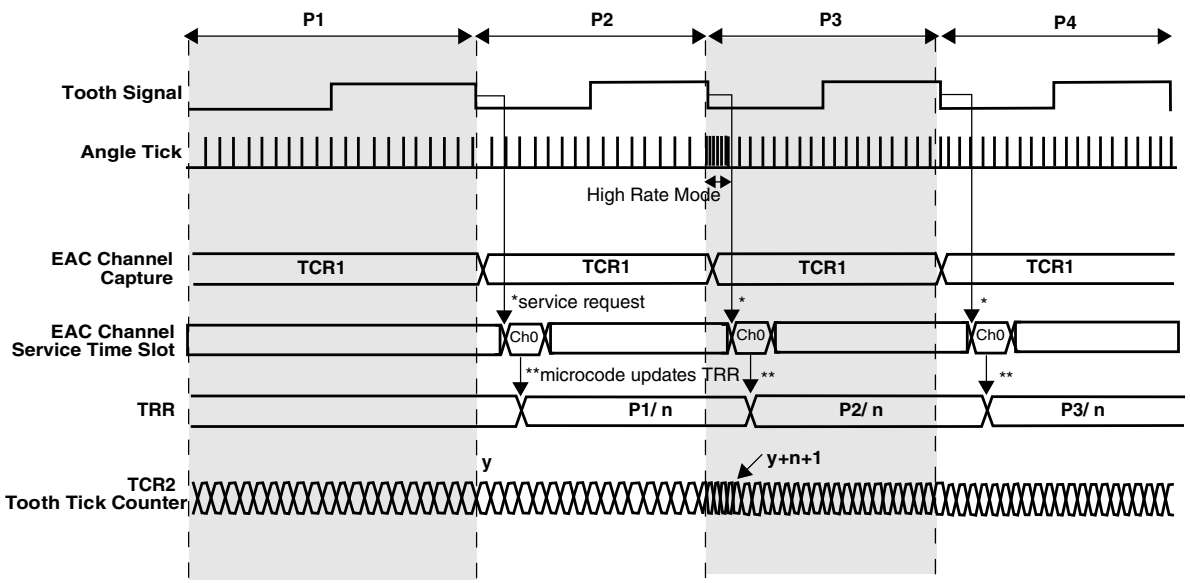

Figure 2-39. High Rate Mode - Acceleration

2.14.7.6 Special Cases of Missing Teeth and Last Tooth

The EAC handles cases of up to three missing teeth and the last tooth in the engine cycle. The following paragraphs describe these functions.

2.14.7.6.1 Handling the Last Tooth

The microcode can set the TCR2 counter to work in engine periods (wrap-around count) or continuous angle measurement.

For periodic operation, during the last engine cycle tooth the EAC microcode has to set the LAST flag in TPR. As a result, when the tooth period is ended, the Counter Control Logic generates a reset command to both the Tooth Tick Counter and TCR2 instead of an advance command. The operation resets the TCR2 based angle count, indicating a new period of the engine cycle. This implementation provides an engine cycle based periodic angle measurement.

2.14.7.6.2 Handling Missing Teeth

The EAC can handle up to three missing teeth in two ways:

- Count the angle ticks relative to the last physical tooth. The microcode should update the TPR TICKS field to the number of angle ticks included in two, three or four teeth, according to the flywheel type (one, two or three missing teeth). EAC hardware works in its regular manner.
- Insert a "dummy" tooth instead of the missing tooth, at the estimated point in time. After the "dummy" tooth, the Angle Tick Counter is incremented as if there was a physical tooth. A "dummy" tooth can be inserted only during Normal or High Rate operation modes. The microcode inserts "dummy" teeth by writing to the MISSCNT field in TPR.

In the first option the missing tooth is not counted on the angle measurement. For example, a flywheel with 59 physical teeth and one missing tooth can be considered as 58 identical teeth numbered (0-57) and tooth number 58 has a double number of angle TICKS. In this case a 720 degrees engine cycle has 118 teeth. TCR2 reflects the real angle, since it counts angle ticks continuously.

In the second option, the missing teeth are counted as "regular" teeth by automatic insertion of "dummy" teeth. The microcode has to write a non-zero value to the MISSCNT field in TPR. This field is a 3-bit down counter which affects the operation of the Counter Control logic.

For example, a flywheel with 59 physical teeth (0-58) and one missing tooth (59) can be considered as 60 teeth numbered (0-59), all having the same number of angle ticks. The microcode has to write "001" to the MISSCNT bits during the period of tooth number 58 to indicate that next tooth (59) is missing.

When the Tooth Tick Counter reaches the TICKS value, TCR2 is incremented as if a physical tooth has been detected. In addition, the MISSCNT value initializes a "dummy tooth counter" which is decremented to indicate the number of left "dummy teeth" which still need to be generated. Because a dummy tooth was counted, EAC does not enter Halt Mode and Tooth Tick Counter continues incrementing in the absence of a physical tooth detection.

In case of extreme acceleration on very low RPM (cold start) there can be a situation that the first physical tooth after one or two missing teeth appears even before the "dummy" tooth is generated. Due to the acceleration the EAC switches to High Rate mode in order to run through all the valid angle values, including the dummy teeth. When the Tooth Tick Counter reaches the TICKS value on High Rate mode, and the "dummy tooth" down counter is not zero, the generated "dummy tooth" advances to the next tooth and decrements the "dummy tooth" counter, but does not switch the EAC back to Normal mode. The last "dummy tooth" decrements the counter to zero, indicating that no more dummy teeth are to be inserted, and the next tooth is an estimated physical tooth. The EAC continues at High Rate mode until the Tooth Tick Counter reaches the TICKS value again, then advances to the next tooth while switching back to Normal mode. When in High Rate mode, the TPR register does not reflect the MISSCNT downcounting, see TPR Buffering for details.

MISSCNT can be rewritten before it reaches 0, allowing it to count more than 7 missing teeth, as long as no physical tooth arrives between the first MISSCNT write and the rewrite.

2.14.7.6.3 Combining Missing Teeth and Last Tooth

The Last Tooth indication takes effect when there are no more missing teeth to be generated, i.e the "dummy tooth" counter value is zero. If, for example, the microcode sets the missing teeth counter to "10" (two missing teeth) and sets the LAST flag, the first and the second dummy teeth will increment TCR2, and the third estimated tooth, which correlates with the physical tooth (the first of the next cycle), will reset TCR2, because LAST was set. This scheme enables the microcode to define one or more missing teeth to be replaced by "dummy tooth" insertion, and the end of the engine cycle in one service request. It is assumed that the two missing teeth must come together in the same engine cycle, and not split between two engine cycles (either the missing teeth are both last in an engine cycle or both not last, but not last in one engine cycle and first in the next).

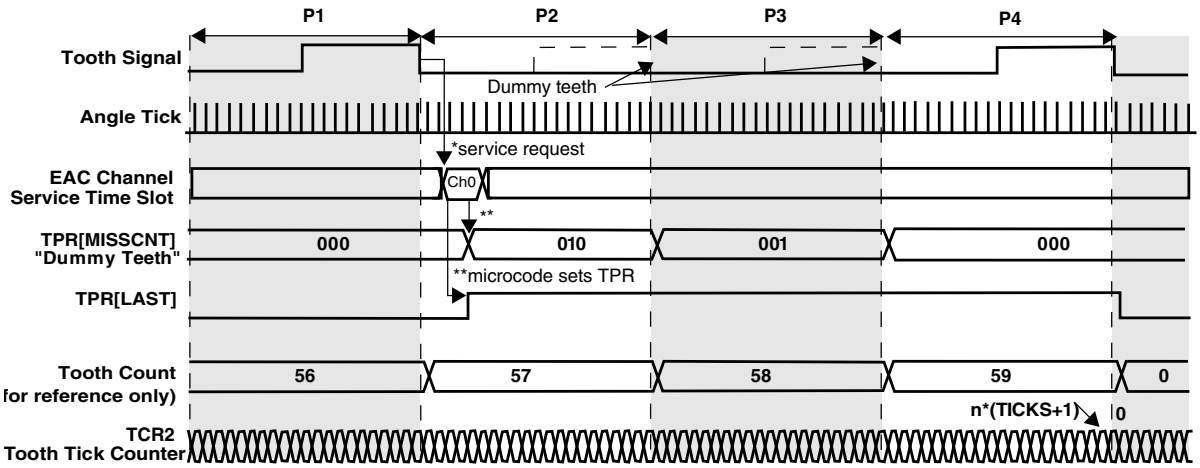

Figure 2-40. Missing Teeth and Last Tooth Combination

2.14.7.7 Handling Mechanical Tooth Correction

The EAC can handle tooth edge detection errors caused by flywheel mechanical errors. The eTPU application can hold a vector of tooth mechanical errors with one entry per tooth. This error can be measured in angle ticks which are independent of engine RPM. The TRR can be updated to the fixed period of any tooth, including its mechanical error.

Because TCR2 counts continuously, without being reset, the mechanical correction is transparent. Though the tooth has its own programmed TICKS value, TCR2 simply counts angle ticks, disregarding the boundary between two adjacent teeth.

2.14.7.8 Handling Mis-detected Tooth

When a physical tooth signal is missed by the engine sensor, the EAC may get into Halt mode at the end of the estimated tooth period, expecting the physical arrival. In this case, a Match timeout event of EAC channel will call service which detects extreme deceleration. The microcode can assert the IPH bit in TPR, to force the detection of the missed physical tooth. It can also calculate the accumulated angle bus error, and fix the next estimated tooth period, to close the gap.

2.14.7.9 Handling False Tooth Detection

Most of the false tooth detection, caused by noises on the engine tooth sensor, can be eliminated by the window blanking filtering, timed by EAC channel match recognitions. The EAC also provides means of fixing false detection of an additional tooth which passed the window filter. When such an event occurs, the EAC switched to High Rate

mode (advancing to the next tooth) and when the next physical tooth arrives, an extreme acceleration is detected: the EAC sees the remaining portion of the current tooth period as another tooth period. The microcode can detect the situation when the acceleration in not realistic, or when immediately after the detection of this extreme acceleration, the following tooth indicates extreme deceleration back to the original RPM.

When the microcode detects such a case, the Tooth Counter has been advanced by mistake to the next tooth. The microcode can set the HOLD bit in the TPR, forcing the EAC to freeze and wait for the next physical tooth to close the gap. When the next physical tooth arrives, HOLD is automatically negated and the EAC proceeds from that point to the remaining portion of the tooth period, in the same mode it was when HOLD bit was asserted.

2.14.7.10 Angle Logic and Channel Modes

The TCRCLK transition detection is qualified by a signal that comes from channel 0 (see Figure 2-35) and depends on the particular mode (PDCM) programmed for that channel. This configures a window for TCRCLK detection for the angle logic which is the same (except on High Rate mode, see High Rate Mode (Acceleration)) used to set the TDLA flag on single transition modes, and TDLB on double transition modes (see signals TSE1,TSE2 in Figure 2-18). The same applies when channels 1 or 2 are used to control EAC (see signals TS1, TS2 in Figure 2-18) . As a consequence, the window depends on the channel mode as follows:

- on all modes, the window closes upon a tooth edge detection: TDLA asserted on single transition modes, TDLB asserted on double transition modes.
- on mode m2_st: the window opens on Match A (which enables Transition A) and does not close with Match B. If Match B comes before Match A, it blocks Match A and, hence, Transition A.
- on mode m2_o_st: the window opens on Match A (which enables Transition A) and closes on Match B. Match B is enabled by Match A, so it cannot come before.
- on all other Single Transition modes, the window is "always open", independently of matches.
- on mode m2_dt: the window opens on Transition A, which is enabled by Match A. The window does not close with Match B, but if it comes before Match A the later gets blocked and, hence, blocks Transitions. Match A is also a condition for the window, so the microcode closes it by clearing MRLA.

- on mode m2_o_dt: the window opens on Transition A, which is enabled by Match A. The window closes on Match B, which is enabled by Match A. Match A is also a condition for the window, so the microcode closes it by clearing MRLA.
- on all other Double Transition modes, the window opens on Transition A.

2.14.7.11 Restarting angle logic

It is not recommended to change the eTPU_TBR_TBCR_ENG*n*[AM] field while GTBE=1. However, if the angle logic must be restarted without interfering with the timebase count running on TCR1, the procedure below must be followed:

1. Program eTPU_TBR_TBCR_ENG*n*[AM]=00 and TCR2CTL=111 at once. That prevents TCR2 from incrementing while the angle logic is disabled. The angle logic state machine resets to Normal mode and the tick prescaler to the initial count with AM=00, but not the microengine registers TPR and TRR.
2. Start a thread to reconfigure the EAC. The thread must set the EAC controlling channel (0, 1 or 2) flags in a state, depending on the channel mode, that lets the channel tooth detection window open (see Angle Logic and Channel Modes). It can optionally write TCR2 with an angle preset value equivalent to the first tooth expected after restart. The thread must also set TPR bit HOLD=1. The TPR bit IPH must be 0.
3. After the thread is finished, program eTPU_TBR_TBCR_ENG*n*[AM]=01, 10 or 11, and TCR2CTL according to the desired tooth edge selection if AM=01.

The first tooth detected after this procedure restarts the TCR2 counting, unfreezing the Angle Mode logic into normal mode.

2.14.7.12 Special TPR write cases

This section describes how simultaneous modification of TPR fields are resolved, and how the effect of TPR writes depend on the EAC mode.

2.14.7.12.1 TPR Buffering

In High Rate mode (see High Rate Mode (Acceleration)), TPR writes are immediately effective only for bits IPH and HOLD. Writes to all other fields are "buffered" and become effective when EAC leaves High Rate mode. However, if TPR is written a

second time right after IPH is asserted in Normal mode, this second write behaves as if EAC is still in Normal mode. Only in the next microcycle (after execution of a nop, for instance) the TPR writes are buffered, acknowledging High Rate mode.

MISSCNT and LAST can be written any value during High Rate mode, and the value that prevails for the next tooth is the one sampled when EAC goes back to Normal mode (or the value written in Normal or Halt mode thereafter). If MISSCNT and/or LAST are not zero when High Rate mode begins, they are sampled into the internal EAC logic and are effective while High Rate lasts (missing teeth count continues, and TCR2 is reset at the end of High Rate if LAST=1). However, their values in TPR are reset when High Rate mode starts. After that and until the end of High Rate mode, the value read by microcode is the same written. This behavior prevents read-modify-writes to TPR from unwillingly rewriting LAST or MISSCNT.

2.14.7.12.2 IPH and LAST

If both IPH and LAST are asserted in the same microinstruction with HOLD=0, the EAC acts as if LAST was set first and then IPH right after, so that:

- in Normal mode, it goes to High Rate with LAST=1;
- in Halt mode, it goes to Normal Mode resetting LAST (and TCR2);
- in High Rate mode, IPH is ignored and LAST becomes effective in the next tooth (physical or inserted) after it goes back to Normal mode.

2.14.7.12.3 IPH and TICKS

Because of different results depending on the EAC mode at the time of TPR write, it is not advisable to write 1 to IPH and change TICKS at the same microinstruction. A consistent behavior is obtained if IPH is written first and TICKS on the second microinstruction after (for instance with a nop between them), making the new TICKS value valid for the next tooth regardless of the mode.

The mode-dependent behavior is (assuming HOLD=0):

- in Normal mode, the new TICKS value becomes valid before EAC goes High Rate due to the IPH;
- in Halt mode, the EAC goes to Normal mode, and new TICKS is valid for the next tooth;
- in High Rate mode, the new TICKS value is effective when EAC leaves High Rate mode, and IPH is ignored;

2.14.7.12.4 IPH and MISSCNT

If both IPH and MISSCNT are written non-zero values with HOLD=0:

- in Normal mode, at the next microcycle the EAC goes to High Rate mode, the MISSCNT field in TPR goes to 0, and the missing teeth are counted in High Rate mode.
- in Halt mode, the EAC goes to Normal mode for one microcycle and then, yet another microcycle later, goes to High Rate mode, counting the missing teeth. The TPR fields IPH and MISSCNT are zeroed on the transition from Normal to High Rate mode.
- in High Rate mode, IPH is ignored (resetting at the next microcycle) and MISSCNT is buffered (see TPR Buffering).

2.14.7.12.5 IPH and HOLD

If IPH and HOLD are asserted at once, IPH cancels the HOLD and both reset. The EAC is not frozen, regardless of the EAC mode (High Rate, Normal or Halt).

2.14.7.12.6 LAST and HOLD

If LAST and HOLD are written 1 at once, LAST asserts and EAC is frozen. Afterwards, when a physical tooth is detected or IPH is asserted, the EAC is unfrozen in the same state it was before, and LAST is kept asserted.

2.14.8 Microengine

Each eTPU engine has a microengine that fetches, decodes and executes microinstructions. The Microengine only works when there are service requests to be attended, otherwise it turns to idle state, controlled by Hardware Scheduler (see Scheduler).

Microcode is stored in Shared Code Memory (SCM) that is 32-bit wide. Microengine can access SDM using a different bus from the one used to accesses code memory, so that code and data can be accessed at the same time (Harvard Architecture).

Some of eTPU functionality can only be made through the microengine, like configuring channels and interrupting host. Microengine gives eTPU a high degree of flexibility, since any desired treatment for channel's events can be implemented; however, that

flexibility comes at the cost of channel service's latency. Latency is worsened when channels from a same eTPU engine contend for microengine service. In the figure below, a block diagram of microengine architecture is shown.

Follows a summary of Microengine features:

- P, DIOB, A, B, C, D, SR, RAR, LINK, CHAN, MACL, MACH, ERTA, ERTB, TCR1, TCR2, TPR, TRR registers are accessible by microcode.
- 24-bit ALU and Post-ALU shifter performs basic arithmetic and logical operations described in ALU and Post-ALU Shifter.
- MDU (MAC/Divide Unit) performs integer MAC, multiply and divide operations.
- Fixed Microinstruction Size of 32bits.
- Fixed-length instruction execution (2 eTPU clocks)
- Static superscalar operation

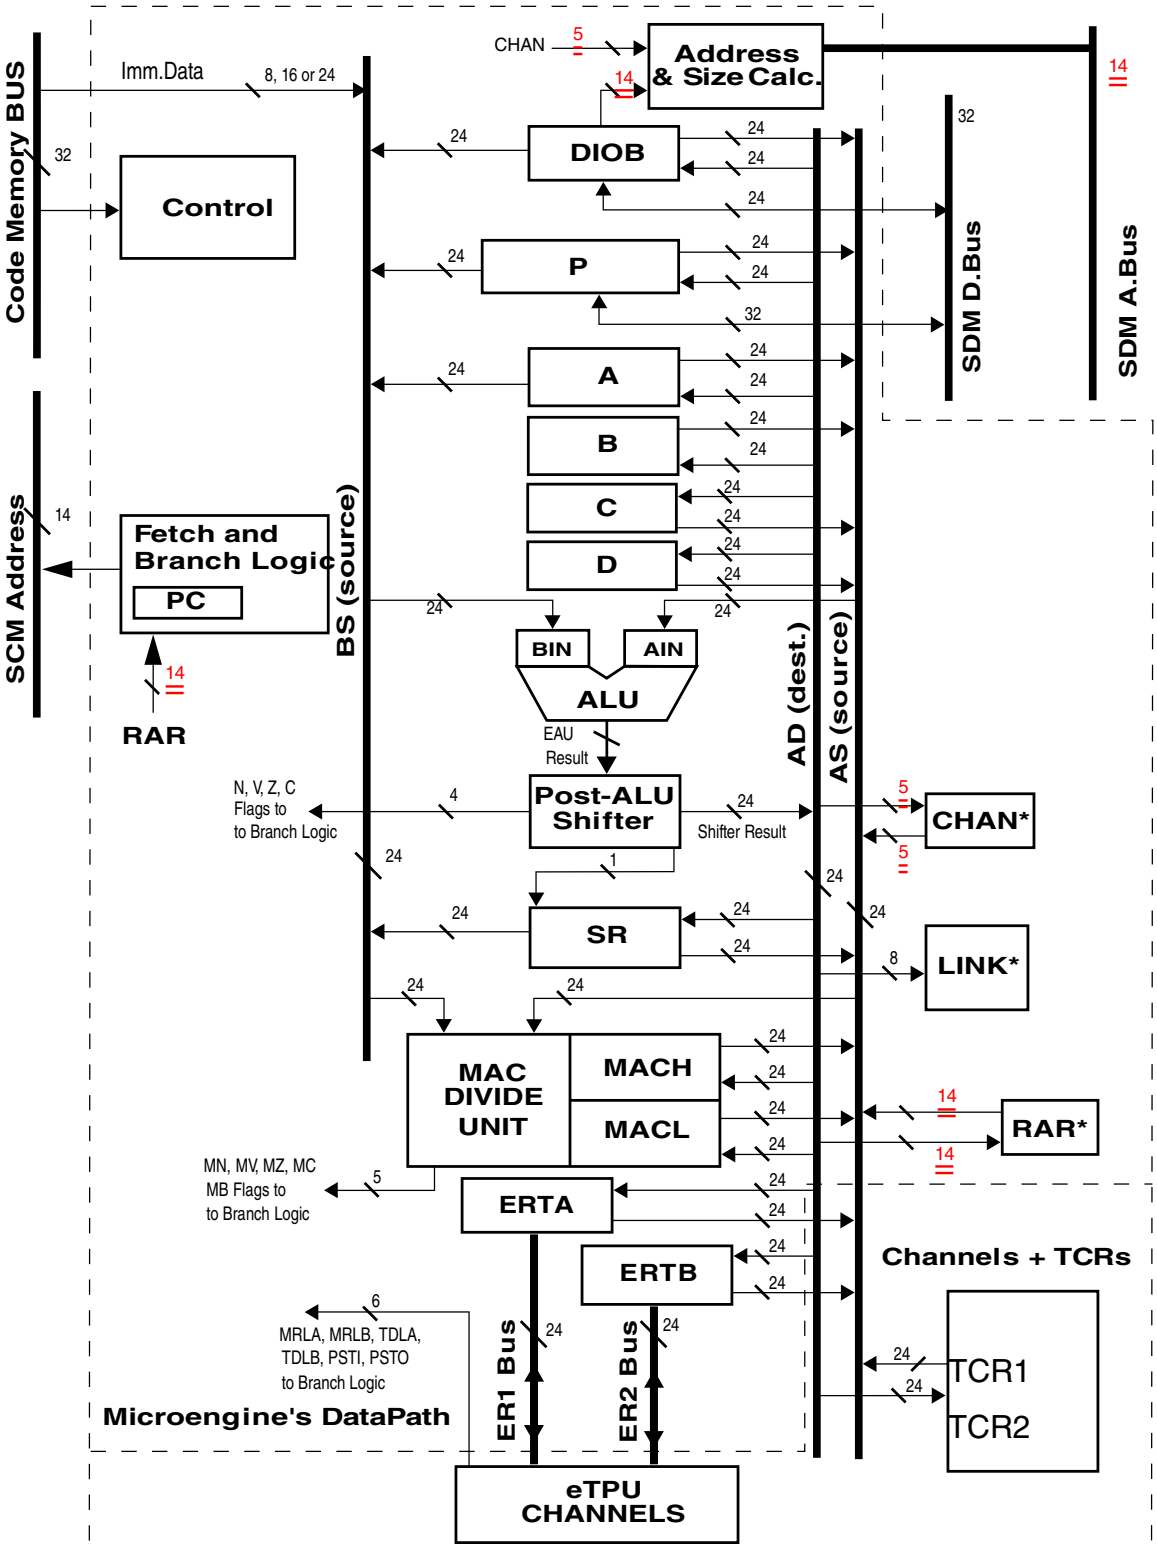

Figure 2-41. Microengine Block Diagram

2.14.8.1 Registers

eTPU microengine accesses a total of 18 registers. Fourteen of them are special purpose (registers A, B, C and D are for general use). Special purpose registers except CHAN and LINK can also be used as general use if the operation that use their contents are not performed. Register description is intended to just introduce their functionalities and not to provide detailed explanation of it since it will be described in Microinstruction Set. Registers less than 24 bits in size are right-justified.

None of the registers have guaranteed reset values. However, some are initialized just before the thread starts (see Time Slot Transition).

2.14.8.1.1 P Register

P register is the only one that is 32-bit wide. It can be used as source and destination for arithmetic/logical operation, and as source and destination for SDM read/write operations.

For P source/destination possibilities in ALU/MDU microoperations, see Selecting sources and destination.

When P is used as SDM read/write operations source or destination there are only 3 possibilities of access: all 32 bits, lower 24 bits and upper 8 bits. SDM operations are explained in detail in SDM Microoperations.

P is automatically loaded with one parameter before the thread starts (parameter preload). For more information see Entry Point format and Time Slot Transition.

Upper 8 bits of P register can be used as application state, since these bits can be tested as branch conditions. P[31:24] is also used in dispatch microoperation (see Dispatch Microoperation), and bit pairs P[29:28], P[27:26], P[25:24] can be directly copied into Channel flags 1 and 0 using field FLC. Together with Entry Table Condition Encoding, it provides fast state resolution without code execution.

2.14.8.1.2 DIOB Register

DIOB is an abbreviation for Data Input/Output Buffer. DIOB is 24-bit wide and can be used as source and destination for arithmetic/logical operations as well as SDM data source and destination. DIOB only can be accessed as 24 bits, both in arithmetic/logical and SDM read/write operations. When using DIOB to perform an SDM access, only lower 24 bits of SDM will be accessible (SDM upper 8 bits always remains unchanged).

DIOB can also be used as SDM addressing register, when DIOB contents is used as absolute SDM address (14-bit wide). In this case DIOB can also be pre-decremented or post-incremented (see Indirect Addressing Mode).

DIOB is automatically loaded with one parameter before the thread starts (parameter preload). For more information see Entry Point format and Time Slot Transition.

2.14.8.1.3 ERTA and ERTB Registers

ERTA/B registers are 24-bit wide and can be used as source or destination in arithmetic/logical operations. ERTA/B are the only source for channel's match registers write (see Write Channel Match and UDCM Registers). ERTA can also be the source for UDCM write.

When a thread starts to be executed, ERTA and ERTB are loaded with a copy of CaptureA and CaptureB registers respectively. ERTA/B can be used to receive a copy of MatchA and MatchB registers. ERTA/B are the only destination of MatchA/B read operation (see Special T4ABS Source Operation: Read Match Registers).

ERTA and ERTB also receive a copy of CaptureA and CaptureB registers when CHAN register is written (see CHAN Register). For more information about Capture and Match registers see MatchA and MatchB Registers and CaptureA and CaptureB Registers.

2.14.8.1.4 SR register - Shift Register

SR is a 24-bit wide register that can be used as source and destination register for arithmetic/logical operations. SR can shift right its contents by 1 bit at time and, at the same time, receive in its bit 23 the lost bit of a shift-right operation in post-ALU shifter (ALU and Post-ALU Shifter), allowing SR to be used to perform 48-bit shift right (see Shift Operations).

2.14.8.1.5 MACH and MACL Registers

Both MACH and MACL are 24-bit registers, part of MAC/Divide unit (see MAC and Divide Unit (MDU)). They can be used as source and destination in most arithmetic/logic operations. When multiply or divide operations are used (multiply-accumulate included), MACH and MACL have special purpose and some restrictions apply, see MAC and Divide Unit (MDU) for more information.

2.14.8.1.6 LINK Register

Link Register is an 8-bit wide register and can be used only as destination in arithmetic operations. LINK is a write-only command register, which precludes its use as a source register for ALU operations. When LINK register is written, it issues a service request for the channel number and eTPU engine equal to the number written in LINK register (see Functions and threads and Channel Link for information about Link Service Request).

2.14.8.1.7 RAR Register

RAR is a 14-bit register and can be used as source and destination in arithmetic operations. RAR also receives the contents of PC register when a subroutine call is executed. The contents of RAR register is loaded into PC when a return from subroutine is executed. RAR is loaded with value 0x3FFF during TST. For more information about subroutine call and return see Branch Operations and Return from subroutine respectively.

2.14.8.1.8 CHAN Register

CHAN is a 5-bit register that can be used as source and destination in arithmetic operations. The contents of CHAN register affects the execution of many channel-related microinstructions, because its number indicates the **selected channel** . CHAN register must not be used to store temporary values in arithmetic operations. For more details, refer to Channel Selection Register - CHAN.

2.14.8.1.9 Counter Registers: TCR1, TCR2, TPR and TRR

All these registers are 24-bit wide except TPR, which is a 16-bit register. They can be read or written in arithmetic/logical operations, and have special-purpose uses for time base and angle mode operations. For more information about those registers see Time bases and EAC - eTPU Angle Counter.

2.14.8.1.10 General Purpose Registers: A, B, C and D

A, B, C and D are 24-bit general purpose registers, which can be used to store intermediate values and do not have other specific uses with any eTPU feature.

2.14.8.2 ALU and Post-ALU Shifter

The ALU executes 24-bit arithmetic and logical operations. ALU's output goes directly to a 1-bit shifter, called post-ALU shifter, so it is possible, for example, to add and shift using only one microinstruction.

In some microinstruction formats, it is not possible to specify the operation executed by ALU. In these cases ALU will always perform addition.

In formats which have the field ALUOP for ALU operation selection, all of them can be performed, including add/subtract using C (carry) flag as ALU's carry-in, bitwise AND/OR/NOT/XOR, and shift/rotate of 2, 4, 8 and 16 bits. See ALU/MDU Operation Selection.

Subtraction, inversion, increment and decrement can be performed by combinations of source inversion and setting ALU's carry-in to 1.

ALU always performs 24-bit operations on its inputs, called **A-source** and **B-source**, and outputs a 24-bit result. 8-, and 16-bit inputs are zero padded to 24 bits. Likewise, ALU 24-bit output is always truncated to the destination register size.

2.14.8.2.1 ALU flags

Four flags - Carry, Negative, Overflow, Zero - described below, are related to ALU and post-ALU shift operations. Operation size and shifting affect flags generation logic. Operation size determines the result boundary to be used for flags generation. Operation size is determined by size of sources and destination (see Flags Sampling Control). For more information about flag generation, see Flags Sampling Control. ALU flags can be used as branch condition (see Conditional/unconditional branch) or conditional ALU/MDU operation (see Conditional ALU/MDU Operation Execution).

Field CCS/CCSV in microinstructions can force **no update** of all flags. Not all flags are updated in all ALU operations: Overflow is updated only on addition and absolute value operations, Carry flag is updated in most ALU operations, and only Zero and Negative are updated in all ALU operations.

ALU flags are never updated when microinstruction starts an MDU operation, regardless of CCS/CCSV, but are updated normally afterwards, on ALU operations that are executed in parallel with an ongoing MDU operation (MDU has its own flags).

Note

Operation size can be smaller than destination register. For example: 0xFFFF + 0x0001 (both 16-bit sources) stores 0x10000 in a 24-bit register and sets Zero and Carry flags because operation size is 16 bits.

2.14.8.2.1.1 Carry flag (C)

In an unsigned addition without shifting, Carry flag is the ALU carry from bit 7 to 8, 15 to 16, or 23 to 24 on 8-, 16- and 24-bit operation sizes respectively. In an unsigned subtraction without shifting, Carry Flag represent the sign of ALU's result considering operation size (Carry Flag equal to 1 means a negative result).

Carry flag definition is operation-dependent. The Carry flag in add/subtraction with Post-ALU shift is defined in Table 2-51 . Find the definitions for other operations in the following sections.

2.14.8.2.1.2 Negative flag (N)

Negative flag indicates the sign of result based on the operation size, regardless of the operation performed, as shown in the following table.

Table 2-47. Negative (N) flag behavior

Operation size	Value
8 bits	N = result[7]
16 bits	N = result[15]
24 bits	N = result[23]

Note

The N flag may not reflect the sign of the value actually written into the destination register, if it does not have the same size of the operation (see Flags Sampling Control). This is always the case for registers RAR (14 bits) and CHAN (5 bits).

2.14.8.2.1.3 Overflow (V)

Overflow is updated only on addition (with or without carry) and absolute value operations. In signed operations, overflow flag indicates that the result of arithmetic operation (add or subtraction) can not be represented by a word of the size of the operation. Overflow flag behavior for addition is defined in the following table. Overflow flag for Absolute operation is explained in Absolute Value operation . V Flag is calculated using ALU adder output (i.e., it is not affected by 1-bit shift/rotate operations).

Table 2-48. Overflow flag on addition - V

Op. size	Value[1]
8 bits	(AS[7] & BS[7] & !alu_adder_output[7]) | (!AS[7] & !BS[7] & alu_adder_output[7])
16 bits	(AS[15] & BS[15] & !alu_adder_output[15]) | (!AS[15] & !BS[15] & alu_adder_output[15])
24 bits	(AS[23] & BS[23] & !alu_adder_output[23]) | (!AS[23] & !BS[23] & alu_adder_output[23])

1. BS is taken after any inversion by the BINV field, but not added to the carry bit (CIN field)

NOTE

For V-flag definition on the absolute operation, see “Absolute Value Operation".

2.14.8.2.1.4 Zero flag (Z)

Zero flag equal to 1 indicates that the result from the ALU, limited to the operation size, is zero, regardless of the operation performed, whether the result is written, or where it is written. It depends on the operation size, as shown in the following table.

Table 2-49. Zero flag - Z

Operation size	Value
8 bits	Z = (result[7:0] == 0x00)
16 bits	Z = (result[15:0] == 0x0000)
24 bits	Z = (result[23:0] == 0x000000)

2.14.8.2.2 ALU ADD operation with and without shifting

ADD operation is selected by ALUOP or ALUOPI fields and when none of them is available in a microinstruction format[30]. Optionally, result can be shifted or rotated right by 1 bit, which is selected by SHF, ALUOP or ALUOPI fields. See Microinstruction Set for more details. The following table describes how CIN and BINV fields change ADD operation behavior.

Table 2-50. Types of ADD operations

BINV	CIN	Operation (adder output)
1	1	AS + BS
1	0	AS + BS + 1
0	0	AS - BS
0	1	AS - BS - 1

ALU adder output can be 1-bit shifted or 1-bit rotated right as follows:

Shift right:

```
if BINV==1
  result [23:0] = adder_output[24:1]
else
  result [23:0] = adder_output [24:1] xor 0x800000
endif
```

Shift left:

30. ALU operations only occur on formats where a destination field is found (T2ABD/T2D).

```
result[23:1] = adder_output[22:0]
result[0]    = 0
```

Rotate right:

```
case(opsize/CCSV)
8-bit:
  result[6:0]   = adder_output[7:1]
  result[7]     = adder_output[0]
  result[23:8]  = adder_output[23:8]
16-bit:
  result[14:0]  = adder_output[15:1]
  result[15]    = adder_output[0]
  result[23:16] = adder_output[23:16]
24-bit:
  result[22:0]  = adder_output[23:1]
  result[23]    = adder_output[0]
```

Note

Only for the Post-ALU rotate right, the operation size is determined by the field CCSV (see Flags Sampling Control). For example: if CCSV=00, T4ABS=P (24-bits), T4BBS=A (24 bits), T2ABD=B (24 bits), and ALUOP="Add ROR", then B gets A+P with bits 7:0 rotated, even though the operation size is 24 bits.

The following table describes Carry flag behavior.

Table 2-51. Carry flag update on ADD operation

BINV[1]	Op. size	shift/rotate	Value
1	8 bits	none	adder carry from bit 7 to bit 8
1	16 bits	none	adder carry from bit 15 to bit 16
1	24 bits	none	alu_adder_output[24]
0	8 bits	none	!adder carry from bit 7 to bit 8
0	16 bits	none	!adder carry from bit 15 to bit 16
0	24 bits	none	!alu_adder_output[24]
0 or 1	8 bits	shift left	alu_adder_output[7]
0 or 1	16 bits	shift left	alu_adder_output[15]
0 or 1	24 bits	shift left	alu_adder_output[23]
0 or 1	x	shift right	alu_adder_output[0]
1	8 bits	rotate right	adder carry from bit 7 to bit 8
1	16 bits	rotate right	adder carry from bit 15 to bit 16
1	24 bits	rotate right	alu_adder_output[24]
0	8 bits	rotate right	!adder carry from bit 7 to bit 8
0	16 bits	rotate right	!adder carry from bit 15 to bit 16
0	24 bits	rotate right	!alu_adder_output[24]
			except on max-constant generation (see Max Const Generation With T4BBS=111)

1. BINV has no effect on carry-out when used to code max constant (see Max Const Generation With T4BBS=111).

Flags N and Z on shift are updated according to the result after shift. Flag V with shift is updated according to the ADD operation only, the same way as without shift.

2.14.8.2.3 ADC Operation

ADC operation is selected by the ALUOP field. CIN field is ignored when this operation is selected. The following table describes how BINV change ADC operation behavior.

Table 2-52. Types of ADC operations

BINV	CIN	Operation
1	x	AS + BS + C flag
0	x	AS - BS - C flag

Flags behave exactly the same way as for ADD operation without shift/rotate.

2.14.8.2.4 Bitwise Operations

Bitwise AND, OR and XOR are selected by ALUOP field. On these operations CIN field is ignored and BINV field inverts (bitwise NOT) BS. C and V Flags are never updated on these operations. The following table describes AND, OR and XOR bitwise operations.

Table 2-53. Types of Bitwise Operations

ALUOP	BINV	Operation
10000	1	AS | BS
10000	0	AS | (~BS)
10001	1	AS ^ BS
10001	0	AS ^ (~BS)
10010	1	AS & BS
10010	0	AS & (~BS)

2.14.8.2.5 Set Bit / Clear Bit Operations

These operations set or clear the AS bit determined by BS[4:0]. If the bit number resolves to a value greater than 23, no bit is set or cleared (i.e., result is equal to AS). On these operations CIN field is ignored and BINV field inverts (bitwise NOT) BS. C and V flags are never updated for set/clear bit operations. These operations **override** B-Source size to 8 bits.

set bit (BINV = 1):

```
result = AS | (1 << BS)
```

clear bit (BINV = 1):

```
result = AS & ~(1 << BS)
```

set bit (BINV = 0):

```
result = AS | (1 << (31 - BS))
```

clear bit (BINV = 0):

```
result = AS & ~(1 << (31 - BS))
```

2.14.8.2.6 Exchange Bit

Exchange the AS bit determined by BS with C flag. If the bit number resolves to a value greater than 23, no exchange is performed (i.e., result is equal to AS and C flag is not updated). This operation **overrides** BS size to 8 bits. On this operation, CIN field is ignored and BINV field inverts (bitwise NOT) BS. V flag is never updated on exchange bit operation. C flag is always updated, regardless of CCSV, unless BS > 23.

Exchange Bit (BINV=1):

```
if BS <= 23
begin
  temp_C_flag = AS[BS]
  if C_flag == 1
    result = AS | (1 << BS)
  else
    result = AS & ~(1 << BS)
  C_flag = temp_C_flag
end
```

Exchange Bit (BINV = 0):

```
if (31 - BS) <= 23
begin
  temp_C_flag = AS[31 - BS]
  if C_flag == 1
    result = AS | (1 << (31 - BS))
  else
    result = AS & ~(1 << (31 - BS))
  C_flag = temp_C_flag
end
```

2.14.8.2.7 Multibit shift/rotate operations

These operations shift or rotate AS by 2, 4, 8 or 16 bits. Size of shift/rotate is determined by BS[1:0]. The following table describes the number of shifted/rotated bits depending on BS[1:0] value.

Table 2-54. Number of shifted/rotated bits for each BS[1:0] value

BS[1:0]	Bits shifted/rotated
0	2
1	4
2	8
3	16

Shift right is a logical operation (i.e., zeros are inserted on left). Multibit shift and rotate operations **overrides** BS size to 8 bits. The shifts and rotate operate on 24 bits, independently of the operation size.

V flag is never updated for multibit shift or rotate operations. Carry flag behavior is described in the following table. CIN is ignored in these operations, but BINV is effective.

Table 2-55. Carry flag value on multibit shift/rotate operations

ALUOP	BS[1:0]	C flag value[1]
11001 (shift left)	0	AS[22]
11001 (shift left)	1	AS[20]
11001 (shift left)	2	AS[16]
11001 (shift left)	3	AS[8]
11010 (shift right)	0	AS[1]
11010 (shift right)	1	AS[3]
11010 (shift right)	2	AS[7]
11010 (shift right)	3	AS[15]
11011 (rotate right)	0	AS[2]
11011 (rotate right)	1	AS[4]
11011 (rotate right)	2	AS[8]
11011 (rotate right)	3	AS[16]

1. CCS/CCSV can disable flag update on multibit shift/rotate, but the specified flag size in CCSV is ignored for the C flag.

2.14.8.2.8 Absolute Value operation

Absolute Value operation is selected by ALUOP field. On this operation, AS is interpreted as a signed number and its absolute value is the result. V and N flags are updated with the result signal determined by the operation size. AS bit 23 after size override and sign extension (if any, see A-Source Size Override), regardless of A-source register size, is used to check the operand signal and is copied to C-flag. Note that if AS is 8-bit or 16-bit, its sign is taken into account and copied to C only if sign-extension is performed. The following table summarizes flag updating for Absolute Value operation.

This operation is independent of B-source. Instruction fields T4BBS, BINV and CINV are ignored in this operation. The Absolute Value operation size is the minor between A-source size and Destination size.

Table 2-56. ALU flags in Absolute Value operation

operation size	V, N[1]	C	Z
8	alu_output[[7]	AS[23]	alu_output[7:0] == 0
16	alu_output[15]		alu_output[15:0] == 0
23	alu_output[23]		alu_output[23:0] == 0

1. V, N can be 1 on 8- and 16-bit Absolute Value, because the operand sign is always taken from bit 23. V, N can also be 1 in 23-bit Absolute Value (or 8-bit and 16-bit with sign extension), if the operand is 0×800000 (0×80, 0×8000).

2.14.8.3 MAC and Divide Unit (MDU)

MDU is an autonomous resource in the microengine which can carry out sequential multiply, multiply-accumulate, fractional multiplication and divide operations, selected through the microinstruction fields ALUOP or ALUOPI. The unit supports signed and unsigned multiply and fractional multiplication of any combination of 8, 16 or 24 bit operands [31], and also signed and unsigned 24-bit multiply-accumulate. Divide operation is unsigned, and both operands are always 24-bit wide.

Depending on the size of operands and the type of operation, MDU can take more than one microcycle to execute the operation, but microengine continues to execute microinstructions in parallel. When the microcode issues an END command, any MDU executing operation terminate immediately and is left incomplete. When selecting an operation that uses MDU, the result is always placed in MACH and MACL registers, and the register selected as destination does not have its value changed (Selecting sources and destination). During calculations, MACH and MACL holds temporary values and should not be written, otherwise the result is unspecified. One must not start an MDU operation while MDU is already busy: the result is unspecified for both the ongoing operation and the started one.

MDU Operations update its own set of 5 flags, described in MDU Flags. MDU operations never update C, N, V and Z flags. CIN and BINV microinstruction fields affect MDU operations according to the follwoing table.

Table 2-57. CIN and BINV with MDU Operations

B-source operand	BINV	CIN	Op. Performed
signed	1	1	AS mdu_op BS

Table continues on the next page...

31. There is no distinct selection of 24-bit fractional multiplication, for it works exactly as a 24-bit ordinary multiplication.

Table 2-57. CIN and BINV with MDU Operations (continued)

B-source operand	BINV	CIN	Op. Performed
	0	0	AS mdu_op (-BS)
	1	0	reserved
	0	1	reserved
unsigned[1]	1	1	AS mdu_op BS
	1	0	AS mdu_op (BS+1)
	0	x	reserved

1. includes the B-source (unsigned) in fmults (signed) operations.

2.14.8.3.1 Multiply and Multiply-Accumulate Operation Length

MDU needs 2 sources, A source and B source, to perform an operation. The time needed to perform a multiply or multiply-accumulate is:

- on 24-bit x 8 bit multiplies: 2 microcycles (one start-MDU plus one execution microcycle)
- on 24-bit x 16 bit multiplies: 3 microcycles (one start-MDU plus two execution microcycles)
- on 24 bit x 24 bit multiplies/macs: 4 microcycles (one start-MDU plus three execution microcycles)

An internal pipeline in MDU allows multiply-accumulate (or even non-fractional multiply) operations to start one microinstruction before a multiplication or multiply-accumulate (signed or unsigned) has been completed (e.g., one can start one multiply or multiply-accumulate once every three microinstructions). However, by doing that it is not possible to read the result in MACH and MACL (although the MDU flags can be tested), so this is intended to be used in a multiply-accumulate sequence. It is also allowed to mix different sizes in multiply/mac sequences.

Multiply-accumulate operations are similar to multiply operations, except that the contents of MACH and MACL registers are added to the multiplication result.

When multiply or multiply accumulate operations finish, MACL and MACH hold the least and the most significant 24-bit words, respectively.

2.14.8.3.2 Divide Operation Length

The divide operation is always unsigned. The division completes in 13 microcycles, meaning that after the start divide microinstruction, one has to wait for 12 microcycles and then read the result and the remainder in MACH and MACL registers. During the 12 execution microcycles, microengine can execute microinstructions unrelated to the MDU.

2.14.8.3.3 Signed Multiplication (mults)

MDU signed multiplication is defined as follows:

```
(signed) MACH,MACL = (signed) AS * (signed) BS
```

MC and MV flags are reset. MZ is set if result is 0, resets otherwise. MN is set if result is negative.

2.14.8.3.4 Unsigned Multiplication (multu)

MDU unsigned multiplication is defined as follows:

```
(unsigned) MACH|MACL = (unsigned) AS * (unsigned) BS
```

MC and MV flags are reset. MZ is set if result is 0, resets otherwise. MN is a copy of the most significant bit of result.

2.14.8.3.5 Signed Multiply-Accumulate (macs)

MDU signed multiply-accumulate is defined as follows:

```
(signed/unsigned) {MACH,MACL} += (signed) AS * (signed) BS
```

MC is not altered.

MV is set if result can not be represented by a 48-bit signed number. MACS never resets MV flag: it is left as is if no overflow occurs, or set it otherwise. This allows checking the overflow flag only once at the end of a series of multiply-accumulate operations in a scalar product calculation.

```
if (({MACH,MACL} += AS * BS < -2^47) || ({MACH,MACL} += AS * BS > 2^47 - 1))
  MV = 1
```

MZ is set if result is 0, resets otherwise. MN is a copy of the most significant bit of result.

Note that only 24-bit multiply-accumulate is available.

2.14.8.3.6 Unsigned Multiply-Accumulate (macu)

MDU Unsigned Multiply-Accumulate is defined as follows:

```
(signed/unsigned) {MACH,MACL} += (unsigned) AS * (unsigned) BS
```

MC is set if result can not be represented by a 48-bit unsigned non-negative number. MACU never resets MC flag: MC flag is left as is if no carry occurs, or set otherwise. This allows checking the carry flag only once at the end of a series of multiply-accumulate operations in a scalar product calculation.

```
if (({MACH,MACL} += AS * BS < 0) || ({MACH,MACL} += AS * BS > 2^48 - 1))
  MC = 1
```

MV is not altered.

MZ is set if result is 0, resets otherwise. MN is a copy of the most significant bit of result.

Note that only 24-bit multiply-accumulate is available.

2.14.8.3.7 Signed Fractional Multiplication (fmults)

MDU Signed Fractional Multiplication takes the B-Source as an **unsigned** 8- or 16-bit[32] fraction between 0 and $(2^8 - 1)/2^8$ (inclusive) for the 8-bit operation, or between 0 and $(2^{16}-1)/2^{16}$ (inclusive) for the 16-bit operation. Only A-Source is taken as a signed number. The value of B-Source is considered the unsigned numerator of a fraction with denominator 2^8 or 2^{16} for the 8- and 16-bit operations, respectively.

The integer part of the result is stored in MACH, and the fractional part in MACL. The result is signed, so that the concatenation of MACH and MACL form a 48-bit fixed point number with a 24-bit integer part, both for 8- and 16-bit operations. To calculate the unsigned numerator of the fractional part (with denominator 2^{24}) of the result, one must take the absolute value of MACL considering the signal of the result (not MACL alone), i.e.: if flag MN=1, invert MACL and add 1.

MDU flags are updated in the same way as in the Signed Multiplication.

2.14.8.3.8 Unsigned Fractional Multiplication (fmultu)

MDU Unsigned Fractional Multiplication takes both A-Source and B-Source as unsigned operands. B-Source is taken as an 8- or 16-bit[1] fraction between 0 and $(2^8 - 1)/2^8$ (inclusive) for the 8-bit operation, or between 0 and $(2^{16}-1)/2^{16}$ (inclusive) for the 16-bit operation. The value of B-Source is considered the numerator of a fraction with denominator 2^8 or 2^{16} for the 8- and 16-bit operations, respectively.

32. 24-bit fractional signed/unsigned multiplication is equivalent to mults/multu.

The integer part of the result is stored in MACH, and the fractional part in MACL. The fractional part in MACL is the numerator of a fraction with denominator 2^{24} . The concatenation of MACH and MACL form a 48-bit fixed point number with a 24-bit integer part, both for 8- and 16-bit operations.

MDU flags are updated in the same way as in the Unsigned Multiplication.

2.14.8.3.9 Unsigned Divide (div)

At the end of a divide operation MACL holds the result of the division, taking A-source as numerator and B-source as denominator, while MACH holds the remainder. If a divide by 0 is executed, MACL holds the maximum unsigned number (0xFFFFFF) as result and flag MV is set to indicate division by 0 (otherwise reset). The contents of MACH become indetermined.

MC flag is always reset.

MZ flag is set if MACL equals 0, and reset otherwise.

MN receives a copy of MACH bit 23 (msb from the remainder).

Note that signed division is not available.

2.14.8.3.10 MDU Flags

MDU has its own flags to indicate the result and status of an MDU operation. They are: MC, MZ, MV, MN and MB. All MDU flags are updated with the final result at the end of the operation, and do not change until the next operation finishes. Therefore it is possible to start a new MDU operation and test the flags of the previous one in parallel, except for mult/mac with 8-bit operand (takes only 1 microcycle).

2.14.8.3.10.1 MDU Negative Flag - MN

MN flag is always a copy of MACH bit 23 at the end of the operation, either in signed or unsigned ones. Note that MACH holds the rest of a division operation, which is always unsigned.

2.14.8.3.10.2 MDU Carry Flag - MC

MDU carry flag indicates if the result cannot be represented by a 48-bit number, in Signed and Unsigned Multiply Accumulates. It is reset in the other operations.

2.14.8.3.10.3 MDU Zero Flag - MZ

In multiply and multiply-accumulate operations, MDU zero flag is asserted if MACH and MACL are equal to zero at the end of an operation. In divide operations, zero flag is asserted if MACL (result) is equal to 0.

2.14.8.3.10.4 MDU Overflow Flag - MV

In multiply operations, MV flag is negated and keeps negated in the end, because the result of a multiplication can always fit in a 48-bit result (MACH and MACL concatenated). In a multiply-accumulate operation, MV is asserted if the result size is wider than 48 bits. MV flag work in both signed and unsigned operations.

In divide operations it is only asserted if a divide-by-zero operation was executed.

2.14.8.3.10.5 MDU Busy Flag (MB)

MB tests as true at the next microinstruction after the MDU start operation, and as false at the last microcycle of any MDU operation execution.

2.14.8.4 Branch conditions

Microengine allows conditional branch. There are five sets of flags that can be tested in a conditional branch: ALU flags, MDU flags, P flags, Channel flags, and Semaphore flag (flag SMLCK).

When a thread starts to be executed, the values in MDU and ALU flags are not initialized. ALU flags are described in ALU flags, MDU flags are described in MDU Flags. MDU and ALU flags are updated during execution of microinstructions.

P flags are actually the upper byte of P register, which optionally can work as user defined flags (see P Register).

Channel flags Flags0, Flag1, MRLA, MRLB, TDLA, TDLB, PSS, PRSS and PSTO are obtained from the selected channel (value in CHAN register), while channel flags, LSR, FM[0] and FM[1] are selected by the serviced channel, regardless of the CHAN value[33] .

Flags TDLA/B, MRLA/B, LSR, FM and PSS, are sampled at the beginning of a thread. Flag PSS does not change during its execution while CHAN register is not written. When a write in CHAN register is performed, all flags except LSR and FM are updated according to the channel specified by CHAN value. Flags MRLA/B and TDLA/B are reset when their respective latches in channel are cleared by microcode.

33. Serviced channel does not change during execution of a thread, and it is the channel that requested a service (initial value of CHAN register when a thread starts).

Table 2-58. Channel flags as branch condition

Flag	Description	Service or selected channel
Flag0	State Resolution flag	reflects the selected channel (CHAN)
Flag1	State Resolution flag	reflects the selected channel (CHAN)
MRLA	Match A Recognition Latch	these flags reflect the selected channel (CHAN)see MRLA/B - Match Recognition Latches and TDLA/B - Transition Detect Latches for more information.
MRLB	Match B Recognition Latch	
TDLA	Transition A Detection Latch	
TDLB	Transition B Detection Latch	
LSR	Link Service Request	reflects the serviced channel.
PRSS	Input Pin state sampled at service request	reflects the selected channel (CHAN). Does not change if CHAN is not changed.
PSS	Sampled Input Pin State	reflects the selected channel (CHAN). Does not change if CHAN is not changed (see Pin Control Registers).
PSTI	Current Input Pin State.	reflects the selected channel (CHAN). Changes any time.
PSTO	Current Output Pin State	reflects the selected channel (CHAN). Changes any time.
FM	Function Mode Bits	reflects the Function Mode for serviced channel (see eTPU Channel n Status Control Register for Engine 1 (eTPU_CCCR_C*n*SCR_ENG1) and eTPU Channel n Status Control Register for Engine 2 (eTPU_CCCR_C*n*SCR_ENG2))

Semaphore condition SMLCK always indicates if a semaphore is locked for the Engine, resolving as false before any lock attempt. For each trial, the SMLCK flag is updated. The SMLCK value set in one thread is not meaningful to the other. After a free, the SMLCK condition tests as false until a new lock attempt on the same thread.

Branch conditions are selected through instruction fields BCC and BCF (see Conditional/unconditional branch).

2.14.9 Microinstruction Set

Each microinstruction can execute up to 3 microoperations in parallel. Microinstructions are grouped into formats, and there are four types of microoperations:

- ALU/MDU Operations
- SDM Operations
- Channel Configuration/Control Operations
- Flow Control Operations

Each microinstruction format is defined by a set of microinstruction fields, which determine the operations, each belonging to one of the groups above (there may be several in one group). Complete microinstruction formats are shown in Microinstruction formats.

Parallelism conflicts may arise when two operations are executed in the same microinstruction. These situations are explained in Microinstruction Parallelism Issues.

2.14.9.1 SDM Microoperations

The access to SDM is made by providing an address and a register to perform a data transfer, except semaphore operations, which are also classified in the SDM group. Only P and DIOB registers can exchange data with SDM. Microengine always addresses SDM in 32-bit boundaries, for 8, 24, or 32 bit wide data.

Direction is determined by the field RW in all addressing modes: RW=0 selects read and RW=1 selects write.

2.14.9.1.1 SDM Addressing Modes

There are 4 addressing modes in eTPU:

- Absolute
- Selected Channel Relative
- Indirect
- Engine Relative

The addressing modes Absolute and Selected Channel Relative use immediate bits to form the physical address of SDM, which is identified in microinstruction as a field called AID. AID field can be 3-, 7-, or 8-bit wide depending on the addressing mode.

2.14.9.1.1.1 Absolute Addressing Mode

In Absolute addressing mode, the address range is 256 parameters, addressed by field AID, which in this mode is 8-bit wide. These parameters are located in SDM addresses from 0 to 255.

```
physical_address = AID[7:0]
```

2.14.9.1.1.2 Selected Channel Relative Addressing Mode

In Selected Channel Relative addressing mode, only the first 8 (with 3-bit AID) or 128 (with 7-bit AID) parameters of the selected channel are accessible, depending on the microinstruction format. Physical address is calculated using the channel parameter base address that is specified in the CPBA field of eTPU Channel n Configuration Register for Engine 1 (eTPU_CCCR_C*n*CR_ENG1) and eTPU Channel n Configuration Register for Engine 2 (eTPU_CCCR_C*n*CR_ENG2). AID field is added to channel parameter base address to compose the physical address. The address equation is:

```
physical_address = selected_channel_parameter_base_address + AID[6:0], or
physical_address = selected_channel_parameter_base_address + AID[2:0]
```

2.14.9.1.1.3 Indirect Addressing Mode

In Indirect Addressing mode the physical address is taken from DIOB register. Only DIOB bits 14 to 2 are relevant. Since the SDM word address is shifted two bits up in DIOB, its contents hold the same parameter address value used by Host. The address equation for SDM access is:

```
physical_address = DIOB[13:2], or
physical_address = (truncated to 12 bits) (DIOB / 4)
```

Indirect addressing mode is used to access the Shared Subsystem Area when eTPU_CCCR_C*x*CR_ENG*n*[SSMAE]=1 and DIOB addresses the 16 Kbytes just above the SDM range (DIOB bit 14 = 1). See Shared Subsystems support for more details. If SSMAE=0, accesses with DIOB bit 14 = 1 hit the same SDM addresses as with bit 14 = 0, providing full backwards compatibility with respect to DIOB contents.

Indirect addressing mode can have post-increment or pre-decrement on DIOB, allowing stack operations. See DIOB stack operation for more information.

2.14.9.1.1.4 Engine Relative Addressing Mode

In Engine Relative Addressing mode the physical address is the concatenation of the eTPU_SCR_ECR_ENG*n*[ERBA] field (see eTPU Engine 1 Configuration Register (eTPU_SCR_ECR_ENG1) and eTPU Engine 2 Configuration Register (eTPU_SCR_ECR_ENG2)) with the 7-bit AID instruction field. This allows the same function microcode, when running on distinct engines, to access different address spaces, global to the engine only.

The SDM physical word address in Engine Relative Addressing mode is calculated as follows:

```
physical address = (eTPU_SCR_ECR_ENGn[ERBA]<< 7) + AID[6:0]
```

2.14.9.1.2 SDM source/destination registers

When performing an SDM operation, only DIOB or P can be used as data source or destination. P is 32-bit wide, and DIOB is 24-bit wide. Microinstruction field P/D (1 bit) is used to choose between P and DIOB as data the source or destination. When the P/D field is not available in microinstructions that support SDM access, the source/destination is P.

Table 2-59. SDM source/destination Register Selection

P/D	Meaning
0	P access
1	DIOB access

2.14.9.1.3 SDM Operation Size

When using DIOB register to perform SDM data transfers, the operation size is always 24-bit wide (lower 24 bits of SDM). When using P register, the operation size can be 8-, 24- or 32-bit wide, which is controlled by microcode RSIZ field (2 bits). RSIZ meaning is shown in the following table.

Table 2-60. SDM P access Size

RSIZ	P access	DIOB access
00	full 32-bit access (i.e. P[31:0]=SDM[addr] [31:0])	RESERVED
01	only upper 8 bits are transferred (i.e. P[31:24] = SDM[addr] [31:24])	RESERVED
10	only lower 24 bits are transferred (i.e. P[23:0] = SDM[addr] [23:0])	DIOB = SDM[addr] [23:0
11	RESERVED	RESERVED

RSIZ is not available in all microinstructions that support SDM access. In microinstructions where RSIZ field is not available, SDM access will be 24 bits by default.

When performing a Zero SDM write operation (see Zero SDM Operation), RSIZ defines the size of operation regardless of the P/D field (SDM source/destination registers).

2.14.9.1.4 SDM access direction

RW field defines the direction of the access in the SDM. The access direction is summarized in the following table.

Table 2-61. SDM access direction

R/W	Meaning
0	read SDM parameter into P or DIOB registers
1	write SDM parameter from P or DIOB registers

2.14.9.1.5 Zero SDM Operation

Zero SDM operation is controlled by microcode field ZRO (1bit). When ZRO field is 0, the data portion written in SDM or in P/DIOB (SDM read) registers will always be 0x0. When performing a Zero SDM write operation, the RSIZ is relevant regardless of the P/D field (usually RSIZ is meaningful only for P/D = 0), which means that zero SDM write operation can be performed with 32, 24 or 8 bits according to SDM operation size. These conditions are summarized in the following table.

Table 2-62. Zero SDM Operation

ZRO	RW	P/D	Meaning
0	0	0	Clear P register. Size is determined by RSIZ field. See SDM Operation Size
0	0	1	Clear DIOB (all 24 bits), independently of RSIZ
0	1	x	Clear SDM parameter. Size is determined by RSIZ field. See SDM Operation Size
1	RW	P/D	Regular SDM operation

Note

When field STC is present, STC=11 also disables Zero SDM operation (see Table 2-63). The conflicts with DIOB operations (see DIOB stack operation) and ALU operations are resolved like a normal SDM operation (see Table 2-104).

Zero SDM read operations do check memory errors on the read data, however discarded. Zero SDM write operations normally update the ECC of the written data.

2.14.9.1.6 DIOB stack operation

SDM Indirect Addressing Mode (see Indirect Addressing Mode) is used if STC field (2 bits) exists in the microinstruction, controlling automatic increment/decrement of DIOB register, as shown in the following table, thus allowing stack operations. DIOB is incremented and decremented in word addresses, only from bits 15 downto 2, i.e.: the bits 23 to 16 and 1 to 0 are left untouched by STC pre-decrement and post-increment.

Table 2-63. DIOB Post-Increment / Pre-Decrement - STC

STC	Meaning
00	Post-Increment of DIOB
01	Pre-Decrement of DIOB
10	No Increment/Decrement (normal access)
11	No SDM Access[1]

1. Also disables Zero SDM operation.

2.14.9.1.7 Semaphore Operations

Semaphore lock and free operations are available through eTPU microcode. For more information about semaphores see Hardware Semaphores. There are 2 microinstruction fields that control semaphore operations: FL (1 bit) and SMPR (2 bits). Serviced channel sees 4 semaphores, selected by field SMPR.

Table 2-64. Semaphore Operations Fields

Field	Meaning
FL	0 = free semaphore, 1 = lock semaphore
SMPR	semaphore number selector

When freeing a semaphore, the field SMPR has no meaning. This is because only one semaphore can be locked at a time by each engine, so when freeing a semaphore it is not necessary to specify its number.

Note

If microcode tries to lock a semaphore already locked for the same Engine, the semaphore continues locked for the Engine and the SMLCK branch condition resolves as true.

2.14.9.2 ALU/MDU Operations

ALU/MDU microoperations mostly comprises two sources, one destination and one operation. The operation is generally selected through fields ALUOP, ALUOPI or SHF. In formats where there is no operation selection field (ALUOP, ALUOPI or SHF), the operation performed is always addition; however, it is possible to perform subtraction, increment or decrement using fields BINV (see B-Source Inversion) and CIN (see Carry-in Control).

2.14.9.2.1 Source and Destination Register Set Selection

Microcode field T4ABS allows selection of a source from either one of two register sets, shown in Table 2-68. The same applies to T2ABD, used for ALU destination selection with other two register sets, as shown in Table 2-69. Microinstruction fields ABSE and ABDE control the register set selection for source and destination, respectively, when available at the format. In formats without ABSE/ABDE, the field T4BBS determines the register sets used by T2ABD and T4ABS, as shown in Microinstructions without fields ABSE and ABDE.

2.14.9.2.1.1 Microinstructions With Fields ABSE and ABDE

In microinstructions where ABSE and ABDE fields are available (1 bit each), ABSE controls register set selection for T4ABS and ABDE controls register set selection for T2ABD. The following table shows the meaning of values for ABSE and ABDE fields.

Table 2-65. Register Set Selection by ABSE or ABDE

ABSE or ABDE	Register Set Selected
0	second
1	first

2.14.9.2.1.2 Microinstructions without fields ABSE and ABDE

When ABSE and ABDE are not available in a microinstruction format, register set is selected by T4BBS field. The following table explains how to select a register set either for T4ABS and T2ABD.

Table 2-66. Register set selection by T4BBS without ABSE and ABDE

T4BBS	Register set for T2ABD	Register set for T4ABS
0xx	first	first
100	second	second
101	second	first
110	first	second
111	first	first
none[1]	first	first

1. Refers to operations with immediate data as B-source, without ABSE and ABDE.

2.14.9.2.2 Selecting sources and destination

All ALU/MDU operations need 2 sources (called AS and BS) and 1 destination (called AD), except for some of those that use immediate data (see Operations With Immediate Data). Fields T4ABS (4 bits), ABSE (1 bit), T4BBS (3 bits) select sources, while T2ABD (4 bits) and ABDE (1 bit) select the destination. When MDU is used (multiply/divide), T2ABD destination selection is ignored and results are stored in MACH and MACL (see MAC and Divide Unit (MDU)). ABSE and ABDE are not available in some microinstruction formats that support ALU/MDU operations. However, in all formats where ABSE is available, ABDE is also available and vice-versa. The existence of ABSE/ABDE fields changes the meaning of T4BBS field, as shown in the table below. On instructions with immediate data, it is used as B-source (see Operations With Immediate Data).

All sources and destinations have a size associated to it, and these sizes are used to select flag sample position (see Flags Sampling Control). Sizes can be 8, 16 or 24 bits. Registers that are not exactly of one of these sizes are treated as the immediately upper size (e.g., CHAN[4:0] is an 8-bit source). See Flags Sampling Control for more information.

Some parallelism issues arise when selecting P, DIOB, ERTA or ERTB as destination registers, since they can be modified by other microoperations in the same microinstruction (see Microinstruction Parallelism Issues for details).

Table 2-67. B source selection - T4BBS

T4BBS	Meaning in microinstruction formats with ABSE/ABDE	Meaning in microinstruction formats without ABSE/ABDE[1]
000	BS[23:0] = P[23:0]	
001	BS[23:0] = A[23:0]	
010	BS[23:0] = SR[23:0]	
011	BS[23:0] = DIOB[23:0]	
100	reserved	BS = 0
101	reserved	BS = 0
110	reserved	BS = 0
111	BS=0, or Max const., if CIN=0 and BINV=0 (see Generating "max" constant).	

1. T4BBS also selects A-source and destination register set in this case, according to Table 1.

T4ABS selects one source from 2 register sets, shown in the following table. ABSE and T4BBS control which set T4ABS field uses to select the source. For more information about how to select a register set for T4ABS and T2ABD see Source and Destination Register Set Selection . All sources are zero-filled to 24 bits, unless sign-extension is specified (see A-Source Size Override).

Table 2-68. A source selection - T4ABS

T4ABS	First register set		Second register set	
	Selected register	Size	Selected Register	Size
0000	AS[7:0]=P[7:0]	8	AS[7:0]=0	8
0001	AS[7:0]=P[15:8]	8	AS[23:0]=C[23:0]	24
0010	AS[7:0]=P[31:24]	8	AS[15:0] = TPR[15:0]	16
0011	AS[23:0] = ERTB[23:0]	24	AS[23:0] = B[23:0]	24
0100	AS[23:0] = D[23:0]	24	AS[23:0] = TRR[23:0]	24
0101	AS[15:0] = P[15:0]	16	AS[7:0] = 0, read_match[1]	8
0110	AS[15:0] = P[31:16]	16	AS[13:0] = RAR[13:0]	16
0111	AS[7:0] = P[23:16]	8	AS[23:0] = MACH[23:0]	24
1000	AS[23:0] = P[23:0]	24	AS[23:0] = MACL[23:0]	24
1001	AS[23:0] = A[23:0]	24	AS[4:0]=CHAN[4:0]	8
1010	AS[23:0] = SR[23:0]	24	AS[14 :2] = CHAN_BASE[2]	16
1011	AS[23:0] = DIOB[23:0]	24	AS[13:0] = ENGINE_BASE[3]	16
1100	AS[23:0] = TCR1[23:0]	24	Reserved	-
1101	AS[23:0] = TCR2[23:0]	24	Reserved	-
1110	AS[23:0] = ERTA[23:0]	24	Reserved	-
1111	AS[23:0] = 0	24	Reserved	-

1. T4ABS=0101 with second register set also reads MatchA/B registers into ERTA/B (see Special T4ABS Source Operation: Read Match Registers).
2. CHAN_BASE is the selected channel's base SDM address in channel relative address mode (see CHAN_BASE as a source).
3. ENGINE_BASE is the eTPU_SCR_ECR_ENG*n*[ERBA] field shifted left 9 positions.

T2ABD selects the destination from 1 of 2 register sets, shown in the following table. ABDE and T4BBS control which set T2ABD field uses to select the destination.

Table 2-69. Destination selection - T2ABD

T2ABD	First register set		Second register set	
	Selected register	Size	Selected Register	Size
0000	A[23:0] = AD[23:0]	24	C[23:0] = AD[23:0]	24
0001	SR[23:0] = AD[23:0]	24	LINK[7:0] = AD[7:0]	8
0010	ERTA[23:0] = AD[23:0][1]	24	TPR[15:0] = AD[15:0]	16
0011	ERTB[23:0] = AD[23:0][2]	24	B[23:0] = AD[23:0]	24
0100	DIOB[23:0] = AD[23:0]	24	CHAN[4:0] = AD[4:0]	8
0101	P[15:0] = AD[15:0]	16	D[23:0] = AD[23:0]	24
0110	P[31:16] = AD[15:0]	16	RAR[12:0] = AD[12:0]	16
0111	P[23:0] = AD[23:0]	24	MACH[23:0] = AD[23:0]	24
1000	TCR1[23:0] = AD[23:0]	24	MACL[23:0] = AD[23:0]	24
1001	TCR2[23:0] = AD[23:0]	24	Reserved	-
1010	P[31:24] = AD[7:0]	8	Reserved	-

Table continues on the next page...

Table 2-69. Destination selection - T2ABD (continued)

T2ABD	First register set		Second register set	
	Selected register	Size	Selected Register	Size
1011	P[23:16] = AD[7:0]	8	Reserved	-
1100	P[15:8] = AD[7:0]	8	Reserved	-
1101	P[7:0] = AD[7:0]	8	Reserved	-
1110	TRR[23:0] = AD[23:0]	24	Reserved	-
1111	no destination selected[3]	24	Reserved	-

1. T2ABD=0010 with first register set also writes to MatchA or UDCM registers of the selected channel if field ERWA=0 (see Write Channel Match and UDCM Registers).
2. T2ABD=0011 with first register set also writes to MatchB register of the selected channel if field ERWB=0.
3. if no destination is selected, ALU flags are updated, although the result is lost.

2.14.9.2.2.1 Max Const Generation With T4BBS=111

When T4BBS = 111, BINV = 0, and CIN = 0, the value assigned to BS will be 0x800000, and not 0x0 as expected. See Generating "max" constant for detailed explanation about this.

2.14.9.2.2.2 Special T4ABS Source Operation: Read Match Registers

When T4ABS = 0101 and the source for T4ABS is selected from the second register set, the constant 0x00 is used as AS (8-bit size) and the following register transfer is performed in parallel as well: match registers of the selected channel (value in CHAN register) are copied to ERTA/ERTB registers, where ERTA receives the value of MatchA register and ERTB receives the value of MatchB register (see ER - Event Registers). Note that ALU destination can still be chosen by T2ABD in parallel. When ERTA or ERTB is selected by T2ABD, a parallelism issue arises (see ALU Operations and Read Match Registers).

2.14.9.2.2.3 CHAN_BASE as a source

Each channel has a parameter base address in SDM, which is configured in the CPBA field of eTPU Channel n Configuration Register for Engine 1 (eTPU_CCCR_C*n*CR_ENG1) and eTPU Channel n Configuration Register for Engine 2 (eTPU_CCCR_C*n*CR_ENG2). CHAN_BASE, which represents a parameter address (CPBA*2), can be used as A-source using T4ABS=1010 when T4ABS selects a source from the second register set. In this case, CHAN_BASE is loaded into AS[13:2] to form the byte address (AS[23:14]=0, AS[1:0]=0). For example, in Indirect addressing mode, where the destination register is DIOB, CHAN_BASE is loaded into DIOB[13:2], which is the parameter address, and DIOB[13:0] represents the byte address. CHAN_BASE is the base address of the selected channel (given by CHAN register).

2.14.9.2.3 Flags Sampling Control

This section explains how the flags Z (zero), C (carry), N (negative) and V (overflow) are updated in an ALU operation. When there are post-ALU shift operations, the ALU Carry Out is not directly sampled in Carry flag, but passed to the post-ALU shifter (see Shift Operations). Since the size of source operands in ALU operations is variable, flags can be sampled as an operation of 8, 16 or 24 bits wide. The operation size selection is automatic, based on defined sizes of sources and destination, using the equation:

```
operation_size = minor(size_of(destination), greater(size_of(A-Source),
size_of(B-Source)))
```

Operation size can also be shown with the following table:

Table 2-70. Operation Size Determination

A Source	B Source	Destination	Operation Size
x	x	8 bits	8 bits
8 bits	8 bits	x	8 bits
16 or 24 bits	x	16 bits	16 bits
16 bits	8 or 16 bits	24 bits	16 bits
8 or 16 bits	16 bits	24 bits	16 bits
24 bits	x	24 bits	24 bits
x	24 bits	24 bits	24 bits

Note

Whenever BS = (constant) 0, its size is considered 8 bits, and all 24 bits in B-bus are set to 0. Therefore, all operations with BS = (constant) 0 have their size determined by AS and Destination only.

CCS field (1 bit) controls whether flags will be updated or not (Table 2-72). When CCS bit exists in a microinstruction, the operation size will be used to sample flags. In some microinstructions CCS field is replaced by CCSV (2 bits, Table 2-71). Flag sampling according to CCSV can be set as defined by the operation size, or fixed as 8 or 16 bit operations.

Note

For the post-ALU rotate right operation, CCSV also determines the rotate size: whether 8-bit, 16-bit, or determined by the operation size.

Table 2-71. Flag Sampling Using CCSV field

CCSV	Meaning
00	sample flags as an 8 bit operation
01	sample flags as a 16 bit operation
10	sample flags as defined by operation size
11	do not sample flags

Table 2-72. Flag Sampling Using CCS field

CCS	Meaning
0	sample flags as defined by operation size
1	do not sample flags

When neither CCS nor CCSV are present in the microinstruction, flags are not sampled. CCS and CCSV do not affect the Carry update on Exchange Bit operation (see Exchange Bit), but does control the N and Z flags.

2.14.9.2.4 B-Source Inversion

The data selected as second source (T4BBS) can be inverted (bitwise boolean NOT) before operation. This is controlled by microinstruction field BINV (1 bit, in the following table). A zero value for BINV activates B-source inversion.

Table 2-73. B-Source Inversion - BINV

BINV	Meaning
0	invert B-source[1]
1	keep B-source bus unchanged

1. Except on max-constant selection, see Generating "max" constant .

BINV also selects between *adc* or *sbc* enhanced ALU operation, using inverted C flag as carry-in besides BS inversion for *sbc* . Note that BINV does not invert carry in fixed-carry operations (see Table 2-74).

When BINV = 0, T4BBS = 111 and CIN = 0, the value assigned to BS is 0x800000, instead of 0x0. See Generating "max" constant for more details.

2.14.9.2.5 Carry-in Control

CIN field (1 bit, Table 2-74) controls the carry-in for addition/subtraction operations. Functionality of CIN field depends on the arithmetic operation selected by ALUOP. When ALUOP is not available in microinstruction, the operation selected is *add* . For carry-in control in MDU operations, see the following table.

Table 2-74. ALU Carry-In Control

operation	CIN=0	CIN=1
add (addition)	carry-in used is 1[1]	carry-in used is 0
adc (addition with carry)[2]	carry-in used is C flag	
sbc (subtraction with borrow)[3]	carry-in used is inverted C flag	

1. Except on max-constant selection, see Generating "max" constant .
2. Selected by ALUOP=11000 and BINV=1
3. Selected by ALUOP=11000 and BINV=0

2.14.9.2.5.1 Generating "max" constant

When T4BBS = 111, CIN = 0 and BINV = 0, BS is assigned to 0x800000 (called "max constant") instead of 0x000000. This is an exception for CIN and BINV fields: when "max constant" is selected, the carry in is 0 and B-source ("max constant" itself) is not inverted, neither the carry out.

"Max constant" is the value which, added to a time base value minus 1, gives the farthest wrapped time base value that satisfies a channel greater-equal comparison. See Enhanced Channels for more info.

2.14.9.2.6 Shift Operations

There are three types of shift operations: ALU, post-ALU and Shift Register. ALU shift operations are covered in ALU/MDU Operation Selection . Post-ALU and Shift Register are covered in the following sections.

2.14.9.2.6.1 Shift Register Operations

SR can be used as a general purpose register and it can easily shift-right its contents, combined or not to post-ALU shift operations. If field SRC (1 bit) in microcode is 0, SR will shift its contents 1 bit to the right according to the algorithmic description below. SR shifting operation depends also on SHF or ALUOP fields. ALUOP and SHF never exist both on the same microinstruction format.

Table 2-75. Shift Register Control - SRC

SRC	Meaning
0	shift right SR 1 bit
1	no shift

SR Operation:

```
SR[22:0] = SR[23:1];
if SHF == "01" or ALUOP == "10110" then
 SR[23] = ALU_OUT[0];
else
  SR[23] = 0;
endif;
```

2.14.9.2.6.2 Post-ALU shift operations

Post-ALU shift can be selected by SHF field (2 bits) or by some specific ALUOP field values. SHF and ALUOP fields are never both available in the same microinstruction format. When selecting post-ALU shift operation using ALUOP field, ALU will always add the sources before shifting the result.

Table 2-76. Post-ALU shift operation

Post ALU operation	SHF[1]	ALUOP
shift left (1 bit)	00	10101
shift right (1 bit)	01	10110
rotate right (1 bit)	10	10111
no shift/rotate	11	any other[2]

1. ALU performs AS+BS before shift/rotate for all SHF values.
2. Some ALUOP combinations perform shift/rotate, but not using the Post-ALU Shifter (see Table 1)

Carry flag is only updated when CCS or CCSV fields allow it (see Flags Sampling Control). Algorithmic descriptions of post-ALU shift operations are presented in ALU ADD operation with and without shifting .

2.14.9.2.7 Conditional ALU/MDU Operation Execution

The 3-bit field AS/CE allows conditional execution of arithmetic operation, as shown in the following table . The same field can also be used for overriding the size of A-Source (see A-Source Size Override).

Table 2-77. ALU/MDU Conditional Execution

AS/CE	Meaning
000	used for A-Source size override (see A-Source Size Override)

Table continues on the next page...

Table 2-77. ALU/MDU Conditional Execution (continued)

AS/CE	Meaning
001	
010	execute if C = 1
011	execute if C = 0
100	execute if Z = 1
101	execute if Z = 0
110	execute if N = 1
111	execute unconditionally/no size override

Other operations not related to ALU/MDU in the same microinstruction are not affected by the AS/CE field.

If a conditional operation is selected, there is no A-Source size override; similarly, when size override for A-Source is selected, the ALU/MDU operation executes unconditionally.

When a conditional ALU/MDU operation is not executed:

- the destination register is not updated. If the destination is CHAN, no actions associated with CHAN assignment occur (see Channel Selection Register - CHAN).
- the ALU and MDU flags are not updated.
- MDU does not start any operation, i.e., MACH and MACL are not updated.
- SR does not shift.
- T4ABS-selected read-match does not occur.

2.14.9.2.8 A-Source Size Override

Some values if the AS/CE field are used for A-Source Size Override, as shown in the following table.

Table 2-78. A-Source Size Override

AS/CE	Meaning
000	A-source size override to 8 bits
001	A-source size override to 16 bits
010	used for conditional execution (see Conditional ALU/MDU Operation Execution)
011	
100	
101	

Table continues on the next page...

Table 2-78. A-Source Size Override (continued)

AS/CE	Meaning
110	
111	execute unconditionally/no size override

Register size override zero-pads an overridden source to 24-bits (if no sign extension is performed, see A-source Sign Extension) and affects operation size calculation. When register source is wider than size override, most significant bits of selected register are not used as A source (zeros are used instead). When size override is wider than selected register, register value is padded to zeros.

When size override is used with MDU operations, it affects only the operand values, but not the operation size: MDU operation size is fully determined by the operation definition (fields ALUOP, ALUOPI).

Table 2-79. AS/CE field A source size override funcionality

Size Override	Size of Selected Register	AS Value[1]
8 bits	8 bits	reg[7:0]
8-bits	16 bits	reg[7:0]
8bits	24 bits	reg[7:0]
16 bits	8 bits	reg[15:0]
16 bits	16 bits	reg[15:0]
16 bits	24 bits	reg[15:0]

1. All values are zero-padded to 24 bits

2.14.9.2.9 A-source Sign Extension

The SEXT microinstruction field forces sign extension of A source according to the size of A operand, either overridden or not by AS/CE field, according to the following table. The sign is taken from the size-overridden value, not the original one.

Table 2-80. A source Sign Extension

SEXT	Meaning
0	extends sign of A source from its size to 24-bits
1	does not extend sign of A source

A-source sign is not extended in microinstructions without SEXT field, even if AS/CE field is present.

2.14.9.2.10 ALU/MDU Operation Selection

When field ALUOP is available in microinstruction, enhanced ALU operations shown in the following table can be performed, otherwise addition is performed. The ALU operations are defined in ALU and Post-ALU Shifter. The MDU operations are defined in MAC and Divide Unit (MDU).

Table 2-81. ALU Operation Selection - ALUOP

ALUOP	Operation	Comment
00000	AS mults BS[7:0]	signed multiplication
00001	AS multu BS[7:0]	unsigned multiplication
00010	AS fmults BS[7:0]	signed fractional multiplication
00011	AS fmultu BS[7:0]	unsigned fractional multiplication
00100	AS mults BS[15:0]	signed multiplication
00101	AS multu BS[15:0]	unsigned multiplication
00110	AS fmults BS[15:0]	signed fractional multiplication
00111	AS fmultu BS[15:0]	unsigned fractional multiplication
01000	AS mults BS[23:0]	signed multiplication
01001	AS multu BS[23:0]	unsigned multiplication
01010	AS macs BS[23:0]	signed multiply-accumulate
01011	AS macu BS[23:0]	unsigned multiply-accumulate
01100	AS div BS[7:0]	unsigned division by 8-bit value
01101	AS div BS[15:0]	unsigned division by 16-bit value
01110	AS div BS [23:0]	unsigned division by 24-bit value
01111	n.a.	RESERVED
10000	AS[23:0] | BS[23:0]	24 bit bitwise OR
10001	AS[23:0] ^ BS[23:0]	24 bit bitwise XOR
10010	AS[23:0] & BS[23:0]	24 bit bitwise AND
10011	abs(AS)	absolute value of AS
10100	AS + BS	arithmetic addition
10101	(AS + BS) shl 1	arithmetic addition with 1-bit post-ALU shift left. (Post-ALU shift operations)
10110	(AS + BS) shr 1	arithmetic addition with 1-bit post-ALU shift right (Post-ALU shift operations)
10111	(AS + BS) ror 1	arithmetic addition with 1-bit post-ALU rotate right (Post-ALU shift operations)
11000	AS adc/sbc BS[1]	addition/subtraction with C flag (Carry-in Control)
11001	AS shl (2^(BS[1:0]+1))	AS is shifted left: 2 bits for BS=0; 4 for BS=1; 8 for BS=2; 16 for BS=3
11010	AS shr (2^(BS[1:0]+1))	AS is shifted right: 2 bits for BS=0; 4 for BS=1; 8 for BS=2; 16 for BS=3
11011	AS ror (2^(BS[1:0]+1))	AS is rotated right: 2 bits for BS=0; 4 for BS=1; 8 for BS=2; 16 for BS=3
11100	AS exch BS[4:0]	exchange C flag and AS bit determined by BS (Exchange Bit)
11101	AS setb BS[4:0]	set bit in AS determined by BS [2]
11110	AS clrb BS[4:0]	clear bit in AS determined by BS[3]
11111	n.a.	RESERVED

1. Addition/Subtraction is selected by field BINV (see B-Source Inversion)

2. In setb and clrb operations, the register that drives A source is not changed, unless selected as destination of the operation.
3. In setb and clrb operations, the register that drives A source is not changed, unless selected as destination of the operation.

2.14.9.2.11 Operations With Immediate Data

Immediate data can be used with some specific microinstruction formats. eTPU microcode allows 8-, 16- or 24-bit immediate data. Immediate data is loaded as B-source, so T4BBS field is not available. When using 24-bit immediate, an add is performed with A-source = 0 and flags are not updated. ALU operations are available with 8-bit immediate, although the field that selects ALU operation in this case is ALUOPI.

2.14.9.2.11.1 24-bit Immediate Destination

When using 24-bit immediate data, the destination register is selected by T2D field (2 bits), according to the following table.

Table 2-82. 24-bit Immediate Destination - T2D

T2D	Target Register
00	P[23:0]
01	A
10	SR
11	DIOB

2.14.9.2.11.2 Enhanced ALU Operations With Immediate Data

Enhanced operations with immediate data, selected by ALUOPI (5 bits) are allowed only with an 8 bit immediate operand (see the following table).

Table 2-83. ALU Operation Selection With Immediate Data - ALUOPI

ALUOPI	Operation	Comment
00000	AS mults #imm8	signed multiplication
00001	AS multu #imm8	unsigned multiplication
00010	AS fmults #imm8	signed fractional multiplication
00011	AS fmultu #imm8	unsigned fractional multiplication
00100	AS div #imm8	unsigned division
00101	n.a.	reserved
00110	n.a.	reserved
00111	n.a.	reserved

2.14.9.3 Channel Control and Configuration Microoperations

Channel Control and Configuration fields set configuration values in the channel logic of the channel selected by the CHAN register, except fields LSR and CIRC.

2.14.9.3.1 Channel flags operations

Each channel has two associated hardware flags, called Channel Flag 0 and Channel Flag 1. Microcode field FLC (3 bits) allows them to be set or cleared, as shown in the following table. These flags can be tested by microcode as a branch condition, and may also influence in the Entry Point taken, allowing fast state decoding. For more details, see Entry Points.

Table 2-84. P flags operation - FLC

FLC	Meaning
000	Clear flag0
001	Set flag0
010	Clear flag1
011	Set flag1
100	Copy flag1:flag0 from P[25:24]
101	Copy flag1:flag0 from P[27:26]
110	Copy flag1:flag0 from P[29:28]
111	No operation

2.14.9.3.2 Comparator and Time Base Selection

TBSA and TBSB fields (4-bit wide each) are used to configure the type of the comparator and the time bases used for match or capture (see the following tables). TBSA can also be used to control the Output Buffer Enable signal (See Pin Control Registers).

Table 2-85. Time Base Selection A - TBSA

TBSA[3] = 0	**TBSA bit**	**2**	**1**	**0**
	bitfield	**Comparator selection**	**Capture selection**	**Match TB selection**
	0	greater or equal	TCR1	TCR1
	1	equal-only	TCR2	TCR2
TBSA[3] = 1	**action**	**2**	**1**	**0**
	set OBE=1	0	0	0

Table continues on the next page...

Table 2-85. Time Base Selection A - TBSA (continued)

	set OBE=0	0	0	1
	do nothing	1	1	1
	reserved	all other values		

Table 2-86. Time Base Selection B - TBSB

TBSB[3] = 0	**TBSB bit**	**2**	**1**	**0**
	bitfield	**Comparator selection**	**Capture selection**	**Match TB selection**
	0	greater or equal	TCR1	TCR1
	1	equal-only	TCR2	TCR2
TBSB[3] = 1	action	**2**	**1**	**0**
	do nothing	1	1	1
	reserved	all other values		

2.14.9.3.3 Transition Detection and Pin Action Control

IPACA/B and OPACA/B fields are used to configure transition detection sensitivity (for the channel input signal) or output pin action control (for the channel output signal), as defined in the table below. IPACA and IPACB have the same format, where IPACA is related to Match A and first transition detection, and IPACB to Match B and second transition detection. The same applies in analogue way to OPACA and OPACB.

For the output signal, configuring OPAC registers does not change the current signal state, but defines the action to be done when a match or transition detection occurs. See Match Recognition and Channel Modes on Output Signal Generation for more information.

IPACA/B=1xx also enables assertion of MRLA/B during Time Slot Transition. See Match Recognition.

Table 2-87. Input and Output Pin Action Control - IPACA/B and OPACA/B

value	IPAC meaning	OPAC meaning
000	Do not detect transitions	Do not change output signal
001	Detect rising edge only	Match[1] sets output signal high
010	Detect falling edge only	Match[1] sets output signal low
011	Detect both edges	Match[1] toggles output signal
100	Detect input signal = 0 on Match[1]	Transition detection sets output signal low
101	Detect input signal = 1 on Match[1]	Transition detection sets output signal high
110	reserved	Transition detection toggles output signal
111	do not change IPAC	do not change OPAC

1. Match A is used for IPACA/OPACA, and Match B for IPACB/OPACB.

2.14.9.3.4 Immediate Pin State Control

It is possible to change output signal state immediately by using PSC (2 bits) and PSCS (1 bit) fields.

Table 2-88. Immediate Pin State Control - PSC and PSCS

PSC	PSCS	Meaning
00	0	set signal as specified by OPACA (see Transition Detection and Pin Action Control)
00	1	set signal as specified by OPACB (see Transition Detection and Pin Action Control)
01	x	set signal high
10	x	set signal low
11	x	don't change signal state

2.14.9.3.5 Write Channel Match and UDCM Registers

Match registers can have their values changed using ERWA and ERWB fields (1 bit each). They also set their respective MRLE register (see Match Recognition).

ERWA can also be used to program the UDCM register (see UDCM - User Defined Channel Mode). The field CMW selects where the contents of ERTA is copied when ERWA is active (see the following table).

Table 2-89. Write MatchA/B - ERWA/B

Field	CMW	Value	Action
ERWA	1	0	write ERTA value in MatchA. Enable matches for MatchA register (MRLEA=1)
	0	0	write ERTA value into UDCM
	1	1	don't change UDCM, MatchA and MRLEA
	0	1	reserved
ERWB	1	0	write ERTB value in MatchB. Enable matches for MatchB register (set MRLEB=1)
	1	1	don't change MatchB and MRLEB
	0		
	0	0	reserved

If ERTA or ERTB is a destination of an ALU operation and, at the same time, the respective ERWA/B field is active, the new ERTA value is the one written into the MatchA/B register or the UDCM register.

2.14.9.3.6 Clear Transition/Match Event Registers

Flags MRLA, MRLB, TDLA and TDLB (see ER - Event Registers) indicate the state of matches and transitions detected in the selected channel, and it is possible to clear those flags using the microcode fields MRLA, MRLB (1 bit each) and TDL (1 or 2 bits, depending on the format). The flags cleared by these microcode fields are the actual channel flags, and also the ones sampled into the branch logic.

TDL can be one or two bits wide, depending on the microinstruction format (see Microinstruction formats). Two-bit TDL allows independent clearing of TDLA and/or TDLB . Table 2-91 defines the two-bit TDL field.

Table 2-90. Clear Transition/Match Event Registers - MRLA/B, TDL

Field	Meaning
MRLA	0 = clear MRLA event register, 1 = don't change
MRLB	0 = clear MRLB event register, 1 = don't change
TDL (1 bit)	0 = clear TDLA and TDLB flags, 1 = don't change

Table 2-91. Independent TDLA/B clear - two-bit TDL

value	Meaning
0 0	clear TDLA
0 1	clear TDLB
1 0	clear both TDLA and TDLB
1 1	do not clear TDLA or TDLB

2.14.9.3.7 Disable Matches

Microcode field MRLE (1 bit) allows disabling matches on channel selected by CHAN register, for both MatchA and MatchB registers, by clearing their respective MRLE bits. Matches can be enabled for each Match register using ERWA and ERWB fields (see Write Channel Match and UDCM Registers).

Table 2-92. Disable Matches - MRLE

MRLE	Meaning
0	Disable matches for Match A and Match B
1	don't change match enabling

Some instruction formats have a two-bit MRLE field (see Microinstruction formats) which allows independent disabling of Matches 1 and 2, as shown in the following table.

Table 2-93. Two-bit MRLE

MRLE	Meaning
0 0	Disable Match A (clear MRLEA)
0 1	Disable both Matches (clear MRLEA and MRLEB)
1 0	Disable Match B (clear MRLEB)
1 1	nop

2.14.9.3.8 Disable Match and Transition Service Requests

Microcode field MTD (2 bits) disables match and transition service requests for the selected channel. MTD does not disable Link Service Request and Host Service Request. MTD sets or resets register SRI (for more details see SRI - Match/Transition Service Request Inhibit Latch) and TCCEA (see TCCEA - Transition Continuous Capture Enable) .

Table 2-94. Disable Match and Transition Service Request - MTD

MTD	Action on SRI	Action on TCCEA
00	SRI = 0: enable service requests for match and transition	TCCEA = 0: disable transition captures[1] when TDLA = 1
01	SRI = 1: disable service requests for match and transition	
10	SRI = 1: disable service requests for match and transition	TCCEA = 1: enable transition captures[2] when TDLA = 1
11	don't change	

1. Disables only captures on transition events specified by IPACA.
2. Enables only captures into CaptureA register, on transition events specified by IPACA.

2.14.9.3.9 Predefined Channel Modes

Microcode PDCM field (4 bits) defines the channel mode (see Channel Modes).

PDCM coding is shown in the table below. Note that PDCM bit 0 selects between Single Transition (PDCM[0]=0) and Double Transition (PDCM[0]=1) predefined modes.

PDCM is also used to select the user-defined channel mode, defined by the channel register UDCM (see UDCM - User Defined Channel Mode).

Table 2-95. Predefined Channel Modes

PDCM	Channel mode
0000	em_b_st
0001	em_b_dt
0010	em_nb_st
0011	em_nb_dt

Table continues on the next page...

Table 2-95. Predefined Channel Modes (continued)

PDCM	Channel mode
0100	m2_st
0101	m2_dt
0110	bm_st
0111	bm_dt
1000	m2_o_st
1001	m2_o_dt
1010	**user-defined channel mode**
1011	reserved
1100	sm_st
1101	sm_dt
1110	sm_st_e
1111	keep current channel mode

2.14.9.3.10 Channel Interrupt and Data Transfer Requests

Microcode can issue Interrupt Requests, Data Transfer Requests and Global Exception through CIRC field. For more information see Interrupts and data transfer requests.

Table 2-96. Channel and Data Transfer Requests - CIRC

CIRC	Meaning
000	Channel Interrupt Request from selected channel
001	Data Transfer Request from selected channel
010	Channel Interrupt and Data Transfer requests from selected channel
011	Channel Interrupt and Data Transfer requests from serviced channel
100	Channel Interrupt Request from service channel
101	Data Transfer Request from service channel
110	Global Exception
111	don't request interrupt

2.14.9.3.11 Clear Link Service Request

Microcode LSR field (1 bit) is used to clear the Link Service Request flag of the serviced channel (may not be the one selected by CHAN). The LSR branch condition is always cleared, but not the Link Service Request, if another channel link was received by the serviced channel during the executing thread. See Channel Link for more information.

Table 2-97. Link Service Request Negation Control - LSR

LSR	Meaning
0	clear Link Service Request (flag LSR)
1	don't change

2.14.9.4 Flow Control Microoperations

eTPU has *jump* and *call* microoperations to change microcode flow. Besides, eTPU has *dispatch jump* and *dispatch call* that can be used to implement a jump table. In *call* (or *dispatch call*) microoperation, the return address is saved in RAR register. If nested sub-routine calls are necessary, return address values have to be saved in a stack, usually implemented with DIOB register.

Flow Control microoperations are also provided to repeat a given microinstruction, to finish the current thread execution, and to halt the microengine.

2.14.9.4.1 Ending Current Thread - END

Microcode END field (1 bit) finishes current thread and allows other channels to be serviced. If END field is 0, the current instruction is completed and the thread is finished. END = 1 has no effect, and the next microinstruction is executed Any MDU operation (see MAC and Divide Unit (MDU)) that could be still pending when the thread is finished is left incomplete. END also releases any semaphore locked by the Engine.

2.14.9.4.2 Branch Operations

Branch operations can be **jump** or **call** . The target address of *jump* or *call* microoperations is always immediate and absolute. Branch microoperation is affected by FLS field (refer to Flush Pipeline).

2.14.9.4.2.1 Selecting Jump or Call Microoperations

The only difference between *jump* and *call* microoperations is that when a *call* is executed the value of PC or PC+1 (depending on flush, see Flush Pipeline) is saved in RAR register. The microcode field J/C (1 bit) selects whether *jump* or a *call* is executed, according to the following table.

Table 2-98. Jump / Call Selection - J/C

J/C	Meaning
0	jump
1	call

2.14.9.4.2.2 Branch Target Address

Microcode BAF field (14 bits) indicates the absolute address of a *jump/call target*.

2.14.9.4.2.3 Conditional/unconditional branch

Jump and *call* can be conditional or unconditional, depending on the BCC (6 bits) and BCF (1 bit) fields, as shown in Table 2-99 and Table 2-100 . BCF determines whether branch is taken when condition specified by BCC is true or false. When a branch condition uses the channel flags, the channel context is related to the channel number written in CHAN register.

Table 2-99. Branch Condition Inversion - BCF

BCF	Meaning
0	branch if condition determined by BCC is false
1	branch if condition determined by BCC is true

Table 2-100. Branch Condition Selection - BCC

BCC	Meaning	BCC	Meaning
001110	Flag 0	001111	Flag 1
100000	V ALU flag	110000	PSS channel flag
100001	N ALU flag	110001	PRSS channel flag
100010	C ALU flag	110010	"Less Than" ALU flag combination (signed) [1]
100011	Z ALU flag	110011	"Lower or Equal" ALU flag combination (unsigned)[2]
100100	MV MDU flag	110100	P[24]
100101	MN MDU flag	110101	P[25]
100110	MC MDU flag	110110	P[26]
100111	MZ MDU flag	110111	P[27]
101000	TDLA channel flag	111000	P[28]
101001	TDLB channel flag	111001	P[29]
101010	MRLA channel flag	111010	P[30]
101011	MRLB channel flag	111011	P[31]
101100	LSR channel flag	111100	PSTO channel flag
101101	MB flag MDU flag	111101	PSTI channel flag

Table continues on the next page...

Table 2-100. Branch Condition Selection - BCC (continued)

BCC	Meaning	BCC	Meaning
101110	FM[1] channel flag	111110	SMLCK semaphore flag
101111	FM[0] channel flag	111111	false
all other values reserved			

1. "less than" is a signed comparison, equal to the xor between ALU flags V and N; e.g., 0 < 0xFFFFFF tests as false (0 < -1).
2. "lower equal" is an unsigned comparison, equal to Z or C; e.g., 0 < 0xFFFFFF tests as true.

2.14.9.4.3 Dispatch Microoperation

Dispatch microoperation is an unconditional branch where the target address is always PC+P[31:24] (unsigned). Dispatch is affected by FLS field (refer to Flush Pipeline). Dispatch microoperation is defined by R/D field (2 bits, see the following table). Field R/D can also be used to define return from sub-routine (see Return from subroutine).

Table 2-101. Return and Dispatch - R/D

R/D	Meaning
00	return from subroutine (see Return from subroutine)
01	dispatch jump
10	dispatch call
11	don't change microinstruction flow

2.14.9.4.4 Return from subroutine

When a subroutine *call* or a *dispatch call* microoperation is executed, the return address is saved in RAR register. To return from a subroutine a microoperation is available to load the contents of RAR register back to the PC. Fields R/D (2 bits) or RTN (1 bit, see the table below) can be used to return from subroutine. For R/D field, see Table 2-101.

Return from subroutine microoperation is affected by FLS (see Flush Pipeline) when field R/D is used. Return execution through RTN always flushes the pipeline.

Table 2-102. Return from subroutine - RTN

RTN	Meaning
0	Return with pipeline flush
1	Do not return

2.14.9.4.5 Flush Pipeline

When a branch, dispatch or subroutine return microoperation is executed, the next microinstruction can be executed unconditionally before the flow change takes effect, since microengine has a three-stage pipeline. Executing the next microinstruction after a branch maximizes execution performance. This feature is controlled by field FLS (1 bit, see the table below). When FLS=0 the pipeline is flushed, so the next microinstruction placed after a branch is decoded as NOP if the branch is taken. If FLS=1, the microinstruction placed after the branch is executed, either if the branch is taken or not, as shown in the figure below.

Flush also controls which value is stored in RAR in a call: in case of no flush, it is the address of the branch/dispatch instruction + 2, even if RAR is the ALU destination of the instruction after the call; in case of a flush, it is the address of the instruction following branch/dispatch.

If a branch with no flush is followed by another branch with no flush, the instructions are executed in the following order:

1. first branch
2. second branch
3. first branch's destination instruction
4. second branch's destination instruction, and the flow proceeds normally from then on

The destination of the first branch must not be another flow changing instruction (branch, return or dispatch). Similar flows apply when returns or dispatches are used instead of branches. This scheme can be used to implement quick table look-ups with a dispatch replacing the first branch, for instance.

Table 2-103. Flush Pipeline - FLS

FLS	Meaning
0	flush pipeline when jump / call / dispatch jump / dispatch call / return is executed
1	do not flush pipeline when jump / call / dispatch jump / dispatch call / return is executed

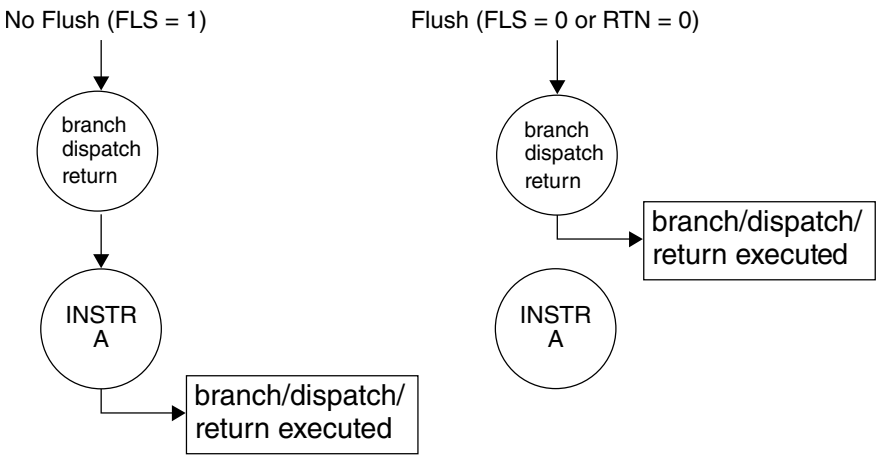

Figure 2-42. Flush Pipeline

2.14.9.4.6 HALT microinstruction

HALT is a microinstruction provided to implement software breakpoints (see Software breakpoints). Note that HALT is coded as a microinstruction format, not a field (see Microinstruction formats). The execution of this instruction puts the microengine in halt state. For more information about the implications of microengine halt state, see Microengine Halt State . HALT is valid only if software breakpoints are enabled at the Debug interface . If software breakpoints are not enabled, HALT executes as a NOP and is treated as an Illegal Instruction (see Illegal instructions).

2.14.9.4.7 NOP microinstruction

There is not a unique microinstruction with an assigned opcode to do No Operation. NOP microinstruction is achieved through any of the formats shown on Microinstruction formats where the user can assign to each individual field the corresponding value for "No Operation". However, to prevent future impacts of instruction changes on object code compatibility, the instruction value 0x4FFFFFFF should always be used for NOP.

2.14.9.5 Illegal instructions

An instruction is considered illegal if any reserved field value is used, including when the fields marked rsv in the instruction formats (see Microinstruction formats are assigned value 0. A HALT instruction is exceptionally considered illegal when executed with software breakpoints disabled (see HALT microinstruction). Global Exception may be issued up to two microcycles after instruction fetch. The execution results of an illegal instruction on the microengine, channel logic or host interface are unspecified, except for the HALT case.

If the microengine decodes an illegal instruction, the following actions are taken:

- A Global Exception is issued.
- The ILF1/2 flags in eTPU Module Configuration Register (eTPU_SCR_MCR) are set to indicate this occurrence to the Host.
- A breakpoint occurs, if NDEDI is present and configured to do so (see the NDEDI details for more information).

2.14.9.6 Microinstruction Parallelism Issues

This section clarifies parallelism issues that arise when two non-commutative microoperations appear in the same microinstruction.

2.14.9.6.1 ALU Operations and Read Match Registers

ALU operations have only one destination register, but there is one case where source selection determines destination: read Match register in ERTA and ERTB registers. In this case if ALU destination is ERTA or ERTB a conflict arises. The ALU destination value overwrites the value read from the match registers.

2.14.9.6.2 ALU and SDM Operations

P and DIOB registers can be selected as destination by both ALU and SDM (read) microoperations in the same microinstruction. Since P and DIOB update from SDM data happens after P and DIOB update for ALU/MDU microoperations, the data read from SDM remains in P or DIOB after an operation when one of them is specified as destination for both ALU and SDM microoperations. In this case, the value loaded into P or DIOB is the one read from SDM. However, the ALU operation is executed and its flags are updated accordingly.

When P or DIOB is destination of an SDM read and also an ALU source at the same microinstruction, the value before the read is used for the ALU operation.

If DIOB is the ALU destination and P is loaded from SDM or vice-versa, no conflict occurs, and the result is the same as if operations occurred separately.

All the above also applies to Zero SDM operations.

When using P or DIOB as destination for ALU operations and also as source for a SDM write operation, the data written in SDM is the one calculated by ALU, which means it is possible to calculate a value and write it in an SDM address using only one microinstruction.

The old value of DIOB or the old value minus 4 (pre-decrement) is always used when DIOB is selected as address (indirect address mode), no matter if DIOB is selected as destination of either the SDM or ALU. For the value loaded into DIOB, refer to the following table.

Table 2-104. DIOB load from SDM and ALU

DIOB selected as SDM read destination?	DIOB selected as ALU destination?	DIOB load value
no	no	DIOB, --DIOB (pre-decrement), or DIOB++ (post-increment)
yes	no	SDM read data (post-inc and pre-dec ignored)
yes	yes	SDM read data (post-inc, pre-dec and ALU result ignored)
no	yes	ALU result (post-inc an pre-dec ignored)

When CHAN is the destination of an ALU operation in parallel with a channel-relative SDM access, the CHAN value used to calculate the address is the one before the ALU operation.

2.14.9.6.3 ERTA/B as ALU destination and ERWA/B

The value in ERTA and ERTB registers can be written in match registers of the selected channel by using fields ERWA and ERWB (Write Channel Match and UDCM Registers). If, at the same microinstruction, ERTA or ERTB is destination of an ALU/MDU microoperation, the value written in Match registers is the ALU/MDU result.

The same applies to UDCM when ERTA is the destination of an ALU operation and instruction fields ERWA and CMW are active .

If an ALU operation occurs in parallel with ERWA/B but ERTA/B are not the destination of an ALU/MDU operation, then UDCM and MatchA/B receives the ERTA/B value.

2.14.9.6.4 ERWA/B and MRLE

ERWA/B automatically sets the MRLEA/B channel latch, respectively (see Write Channel Match and UDCM Registers). Microinstruction fields ERWA/B independently sets MRLEA/B channel flags, regardless of MRLE.

2.14.9.6.5 CHAN assignment, Read Match and ERWA/B

When CHAN is a destination of an ALU operation it causes a read of the CaptureA/B register values into ERTA/B. The Capture registers loaded into ERTA/B are selected by the new CHAN value. The value of the CaptureA/B registers overwrites any read-match commanded simultaneously.

If CHAN assignment happens with an ERWA/B operation in the same instruction, the updated Match register(s) belong to the new selected channel.

2.14.9.6.6 Read Match and ERWA/B

If a read match operation is executed with ERWA/B in the same microinstruction, the MatchA/B registers receive the old values of ERTA/B, and the ERTA/B registers receive the old MatchA/B values simultaneously, i.e.: ERTA/B and MatchA/B swap their values.

If ERTA/B is the destination of an ALU operation at the same instruction, MatchA/B gets the ALU result (see ERTA/B as ALU destination and ERWA/B), but the ERTA/B not being written still receives the old MatchA/B values.

Note

Read match, ERWA/B and CHAN assignment can be active at the same instruction. Combining rules CHAN assignment, Read Match and ERWA/B and Read Match and ERWA/B, the result is: ERTA/B receives the CaptureA/B values of the new CHAN value, and MatchA/B of the new channel receives the old ERTA/B value(s).

2.14.9.6.7 Stack accesses and ALU operations

Post-increment is ignored in a stack operation (field STC) if DIOB is loaded from SDM: DIOB keeps the value read from SDM. Pre-decrement is ignored in a stack operation (field STC) if DIOB is destination of an ALU operation, for DIOB load value, but not for DIOB as address. Post-increment/pre-decrement remains valid in all other situations. These rules can be summarized in the following equivalent C code, and in Table 2-104.

```
DIOB = *DIOB[15:2];       // read without posinc/predec
*DIOB[15:2] = DIOB;       // write without posinc/predec
```

```
DIOB = *(--DIOB[15:2]);  // read with predec
DIOB = *DIOB[15:2];      // read with posinc (ignored)
*(--DIOB[15:2]) = DIOB;  // write with predec
*DIOB[15:2]++ = DIOB;    // write with posinc (value written is before
increment)
```

2.14.9.6.8 SRC and ALU/MDU operations

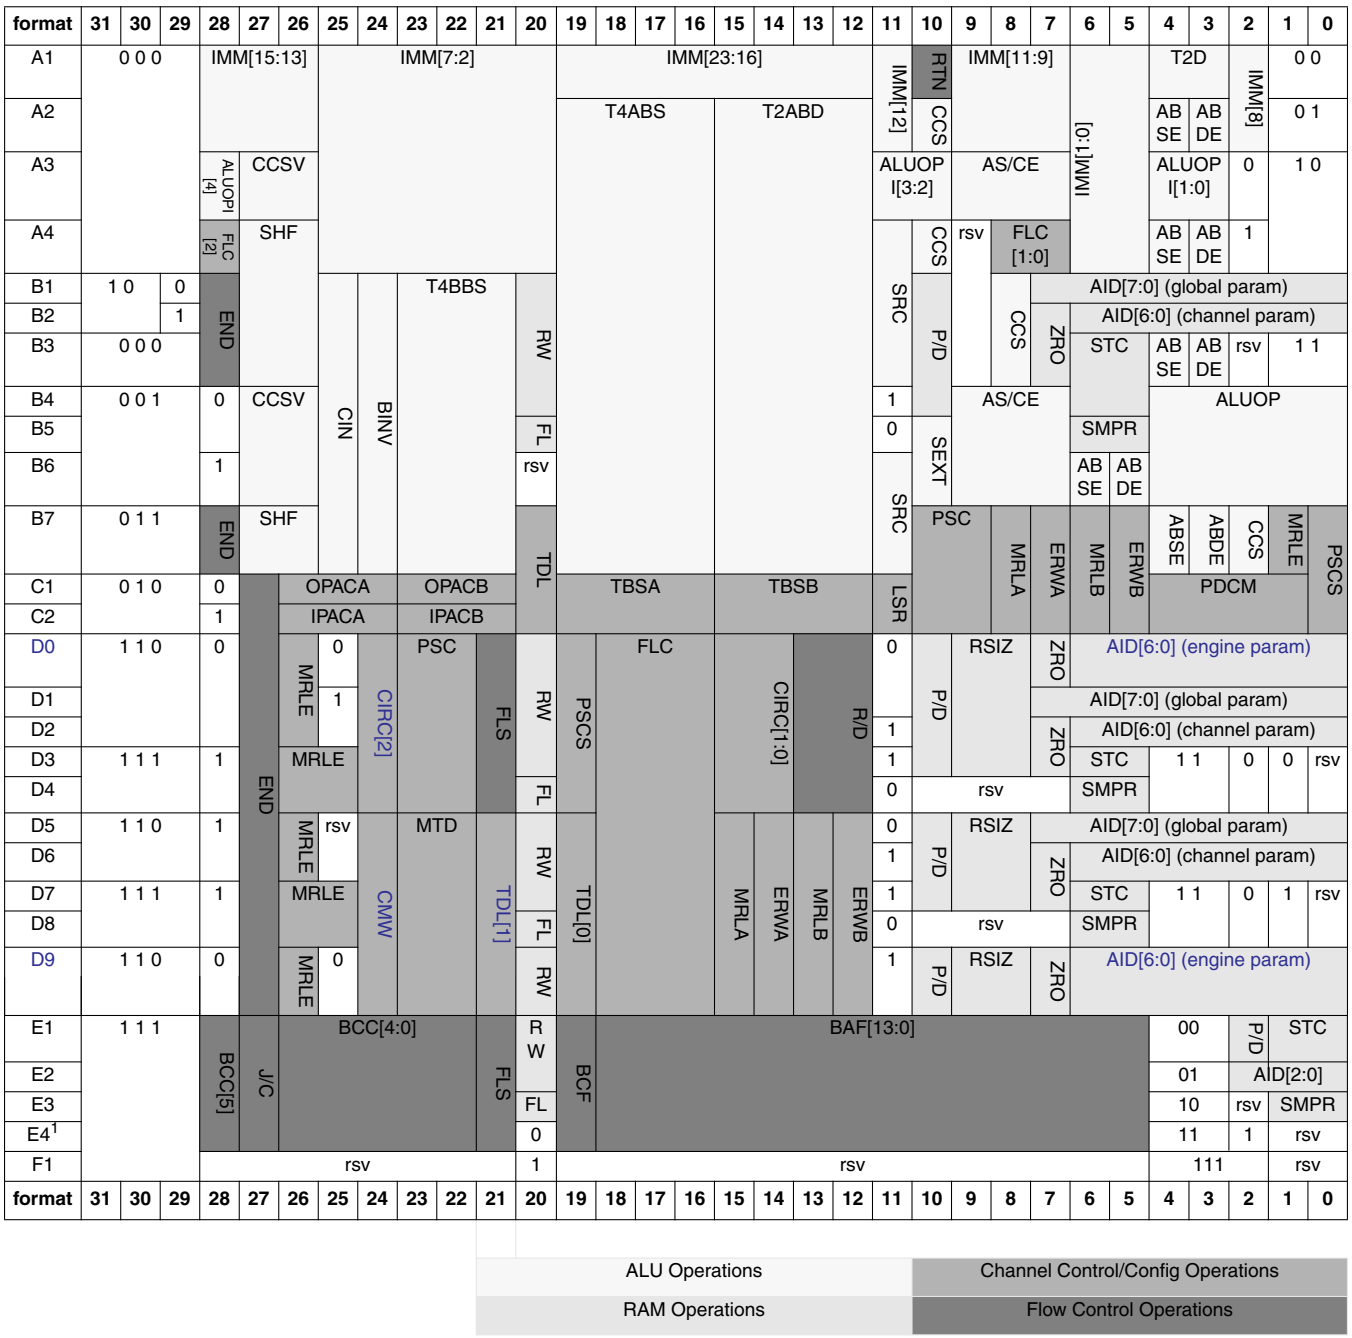
If operation SRC is active (field SRC = 0) and register SR is selected as destination of an ALU operation, the value of the ALU operation prevails over the shifted value.

The value of SR used as source in the ALU/MDU operation is the one before the shift.

2.14.9.6.9 Semaphore lock/free and SMLCK branch condition

When the SMLCK branch condition is tested at the same microinstruction of a semaphore lock or free, the condition is evaluated after the semaphore action (either free or lock) is taken.

2.14.9.6.10 Dispatch and SDM Read



When the most significant byte of P is read from SDM (read 8 msb bits or 32 bits) and a dispatch instruction is executed simultaneously, the dispatch target address is calculated upon the P value before the read.

2.14.9.6.11 CHAN Assignment, PSC/PSCS, and clear MRLEA/B, MRLA/B, TDLA/B

When clear MRLEs, MRLA/B or TDLs is done and a CHAN assignment is done at the same time, the flag selected by the old CHAN value is cleared in the channel, but the branch conditions receive the state of the flags selected by the new CHAN.

When a pin action is commanded through PCS/PSCS and a CHAN assignment is done simultaneously, the output signal affected is selected with the old CHAN value.

2.14.9.7 Microinstruction formats

NOTES:
1 format E4 is deprecated; the same result can be obtained with format E1 with field STC=11

Figure 2-43. Microinstruction formats

All bits marked "rsvd" are reserved, and must be coded as 1.

2.14.10 Shared Subsystems support

Shared Subsystems support allows eTPU to control other modules, either independently or sharing control with the host. A notable example of shared subsystem is the Reaction Module (see the Reaction Module chapter for details), which is connected to the eTPU as shown in the figure below. The host CPU accesses the Reaction Module through the eTPU, which can also access the same registers.

When the SSMAE field in eTPU Channel n Configuration Register for Engine 1 (eTPU_CCCR_C*n*CR_ENG1) or eTPU Channel n Configuration Register for Engine 2 (eTPU_CCCR_C*n*CR_ENG2) is 1, the eTPU channel's threads can control shared subsystems by accessing their registers, which are mapped onto the higher 16 Kbytes of the microcode data address space (byte addresses/DIOB values 0x4000 to 0x7FFF, equivalent to parameters 0x1000 to 0x1FFF), as shown in Figure 2-45. The shared subsystem registers are accessible by microcode only with the indirect address mode (see SDM Addressing Modes).

When the SSMAE field in eTPU Channel n Configuration Register for Engine 1 (eTPU_CCCR_C*n*CR_ENG1) or eTPU Channel n Configuration Register for Engine 2 (eTPU_CCCR_C*n*CR_ENG2) is 0, the channel's threads can access only the SDM, mirrored throughout the whole DIOB address range.

The same Shared Subsystem register address space is accessible by the host through the Shared Subsystem Area within the eTPU memory map (see Figure 2-45 and Memory map), allowing shared control and/or supervision between the host and the eTPU. The arbitration mechanism between host and eTPU accesses is the same used for SDM accesses (see SDM arbitration). The CDC (see Coherent Dual-parameter Controller (CDC)) cannot be used for coherent transfers between SDM and the Shared Subsystem Area, or within the Shared Subsystem Area itself.

Note

The detailed register map within the Shared Subsystem Area depends on the subsystem module.

A Shared Subsystem may be divided into submodules or channels, hereafter called **Shared Subsystem Units** (or **Shared Units** for short), which can be individually controlled by an eTPU function (see Functions and threads)

A Shared Unit is logically linked with an eTPU channel through the eTPU_SSIR_ETPUSSSIR*n* configuration[34]. There is one eTPU_SSIR_ETPUSSSIR register for each Shared Unit to configure its interface with the eTPU (see eTPU Shared Subsystem n Integration Register (eTPU_SSIR_ETPUSSSIR*n*)). The Shared Unit uses

34. However, in the case of Reaction Module, the eTPU_SSIR_ETPUSSSIR*n*configuration does not determine which eTPU channel output enables the Reaction Channel modulation; this is defined in the Reaction Module configuration.

the Link Service Request (LSR) mechanism to request service to the eTPU. The Link Service Request is targeted to the channel/engine configured in LENG and LCHAN. The function assigned to this channel must be written to service the Shared Unit. The Shared Unit link service request may have the same source as an interrupt to the host.

Note

Shared Unit link service requests are level-sensitive to the eTPU. If it comes from an interrupt source, the link service request stays asserted as long as the interrupt is asserted and enabled, so the interrupt request must be cleared before the clear of the LSR flag in the link service request thread.

LENG can also be used by the host to disable Link Service Requests to the eTPU. The eTPU microcode can only disable LSRs from the Shared Unit through configuration specific to the Shared Unit itself.

Note that more than one Shared Unit can generate LSRs to the same eTPU channel, in which case the LSR source can be determined by microcode through the Shared Unit status register(s). An eTPU channel configured as a Shared Unit LSR target can also receive Link Service Requests from other eTPU channels or Shared Units. The same LSR service and flag behavior found in links between eTPU channels applies to Shared Unit links (see Channel Link).

The table below summarizes the mapping of Reaction Module resources into Shared Subsystem Support.

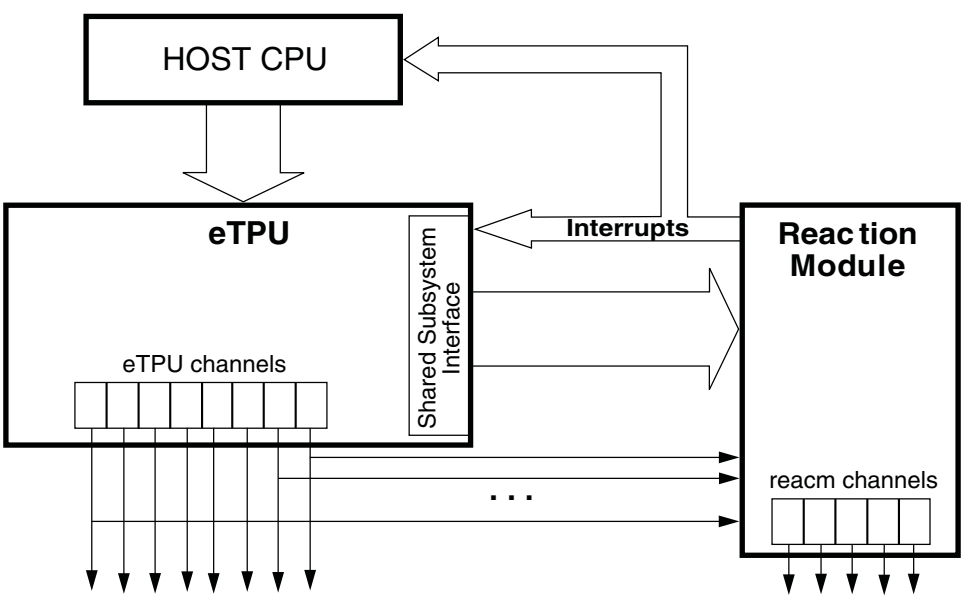


Figure 2-44. Shared Subsystem block diagram example: Reaction Module

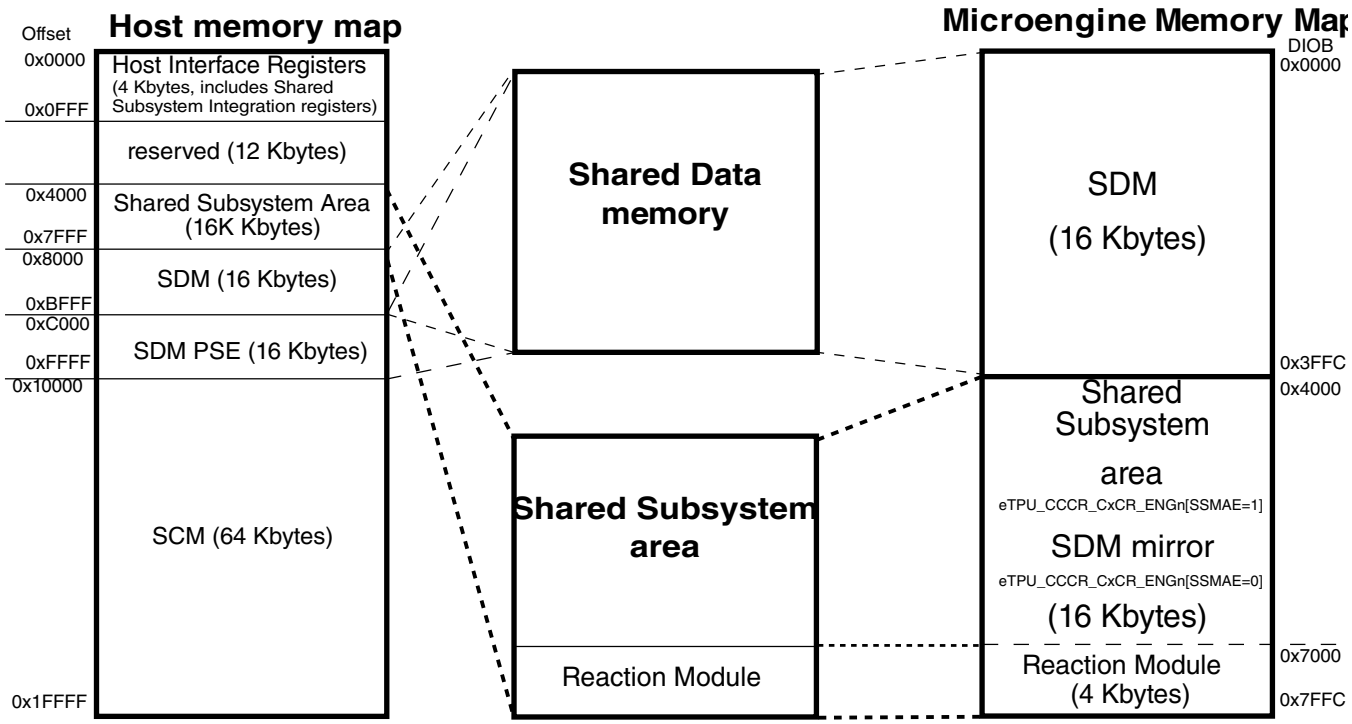

Figure 2-45. Shared Subsystem memory mapping

Table 2-105. Reaction Module Shared Subsystem support

Reaction Module resource	Host mapping	eTPU/microengine mapping
Register access	eTPU Base + 0×7000	DIOB address 0×7000 (indirect address mode)
Interrupts	See Interrupts chapter	Link Service Requests mapped through Subsystem Integration registers eTPU_SSIR_ETPUSSSIR*n*
DMA Requests	See eDMA chapter	Not applicable

2.14.11 Development support features

Following sections describe several features available to support development. Most debug features are accessible through a separate debug bus, and are not available through registers in the standard eTPU memory map. The details of the access to this interface are MCU-dependent (see Debug Interface chapter). The microengines can also be put in halt state by a device-level debug request.

NOTE

The behavior of the debug support logic is not specified in the event of a non-correctable memory error on either SCM or SDM (see Memory error support).

2.14.11.1 Nexus Class 3 Support

NDEDI is an IP block designed to support Nexus functionality for the eTPU. It provides a Nexus class 3 or class 1 debug interface, depending on the MCU (see Configuration section). Nexus is a development support external interface defined by the **IEEE standard ISTO 5001-1999**. More details about it can be found in the NDEDI details.

Some of the next subsections describe debug features provided by the eTPU microengine debug support combined with the NDEDI block.

2.14.11.2 Microengine Halt State

Halt is a microengine state where it suspends execution during a thread, or does not start executing a scheduled thread from idle state. While Idle State is entered from END execution without any other scheduled thread, microengine enters Halt State by any of the following events:

- execution of the HALT microinstruction (software breakpoint).
- external halt request through the Debug Interface (includes Nexus breakpoint request via EVTI input pin - see Nexus Class 3 Support).
- the other Engine enters halt state and they are configured to halt simultaneously (bit HTWIN is asserted via Nexus Interface).
- System level device debug request assertion and NDEDI register NDEDIETPUx_DC field CBI=1. If same register's field CBT=1, microengine halts at the next time-slot boundary, if CBT=0 it halts immediately. As a particular case, microengines come halted out of reset if device debug request is asserted, since CBI reset value is 1. Microengine does not execute out of reset, either in halt (device debug request asserted) or idle state (device debug request negated), but halt enables several other features (see below).

- occurrence of any of the hardware breakpoint conditions. See Hardware breakpoints for details.
- execution of a single-step microinstruction: microengine returns to halt state after executing a single microinstruction while in halt state. See Single-step Execution and Forced microinstruction execution for details.

When microengine enters halt state, it automatically triggers the following actions:

- suspends input signal sampling and filters (respective Engine channels only), if NDEDI_ENGINEx_DC[PINS] = 1 at the Debug Interface.
- releases the SDM arbitration for Host or CDC accesses, no matter if microengine was halted in the middle of a dual parameter (back-to-back) access.
- stops TCR1/2 clocks of the respective Engine, if signal ndedi_stop_tcr is asserted at the Debug Interface.
- if the other Engine is also in halt state or stopped, allows turning the eTPU Module Configuration Register (eTPU_SCR_MCR) VIS bit to 1.

If all halt conditions are cleared when VIS=1, microengine(s) keep on halt state until VIS=0, when it automatically exits halt state, except on single-step (see Single-step Execution), so that single-step execution is ignored while VIS=1.

MDU continues executing until it finishes any ongoing operation even if microengine is in halt state, except when the halted instruction is an END.

There are two kinds of halt state, depending on the previous microengine state when halted:

1. **halt_idle**, if the engine was not executing a thread when halted; the engine cannot leave halt_idle to fetch instructions, so one cannot single-step or follow a program flow; it can, however, execute forced instructions (see Forced microinstruction execution).
2. **halt_exec**, if the engine was executing a thread when halted. The engine can single-step and continue a program flow from halt_exec.

When microengine exits halt state, any dependable action is suspended and, if exiting halt_exec, the instruction pointed by the PC is fetched, while the instruction already fetched before halt is executed. Note that both the PC and the prefetched instructions can be modified during halt state, with a forced execution of a branch instruction (see Forced microinstruction execution).

2.14.11.3 Hardware breakpoints

Microengine can enter halt state through a command from the Debug Interface, configuring a hardware breakpoint. Hardware breakpoints can halt the microengine on specific conditions, listed below. These conditions depend on NDEDI configuration (see the NDEDI details for more information).

- CHAN register assignment (only by microcode, not by time slot transition).
- SDM read and/or write to a given address and/or write data. The breakpoint is always qualified by the SDM address, but the following variations are allowed:
  - break on write only, read only, or read-and-write.
  - break on higher-byte write data value, lower 24-bit write value, full word (32-bit) write value, or regardless of data. Break on read data is not supported.
- PC (program counter) value.
- Beginning of a thread with a Host Service Request pending.
- Beginning of a thread with a Link Service Request pending.
- Beginning of a thread with a Match Service Request pending.
- Beginning of a thread with a Transition Service Request pending.
- End of a thread.
- Illegal instruction execution.

All these conditions can also be qualified by the value of the CHAN register.

NOTE

Data breakpoints are not supported on Shared Subsystem Area accesses (see Shared Subsystems support).

Hardware breakpoints halt the microengine before the halted instruction is executed, except on data breakpoints. Data breakpoints allow the instruction that performs the data access to be executed before the microengine is halted.

Note

Data breakpoints in eTPU versions before eTPU2 halt the breakpoint instruction before its execution in all cases, including data breakpoints.

On any of these conditions, halt of one microengine does not depend on the halt of the other, unless the other engine is configured to do so, via Nexus Interface. Occurrence of any of these conditions halts the microengine, i.e., the conditions are logically ORed together, and they can be individually enabled.

While in halt state, the microengine can also execute any forced microinstruction not in the normal program flow (see Forced microinstruction execution) or, if in halt_exec, in single-step (see Single-step Execution).

There are situations when requests for stopping an engine, breakpoint and service can occur simultaneously. Breakpoint requests always prevails over a stop request (eTPU Engine 1 Configuration Register (eTPU_SCR_ECR_ENG1) or eTPU Engine 2 Configuration Register (eTPU_SCR_ECR_ENG2) bit MDIS=1 or device debug request=1). When the eTPU is idle: stop request prevails over Service Request if there is not a hardware breakpoint request; a hardware breakpoint request leads to debug mode immediately if there is no Service Request, and after TST if there is Service Request (regardless of stop requests). The rules above are summarized in the the following table, showing the destination state of the microengine in each situation.

Table 2-106. Breakpoint, stop and service requests resolution from idle

Breakpoint request	MDIS	Service request	Final state
no	0	0	Idle
no	1	0	Stop
no	0	1	TST
no	1	1	Stop
Yes	0	0	Halt_idle
Yes	1	0	Halt_idle
Yes	0	1	TST[1]
Yes	1	1	TST[1]

1. Breaks after TST, if signal ndedi_sync_break is still asserted.

When a thread is ending, it goes to Idle or TST only if there is neither a hardware breakpoint request nor a request to stop (eTPU Engine 1 Configuration Register (eTPU_SCR_ECR_ENG1) or eTPU Engine 2 Configuration Register (eTPU_SCR_ECR_ENG2) bit MDIS=1 or device debug request=1). When thread is ending and there are simultaneous hardware breakpoint and stop (MDIS=1 or device debug request=1) requests, hardware breakpoint prevails and the engine enters Debug mode (Halt_idle state).

If the engine entered Debug mode after a thread finished (Halt_idle state) and a "go" command comes from the debug interface, the engine state machine goes to Idle and the rules above apply. It means that if a "go" is issued in Halt_idle state with MDIS=1, the engine goes to Idle for one microcycle and then stops (if MDIS or device debug request keeps asserted and there is no other breakpoint request).

Note

Hardware breakpoint requests are ignored for the first microinstruction executed when microengine leaves halt.

2.14.11.4 Hardware Watchpoints

Debug Interface allows watchpoints on the same conditions available for hardware breakpoints (see Hardware breakpoints).

Note

Data breakpoints are not supported on Shared Subsystem Area accesses (see Shared Subsystems support).

2.14.11.5 Software breakpoints

A software breakpoint occurs when microengine executes a HALT microinstruction. Any number of software breakpoints can be set in code, usually replacing an active microinstruction.

Like any other microinstruction, HALT increments the PC and pre-fetches the next instruction. So, before the halt state is suspended, if the original program flow must be followed, the original instruction at the HALT address must be executed, regardless if the software breakpoint is removed (replacing HALT by the original microinstruction) or not. Follows the procedure to resume execution from a software breakpoint:

1. restore the original instruction in SCM (replace HALT).
2. force a jump with flush to the original instruction (see Forced microinstruction execution).
3. if the software breakpoint must be kept: single-step and replace the original instruction with a HALT.
4. let the flow continue, issuing a GO command (leaving halt state).

Special care must be taken if HALT is followed by another HALT, and the second HALT is removed when microengine was halted by the first one. In this case, replacing the second HALT with the original microinstruction is not enough to remove the second breakpoint, because the second HALT was already prefetched and would be executed anyway when halt was suspended. The debugger must also do a forced execution of unconditional branch with flush to the original microinstruction address. That will clear the pipeline, replacing the prefetched instruction with a NOP, and load PC with the address of the removed breakpoint. So, when halt state is suspended, the original microinstruction will be fetched while NOP is executed, and program flow continues normally from then on.

Note

A HALT instruction placed after a no-flushing branch, dispatch or return may be a problem from the debugger application standpoint: after the HALT is executed, the eTPU debug interface informs the address of the branch/dispatch/return destination, and the debugger application has no direct way to identify which HALT instruction was executed, if multiple HALTs lead to the same address. This can be solved if the debug support block (NDEDI) has a register holding the address of the last instruction executed, otherwise one should forbid non-flushed HALT instructions. See the NDEDI details.

Software breakpoint setting and removal is possible only with SCM RAM implementations or ROM implementations with SCM RAM emulation (see). There is only one way of inserting software breakpoints into SCM RAM: programming VIS=1 in eTPU Module Configuration Register (eTPU_SCR_MCR), and then accessing SCM as an ordinary RAM from the slave bus. This can be done only if both Engines are halted or stopped.

2.14.11.6 Single-step Execution

When microengine is already in halt_exec state, it can run the next microinstruction in the normal program flow and get back to halt state. PC is incremented, or assigned the BAF value in a branch with satisfied condition. Note that the executed instruction was already prefetched in the instruction pipeline, and a new microinstruction is fetched during its execution. The prefetched instruction may be cleared during halt state by the forced execution of a branch with flush (see Forced microinstruction execution), making single-step execute a NOP instead of the next instruction in the program flow.

Single-step execution is controlled by the debug interface, and is a feature available from Nexus if eTPU is connected to the NDEDI block (see NDEDI details).

The single-step execution of a NOP instruction can be useful to control input signal sampling and filtering, if NDEDI_ENGINEx_DC[PINS] = 1 at the Debug Interface (see NDEDI details). Single-step does not happen if VIS=1.

2.14.11.7 Forced microinstruction execution

When microengine is already in halt state (either halt_idle or halt_exec), it can run forced microinstructions through the debug interface. This feature is available from Nexus if eTPU is connected to the NDEDI block (see NDEDI details). The microinstruction, specified by the user, is not fetched from SCM and comes directly from the debug interface. MDU start commands issued by forced instructions are executed, and the MDU runs the operation until the end, independently of the halt state. The microinstruction field END is ignored.

During forced execution of any instruction except Branches, Returns and Dispatches, the PC does not change, and the prefetched instruction in the pipeline is bypassed, but not discarded. When halt state is suspended, the prefetched instruction is executed and the instruction pointed by the PC is prefetched in parallel (two-stage pipeline).

Forced execution of a Branch, Dispatch or Return loads the PC with the BAF field (if branch condition is satisfied), PC+P or RAR, respectively. If branch condition is not satisfied, PC value stays unaltered. The flush control (field FLS) also works, so that a successful forced branch with flush replaces the prefetched instruction with a NOP. So, to clear the instruction pipeline during halt, all one has to do is an unconditional branch to the desired address with flush. HALT instructions must not be executed as forced.

Forced operations that depend on the serviced channel are unspecified when executed in halt_idle and must be avoided.

Note

Forced instructions must not be commanded when eTPU Module Configuration Register (eTPU_SCR_MCR) field VIS=1.

2.14.11.8 Microengine Register Access

eTPU provides no direct access to microengine and channel registers from the slave bus or any other interface. However, these registers can be read and written in halt state by executing forced microinstructions (see Forced microinstruction execution). Immediate

data microinstructions may be used to set register values. Some registers are not selectable for immediate data destination, so intermediary register(s) - notably P - may have to be used to carry the desired new value to the target register in two or more microinstructions. Usually the previous values of intermediary register(s) must be previously saved and restored after the whole operation.

Similar procedures apply for register reads: their contents must be dumped to SDM, where they can be read from the slave bus.

2.14.11.9 Microengine Flag Access

Microengine halt state allows reading the branch conditions flags through forced microinstructions or, more easily, through the NDEDI register NDEDI_ENGINEx_CFSR (see the NDEDI details). Flag conditions set by the user are seen by microengine for the next microinstruction execution. The flag set options are limited by the possibilities of forced microinstruction execution.

If the eTPU runs (not single-stepping) after exiting the halted state, the conditions modified during halt may remain only for the first microcycle after the halted state. After the first microcycle, branch conditions are altered only according to their regular update scheme.

2.14.11.10 Microengine Stall

Microengine can get into a stall state, attending a request from a debug interface signal assertion. The reason for a Stall request from NDEDI (or from any other debug support block) should be a temporary lack of resources, for instance queue full. During stall the microengine suspends execution, but all the other Engine logic continues operating: time bases, angle logic, channel logic, input sampling and filters. Stall differs from Halt, not enabling any of the debug features that Halt enables (see Microengine Halt State). It also does not break an atomic microengine access, unlike halt.

The Microengine can be stalled when idle and from the moment TST ends, before executing the first thread microinstruction, until just before the last thread microinstruction is executed. Stall requests are ignored in any other occasions. Microengines in a dual engine system can be independently stalled. If a forced end is issued when microengine is in stall coming from execution, the END is executed only when the microengine resumes execution from stall.

2.14.12 Safety features

This section describes embedded safety features: MISC and memory error support.

The Multiple Input Signature Calculator - MISC - is an SCM test feature accessible through eTPU Module Configuration Register (eTPU_SCR_MCR) and eTPU MISC Compare Register (eTPU_SCR_MISCCMPR). MISC allows SCM test "on the fly", i.e., while eTPU is running, with no impact on eTPU functionality or performance.

Memory Error support features comprises SCM and SDM error detection, correction, report, and soft error.

2.14.12.1 SCM Test - Multiple Input Signature Calculator

The Multiple Input Signature Calculator (MISC) comprises special hardware that sequentially reads all SCM positions and calculates, in parallel, a 32-bit signature from a 32-input CRC signature calculator with the following polynomial:

$$1 + x^{1} + x^{2} + x^{22} + x^{31}$$

A complete description of the signature calculation procedure can be found in MISC Algorithm.

Once started by the Host the MISC runs continuously, restarting after the completion of each cycle, when it sets SCMMISC. The average time for a MISC calculation can be measured by checking SCMMISC state at regular intervals, incrementing a counter and clearing SCMMISC if it is set.

MISC accesses to the SCM array are executed if none of the engines is accessing the SCM, to avoid degradation of the microengine performance: it happens while no channel is being serviced. An ongoing MISC operation can be aborted by writing 0 to SCMMISEN.

The Host must load eTPU MISC Compare Register (eTPU_SCR_MISCCMPR) with the expected value to be found at the end of the MISC cycle, and then start the signature calculation by programming field SCMMISEN=1 in eTPU Module Configuration Register (eTPU_SCR_MCR). MISC zeroes the signature accumulator and starts reading SCM data and calculating the signature. After last SCM position is read, MISC compares the value in signature accumulator against the value in eTPU_SCR_MISCCMPR: if there is a mismatch MISC stops, a Global Exception is issued and SCMMISF assumes value 1. If no mismatch is found, MISC repeats the procedure automatically. When signature is being calculated, SCM address starts at the last SCM address and counts down to 0. The conditions for executing a MISC operation are (see also Table 2-26):

- Both microengines in idle state (no channel is being serviced) or stopped, in any combination (e.g., engine 1 idle with engine 2 stopped).
- VIS =0.
- SCMMISEN =1.

Note that MISC can run regardless of SCM implementation type (RAM or ROM).

If SCMMISEN=0 or VIS=1, the MISC logic stays at its initial state, with address counter pointing to the last SCM position and accumulator reset.

MISC can also be used to perform single-bit error fixes in the SCM. For more details, see Error fixing.

2.14.12.2 Memory error support

Error Correction Code (ECC) support for SDM and SCM provides guaranteed single bit error correction and double bit error detection. Error detection and correction is performed on read accesses and on write accesses less than 32-bit wide to the SCM.

SDM ECC is calculated per byte, 5 bits wide each, totalling 20 ECC bits for each 32-bit word. That allows the ECC to be updated without a read-modify-write operation on writes of any size.

Error is not checked on bytes not selected on SDM read accesses, either by the Host, CDC or microengine. For instance, the most significant byte is not checked for errors on a microengine 24-bit read access.

Error detection also works for host accesses to the PSE area (see Parameter Sign Extension area). In this case, error is not detected in the most significant byte (bits 31:24). Also, because of sign extension, error is always detected on the bits 23:16, regardless if they are selected, whenever the most significant byte is read.

SCM ECC is 7 bits wide, comprising the whole 32-bit word. Read-modify-write is automatically made when 16-bit or 8-bit wide writes are made into the SCM in a host access. SCM errors are also detected on Entry Table accesses during TST (see Time Slot Transition) and on MISC accesses, which are considered microengine accesses with regards to interrupt generation and error reporting.

2.14.12.2.1 Error detection disabling

The error detection logic in SDM and SCM can be disabled by setting the eTPU Memory Error Control Register (eTPU_MESR_MECR) bits DEDD and CEDD, respectively. The disabled state turns ineffective any action due to error detection, including error correction. Note that error detection is always enabled out of reset.

2.14.12.2.2 Memory error flags

SDM single (correctable) and non-correctable bit errors are flagged in eTPU Memory Error Status Register (eTPU_MESR_MESR) fields DCERR and DNCERR, respectively.

SCM correctable and non-correctable errors are flagged in the eTPU_MESR_MESR fields CCERR and CNCERR, respectively.

Double bit errors are guaranteed to be flagged, while three or more simultaneous bit errors in an SDM byte or SCM word are not. An error flagged as non-correctable can be in two or more bits.

Overrun flags DCOVR and CCOVR indicate, for SDM and SCM respectively, when a correctable error occurs when DCERR, CCERR are already asserted. Similarly, overrun flags DNCOVR/CNCOVR assert when a non-correctable error occurs when DNCERR/ CNCERR are asserted already.

2.14.12.2.3 Memory error reports

The address, syndrome and data of a non-correctable SDM access can be sampled into eTPU Data Error Report Address Register (eTPU_MESR_DERAR), eTPU Data Error Report Syndrome Register (eTPU_MESR_DERSR), and eTPU Data Error Report Data Register (eTPU_MESR_DERDR), respectively. eTPU_MESR_DERAR also captures the SDM read access originator, whether the host, CDC, or specific eTPU channel service.

Similarly, non-correctable SCM accesses address, syndrome and data are stored in eTPU Code Error Report Address Register (eTPU_MESR_CERAR), eTPU Code Error Report Syndrome Register (eTPU_MESR_CERSR), and eTPU Code Error Report Data Register (eTPU_MESR_CERDR), respectively. eTPU_MESR_CERAR also captures the SCM read access originator, whether the host, MISC, or specific eTPU channel service. The occurrence of a non-correctable error overwrites the report register values from a correctable error, either on SDM (DCERR=1) or SCM (CCERR=1).

The last address, syndrome and data of a correctable SDM access can also be sampled into eTPU_MESR_DERAR, eTPU_MESR_DERSR, and eTPU_MESR_DERDR, but only if DNCERR is 0. That prevents access address, syndrome and data from a correctable error to overwrite the same information from a non-correctable access.

Similarly, the last address, syndrome and data from a correctable SCM access are stored in eTPU_MESR_CERAR, eTPU_MESR_CERSR, and eTPU_MESR_CERDR only if CNCERR is 0.

For either SDM or SCM, a new correctable error overwrites the report registers' values from an earlier correctable error, but report values from a non-correctable error are not overwritten, as long as bit DNCERR/CNCERR is asserted, neither by a new correctable error nor by a non-correctable one.

The sampling of SDM and SCM error report registers can be disabled through the eTPU_MESR_MECR fields DRDIS and CRDIS, respectively. When DRDIS (CRDIS) is asserted, the update of the SDM (SCM) error report registers is disabled, but not of eTPU_MESR_MESR fields DCERR, DNCERR (CCERR, CNCERR). DRDIS, CRDIS must be set before reading the respective report registers to assure their coherent reading, preventing them to be updated between reads.

2.14.12.2.4 Error detection and wait-states

Microengine SDM accesses do not take any wait-state due to ECC support. Host SDM read accesses take two wait-states minimum[35] in MCUs with SDM ECC support, regardless if an error was detected or not, if the SDM error detection is enabled (eTPU Memory Error Control Register (eTPU_MESR_MECR) field DEDD=0). Host SDM read accesses take a minimum of one wait-state if the SDM error detection is disabled (eTPU_MESR_MECR[DEDD]=1). Host SDM write accesses take one wait-state minimum, regardless of ECC support presence or enabling.

Host SCM read accesses have two wait-states[35], regardless if an error was detected or not. Writes from the host to the SCM take one wait-state on 32-bit accesses, and one additional wait-state (two wait-states total[35] on 16-bit and 8-bit wide accesses. Those figures are not affected by the SCM error detection disabling (eTPU_MESR_MECR[CEDD]).

2.14.12.2.5 Memory error interrupts

For **microengine accesses**, the Global Exception interrupt asserts whenever a non-correctable error is detected, either on SCM or SDM (see Interrupts and data transfer requests). These errors are flagged by eTPU Module Configuration Register (eTPU_SCR_MCR) fields SCMERR and SDMERR, respectively. Single bit errors are corrected and activate the Memory Error Correction Interrupt if it is enabled (see Interrupt types and sources), but do not generate Global Exceptions.

35. One wait-state more, compared with eTPU versions before eTPU2 and previous eTPU2 without ECC support

For **host accesses** a bus error is issued whenever a non-correctable error is detected, either on SCM or SDM (but not through the CDC) and it also generates a Global Exception. Single bit errors are corrected (if the error correction feature is available) and do not cause bus transfer errors, but assert the Memory Error Correction Interrupt if it is enabled (see Interrupt types and sources).

2.14.12.2.6 Effect of errors on microcode execution

Correctable errors, either on SCM or SDM, do not affect microcode execution if detection/correction is enabled.

The executing thread is affected by a non-correctable SDM error as follows:

- If DTEND =1: on SDM errors due to a read operation, if the instruction is not also an END, the following instruction automatically executes an END, and its operations may be executed, totally or partially. On SDM errors during the TST preload, the thread automatically ends on the first instruction, if the error occurs on a preload parameter selected by the entry point bit PP (see Entry Point Format section.) The first instruction may be executed totally or partially. Data read into P or DIOB may be corrupted in either case.
- If DTEND =0: the TST or thread continues the execution flow normally. Data read into P or DIOB may be corrupted in either case.

The executing thread is affected by a non-correctable SCM error as follows:

- If CTEND =1: on SCM errors, the corrupted instruction is not executed, instead replaced by a simple END. Due to instruction prefetching, an error may be detected and yet not affect the thread execution. However, an error detected in a prefetched instruction may cause error report and global or memory error interrupts, even if not executed. If a non-correctable error occurs on the entry table read during TST (see Time Slot Transition section), the first instruction in the thread is replaced with a simple END, a global exception is issued and the reports and flags are normally updated.
- If CTEND =0: the execution flow continues normally, and the results depend on the particular instruction corruption.

Table 2-107. Error support summary if CEDD = DEDD = 0

Action		SCM		SDM	
		single bit error	double bit error	single bit error	double bit error
Memory Error Correction Interrupt		Asserts	Not asserted	Asserts	Not asserted
Global Exception		Not asserted	Asserts	Not asserted	Asserts
Bus Error (host reads)		Not issued	Issued	Not issued	Issued
Thread	CTEND = 0	Normal execution	Potential erroneous execution[1]	Normal execution	see DTEND

Table continues on the next page...

Table 2-107. Error support summary if CEDD = DEDD = 0 (continued)

Action		SCM		SDM	
		single bit error	double bit error	single bit error	double bit error
	CTEND = 1		Terminates before erroneous execution[2]		
	DTEND = 0		see CTEND		Potential erroneous execution
	DTEND = 1				Terminates after erroneous read[3]
Code Error Report Registers	CNCERR = 0	Updates eTPU_MESR_CERAR, eTPU_MESR_CERSR, eTPU_MESR_CERDR		Not related	
	CNCERR = 1	eTPU_MESR_CERAR, eTPU_MESR_CERSR, eTPU_MESR_CERDR not updated			
Data Error Report Registers	DNCERR = 0	Not related		Updates eTPU_MESR_DERAR, eTPU_MESR_DERSR, eTPU_MESR_DERDR	
	DNCERR = 1			eTPU_MESR_DERAR, eTPU_MESR_DERSR, eTPU_MESR_DERDR not updated	

1. The thread executes correctly if the error is detected on an instruction fetched but not executed.
2. The erroneous instruction is not executed at all, and replaced by a simple END.
3. The instruction following the erroneous read may be executed totally or partially.

2.14.12.2.7 Error Correction Code (ECC) and syndrome definition

SDM ECC is composed of 5 Hsiao code[36] bits for each data byte. **SCM ECC** is composed of 7 Hsiao code bits for each 32-bit word.

Table 2-108 shows the encoding of the SDM syndrome and global parity fields as they read on eTPU Data Error Report Syndrome Register (eTPU_MESR_DERSR). There is one syndrome and one global parity for each byte in an SDM word, numbered SYND0 to SYND3 from the least to the most significant.

Table 2-108. SDM syndrome definition

SYNDn (hex)	Result	SYNDn (hex)	Result
0E	error on data bit 8n+7	10	error on **code** bit 8n+4
15	error on data bit 8n+6	08	error on **code** bit 8n+3
07	error on data bit 8n+5	04	error on **code** bit 8n+2
1A	error on data bit 8n+4	02	error on **code** bit 8n+1

Table continues on the next page...

36. Hsiao, M.Y;.A Class of Optimal Minimum Odd-weight-column SEC-DED Codes; IBM Journal of Research and Development http://ieeexplore.ieee.org/xpl/freeabs_all.jsp?arnumber=5391627

Table 2-108. SDM syndrome definition (continued)

SYNDn (hex)	Result	SYNDn (hex)	Result
19	error on data bit 8n+3	01	error on **code** bit 8n
13	error on data bit 8n+2		
16	error on data bit 8n+1	00	no error
1C	error on data bit 8n	any other	non-correctable error

The following table shows the definition of the SCM syndrome field as it reads on eTPU Code Error Report Syndrome Register (eTPU_MESR_CERSR).

Table 2-109. SCM syndrome definition

SYND (hex)	Result	SYND (hex)	Result	SYND (hex)	Result
40	error on **code** bit 6	58	error on data bit 25	46	error on data bit 11
20	error on **code** bit 5	0B	error on data bit 24	4A	error on data bit 10
10	error on **code** bit 4	54	error on data bit 23	52	error on data bit 9
08	error on **code** bit 3	15	error on data bit 22	62	error on data bit 8
04	error on **code** bit 2	16	error on data bit 21	13	error on data bit 7
02	error on **code** bit 1	34	error on data bit 20	29	error on data bit 6
01	error on **code** bit 0	25	error on data bit 19	31	error on data bit 5
		26	error on data bit 18	43	error on data bit 4
49	error on data bit 31	64	error on data bit 17	45	error on data bit 3
0D	error on data bit 30	2C	error on data bit 16	19	error on data bit 2
0E	error on data bit 29	1A	error on data bit 15	51	error on data bit 1
38	error on data bit 28	23	error on data bit 14	61	error on data bit 0
4C	error on data bit 27	2A	error on data bit 13	00	no error
1C	error on data bit 26	32	error on data bit 12	any other	non-correctable error

2.14.12.2.8 Error injection

Errors can be injected into the SDM read data path through eTPU Data Error Injection Address Register (eTPU_MESR_DEIAR), eTPU Data Error Injection Data Pattern Register (eTPU_MESR_DEIDPR) and eTPU Data Error Injection Parity Pattern Register (eTPU_MESR_DEIPPR). They define bit flips on accesses at the specific address specified in eTPU_MESR_DEIAR.

SDM error injection is enabled independently for host and microengine accesses by the eTPU Module Configuration Register (eTPU_SCR_MCR) fields HDEIE and MDEIE, respectively. The user must program eTPU_MESR_DEIAR, eTPU_MESR_DEIDPR,

and eTPU_MESR_DEIPPR with HDEIE=MDEIE=0, and only then enable error injection by setting HDEIE=1 and/or MDEIE=1 to avoid races (see eTPU Memory Error Status Register (eTPU_MESR_MESR)).

Similarly, SCM errors can be injected into the SCM read data path through eTPU Code Error Injection Address Register (eTPU_MESR_CEIAR), eTPU Code Error Injection Data Pattern Register (eTPU_MESR_CEIDPR) and eTPU Code Error Injection Parity Pattern Register (eTPU_MESR_CEIPPR), enabled by the eTPU Module Configuration Register (eTPU_SCR_MCR) field CEIE. Errors are injected on host accesses to the address specified in eTPU_MESR_CEIAR when VIS =1, or on microengine and MISC accesses when VIS=0 .

2.14.12.2.9 Error fixing

Single bit **soft errors** can be fixed by rewriting the right value, as corrected by the ECC logic, into the same address of the erroneous data. eTPU provides means to perform such fixes safely, coherently and concurrently with the normal operation.

SDM fixes can be done using the CDC (see Coherent Dual-parameter Controller (CDC)), limited to the lower 8 Kbytes of SDM. The Host application simply has to program a transfer with both origin and destination positions pointing to the address of the data to be fixed. Because the PBBASE field has an address granularity of 8 bytes, a word adjacent to the one to be fixed must also be rewritten. The CDC transfer is atomic, therefore the fix is done coherently and does not interfere with the application code or data flows.

SCM fixes can be done by programming eTPU Code Error Fix Register (eTPU_MESR_CEFR) (see eTPU Code Error Report Syndrome Register (eTPU_MESR_CERSR)). The fixes are performed by the MISC logic, which must be enabled (see SCM Test - Multiple Input Signature Calculator). The modes available, selected by CFIXM, are:

- **Automatic Fix Mode (CFIXM=11)**: the MISC logic automatically rewrites the contents of an address whenever it finds a correctable error; the CFIXM field keeps its value if a fix is made.

2.14.13 Performance monitoring features

2.14.13.1 Idle Counter

The Idle Counters eTPU Idle Register for Engine 1 (eTPU_ER_IDLER_ENG1) and eTPU Idle Register for Engine 2 (eTPU_ER_IDLER_ENG2) continuously count microcycles in which the microengine is not busy with channel service . They can be used to measure the microengine utilization by rating the count measured during a period of time to the number of microcycles contained in the period. The Idle Counters do not count microcycles when the engine is stopped, or is in TST or halt states.

2.14.13.2 Latency Monitor

eTPU implements six Latency Monitors to measure the time taken to service a request. Each Latency Monitor provides:

- The measure of the greatest latency found during actual thread executions, accessed from eTPU Latency Monitor Measure Register for Engine 1 (eTPU_LMR_LM*n*MR_ENG1) and eTPU Latency Monitor Measure Register for Engine 2 (eTPU_LMR_LM*n*MR_ENG2).
- A comparison between the measured latency and a threshold, determined through eTPU Latency Monitor Measure Register for Engine 2 (eTPU_LMR_LM*n*MR_ENG2) and eTPU Latency Monitor Configuration Register for Engine 2 (eTPU_LMR_LM*n*CR_ENG2).

Each Latency Monitor works independently in one of the following modes, selected with the LMM field in eTPU Latency Monitor Configuration Register for Engine 1 (eTPU_LMR_LM*n*CR_ENG1) and eTPU Latency Monitor Configuration Register for Engine 2 (eTPU_LMR_LM*n*CR_ENG2) :

- **Disabled mode**: no latency measures or actions are taken.
- **Channel mode**: monitors the latency of an individual channel.
- **Priority mode**: monitors the combined latency of all channels in a given priority level - High, Medium or Low (see Scheduler).

Channel and Priority modes are detailed in the subsections below. The following applies to both modes:

- After each latency measurement, the value measured is compared with the LATENCY value in eTPU Latency Monitor Measure Register for Engine 1 (eTPU_LMR_LM*n*MR_ENG1) and eTPU Latency Monitor Measure Register for Engine 2 (eTPU_LMR_LM*n*MR_ENG2). If the new measured value is greater, it replaces the old value in eTPU Latency Monitor Measure Register for Engine 1 (eTPU_LMR_LM*n*MR_ENG1) and eTPU Latency Monitor Measure Register for Engine 2 (eTPU_LMR_LM*n*MR_ENG2).
- After each latency measurement, the value measured is compared with the MAXLAT value in eTPU Latency Monitor Configuration Register for Engine 1 (eTPU_LMR_LM*n*CR_ENG1) and eTPU Latency Monitor Configuration Register for Engine 2 (eTPU_LMR_LM*n*CR_ENG2), and if the new measured value is greater:
  - A Global Exception is issued.
  - The eTPU Module Configuration Register (eTPU_SCR_MCR) flag LTO1 (engine 1) or LTO2 (engine 2) is set, independently of the LATENCY value in eTPU Latency Monitor Measure Register for Engine 1 (eTPU_LMR_LM*n*MR_ENG1) and eTPU Latency Monitor Measure Register for Engine 2 (eTPU_LMR_LM*n*MR_ENG2).

NOTE

The LATENCY value is updated even if MAXLAT=0.

NOTE

MAXLAT=0 just inhibits the assertion of the LTO1/2 flag and Global Exception due to the respective Latency Monitor. Other Latency Monitor instances with non-zero MAXLAT value may assert LTO1/2 and Global Exception.

2.14.13.2.1 Channel mode

When the Latency Monitor operates in Channel mode:

- Only the channel selected by the MONCHAN field in eTPU Latency Monitor Configuration Register for Engine 1 (eTPU_LMR_LM*n*CR_ENG1) and eTPU Latency Monitor Configuration Register for Engine 2 (eTPU_LMR_LM*n*CR_ENG2) is monitored.
- Any combination of Host Service Requests (HSR), Channel Service Requests and Link Service Requests can be selected for monitoring, based on the SRSEL field in eTPU Latency Monitor Configuration Register for Engine 1 (eTPU_LMR_LM*n*CR_ENG1) and eTPU Latency Monitor Configuration Register for Engine 2 (eTPU_LMR_LM*n*CR_ENG2).

- The latency is counted in microcycles, from the moment the logic OR of all the service requests selected by SRSEL asserts to the moment this logic OR negates.
- The latency count is interrupted when the channel is disabled, either by programming the CPR field in eTPU Channel n Configuration Register for Engine 1 (eTPU_CCCR_C*n*CR_ENG1) and eTPU Channel n Configuration Register for Engine 2 (eTPU_CCCR_C*n*CR_ENG2) to 0, or by a watchdog timeout. Latency is counted until the channel is disabled and is not discarded; a new count can start from zero when the channel is re-enabled.

NOTE

If a selected service request type or a combination of them continues asserted during and after its service thread execution, its latency counter will keep on running; this can happen, for instance, if either matches can service requests (e.g. channel modes em_st/em_dt), one match happens before the other is serviced, and only one of them is cleared. The Latency Monitor can, in cases like this, yield pessimistic measurements.

NOTE

The Latency Monitor in channel mode must be disabled before the channel it monitors is disabled.

2.14.13.2.2 Priority mode

When the Latency Monitor operates in Priority mode:

- Only the combination of channels assigned with the priority selected by the SRSEL field in eTPU Latency Monitor Configuration Register for Engine 1 (eTPU_LMR_LM*n*CR_ENG1) and eTPU Latency Monitor Configuration Register for Engine 2 (eTPU_LMR_LM*n*CR_ENG2) is monitored.
- The latency is measured in microcycles, starting from either of these two events, whichever happens first:
  - The logic OR of service requests of the selected priority transitions from 0 to 1 at a moment when all their grants are at state negated.
  - The grants of the selected priority are cleared by the scheduler at the end of the thread, and any of the service requests at the same priority is still active soon after the thread ends.
- The latency is measured until the grants of the selected priority are cleared by the scheduler, after the measurement started.

Note

A Latency Monitor in priority mode must be disabled before any of the channels in the selected priority is disabled, or any disabled channel is assigned with the selected priority.

2.14.13.3 Watchdog Monitor Operation

The watchdog mechanism can also be used to monitor, without interfering with the application execution, whether the execution time of any individual thread or a sequence of threads reaches a given limit. This can be achieved by asserting the WMO field in eTPU Watchdog Timer Register for Engine 1 (eTPU_ER_WDTR_ENG1) and eTPU Watchdog Timer Register for Engine 2 (eTPU_ER_WDTR_ENG2).

2.15 Initialization/application information

2.15.1 Configuration sequence

After initial power-on reset the eTPU remains in an idle state[37], requiring initialization of several registers before any function can begin execution. Also, if the SCM is implemented in RAM, it should be initialized with the eTPU application code prior to configuring the eTPU. Configuration procedures are summarized as follows:

- If SCM is implemented as RAM, load the eTPU application code (see SCM access).
- Initialize SDM (optional if no ECC support available)
- Initialize the SCM MISC logic (optional, see SCM Test - Multiple Input Signature Calculator).
- Initialize Watchdog and Latency Monitors (optional).
- Initialize eTPU Engine 1 Time Base Configuration Register (eTPU_TBR_TBCR_ENG1) and eTPU Engine 2 Time Base Configuration Register (eTPU_TBR_TBCR_ENG2) to set up:
  - TCR1 and TCR2 prescalers and clock sources.
  - Select digital filtering mode.

37. Except when device debug request is asserted on power-on reset: in this case, the microengines wake-up in halt state.

  - TCRCLK signal filter control.
  - Angle mode operation (if necessary).
- Initialize eTPU Engine 1 Configuration Register (eTPU_SCR_ECR_ENG1) and eTPU Engine 2 Configuration Register (eTPU_SCR_ECR_ENG2) to set up:
  - Entry table base.
  - Filter prescaler clock control.
- Initialize eTPU Engine 1 STAC Configuration Register (eTPU_TBR_STAC_ENG1) and eTPU Engine 2 STAC Configuration Register (eTPU_TBR_STAC_ENG2) if you need to set up TCR1/2 resource Client/Server operation.
- Write to eTPU Channel n Configuration Register for Engine 1 (eTPU_CCCR_C*n*CR_ENG1) and eTPU Channel n Configuration Register for Engine 2 (eTPU_CCCR_C*n*CR_ENG2) to choose the Function to be performed by each channel, and its parameter base address.
- Write to eTPU Channel n Status Control Register for Engine 1 (eTPU_CCCR_C*n*SCR_ENG1) and eTPU Channel n Status Control Register for Engine 2 (eTPU_CCCR_C*n*SCR_ENG2) to choose among the possible variations within the function flow (FM bits).
- Write to SDM for parameter initialization of each configured channel.
- Write to eTPU Watchdog Timer Register for Engine 1 (eTPU_ER_WDTR_ENG1) and eTPU Watchdog Timer Register for Engine 2 (eTPU_ER_WDTR_ENG2) if you need to enable and set up the Watchdog(s) mode and timeout.
- Write to eTPU Channel n Host Service Request Register for Engine 1 (eTPU_CCCR_C*n*HSRR_ENG1) and eTPU Channel n Host Service Request Register for Engine 2 (eTPU_CCCR_C*n*HSRR_ENG2) to initialize the active channels.
- Write to eTPU Channel Interrupt Enable Register for Engine 1 (eTPU_GCR_CIER_ENG1) and eTPU Channel Interrupt Enable Register for Engine 2 (eTPU_GCR_CIER_ENG2) if interrupts are to be enabled from the appropriate channels. Likewise for Data Transfer Requests (eTPU Channel Data Transfer Request Enable Register for Engine 1 (eTPU_GCR_CDTRER_ENG1) and eTPU Channel Data Transfer Request Enable Register for Engine 2 (eTPU_GCR_CDTRER_ENG2)). This can also be done through eTPU Channel n Configuration Register for Engine 1 (eTPU_CCCR_C*n*CR_ENG1) and eTPU Channel n Configuration Register for Engine 2 (eTPU_CCCR_C*n*CR_ENG2).

- Write to eTPU Channel n Configuration Register for Engine 1 (eTPU_CCCR_C*n*CR_ENG1) and eTPU Channel n Configuration Register for Engine 2 (eTPU_CCCR_C*n*CR_ENG2) to enable each channel by assigning it a high, middle, or low priority (CPR field).[37]
- Monitor eTPU Channel n Host Service Request Register for Engine 1 (eTPU_CCCR_C*n*HSRR_ENG1) and eTPU Channel n Host Service Request Register for Engine 2 (eTPU_CCCR_C*n*HSRR_ENG2) for completion of initialization.
- Write GTBE =1 to start TCR1/TCR2 time base counting at same time in both Engines (may be done before or never, depending on the particular application and use of Red Line bus).

2.15.2 Reset options

2.15.2.1 Hardware reset

Hardware reset is achieved by assertion of device synchronous reset. Both Engines and common logic is reset, and even the System Configuration and Global Channel registers assume their reset values.

Note

All eTPU input clocks must pulse during reset so that both engines are reset, even if they are in Module Disable or Stop mode.

2.15.2.2 Software reset

eTPU has no software reset. To abort infinite microcode loops, the Force END mechanism must be used (see field FEND in eTPU Engine 1 Configuration Register (eTPU_SCR_ECR_ENG1) and eTPU Engine 2 Configuration Register (eTPU_SCR_ECR_ENG2)).

2.15.3 Multiple parameter coherency methods

Follows a description of two methods for coherent transfer of multiple parameters between Host and eTPU. Both methods involve the use of two parameter areas: the Transfer Parameter Area (hereafter called TPA), which is the SDM area directly accessed by the Host for reads and writes, and the Permanent Parameter Area (hereafter called PPA), which are the SDM positions where channel parameters are normally accessed by the Function microcode. Note that parameters in either TPA or PPA do not have to be in sequential addresses. TPAs and PPAs allocation are completely defined by the application, and there may be any number of them, independently of the channels.

The methods described here are not the only solutions for the coherent transfer problem, and both can coexist in eTPU and even used in combination. Also note that for transfers of a pair of parameters, the Coherent Dual-parameter Controller is faster and have less impact on both eTPU and Host performance. That said, the methods are:

- **Transfer Service**: a microengine thread transfers, upon Host Service Request, data from/to a TPA to/from a PPA.Coherency is guaranteed by the fact that a thread is atomic with respect to other threads in the same Engine, and so are its transfers. If parameters in PPA are shared by both Engines, hardware semaphores have to be used to access them.
- **Mailbox**: for Host to eTPU transfers, the microcode checks a flag, set by the host, indicating the existence of new parameter data in the TPA. It can, then, either access TPA data directly or copy it to the PPA. For eTPU to Host transfers, when microcode changes PPA, it copies them to the TPA and flags updated TPA data to Host, possibly using an Interrupt or a Data Transfer Request. The Mailbox flag is reset when data is copied: by the eTPU microcode, when it transfers TPA to PPA (possibly followed by an Interrupt); by the Host, when it reads data from the TPA. This indicates that TPA is free for another transfer.

Transfer Service has the advantage of separating the task of data transfer from the functional service thread that accesses the parameters, with less impact to the latter. Compared to the Mailbox method, however, it has bigger average latency, because the Transfer Service thread has to contend for a time slot to execute. This latency can be minimized if Transfer Service thread is assigned to a separate channel with higher priority, but even so it does not guarantee that PPA is updated before the next execution of the functional thread that uses it.

Mailbox method, on the other hand, makes the functional thread check for the existence of new data (Host to eTPU). It does not have to be responsible for the transfer, though: it may access the TPA directly, and a Transfer Service can then be used to copy data from TPA to PPA.

2.15.4 Programming Hints and Caveats

2.15.4.1 Atomic dual access after a call, return

A dual, back-to-back parameter access is not atomic after a call, a jump, or a return if they occurred in parallel with an odd SDM access. It is safer to make a pair of parameter accesses that must be coherent begin at the second instruction after a call/jump/return.

2.15.4.2 Resource polling

The use of polling while waiting for a condition or a resource (except semaphore lock) should be avoided in order not to hang the microengine in long loops. This general programming guideline is greatly enforced in eTPU, as a thread cannot be preempted for any reason. Safer polling, albeit with long and indeterministic latency, can be obtained if a thread issues a channel link to the serviced channel and terminates. The microengine is then free to other tasks, and the next poll happens at the next time the channel is serviced. This mechanism can be combined with finite (timed out) loops for better latency.

2.15.4.3 Changing channel function, parameter base, or entry table scheme

Channel function, parameter base address and entry table scheme are determined by the CFS, CPBA, and ETCS fields in eTPU Channel n Configuration Register for Engine 1 (eTPU_CCCR_C*n*CR_ENG1) and eTPU Channel n Configuration Register for Engine 2 (eTPU_CCCR_C*n*CR_ENG2). They cannot be changed when the channel is enabled. If the channel is disabled first, one may still have service requests from the previous function, so before the channel is enabled again one must be sure that:

- the first thread executed in the new function is the initialization one.
- the initialization thread of the new function clears any previously pending service request.

Here is a safe procedure for function changing:

1. Disable the channel (in eTPU Channel n Configuration Register for Engine 1 (eTPU_CCCR_C*n*CR_ENG1) and eTPU Channel n Configuration Register for Engine 2 (eTPU_CCCR_C*n*CR_ENG2), write CPR=00).
2. Change the function configuration (fields CFS and/or CPBA and/or ETCS in eTPU Channel n Configuration Register for Engine 1 (eTPU_CCCR_C*n*CR_ENG1) and eTPU Channel n Configuration Register for Engine 2 (eTPU_CCCR_C*n*CR_ENG2)).
3. Request the initialization thread, writing eTPU Channel n Host Service Request Register for Engine 1 (eTPU_CCCR_C*n*HSRR_ENG1) and eTPU Channel n Host Service Request Register for Engine 2 (eTPU_CCCR_C*n*HSRR_ENG2) with the initialization HSR (channel still disabled).
4. enable the channel (in eTPU Channel n Configuration Register for Engine 1 (eTPU_CCCR_C*n*CR_ENG1) and eTPU Channel n Configuration Register for Engine 2 (eTPU_CCCR_C*n*CR_ENG2) write CPR > 0); the initialization HSR is serviced before any other formerly pending service requests, clearing them.

2.15.4.4 Checking and Clearing Interrupts of a Stopped Engine

An Engine may be stopped with interrupts (or DMA requests) pending. This includes the case when the Engine's MDIS bit is set and a thread is still running: the thread will complete execution, possibly issuing an interrupt or DMA request before the engine stops, setting the STF bit.

As soon as the engine stops the channel registers become inaccessible, issuing bus errors when accessed. Interrupts and DMA requests can still be checked and cleared through the Global Channel Registers, though. DMA requests can also be cleared by the hardware handshaking with the DMA controller when the engine is stopped.

2.15.5 Estimating Worst Case Latency

Reliable systems are designed to work under worst-case conditions. This section explains how to estimate worst-case latency (WCL) for any eTPU function in any system. The appendix covers the following topics:

- Introduction to Worst-Case Latency
- Using Worst-Case Latency Estimates to Evaluate Performance
- Priority Scheme Details used in WCL Analyses

- First-Pass WCL Analysis
- Second-Pass WCL Analysis

The first-pass WCL analysis is based on a deterministic, generalized formula that is easy to apply. Because of the generalizations in the formula, the first analysis result is almost always much worse than the real worst case. If the desired system performance is within the limits of this first analysis, then no further analysis is required; the system is well within the performance limits of the eTPU. If the desired system performance exceeds that indicated by the first analysis, the second-pass WCL analysis should be applied. The second-pass analysis is not a generalized formula, but rather uses specific system details for a realistic worst-case estimation.

2.15.5.1 Using Worst-Case Latency estimates to evaluate performance

Once WCL is found for a channel, the user must determine how to use this number to analyze performance. To analyze the performance of a channel running the PWM function, for example, some information about what happens in each thread is necessary.

The following example refers to old TPU PWM function, which is not optimized to the eTPU enhanced hardware. For PWM, thread 1 is the initialization thread, and threads 2 and 3 are used during normal function execution. (PWM threads 4, 5, and 6 are for special modes and will be assumed to be unused on channel 5). Thread 2 writes a time into the channel 5 match register and performs other operations that will cause the channel 5 signal to go from low to high at the time indicated in the match register (match time). At match time, the signal goes high and channel 5 requests service from the eTPU Microengine to execute thread 3. Thread 3 writes a time into the channel 5 match register and performs other operations that will cause the channel 5 signal to go from high to low at match time. At match time, the signal goes low and channel 5 requests service from the eTPU Microengine to execute thread 2. A PWM wave is kept running on the system by the eTPU executing thread 2, then thread 3, then thread 2, then thread 3, and so on.

Since the definition of worse-case latency assumes a fully loaded running system, initialization threads are not part of worst-case calculations. For the channel 5 example, the two PWM threads in are thus the two normal running threads, threads 2 and 3.

does not define which thread is thread 2 and which is thread 3. Since the worst-case latency derived from the first-pass analysis is the worst case between any2 threads (not counting initialization threads), it is safe to say that the worst-case latency shown in represents both the worst-case high time and the worst-case low time.

Notice in that worst-case latency is drawn from the end of the execution of the first PWM thread to the end of the execution of the next PWM thread. It is drawn from end to end because the microcode instructions that make up the threads control the channel hardware. To make sure that all the microcode instructions needed to change the pin thread have been executed, it is necessary to include the execution time of the second thread.

Thread information for each function is found in the programming notes for individual TPU functions. See NXP Programming Note TPUPN00/D, Using the TPU Function Library and TPU Emulation Mode, for a list of available programming notes. Similar documentation will we provided for the eTPU new functions.

2.15.5.2 Priority Scheme Details Used in WCL Analysis

The user assigns functions to channel numbers and gives each active channel a priority level of high, middle, or low. The Scheduler uses the channel number and channel priority level to determine the order in which to grant service.

The scheduler allocates time slots to specific priority levels of high, middle, or low. One function thread is executed in each time slot. The length of a time slot varies according to the length of the executing thread. When fully loaded, the scheduler always assigns time slots in a seven-slot sequence (see the following table). After a seven-slot sequence is completed, another seven-slot sequence begins (see Figure 2-47). Note that in eTPU, when no service request exists, the scheduler goes to thread 1, but WCL calculation considers full load.

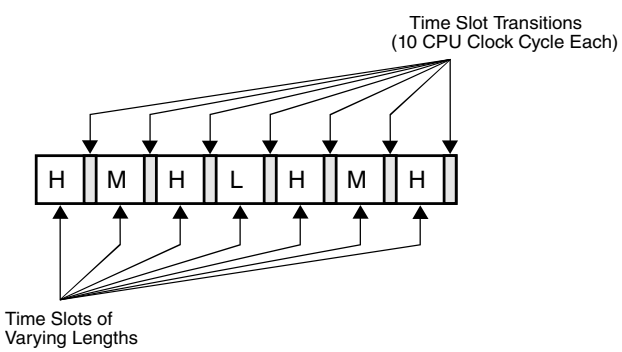

Figure 2-46. Time-Slot Sequence

This sequence scheme gives higher-priority channels more service time than lower-priority channels. High-priority channels are allocated four of seven time slots, middle-priority channels are allocated two of seven time slots, and low-priority channels are allocated one of seven time slots.

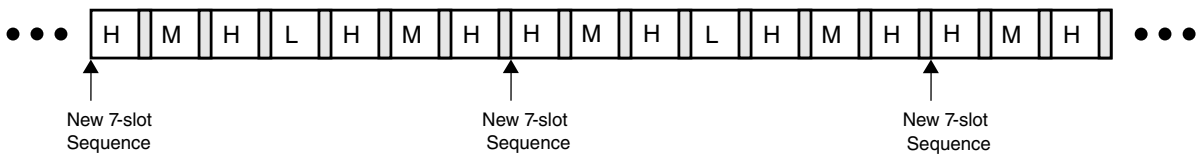

Figure 2-47. Multiple Time-Slot Sequences

2.15.5.2.1 Priority Passing

If no channel of the priority level assigned to the time slot is requesting service, the eTPU scheduler can pass priority to other levels. If no high-level channel is requesting service during a high level time slot, a middle-level channel is granted service; or, if no middle level-channel is requesting service, a low-level channel is granted service. If no middle-level channel is requesting service during a middle-level time slot, a high-level channel is granted service; or, if no high-level channel is requesting service, a low-level channel is granted service. If no low-level channel is requesting service during a low-level time slot, a high-level channel is granted service; or, if no high-level channel is requesting service, a middle-level channel is granted service. If no channel is requesting service, the time slot sequence is reset to state 1 and the scheduler idles until a request is received.

Priority passing is implemented in hardware and does not contribute to worst-case latency.

2.15.5.2.2 Time-slot transition

After each time slot, the eTPU must prepare for the next time slot. This preparation time between each time slot is called a time-slot transition. See Time Slot Transition. Time-slot transitions can take from six up to ten eTPU clocks.

2.15.5.2.3 Channel Number Priority

If more than one channel of a priority level is requesting service, the lowest numbered channel is granted service first. For example, if channels 0, 5, and 9 are all high-level channels requesting service during a high time slot, channel 0 is granted service first. Continuing this example, if channel 0 requests service again immediately after being serviced, it is not serviced again until channels 5 and 9 are serviced. This scheme is implemented so that continuously-requesting low numbered channels do not take all the time on the eTPU execution unit and leave no time for other channels.

The scheduler uses registers to keep track of which channels have been serviced and which require servicing. Each channel has two register bit: a service request register (SRR) and a service grant register (SGR). The SRR is set when a channel requests service. After the channel has been granted service, the SGR is set and the SRR is cleared.

SGRs are not cleared individually by channel, but rather as priority level groups. The clearing of a group of SGRs begins a new cycle for that priority level. An SGR group is cleared on the condition that a channel of that priority level has just been serviced, and no other channel of that priority level is requesting service (has a set SRR) and has not been granted service (has a clear SGR).

For example, if a middle-priority channel has just been serviced (either in a middle-priority time slot or a high or low-priority time slot gained by priority passing), the SRRs and SGRs of all middle-priority channels are compared. If there is no middle-priority channel with its SRR set and SGR cleared, the scheduler clears all middle-level SGRs. If there is a middle-level channel with its SRR set and SGR cleared, the scheduler does not clear the SGR group, and the requesting middle-level channel is serviced on the next middle-level time slot (or possibly sooner by priority passing).

2.15.5.2.4 SDM Collision Rate

Most function threads read or write to the eTPU SDM at least once. Because both the eTPU Microengine and Host can access the SDM but not at the same time, the Microengine may suspend execution during the SDM access while waiting for the Host to finish accessing the SDM. At other times the Host may wait for the Microengine. Wait states can take up to two eTPU clocks, when the Host accesses the SDM directly, without using CDC. Microengine(s) wait-states must be added into the worst-case latency calculation. The system designer should estimate the percentage of SDM accesses in the system that will result in Microengine wait-states. This percentage is called the RAM collision rate (RCR). In each collision with direct Host accesses to the SDM the Microengine(s) wait for two eTPU clocks.

In eTPU the Coherent Dual-parameter Controller (CDC) may also access the SDM for atomic transfers of two parameters. eTPU Microengine may wait on this operation (if it is in service time) until the transfer is complete. CDC always transfers two parameters, making four consecutive accesses (read, write, read, write) of one eTPU clock each. The system designer should estimate the percentage of SDM accesses in the system that will result in a Microengine wait due to coherent transfer, and multiply it with the average number of eTPU clocks the Microengine waits for each transfer. This percentage is called Coherent Parameter Collision Rate (CPCR).

In addition, Microengine to Microengine multiple parameter coherent communication, using the hardware semaphores, may hold one Microengine which waits to lock the semaphore while the other Microengine is holding it. This waiting is due to a software loop, not hardware wait-states. Note that single parameter access of one Microengine does not affect the timing of the other Microengine due to SDM time interlace. This implies that single parameter Microengine to Microengine communication does not affect the performance. The Microengine which waits for the semaphore will loop until it is

freed by the other Microengine. This time depends on the eTPU application. The system designer should estimate the percentage of Microengine to Microengine coherent parameter communication that will result in eTPU semaphore loops, and multiply it with the average number of eTPU clocks the Microengine loops for each such transfer. This percentage is called CCR (Communication Collision Rate).

A 100% collision rate for a system is the theoretical worst case. In many systems, however, the RCR, CPCR and CCR would be very low, sometimes even near 0%. This is because the eTPU is an independent processor capable of servicing most function needs, so that the Host rarely needs to access the eTPU SDM. Also coherent Microengine to Microengine communication of more than one parameter may be rare. To find a realistic RCR, CPCR the system designer should evaluate the Host code and find the percentage of time it accesses the eTPU SDM with or without using the CDC. This percentage gives a good RCR and CPCR. The eTPU application provides a good estimation of CCR.

Note

The programming practice of polling a flag in the eTPU SDM causes a very high RCR and should be avoided in high-performance systems.

After the collision rate for a system is found, it can be applied to the WCL calculations for each channel. The system designer can use the collision percentage and the number of SDM accesses (with and without semaphores) to estimate the eTPU loop time for a function. Note that in old TPU functions CPCR and CCR are both zero.

The estimation of eTPU wait time is as follows:

Variables:

N1 = Number of simple RAM accesses in the longest thread

RCRWait = Maximal eTPU clocks wait time for simple RAM collision = 2

CPCRWait = Average eTPU clocks for Coherent Parameter Transfer (using CDC).

N2 = Number of eTPU-eTPU semaphore RAM accesses in the longest thread

CCRWait = Average eTPU clocks for Microengine-Microengine communication transfer.

Estimated Wait Time:

Function eTPU maximal wait time =

N1 *(RCR * RCRWait + CPCR * CPCRWait) + N2* CCR * CCRWait

2.15.5.3 First-Pass Worst-Case Latency Analysis

Following is the first-pass calculation of worst-case latency for a channel. Remember that this analysis uses generalizations that usually produce a result much worse than the real worst case. If the worst-case result from the first analysis is too long for the desired performance, use the second analysis for a more realistic worst-case analysis.

2.15.5.3.1 Worst-case assumptions and formula

To estimate worst-case latency for a channel, assume this worst-case condition: the channel has just been serviced in a time slot of its priority level, and all other channels in the system are continuously requesting service and have cleared SGRs. The worst-case latency is the time from the end of the channel's service until the end of the channel's next service. See the following figure.

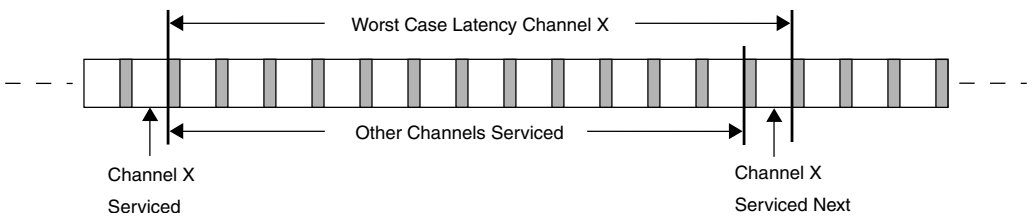

Figure 2-48. First-pass Worst-Case Latency

To estimate worst-case latency:

- Find the worst-case service time for each active channel.
- Using the H-M-H-L-H-M-H time-slot sequence, map the channels that are granted for each time slot.
- Add time for six-clock time-slot transitions.

2.15.5.3.1.1 Mapping the Channels for Each Time Slot

To determine when a channel will be serviced again, it is necessary to determine which other channels will be serviced first. Do this by assuming all channels are continuously requesting service and mapping the channels into the time-slot sequence.

2.15.5.3.1.2 Adding Time for Time-Slot Transitions

Add six eTPU clocks for time-slot transitions which occur after each time slot.

2.15.5.3.2 First-pass analysis Worst-Case Latency examples

The examples in this section assume the system configuration shown in the following table.

Table 2-110. System configuration example

Channel	Priority	Function[1, 2]
0	High	PWM (driving a DC motor)
1	Middle	PPWA (Mode 0, measuring the DC motor speed)
2	Low	DIO (Input)

1. 9% RAM Collision Rate (RCR)
2. CPU clock rate = 40 MHz, or 25 ns per clock period

2.15.5.3.2.1 Finding the WCL for PWM on Channel 0

The following shows how to find the WCL for PWM on channel 0.

1. Find the worst-case service time for each active channel.
   a. Longest thread of PWM is 24 CPU clocks with four RAM accesses.

      24 + ((4 RAM accesses+1) * 0.09 * 2 CPU clock waits) = 24.9 CPU clocks, rounded up to 25 CPU clocks (since there are no partial clock periods)

      Channel 0 worst-case service time = 25 CPU clocks.

   b. Longest thread of PPWA in mode 0 is 44 CPU clocks with nine RAM accesses.

      44 + ((9 RAM accesses+1) * 0.09 * 2 CPU clock waits) = 45.8 CPU clocks, rounded up to 46 CPU clocks

      Channel 1 worst-case service time = 46 CPU clocks.

   c. Longest thread of DIO is ten CPU clocks with four RAM accesses.

      10 + ((4 RAM accesses+1) * 0.09 * 2 CPU clock waits) = 10.9 CPU clocks, rounded up to 11 CPU clocks

      Channel 2 worst-case service time = 11 CPU clocks.

2. Assume channel 0 has just been serviced and that channels 1 and 2 are continuously requesting service. Using the H-M-H-L-H-M-H time-slot sequence, map the channels that are granted for each time slot. See the following figure.

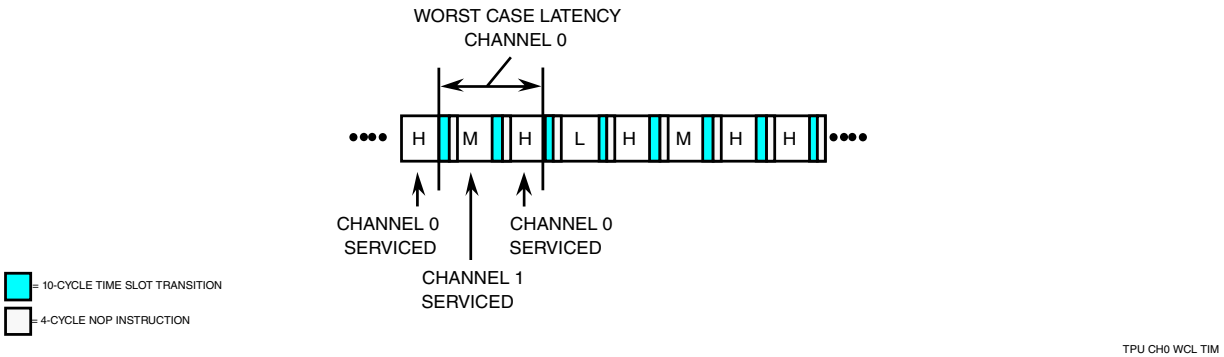

Figure 2-49. Next Servicing for Channel 0

Channel 1 will be serviced in the middle-priority time slot before channel 0 is serviced again.

3. Add time for the six-clock CPU time-slot transitions. See the above figure and the following table.

   A four-clock NOP occurs after each channel is serviced since there is one channel in each priority level, i.e., a new cycle for a priority level is started after each channel is serviced. Time-slot transitions occur after each time slot.

Table 2-111. Worst-Case Latency for Channel 0

Channel 0 worst-case service time	25 clocks
Channel 1 worst-case service time	46 clocks
Two 6-clock time-slot transitions	12 clocks
Total clocks	83 clocks

83 clocks * 25 ns/clock = 2075 ns

Conclusion: in this system configuration PWM can run with a minimum high time or low time of 2075 ns.

Note that in double match eTPU system the PWM can be serviced once in each period, and there is no latency for minimum high time. The latency in eTPU PWM function will represent the minimum PWM period.

2.15.5.3.2.2 Finding the WCL for PPWA on Channel 1

The following shows how to find the WCL for PPWA on channel 1.

1. Find the worst-case service time for each active channel. See step 1 of previous example.
2. Assume channel 1 has just been serviced and that channels 0 and 2 are continuously requesting service. Using the H-M-H-L-H-M-H time-slot sequence, map the channels that are granted for each time slot. See the following figure.

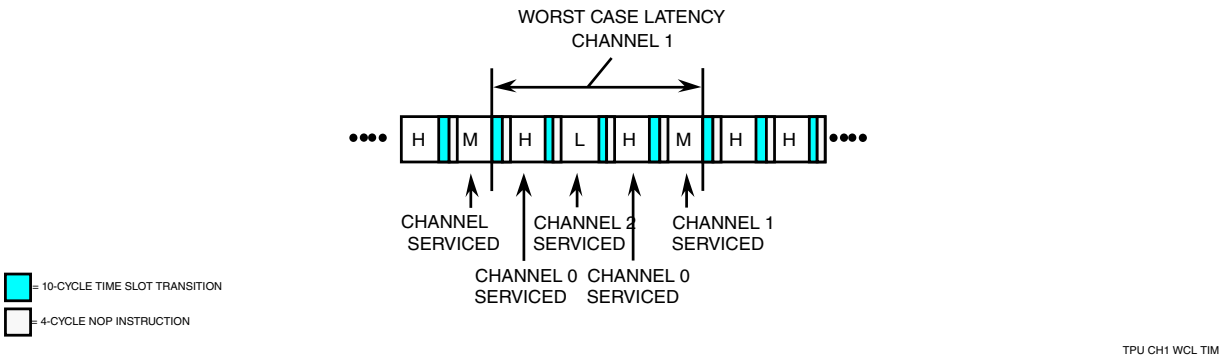

Figure 2-50. Next Servicing for Channel 1

Channel 0 will be serviced twice and channel 2 once before channel 1 is serviced again.

3. Add time for the six-clock CPU time-slot transitions. See the above figure and the following table.

Table 2-112. Worst Case Latency for Channel 1

Two Channel 0 worst-case service times	50 clocks
Channel 1 worst-case service time	46 clocks
Channel 2 worst-case service time	11 clocks
Four 6-clock time-slot transitions	24 clocks
Total clocks	131 clocks

131 clocks * 25 ns/clock = 3275 ns

Conclusion: in this system configuration PPWA can measure a period or pulse of minimum 3275 ns.

Note that PPWA function optimized for eTPU hardware can use double transition mode to measure very narrow pulses with one service after the second transition, and latency will affect only the minimum gap between two input pulses. Also the function threads would have more efficient coding.

2.15.5.3.2.3 Finding the WCL for DIO on Channel 2

The following shows how to find the WCL for DIO on channel 2.

1. Find the worst-case service time for each active channel. See step 1 of previous examples.
2. Assume channel 2 has just been serviced and that channels 0 and 1 are continuously requesting service. Using the H-M-H-L-H-M-H time-slot sequence, map the channels that are granted for each time slot. See the following figure.

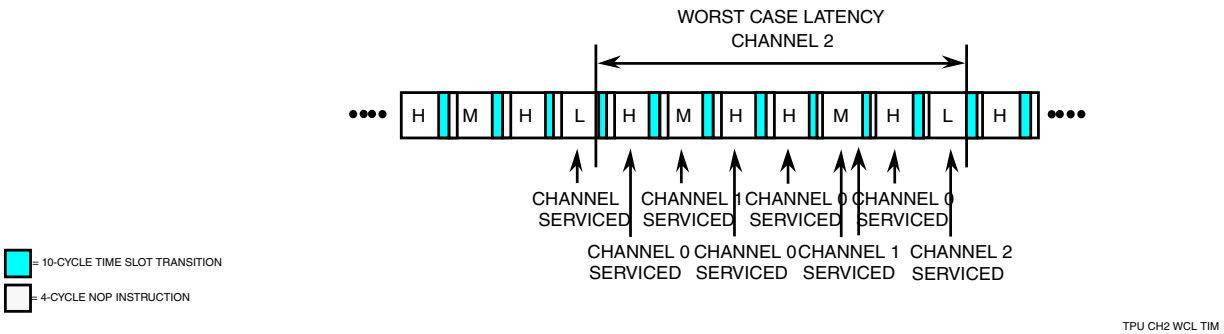

Figure 2-51. Next Servicing for Channel 2

Channel 0 will be serviced four times and channel 1 twice before channel 2 is serviced again.

3. Add time for the ten-clock CPU time-slot transitions and the four-clock NOPs. See the above figure and the following figure.

Table 2-113. Worst Case Latency for Channel 2

Four Channel 0 worst-case service times	100 clocks
Two Channel 1 worst-case service time	92 clocks
Channel 2 worst-case service time	11 clocks
Seven 6-clock time-slot transitions	42 clocks
Total clocks	245 clocks

245 clocks * 25 ns/clock = 6125 ns

Conclusion: in this system configuration DIO can keep track of the input level at a minimum of every 6125 ns.

Note that DIO function optimized for eTPU hardware can use double transition mode to measure two pin transitions at a time and reduce the service time, improving the overall system performance and latency.

2.15.5.4 Second-Pass Worst-Case Latency Analysis

Following is an example of a second-pass analysis for calculating worst-case latency for a channel. The second-pass analysis is useful for higher-performance systems, since it gives a more realistic worst-case latency result than first-pass analysis.

This example uses a relatively simple system in order to illustrate the basic principles of second-pass analysis. For a more complex example of second-pass analysis, refer to Multiphase Motor Commutation TPU Function (COMM)(TPUPN09/ D).

2.15.5.4.1 Second-Pass Analysis Guidelines

Rather than use a fixed formula, a second-pass analysis relies on the application of the following guidelines.

1. The first-pass analysis makes the assumption that all channels in the system are continually requesting service. For many systems this is an unrealistic assumption. For example, if TCR1 is counting at a rate of 2 MHz (500 ns per count) and a channel is running the DIO function with a match rate of 20,000 TCR1 counts, the DIO will request service every 10 ms (20,000 * 500 ns = 10,000,000 ns or 10 ms). It is therefore unrealistic to assume that the channel running this DIO function is continuously requesting service. Figure out a realistic service request rate for each channel. Time slots can then be mapped to each channel at the real rate of request.
2. If a function is active during system initialization but not during the high-speed running mode of the system, then that system does not need to be included in the high-speed worst-case latency calculations.
3. Use a realistic SDM collision rate.
4. Be careful when assigning functions priority levels and channel numbers. Decide which function or functions will be most difficult to make perform at the desired level. Assign those channels high priority and low channel numbers. Try different priority and channel assignments to see how it affects the system.
5. The seven-slot sequence of || H | M | H | L | H | M | H || is asymmetrical when put back-to-back with other seven-slot sequences. Note that in the following sequence there are two high-priority slots next to each other:

|| H | M | H | L | H | M | H |||| H | M | H | L | H | M | H ||

6. Make sure that when mapping out channels to the sequence, you choose a worst-case slot to start the mapping. For example, when estimating WCL for a high-priority channel, do not start the mapping in the last high-priority slot in a seven-slot sequence, as that is a best case for a high-priority channel since another high-priority time slot is next.
7. Instead of always using the longest thread in the function as the worst-case thread, evaluate the threads in the function that will be used in the system and use the appropriate worst-case threads. For example, in the preceding example of first-pass analysis, the PWM was shown to be able to achieve a high time and low time of 2475 ns under worst-case conditions. This was derived using the longest PWM thread of 24 CPU clocks. This longest thread is actually thread 2, the thread that is entered after the pin has just gone high. Thread 3, the thread that is entered after the pin has just gone low, requires only 2 CPU clocks. Therefore, in the first-pass example, the high time was correctly derived, but the low time is actually shorter than was estimated.

2.15.5.4.2 Second-pass analysis example

This example requires three 50% PWM waveforms: one 5 kHz (200 ms/period) and two 50 kHz (20 ms/period), each running DC motors. (Remember that the PWM function requests service from the eTPU after each high time and after each low time, so the eTPU must handle a request every 100 ms for the 5 kHz PWM and every 10 ms for the 50 MHz PWM.)

Note

This example uses square waves for simplicity. Notice that to use a PWM waveform in the typical way, in which the pulse is modulated, the pulse must not be modulated in a way that violates the worst-case latency requirements.

This example also uses one DIO channel monitoring a signal level every millisecond and one PPWA channel in mode 0 monitoring the speed of the 5-kHz DC motor. The PPWA must measure periods of 5 kHz (200 ms/period).

The CPU is interrupted by the channel running the PPWA function after measuring 200 periods (every 40 ms). The interrupt service routine performs an averaging of the period accumulation and checks it against a known parameter. The interrupt service time is so short and infrequent that it is a tiny fraction of total system time. The interrupt service routine contains no polling of the SDM. Therefore a realistic RCR = 0%.

2.15.5.4.2.1 First-Try System Configuration

Try a system configuration that seems likely to work. If it does not, change priority levels or channel numbers.

The 5 kHz and 50 kHz PWMs are the most time-critical functions. Those are assigned high priority. PPWA is assigned middle priority. The DIO is low performance and is assigned low priority. Refer to the following table.

Table 2-114. First-Try System Configuration

Channel	Priority	Function[1], [2]
0	High	PWM at 50 kHz (needs a 4-µs WCL)
1	High	PWM at 50 kHz (needs a 4-µs WCL)
2	High	PWM at 5 kHz (needs a 40-µs WCL)
8	Middle	PPWA at 5 kHz (needs a 80-µs WCL)
15	Low	DIO as input at rate of 1 ms

1. 0% RAM collision rate
2. CPU clock rate = 40 MHz, or 60 ns per clock period

With this system configuration, worst-case service time for each active channel is determined as follows:

1. Longest thread of PWM is 24 CPU clocks with four RAM accesses.

   24 + ((4 RAM accesses+1) * 0 * 2 CPU clock waits) = 24 CPU clocks

   Channels 0-2 worst-case service time = 24 CPU clocks.

2. Longest thread of PPWA in mode 0 is 44 CPU clocks with nine RAM accesses.

   44 + ((9 RAM accesses +1)* 0 * 2 CPU clock waits) = 44 CPU clocks

   Channel 8 worst-case service time = 44 CPU clocks.

3. Longest thread of DIO is ten CPU clocks with four RAM accesses.

   10 + ((4 RAM accesses+1) * 0 * 2 CPU clock waits) = 10 CPU clocks

   Channel 15 worst-case service time = 10 CPU clocks.

   To find the WCL for channel 0, assume channel 0 has just finished service.

   Map the channels in the H-M-H-L-H-M-H sequence. See the following figure.

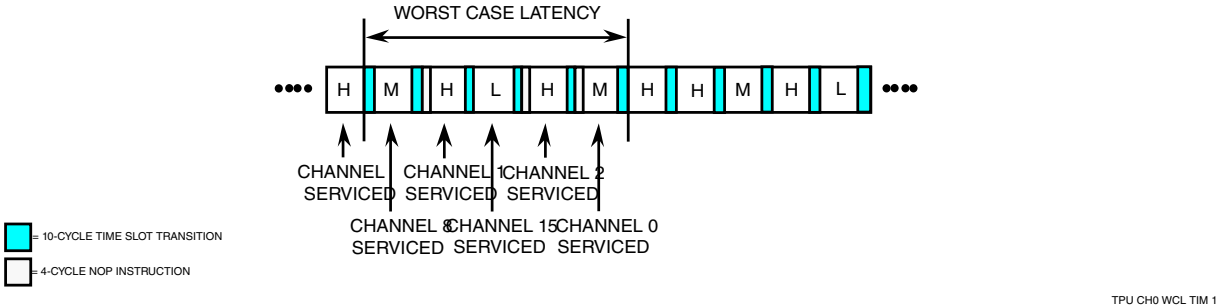

Figure 2-52. Worst-Case Latency for Channel 0 (First Try)

Conclusion: with this system configuration, worst-case latencies for channels 0 and 1 are too high (WCL for channel 1 is the same as WCL for channel 0). Try a different system configuration.

2.15.5.4.2.2 Second-Try System Configuration

The second-try system configuration is shown in the following table.

Table 2-115. Second-Try System Configuration

Channel	Priority	Function[1], [2]
0	High	PWM at 50 kHz (needs a 4-µs WCL)
1	High	PWM at 50 kHz (needs a 4-µs WCL)
2	Middle	PWM at 5 kHz (needs a 40-µs WCL)
8	Middle	PPWA at 5 kHz (needs a 80-µs WCL)
15	Low	DIO as input at rate of 1 ms

1. 0% RAM collision rate
2. CPU clock rate = 40 MHz, or 60 ns per clock period

To find the WCL for channel 0, assume channel 0 has just finished service. Map the channels in the H-M-H-L-H-M-H sequence. See the following figure.

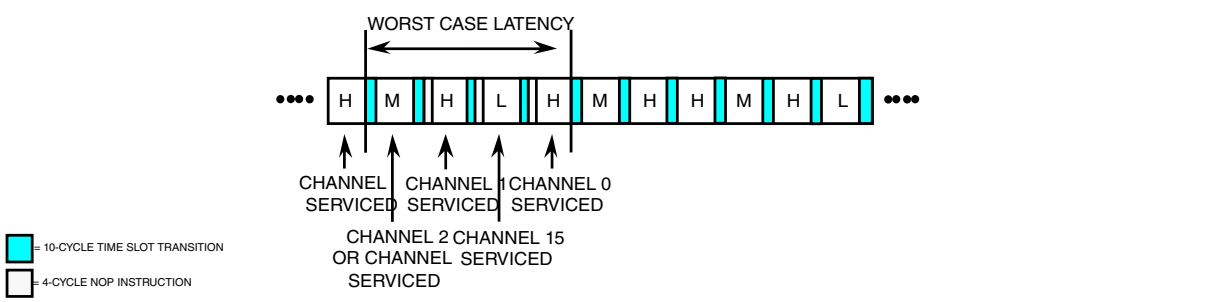

Figure 2-53. Worst-Case Latency for Channel 0 (Second Try)

Conclusion: with this system configuration, the WCL of both channel 0 and channel 1 is 3.85 ms, which is within the limit of 4 ms needed for a 50-kHz PWM.

Next, find the WCL for channel 2. Assume channel 2 has just finished service. Map the channels in the H-M-H-L-H-M-H sequence. See the following figure.

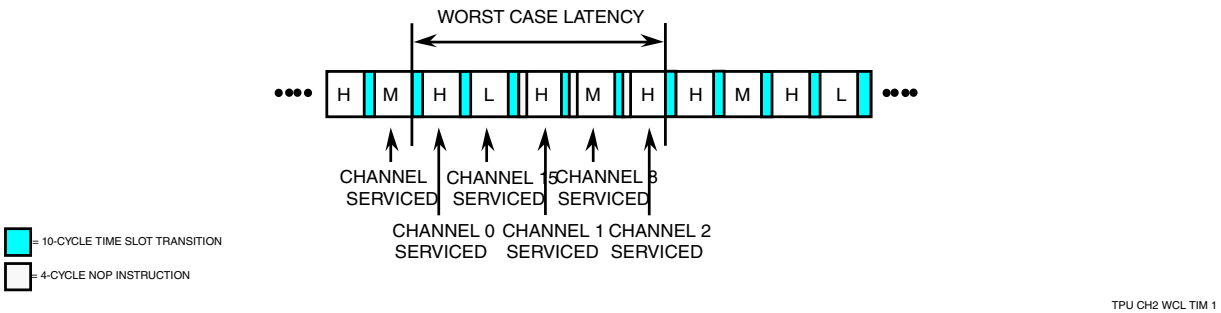

Figure 2-54. Worst-Case Latency for Channel 2

Conclusion: with this system configuration, the WCL for channels 2 and 8 is 4.7 ms, which is within the 40 and 80 ms WCL requirements.

Notice that channels 2 and 8 are well within their WCL requirements. The system could be reconfigured as shown in the following table to give channels 0 and 1 a larger margin while still keeping channels 2, 8 and 15 within their WCL requirements.

Table 2-116. Second-Try System with Channel 0 and 1 Reconfigured

Channel	Priority	Function[1, 2]
0	High	PWM at 50 kHz (needs a 10-µs WCL)
1	High	PWM at 50 kHz (needs a 10-µs WCL)
2	Middle	PWM at 5 kHz (needs a 40-µs WCL)
8	Low	PPWA at 5 kHz (needs a 80-µs WCL)
15	Low	DIO as input at rate of 1 ms

1. 0% RAM collision rate
2. CPU clock rate = 40 MHz, or 60 ns per clock period

2.15.6 Endianness

The following table shows the parameter addresses for big and little endian machines.

Table 2-117. Parameter Addresses and Endianness

Parameter	byte address offset (n = word address offset)	
	big endian	little endian
32-bit	4*n	
24-bit	4*n + 1	4*n
32-bit parameter's most significant byte	4*n	4*n + 3
24-bit parameter's most significant byte	4*n + 1	4*n + 2
least significant byte	4*n + 3	4*n

2.15.7 Memory Error Service Procedures

Follows separate procedures for correctable and non-correctable error interrupt service routines. It is assumed that the non-correctable error ISR has higher priority, and cannot be preempted by the correctable error ISR. For memory error support details, see Memory error support.

Note

The memory error support hardware does not (and is not intended to) guarantee that no error occurred will go unreported. However, combined with the procedures below, the information loss is minimized to statistical irrelevance on most scenarios.

2.15.7.1 Non-correctable error service procedure

The basic procedure below can be followed in a Global Exception or a bus error machine check service routine. It handles the service for both SCM and SDM errors, as they are symmetrical at this level. However, a real implementation is likely to split the procedure in two, one for each memory.

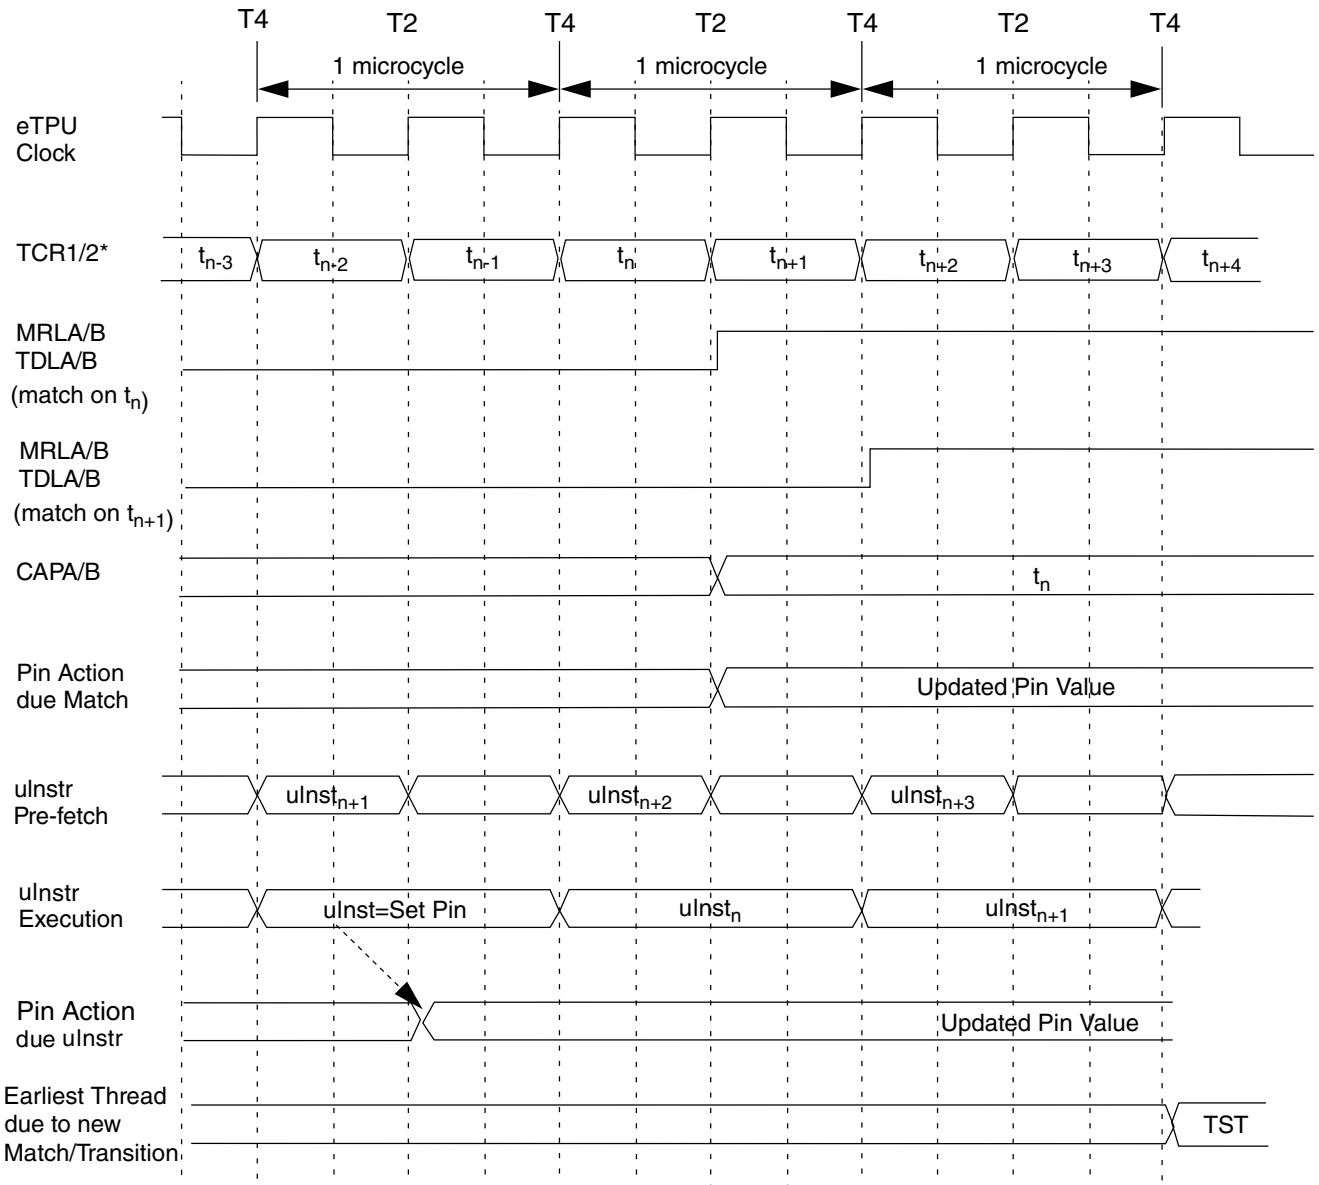
1. Confirm/identify the error source, checking assertion of the eTPU Module Configuration Register (eTPU_SCR_MCR) fields SCMERR and SDMERR.
2. Save the state(s) of eTPU Module Configuration Register (eTPU_SCR_MCR) fields CRDIS/DRDIS.
3. Set the eTPU Module Configuration Register (eTPU_SCR_MCR) CRDIS/DRDIS=1 to disable further updates to the respective report registers, guaranteeing coherency.

4. Check whether the report registers were updated by a correctable or non-correctable error; to do this, check the eTPU Code Error Report Syndrome Register (eTPU_MESR_CERSR) syndrome (for SCM) and/or the eTPU Data Error Report Syndrome Register (eTPU_MESR_DERSR) syndromes (for SDM, only those with the respective BE flags asserted). If it is a correctable error report, skip the steps 5 and 6 for the respective memory.
5. Identify the error source (host, microengine or MISC/CDC) by checking the field ERR_ACC in the register(s) eTPU Code Error Report Address Register (eTPU_MESR_CERAR) and eTPU Data Error Report Address Register (eTPU_MESR_DERAR); take or schedule the appropriate application-dependent recover actions.
6. Update error statistics as needed; it may include recording the access source, address, data and syndrome from:
   - eTPU Code Error Report Address Register (eTPU_MESR_CERAR)
   - eTPU Data Error Report Address Register (eTPU_MESR_DERAR)
   - eTPU Code Error Report Data Register (eTPU_MESR_CERDR)
   - eTPU Data Error Report Data Register (eTPU_MESR_DERDR)
   - eTPU Code Error Report Syndrome Register (eTPU_MESR_CERSR)
   - eTPU Data Error Report Syndrome Register (eTPU_MESR_DERSR)
7. Save the status of non-correctable error overflows flagged in the eTPU Memory Error Status Register (eTPU_MESR_MESR) fields CNCOVR/DNCOVR.
8. Set the eTPU Memory Error Control Register (eTPU_MESR_MECR) fields CRDIS/DRDIS to the state(s) saved in the step 2. That assures the access coherency of a preempted Correctable Error Service Procedure (which may have set CRDIS/DRDIS before this procedure) is not disturbed.
9. Clear the eTPU Memory Error Status Register (eTPU_MESR_MESR) fields CNCOVR/DNCOVR and CNCERR/DNCERR at once, in a single write to eTPU_MESR_MESR.
10. Use the overrun status saved on step 7 to update the error statistics, as needed.
11. Check the other Global Exception flags in eTPU Module Configuration Register (eTPU_SCR_MCR); take or schedule the appropriate (application dependent) recover actions.
12. Clear the Global Exception, programming GEC =1.

2.15.7.2 Correctable error service procedure

The basic procedure below can be followed in a Memory Error Interrupt service routine (see Interrupts and data transfer requests). It handles the service for both SCM and SDM errors, as they are symmetrical at this level. However, a real implementation is likely to split the procedure in two, one for each memory.

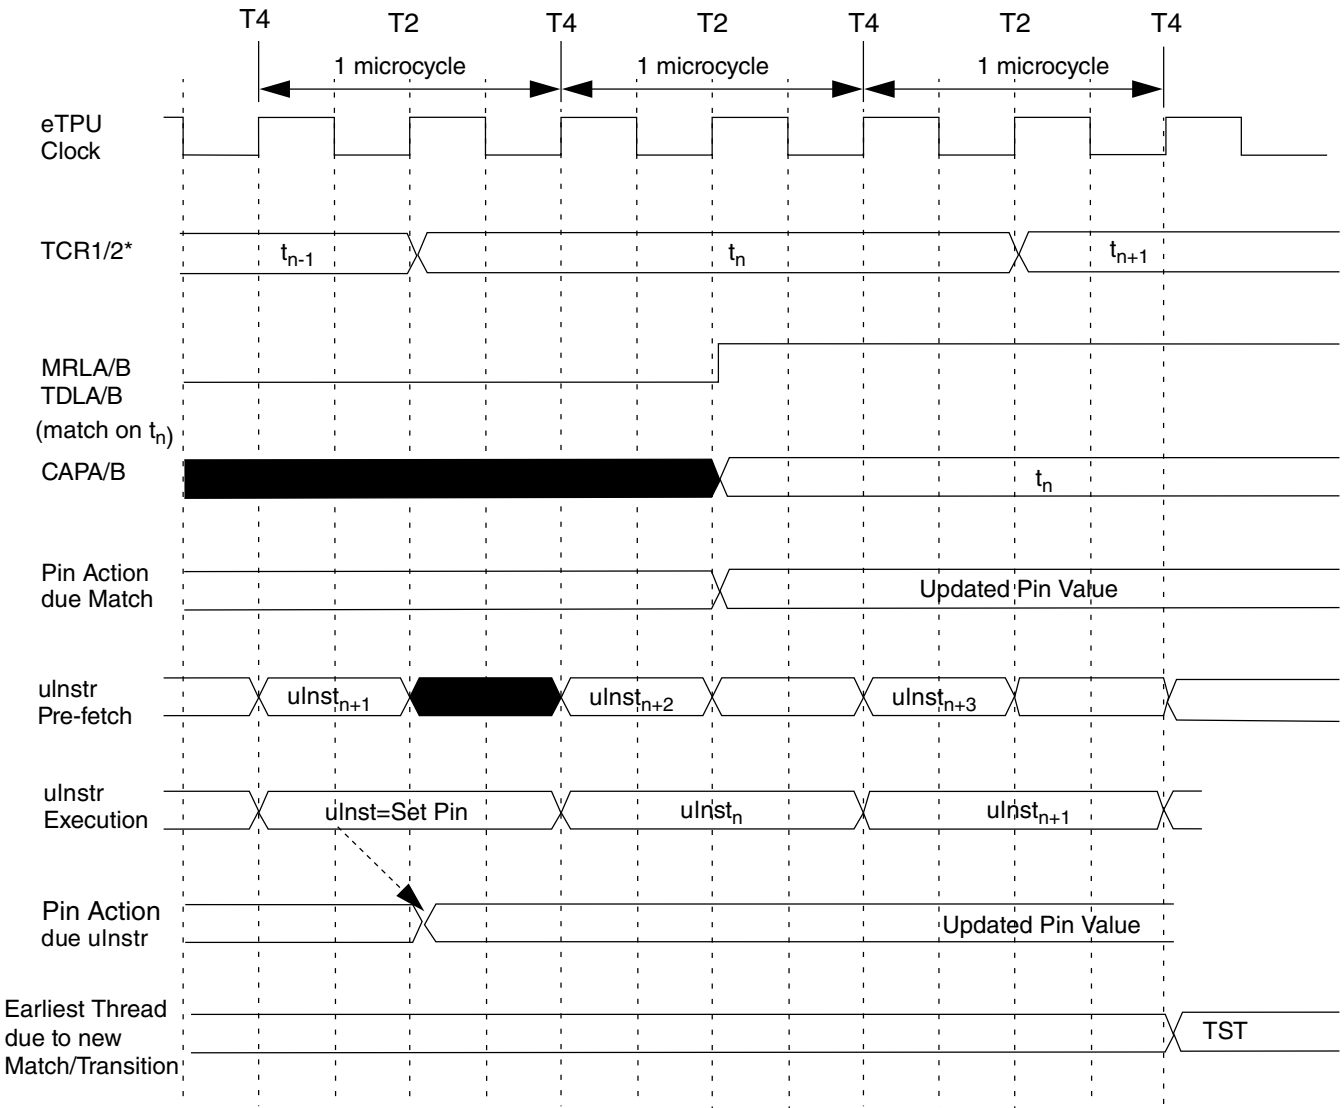
1. Confirm/identify the error source, checking assertion of the eTPU Memory Error Status Register (eTPU_MESR_MESR) fields CCERR/DCERR.
2. Program the eTPU Memory Error Control Register (eTPU_MESR_MECR) fields CRDIS=1 and/or DRDIS=1, to disable further updates to the respective report registers, guaranteeing coherency.
3. Check whether the report registers were updated by a correctable or non-correctable error; to do this, check the eTPU Code Error Report Syndrome Register (eTPU_MESR_CERSR) syndrome (for SCM) and/or the eTPU Data Error Report Syndrome Register (eTPU_MESR_DERSR) syndromes (for SDM, only those with the respective BE flags asserted). If it is a non-correctable error report, skip the steps 4 and 5 for the respective memory.
4. Identify the error source (host, microengine or MISC/CDC) by checking the field ERR_ACC in eTPU Code Error Report Address Register (eTPU_MESR_CERAR) and eTPU Data Error Report Address Register (eTPU_MESR_DERAR); take or schedule the appropriate application-dependent recover actions, which may include soft-error fixing (see Error fixing).
5. Update error statistics as needed; it may include recording the access source, address, data and syndrome from:
   - eTPU Code Error Report Address Register (eTPU_MESR_CERAR)
   - eTPU Data Error Report Address Register (eTPU_MESR_DERAR)
   - eTPU Code Error Report Data Register (eTPU_MESR_CERDR)
   - eTPU Data Error Report Data Register (eTPU_MESR_DERDR)
   - eTPU Code Error Report Syndrome Register (eTPU_MESR_CERSR)
   - eTPU Data Error Report Syndrome Register (eTPU_MESR_DERSR)
6. Save the status of correctable error overflows flagged in the eTPU Memory Error Status Register (eTPU_MESR_MESR) fields CCOVR/DCOVR.
7. Program the eTPU Memory Error Control Register (eTPU_MESR_MECR) fields CRDIS/DRDIS=0.
8. Clear the eTPU Memory Error Status Register (eTPU_MESR_MESR) fields CCOVR/DCOVR and CCERR/DCERR at once, in a single write to eTPU_MESR_MESR.



9. Use the saved overrun status to update the error statistics, as needed.

2.16 Appendices

2.16.1 Microcycle and I/O timing



2.16.1.1 Execution and channel timing

The following figure shows the main timings related to microinstruction execution when channels and timebases run on T2 timing.

Note: *TCR clock/prescaler selection = 1 x eTPU clock

Figure 2-55. Execution, timebase and channel T2 timing

Note: *TCR clock/prescaler selection = 4x eTPU clock

Figure 2-56. Execution, timebase and channel T2/T4 timing

The sequential occurrence of the four T states (T1-T4) constitutes a microcycle. Only T2 and T4 are taken as reference for timings, either internal or external. T2 and T4 have the timing of the positive eTPU clock pulses, and are used in most of the eTPU logic in an edge-triggered design style.

Two additional T states are derived from the eTPU clocks: $\overline{T2}$ and $\overline{T4}$. $\overline{T2}$ occurs when the eTPU loses SDM arbitration to a bus master. $\overline{T4}$ occurs in halt state (due to a breakpoint or device debug request assertion, for instance), or in stall state (due to an NDEDI queue full); see Development support features for more details.

$\overline{T2}$ and $\overline{T4}$ states are defined as microcycle timing states (not to be confounded with logic states) of one eTPU clock in which the T clocks continue to run, but the control signals associated with the clocks are unaffected. That is, no operation occurs during these states.

Both $\overline{T2}$ and $\overline{T4}$ states occur in multiples of two eTPU clocks to keep the microengine synchronized with the free running channels, which are unaffected and keep on working as in T2 and T4.

Thus, the eTPU has two types of timing states:

- $\overline{T2}$: hold execution for SDM access, from clock pulse T2 until one of the next T2 clock pulses of another microcycle.
- $\overline{T4}$: hold execution in debug mode or stall, from clock pulse T4 until one of the next T4 clock pulses of another microcycle.

The two following figures show the timing of $\overline{T2}$ and $\overline{T4}$ timing states, respectively.

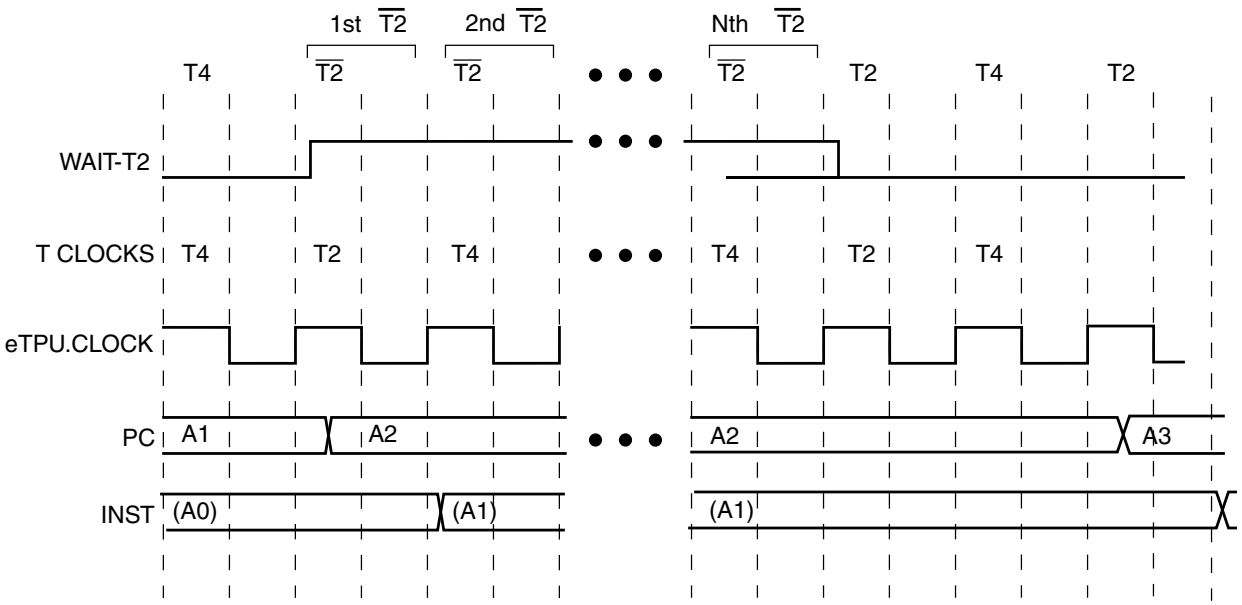


Figure 2-57. $\overline{T2}$ timing

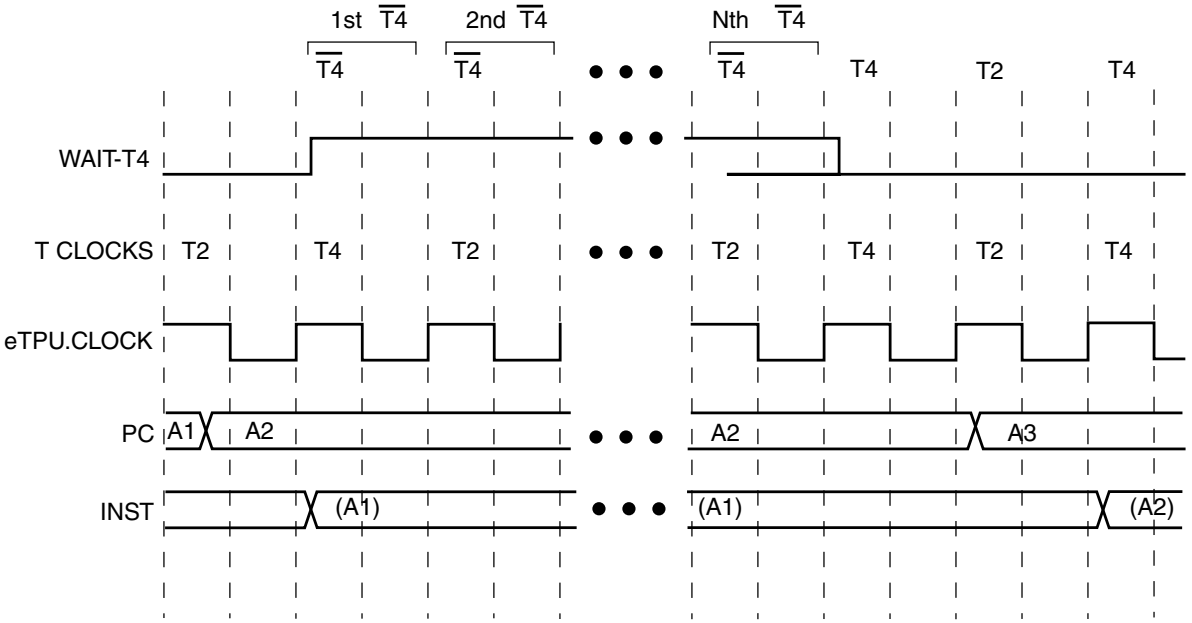

Figure 2-58. $\overline{T4}$ timing

2.16.1.2 Input/Output Signal Delays

The synchronizer, filter and edge detection logic delay the input signal transitions.

The Filter Delay varies with the filter clock (eTPU Engine 1 Configuration Register (eTPU_SCR_ECR_ENG1) and eTPU Engine 2 Configuration Register (eTPU_SCR_ECR_ENG2) field FPSCK) and the filter mode used, as shown in the Table 2-45 . For any given transition, it depends on the phase of the filter clock when the input transition happens. In integration mode (TCRCLK filtering only), it also depends on the state of the integrator counter. The Total Delay is defined as the number of eTPU clock rising edges between the input transition and the setting of TDLA/B, TCR1/2 incrementing, or EAC tooth sensing (TCRCLK) in angle mode. The synchronizer delay is 2 or 3 eTPU clocks, depending on the phase of the synchronizer when the input transition happens. The edge detection takes 1 more eTPU clock. The total delays are, thus:

```
Min. Total Delay = Min. Synchronizer Delay + Min. Filter Delay + Edge Detection Delay
Min. Total Delay = 3 + Min. Filter Delay
Max. Total Delay = Max. Synchronizer Delay + Max. Filter Delay + Edge Detection Delay
Max. Total Delay = 4 + Max. Filter Delay
```

The channel filters can be bypassed, so nullifying the filter delays in the equations above.

See the chip-specific eTPU information for connections between eTPU and input glitch filters.

The channel output flip-flops drive the eTPU output signals directly, without any synchronous delays.

2.16.2 Channel Mode Summary

The initial state considered for all submodes is channel flags MRLEA and MRLEB asserted, MRLA, MRLB, TDLA and TDLB negated. From initial state one can follow the table below and verify how each submode behaves in a determined sequence of events. Note that the actions performed by an event type depend on all previous events following the initial state, for a given channel submode.

There are three columns for each event: one for event type, one for enable/disable actions and one for capture. **Event type** column can be matchA, matchB, transA and transB (for double transition modes). **Enable/disable actions** column (identified as "**[blocks] (enables)**" in column head) specifies which other events are enabled or disabled. Initially disabled events (specified in **"initially blocked"** column) are usually enabled by other events.

In double transition submodes, the first transition detected is always considered transA and the second is considered transB. This means that transA event actually enables the detection of transB event. This is not explicit in the table, since it is a general behavior for all double transition submodes.

A sequence of four events (two matches and two transitions) are necessary to describe the behavior of some channel submodes. When a determined sequence of events has less than four events, the other event columns are left blank.

Cells in an **"event type"** column that have light-grayed background indicate that a service request is generated. More than one event in the same event sequence can issue service request.

Note

The two tables below do not exhaust all possibilities of channel logic event sequences, because it does not account for possible microcode interventions. For instance, if matches are blocked by first transition and microcode resets TDLA, the matches become enabled again, and from this point on the channel behaves as if the first transition had never occurred.

Table 2-118. Channel Mode Summary 1 of 2

2. Shading indicates that a service request is generated.
3. sm_st is compatible with TPU3 channel logic.
4. It is not possible to include all functionality of this submode in table.

2.16.3 MISC Algorithm

The MISC generator is based on the following polynomial:

$G(x) = 1 + x^1 + x^2 + x^{22} + x^{31}$ (equivalent to feedback mask = 0x80400007)

The MISC signature generation starts by clearing the MISC Accumulator value to 0 and preloading the MISC Counter with the highest SCM address. It then steps through each address decrementing the counter, reading 32 bit values and following the algorithm below:

```
If the least significant bit in MISC is 1 then
    MISC = MISC right shifted by 1 bit
    MISC = MISC XOR 0x80400007
else
    MISC = MISC right shifted by 1 bit
end if
MISC = MISC XOR RAM data
```

The code example below shows an excerpt of C code that calculates the MISC signature for a given array of data, based on the previous algorithm:

```
#define SCM_size    (MAX_SCM_ADDRESS / 4)    /* last byte address - converted to 32-bit word */
#define POLY        0x80400007               /* G(x) = 1 + x^1 +x^2 + x^22 + x^31 */
/*****************************************************************************
 FUNCTION : void calc_misc()
 PURPOSE : This function calculates the MISC value.
 INPUTS NOTES : none
 RETURNS NOTES : MISC value
 GENERAL NOTES : the array 'unsigned int data[]' represents the actual memory
                 array, organized in 32-bit words.
*****************************************************************************/
unsigned int calc_misc (void)
```

```
{
  int j; /* loop counter */
  unsigned int misc = 0;
  for (j = (SCM_size-1); j >= 0 ; j--) {   /* SCM_size has the number of 32-bit words in SCM
*/
      if (misc & 0x1) {
          misc >>= 1;
          misc ^= POLY;
      }
      else {
          misc >>= 1;
      }
      misc ^= data[j];          /* data[j] is the actual 32-bit word taken from the SCM
array
*/
  }
  return (misc);          /* final signature calculated */

};
```

The value calculated by this algorithm must be loaded into eTPU MISC Compare Register (eTPU_SCR_MISCCMPR) prior to activating the SCM MISC calculator in eTPU. Once the MISC calculator is activated (bit SCMMISEN in register eTPU Module Configuration Register (eTPU_SCR_MCR) is written to 1) eTPU itself will start this procedure[38] reading the SCM whenever allowed by microengine. At the end of the cycle, when all the array has been read and the SCM signature is calculated, the Host CPU can be notified via Global Exception if the MISC Accumulator does not match the value in eTPU_SCR_MISCCMPR.

The average time taken by MISC to complete the signature of the whole SCM can be given by the formula:

```
Average MISC period = S / (4 * F * (1 - L))
```

where f is clock frequency, S is SCM size in bytes and L is eTPU load (as a percentage of execution clocks over a period of time, including TST clocks).

Further detail on MISC calculation can be found on SCM Test - Multiple Input Signature Calculator. The application note **AN2192 - Detecting Errors in the Dual Port RAM (DPTRAM) Module** is also a good source of information (although it refers to TPU) on MISC signature.

38. eTPU MISC hardware is optimized to read 32-bit words from memory and to calculate this CRC in parallel, rather than shifting one bit at a time. The actual implementation inside eTPU, although bringing to the same results, does not match exactly the algorithm shown here.

Chapter 3
Fault Collection and Control Unit (FCCU)

3.1 FCCU chip-specific module information

This section describes the implementation of this module in the device.

3.1.1 FCCU fault recovery after NMI reaction

When an NMI (Non-Maskable Interrupt) is configured as the internal FCCU reaction for a specific NCF (fault state), the application software should not clear the core's MCSR[NMI] bit field during the execution of the NMI interrupt service routine, unless the FCCU fault source which generated the respective NMI reaction is cleared.

For details on MCSR[NMI] bit field clearing, see Machine Check Syndrome Register (MCSR). For details on FCCU Fault recovery see Fault recovery.

3.1.2 FCCU chip-specific register reset values

The following table shows FCCU registers whose reset values are specific to this chip.

Table 3-1. FCCU chip-specific register reset values

Register	Reset value
FCCU_CFG	See FCCU_CFG register bit value sources (N and C) by event.
FCCU_NCF_CFG0	0xFFFFFFFF
FCCU_NCF_CFG1	0xFFFFFFFF
FCCU_NCF_CFG2	0xFFFFFFFF
FCCU_NCFS_CFG0	0x00002000
FCCU_NCFS_CFG1	0x00000080
FCCU_NCFS_CFG2	0x00000000
FCCU_NCFS_CFG3	0x00000000

Table continues on the next page...

Table 3-1. FCCU chip-specific register reset values (continued)

Register	Reset value
FCCU_NCFS_CFG4	0x00000000
FCCU_NCFS_CFG5	0x00000000
FCCU_NCF_E0	0x00080040
FCCU_NCF_E1	0x00000000
FCCU_NCF_E2	0x00000000
FCCU_NCF_TOE0	0x00000000
FCCU_NCF_TOE1	0x00000000
FCCU_NCF_TOE2	0x00000000
FCCU_NCF_TO	0x0000_FFFF
FCCU_CFG_TO	0x0000_0006

3.1.3 FCCU_CFG register event bit values by source (N and C)

For each bit in the Configuration (FCCU_CFG) register, this table specifies the values of *N* and *C* for this chip. For information on how to interpret and use these values, see FCCU_CFG register bit value sources (N and C) by event.

Bit	N (chip-specific or user-specified value provided by the bit's associated NVMCFG signal)	C (chip-specific value provided by the bit's associated constant inside the module)

3.1.4 Available FCCU output signals

The following table shows the available FCCU output signals implemented on this chip.

Table 3-2. FCCU output signals

FCCU output signal name	Chip-top signal name
EOUT[0]	ERROR0
EOUT[1]	ERROR1

3.1.5 Error signal flow diagram

* This condition must be satisfied only when FCCU is configured for Bistable fault-output mode (FCCU_CFG[FOM]).

Figure 3-1. Error signal flow

3.1.6 FCCU failure inputs from other modules

The following table shows the different failure input signals of the FCCU, how they can be tested, and their default configuration after reset.

NOTE

All the faults shown in the following table require a long functional reset.

NOTE

FCCU Fault Channels 22, 23, and 24 may be asserted after reset. FCCU Fault Channels 51, 52, 69 through 84, 92, and 93 may be asserted during the execution of MBIST and LBIST. Before running MBIST or LBIST, these channels should be configured to NO REACTION. If any of these channels become asserted during MBIST or LBIST testing, the fault should simply be cleared and no further action should be taken.

Table 3-3. FCCU Fault Inputs

NCF Index	Default Reaction Configuration at POR or Destructive Reset	Source	Error Reaction Path Check	Description
0	No Reaction	Temp sensor	Using PMC_TS_FIR register to set the fault at source + Via FCCU Fake bit	Temperature Sensor Event Triggered by PMC_ESR_TD[TEMP1_2, TEMP1_0, TEMP0_2, TEMP0_0] and PMC_TS_FIR[TSNS_FAULT] . For details, see the descriptions of the PMC_ESR_TD and PMC_TS_FIR registers.
1	No Reaction	PMC	Using PMC FIR register to set the fault at source + Via FCCU Fake bit	LVD event to FCCU Triggerred by PMC_LVD_HVD_EVENT_STATUS[LVD_PMC, LVD_SAR_ADC, LVD_IO, LVD_FLASH, LVD_CORE_HOT, LVD_CORE_COLD] and PMC_FIR[LVD_FAULT]. For details, see the descriptions of the PMC_LVD_HVD_EVENT_STATUS and PMC_FIR registers.
2	No Reaction	PMC	Using PMC FIR register to set the fault at source + Via FCCU Fake bit	HVD Event to FCCU Triggered by PMC_LVD_HVD_EVENT_STATUS[HVD_FLASH, HVD_HV, HVD_CORE]. For details, see the descriptions of the PMC_LVD_HVD_EVENT_STATUS register.

Table continues on the next page...

Table 3-3. FCCU Fault Inputs (continued)

NCF Index	Default Reaction Configuration at POR or Destructive Reset	Source	Error Reaction Path Check	Description
3	No Reaction	PMC	Using PMC FIR register to set the fault at source + Via FCCU Fake bit	PMC Self Test Failure Event PMC hard/soft self-test failed: LVD/HVD **NOTE:** When this occurs, single LVD or HVD self-tests should be executed to identify which detection mechanism failed in the SOC: LVD or HVD. For details, see the description of the PMC_SELF_TEST_UM_VD_REG register as well as the flag bits associated to NCF3 (PMC_SELF_TEST_UM_VD_REG [ST_RESULT]). Self test bit definition indicates all valid values for PMC_SELF_TEST_UM_VD_REG[VD_ST_CTRL] while executing single self-tests. LVD-HVD self test mechanism provides details about the available PMC self-tests
4	No Reaction	SSCM	write wrong data to address + Via FCCU Fake bit to set the fault at error path	See SSCM_STATUS[CERS] field description.
5	No Reaction	SSCM	write wrong data to address + Via FCCU Fake bit to set the fault at error path	See SSCM_STATUS[CER] field description.
6	long reset	STCU	SW check of BIST MISR + Via FCCU Fake bit to set the fault at source	Critical Fault of STCU. Set when STCU2_ERR_STAT[UFSF] is set.
7	No Reaction	STCU	SW check of BIST MISR + Via FCCU Fake bit to set fault at source	Non critical Fault of STCU. Set when STCU2_ERR_STAT[RFSF] is set.
8	No Reaction	STCU	STCU activation during user application run Via FCCU Fake bit to set the fault at source	Critical Fault in case LBIST or MBIST control signals go to wrong condition during User application. This fault is set when the self-test was triggered without STCU2_RUN[RUN] bit programming.
9	No Reaction	Checker Shell	Via FCCU Fake bit	out of lockstep fault detected for miscellaneous safety core output
10	No Reaction	Checker Shell	Via FCCU Fake bit to set the fault at error source	out of lockstep fault detected for safety Core dtcm array interface signal
11	No Reaction	Checker Shell	Via FCCU Fake bit to set the fault at error source	out of lockstep fault detected for safety Core I Cache array interface signals
12	Reserved	Reserved		Reserved
13	No Reaction	Checker Shell	Via FCCU Fake bit to set the fault at error source	out of lockstep fault detected for safety Core Amba interface signals
14	No Reaction	DMA Checker Shell	Via FCCU Fake bit to set the fault at error source	out of lockstep fault detected for DMA

Table continues on the next page...

Table 3-3. FCCU Fault Inputs (continued)

NCF Index	Default Reaction Configuration at POR or Destructive Reset	Source	Error Reaction Path Check	Description

88	No Reaction	Computational SMPU	Via FCCU Fake bit to set the fault at error path + LBIST	MPU alarm to the fault collection unit An internal error has happened in the operation of the MPU. Example: MPU erroneously blocked transactions without a real permissions violation will assert this NCF.
89	No Reaction	peripheral SMPU	Via FCCU Fake bit to set the fault at error path + LBIST	MPU transaction monitor error output An internal error has happened in the operation of the MPU. Example: MPU erroneously blocked transactions without a real permissions violation will assert this NCF.
90	No Reaction	Core0/1 IMEM MBIST	Via FCCU Fake bit to set the fault at error path	Mbist multi bit error of IMEM (Core0 or Core1)
91	No Reaction	Flash	Via FCCU Fake bit to set the fault at error path + LBIST	Flash Read Voltage error or reference current error
92	No Reaction	Core0/1 DMEM MBIST	Via FCCU Fake bit to set the fault at error path	Mbist multi bit error of DMEM (Core0 or Core1)
93	No Reaction	Core0/1 ICACHE/TAG MBIST	Via FCCU Fake bit to set the fault at error path	Mbist multi bit error of ICACHE(Core0 or Core1)
94	No Reaction	SRAM MBIST	Via FCCU Fake bit to set the fault at error path	Mbist Multibit error of SRAM
95	No reaction	All Peripheral RAM MBIST	Via FCCU Fake bit to set the fault at error path	Mbist multi bit error from all peripheral RAM

3.1.7 Lockstep Status

RCCU status is evaluated in FCCU_NCF[57] channel.

In debug mode, the cores do not work in lockstep mode and the RCCUs are disabled. The actual enablement/disablement state of the RCCUs (including any automatic disablement by debug) can be read by software.

3.1.8 FOSU Count Value

The fixed preprogrammed value for FOSU_Count is 0x1F40.

3.1.9 FCCU_CFG[FCCU_SET_AFTER_RESET]

FCCU_CFG[FCCU_SET_AFTER_RESET] is not used to control EOUT pads on this chip and hence there will be no effect of writing to this bit. FCCU EOUT pads OBE are controlled either via SIUL or DCF records.

3.2 Introduction

The Fault Collection and Control Unit (FCCU) offers a hardware channel to collect faults and to place the device into a safe state when a failure in the device is detected. No CPU intervention is requested for collection and control operation.

The FCCU offers a systematic approach to fault collection and control. The distinctive features of the module are:

- Redundant collection of fault information from safety relevant modules on the device
- Collection of test results
- Configurable fault control
- Configurable internal reactions for each NCF:
  - No reaction
  - IRQ
  - Short functional reset

  - Long functional reset
  - NMI
- External reactions via configurable output pins
- Watchdog timer for the reconfiguration phase
- Lockable configuration
- Nonvolatile memory interface (NVMCFG signals) for configuration loading
- Self checking capabilities: FSM redundancy and parity check for the configuration register
- One of the fault-output (EOUT) signals is high to indicate operational (OK) state (in bi-stable operation mode). The above is not true in case the error out protocol is configured to be a toggling protocol, for example, dual rail and time switching.
- After power on, the EOUT signals have high impedance.[1] They show operational state only after configuration by software.
- In case of a failure event or on software request for Error pin indication, the pin(s) are set to faulty state for a minimum time T_min, even if SW tries to release it before (for the case of error pin configured in Bi-stable mode only).
- The overall fault detection, processing and indication time is less than 10 ms.
- The actual maximum time is 5 CLKSAFE cycles**.**

The FCCU circuitry is checked at the start-up by the self-checking procedure. The FCCU is operative with the default configuration immediately after the completion of the self-checking procedure. Internal (short or long functional reset request pulse, interrupt request) and external (EOUT signaling) reactions are statically defined or programmable. The default configuration can be modified only in the CONFIG state. FCCU is designed to function when CLKSYS is faster than the CLKSAFE clocks.

3.2.1 Acronyms and abbreviations

Term	Description
CF	Critical fault
CPU	Central processing unit
EOUT	Error out
FOSU	FCCU output supervision unit

Table continues on the next page...

1. Actual value depends on device specific setting at pad level.

Term	Description
FSM	Finite state machine
INTC	Interrupt controller
intf	Interface
IRQ	Interrupt request
MC_ME	Mode entry module
NCF	Noncritical fault
NMI	Nonmaskable interrupt
NVM	Nonvolatile memory
SoC	System-on-chip
STCU	Self-test control unit
SW	Software
WKPU	Wake-up unit

3.3 Main features

- Management of noncritical faults
- HW or SW fault recovery management
- Fault detection and collection
- Fault injection (fake faults)
- External reaction (fault state): EOUT signaling. Error indication via the pin(s) is controlled by the FCCU.
- Internal chip reactions (alarm state): interrupt request
- Internal chip reactions (fault state):
  - long functional reset request pulse
  - short functional reset request pulse
  - NMI
- Bi-Stable, Dual-Rail and Time Switching output protocols on EOUT
- Internal (to the FCCU) watchdog timer for the reconfiguration phase
- Configuration lock
- Nonvolatile memory interface (NVMCFG signals) for configuration loading
- Self-checking capabilities: FSM redundancy and parity check for the configuration registers

3.4 Block diagram

The following figure is a top-level diagram of the FCCU module.

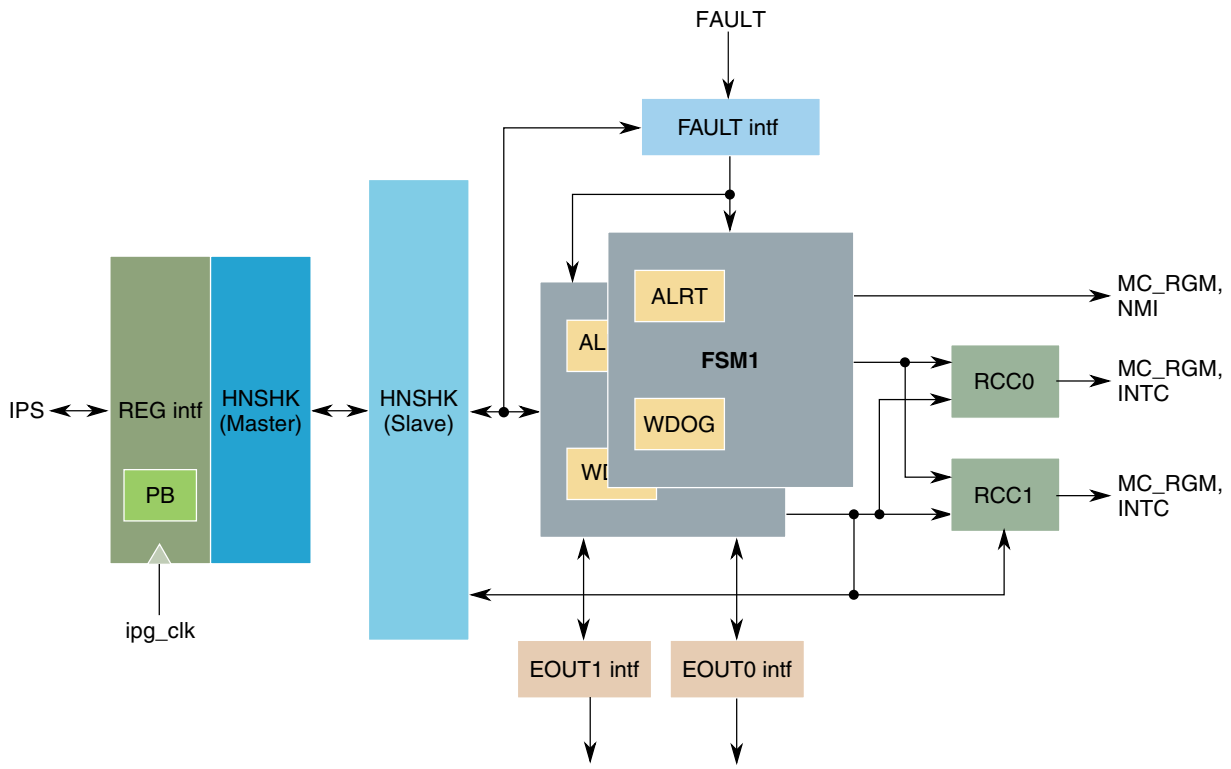

Figure 3-2. FCCU block diagram

This table describes the FCCU submodules.

Table 3-4. FCCU submodules

Submodule	Description
REG intf	Includes the register file, the IPS bus interface, the IRQ interface and the parity block (PB) for the configuration registers
HNSHK blocks (master and slave blocks)	Includes the FSM's ability to support the handshake between the REG interface and the FSM unit due to the usage of 2 asynchronous clocks (IPS system clock and RC oscillator clock)
FSM unit	Implements the main functions of the FCCU. The FSM also includes the: • Watchdog timer (WDG) • Alarm timer (ALRT)
FAULT intf	Implements the interface for the fault conditioning and management
EOUTx units	Implement the output stage to manage the EOUT interfaces
RCCx units	Implement the redundancy control checker to monitor the FSMx unit state and its configuration

3.5 Signal description

3.5.1 Signals

This table describes the signals on the boundary of FCCU.

Signal	Direction	Function	Active level	Clock
Clock and reset				
CLKSYS	Input	System Clock—Supplies the primary clock.	Rising edge	—
CLKSAFE0	Input	Safe Clock 0—Supplies one of two 16 MHz clocks for use by various redundant submodules. This clock and CLKSAFE1 are often referred to as the same clock (CLKSAFE).	Rising edge	—
CLKSAFE1	Input	Safe Clock 1—Supplies one of two 16 MHz clocks for use by various redundant submodules. This clock and CLKSAFE0 are often referred to as the same clock (CLKSAFE).	Rising edge	—
EOUT interface				
EIN[1:0]	Input	Error Input—Provide the mechanism for FCCU to capture the states that off-chip logic drives on the associated EOUT[1:0] signals. (On the chip, the EOUT signals are connected to their corresponding EIN signals.) FCCU captures the states in the EIN1 and EIN0 fields.	—	Asynchronous
EOUT[1:0]	Output	Error Output—Indicate FCCU's condition (Faulty, Nonfaulty, or Configuration) to off-chip logic.	Programmable	CLKSAFE0, CLKSAFE1
FOSU interface				
FIF	Output	FCCU In Fault—Indicates to the FOSU module, if present, that FCCU is recognizing a fault. FCCU asserts and then deasserts this signal in two cases: *Case 1* When the EOUT signals are programmed to be always low (FCCU_SET_CLEAR), FCCU asserts this signal until the EOUT signals are programmed not to be always low. *Case 2*	High	CLKSAFE0, CLKSAFE1

Table continues on the next page...

Signal	Direction	Function	Active level	Clock
		When the EOUT signals are programmed not to be always low (FCCU_SET_CLEAR), FCCU asserts this signal when all of the following are true: • FCCU enters Fault state as the result of a fault. • If the fault is a noncritical fault, and the EOUT signals are in a fault-output mode (FOM) other than Bistable, the associated EOUTENx field is set to enabled. FCCU deasserts this signal when FCCU leaves Fault state.		
WKPU interface				
NMIWKPU	Input	WKPU Nonmaskable Interrupt Request—Receives nonmaskable interrupt requests from the WKPU module.	Low	CLKSYS
WAKEWKPU	Output	Wake WKPU—Wakes the WKPU module to bring the chip out of dormant state when FCCU enters Fault state as the result of a noncritical fault for which NMI is enabled as the reaction (FCCU_NMI_ENa[NMIENx]).	High	CLKSAFE0, CLKSAFE1
Interrupt interface				
NMIOUT	Output	Nonmaskable Interrupt Output—Sends a nonmaskable interrupt request to the processor core or cores when FCCU enters Fault state as the result of a noncritical fault for which NMI is enabled as the reaction (FCCU_NMI_ENa[NMIENx]).	Low	CLKSYS
NVM interface				
NVMCFG[21:0]	Input	Nonvolatile Memory Configuration—Provide the values of certain bits in the Configuration (FCCU_CFG) register when certain events occur. See Configuration (FCCU_CFG). Some or all of these signals may be driven by bits in a data record in nonvolatile (flash) memory or may be tied high (1) or low (0). See FCCU_CFG register bit value sources (N and C) by event.	Static value	—
SSCMDONE	Input	SSCM Done—After an FCCU reset, indicates that the SSCM module is now driving any NVMCFG signals	High	CLKSYS

Signal	Direction	Function	Active level	Clock
		that are associated with a data record stored in nonvolatile (flash) memory.		

3.6 Put FCCU in Configuration or Normal state

3.6.1 Introduction

You put FCCU in Configuration state to change its configuration. You put FCCU in Normal state to save changes to the configuration.

3.6.2 About changing states

When changing states, keep the following in mind:

- To put FCCU in Configuration state, FCCU must be in Normal state.
- After FCCU is reset, the configuration is temporarily locked. You must temporarily unlock the configuration before you can put FCCU in Configuration state.
- When FCCU is in Configuration state, FCCU doesn't actually save the changes you make to the configuration. To save changes to the configuration, you must manually put FCCU in Normal state. If FCCU automatically leaves Configuration state and enters Normal state because the configuration-timer interval (TO) expires (called a Configuration-state timeout), FCCU changes the value of the Configuration (FCCU_CFG) register to its Configuration-state-timeout value and the value of each of the other configuration registers to its reset value. For information on the Configuration-state timeout value, see FCCU_CFG register bit value sources (N and C) by event. For a list of configuration registers, see Configuration registers.

3.6.3 Put FCCU in Configuration state

1. Temporarily unlock the configuration (see Temporarily unlock the configuration).
2. To determine FCCU's state, run the OP3 operation (see Run an operation).
3. Check the operation status (OPS).
   - If the operation status is Successful, go to step 4.
   - If the operation status is Aborted, go to step 2.
4. Check the FCCU status (STATUS).
   - If the FCCU status is Configuration, FCCU is in Configuration state. Stop.

- If the FCCU status is Normal, go to step 5.
- If the FCCU status is Alarm or Fault, go to step 7.

5. To put FCCU in Configuration state, run the OP1 operation (see Run an operation).
6. Check the operation status (OPS).
   - If the operation status is Successful, FCCU is in Configuration state. Stop.
   - If the operation status is Aborted, the configuration is probably permanently locked. Go to step 9.
7. Recover all faults.
8. Go to step 2.
9. Reset FCCU.

3.6.4 Put FCCU in Normal state

1. To determine FCCU's state, run the OP3 operation (see Run an operation).
2. Check the operation status (OPS).
   - If the operation status is Successful, go to step 3.
   - If the operation status is Aborted, go to step 1.
3. Check the FCCU status (STATUS).
   - If the FCCU status is Normal, FCCU is in Normal state. Go to step 8.
   - If the FCCU status is Configuration, go to step 4.
   - If the FCCU status is Alarm or Fault, go to step 6.
4. To put FCCU in Normal state, run the OP2 operation (see Run an operation).
5. Check the operation status (OPS).
   - If the operation status is Successful, FCCU is in Normal state. Go to step 8.
   - If the operation status is Aborted, go to step 4.
6. Recover all faults.
7. Go to step 1.
8. If you want to prevent changes to the configuration, lock it:
   - To require a key to unlock the configuration, temporarily lock the configuration (see Temporarily lock the configuration).
   - To require a reset of FCCU to unlock the configuration, permanently lock the configuration (see Permanently lock the configuration).

3.7 Run operations

3.7.1 Introduction

You run operations to perform actions such as putting FCCU in Configuration state or reading a timer. For a complete list of operations you can run, see OPR.

3.7.2 About running operations

When running operations, keep the following in mind:

- FCCU ignores any operations initiated while the operation status is In Progress.
- Certain operations must be unlocked before you can initiate them. After you initiate them, they are again locked.

3.7.3 Run an operation

1. Check the operation status (OPS).
2. If the operation status is In Progress, go to step 1.
3. If the operation must be unlocked before you can initiate it, unlock the operation (CTRLK) using a 32-bit write.

NOTE

The Control Key (FCCU_CTRLK) register used in this step and the Control (FCCU_CTRL) register used in the next step must be written with consecutive instructions. Do not use read-modify-write instructions, such as bit-field instructions, to modify these registers.

4. Initiate the operation (OPR) using a 32-bit write.
5. Check the operation status (OPS).
6. If the operation status is In Progress, go to step 5.

The operation status is now Idle (OP15 only), Aborted, or Successful.

3.8 Lock and unlock the configuration

3.8.1 Introduction

After you configure FCCU, you can lock its configuration to prevent accidental changes.

3.8.2 About locking the configuration

When locking the configuration, keep the following in mind:

- If you attempt to lock the configuration while FCCU is in Configuration state, FCCU doesn't actually lock the configuration until FCCU leaves Configuration state—that is, either you put FCCU in Normal state, or FCCU puts FCCU in Normal state because the configuration-timer interval (TO) expires.
- After you permanently lock the configuration, you must reset FCCU before you can put FCCU in Configuration state.

3.8.3 Temporarily lock the configuration

1. From Supervisor mode, write a lock value to TRANSKEY.
2. Put FCCU in Normal state if it's in Configuration state (see Put FCCU in Normal state).

3.8.4 Temporarily unlock the configuration

- From Supervisor mode, write the unlock value to TRANSKEY.

3.8.5 Permanently lock the configuration

1. From Supervisor mode, write the lock value to PERMNTKEY.
2. Put FCCU in Normal state if it's in Configuration state (see Put FCCU in Normal state).

The configuration is permanently locked until FCCU is reset.

3.9 Functional description

3.9.1 Definitions

In general, the following definitions are applicable for the fault management:

- HW recoverable fault: the fault indication is an edge-triggered and level-sensitive signal that remains asserted until the fault cause is deasserted. That is, if logical 0 on the fault signal indicates fault, then the status flags are valid as long as the fault line

stays at 0. The status is automatically cleared when the fault signal goes to 1. Typically the fault signal is latched external to the FCCU in the module where the fault occurred. The FCCU state transitions are consequently executed on the state changes of the input fault signal. No SW intervention in the FCCU is required to recover the fault condition.

- SW recoverable fault: the fault indication is a signal asserted without a defined time duration. The fault signal is latched in the FCCU. The fault recovery is executed following a SW recovery procedure (status/flag register clearing).

HW recoverable is an option to exclude the handling of error source/s by FCCU management SW, in case it is known that the fault is recoverable by itself when the fault condition gets corrected.

These type of chip resets reset the FCCU:
- Power-on
- Destructive
- Long functional, when initiated by the assertion of the chip reset pin (RESET_B)

These types of chip resets don't reset the FCCU:
- Long functional, when initiated by anything other than the assertion of the chip reset pin (RESET_B)
- Short functional reset

For more information on each type of reset, see the MC_RGM and reset chapters.

3.9.2 FSM description

FCCU functionality is depicted by the finite state machine (FSM) state diagram.

Basically four states are identified with the following meaning:

- Configuration: Used only to modify the configuration of FCCU from its default. A subset of the FCCU registers, dedicated to define the FCCU configuration (global configuration, reactions to fault, timeout, noncritical fault masking) can be accessed in write mode only in Configuration state.

  Configuration state is accessible only in Normal state and if the configuration is not locked. The permanent configuration lock can be disabled by a reset which also resets the FCCU., The transient lock register is unlocked by writing BCh into it. FCCU gets transiently locked again if an invalid key is written into FCCU_TRANS_LOCK register (that is, other than BCh). Key to lock FCCU permanently is FFh, written in the FCCU_PERMNT_LOCK register.

After the release of reset the state of the transient lock will be locked. The state of the permanent lock will be unlocked.

The locking feature only restricts the FSM movement into Configuration state. Once the user enters Configuration state and then tries to lock the configuration, the locking of configuration will be effective after FCCU moves to Normal state, it will not be effective in the current Configuration state.

The Configuration to Normal state transition can be executed by SW or automatically following a timeout condition of the watchdog. In case the timeout information and the SW request to mode change to Normal appears at the same time, watchdog timeout has the priority and hence the Configuration registers (those that are writable only in Configuration state) are reset to their default values. The movement to Normal is made.

The incoming faults, occurring during the configuration phase (Configuration state) are latched in order to process them when FCCU is moved into Normal state, according to the new configuration.

All pending faults that occur during Configuration state result in both of the following:

- Highest-priority state transition
- Interrupt generation (NMI or alarm IRQ)

If the state transition occurs, it gives the reset reaction corresponding to the worst case based on all the faults (pending or nonpending faults) that occurred during Configuration state.

- Normal: This is FCCU's operating state when no faults are occurring. It is also the default state on the reset exit. Following state transitions occur on one of the following events:
  - unmasked noncritical faults with the timeout disabled → FCCU moves to Fault state
  - unmasked noncritical faults with the timeout enabled → FCCU moves to Alarm state
  - masked noncritical faults → FCCU stays in Normal state
- Alarm: FCCU moves into Alarm state when an unmasked noncritical fault occurs and the timeout is enabled. The transition to Alarm state goes along with an interrupt alarm, if enabled. By definition, this fault may be recovered within a programmable

timeout period, before it generates a transition to Fault state. The timeout is reinitialized if FCCU enters Normal state. The timeout restarts following the recovery from Fault state.

- Fault: FCCU moves into Fault state when one of the following condition occurs:
  - timeout related to a noncritical fault when FCCU is in Alarm state
  - unmasked noncritical faults with the timeout disabled

The transition from Normal/Alarm to Fault state goes along with the generation of:

- NMI interrupt (optional)
- EOUT signaling (optional)
- SW option: Soft reaction (Short functional reset request pulse if configured)
- SW option: Hard reaction (Long functional reset request pulse if configured)
- Non Maskable Interrupt (NMI) is routed only to the Safety Core

After moving to Fault state, if there is either a previous pending fault or a new fault for which NMI is enabled, NMI generation takes place.

Multiple faults can occur at the same time. Consider the case where there is a fault for which Alarm state is enabled and IRQ is programmed along with a fault for which Alarm state is disabled. In that case, the FSM moves to Fault state, but with the generation of alarm IRQ for the fault which has IRQ enabled.

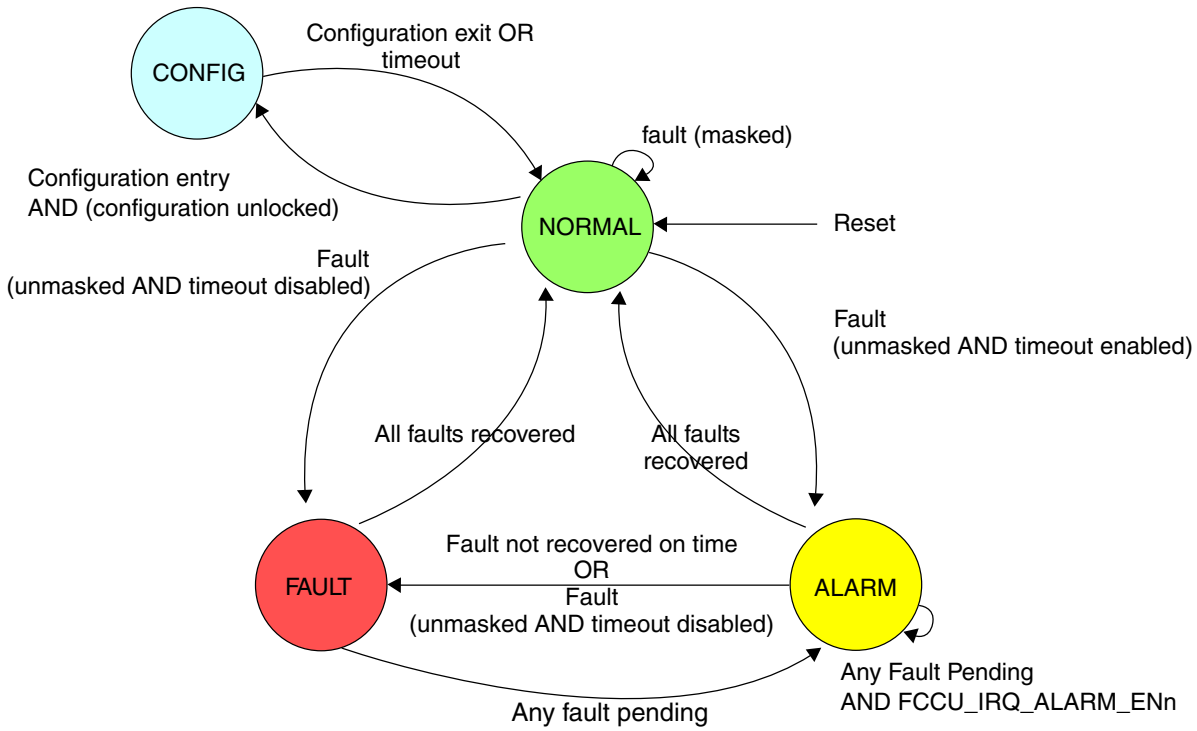

Figure 3-3. FCCU state diagram

3.9.3 Self-checking capabilities

The FCCU includes some features to support self-checking capabilities of the main FSM in running mode. The FSM unit is duplicated and its state (internal state and relevant outputs) is checked by 2 RCCx units (cycle accurate). The following checks (per CLKSAFE cycle) are provided by the RCCx units:

- all the FSM outputs and its internal state for the redundant FSM instances are checked to detect runtime faults on the FSM outputs and its internal state
- parity bits (computed at byte level) on the configuration registers are checked to detect run time faults on the configuration inputs of the FSM
- parity bits (computed at byte level) on the interface used to clear the FCCU_CF_Sx FCCU_UF_Sx and FCCU_RF_Sx status registers
- EOUT protocol state in dual-rail, time-switching and bi-stable mode
- common mode signals (handshake interface signals activated only in CONFIG state) congruence with the FSM state

In case of failure each RCCx unit provides the following reaction:

- an interrupt request to the INTC module.

The RCCx state is freeze in a SC freeze status register (FCCU_SCFS).

To guarantee the self checking capabilities through the FAULT interface, each critical fault source must be duplicated on a couple of critical fault inputs.

Two separate clock inputs (CLKSAFE0 and CLKSAFE1) are routed to the redundant modules (FSMx, RCCx, EOUTx, FAULT-if modules). An off-module monitor of the CLKSAFE clocks and an off-module reaction (functional reset to the MC) is required to cover a potential fault on the CLKSAFE clocks.

Self checking capabilities cover the HW reaction of the FCCU due to the assertion of an external fault. The IPS bus interface and the handshake modules are not covered by self-checking capabilities. Any operation executed by SW (configuration, fault recovery) must be cross-verified by congruence checks via SW (registers read following a write/ clear operation, internal FCCU state, ..).

A typical sequence with self checking failure and related reaction is given inFigure 3-4.

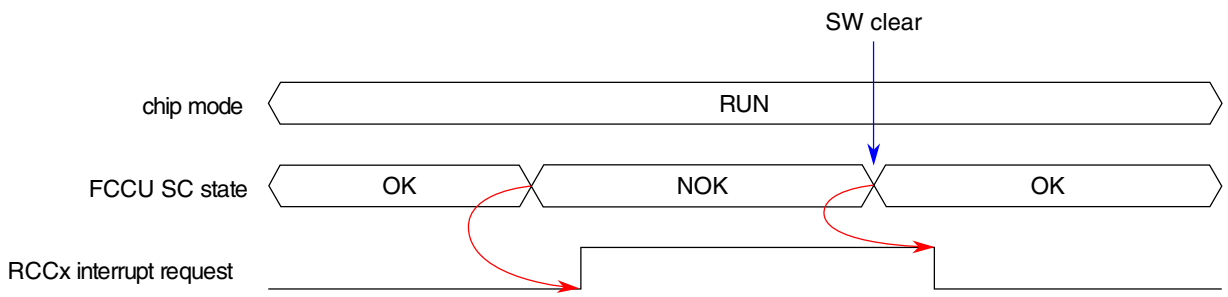

Figure 3-4. Self-checking reaction (interrupt)

For more information about how to enable or disable FCCU Self-checking, see Configuration (FCCU_CFG) and SC Freeze Status (FCCU_SCFS).

3.9.4 Fault priority scheme and nesting

The FAULT state has a higher priority than the ALARM state in case of concurrent fault events (noncritical) that occur in the NORMAL state.

The ALARM to FAULT state transition occurs if a noncritical fault (unmasked and with time-out disabled) is asserted in the ALARM state.

The ALARM to NORMAL state transition occurs only if all the noncritical faults (including the faults that have been collected after the entry in the ALARM state) have been cleared (SW or HW recovery); otherwise the FCCU will remain in the ALARM state.

The FAULT to NORMAL state transition occurs only if all the noncritical faults (including the faults that have been collected after the entry in the FAULT/ALARM state) have been cleared (SW or HW recovery); otherwise the FCCU will move to the ALARM state (if any noncritical fault is still pending and the time-out is not elapsed).

In general, no fault nesting is supported except for the noncritical faults that cause an ALARM to FAULT state transition. In this case the NCF timer is stopped until the FAULT state is recovered. If FCCU is in ALARM state and another fault comes, which has its alarm timeout enabled, then the alarm timer shall not reload and shall not start again.

3.9.5 Fault recovery

The following timing diagrams describe the main use cases of the FCCU in terms of fault events and related recovery.

A typical sequence related to a noncritical FAULT management (ALARM state), see Figure 3-5 and Figure 3-6, is as follows:

- Noncritical fault assertion
- FCCU state transition (automatic): NORMAL → ALARM
  - alarm interrupt request (if enabled)
  - time-out running
- system state: RUN
- alarm interrupt management: FAULT recovery (by SW)
  - FCCU state transition ALARM → NORMAL

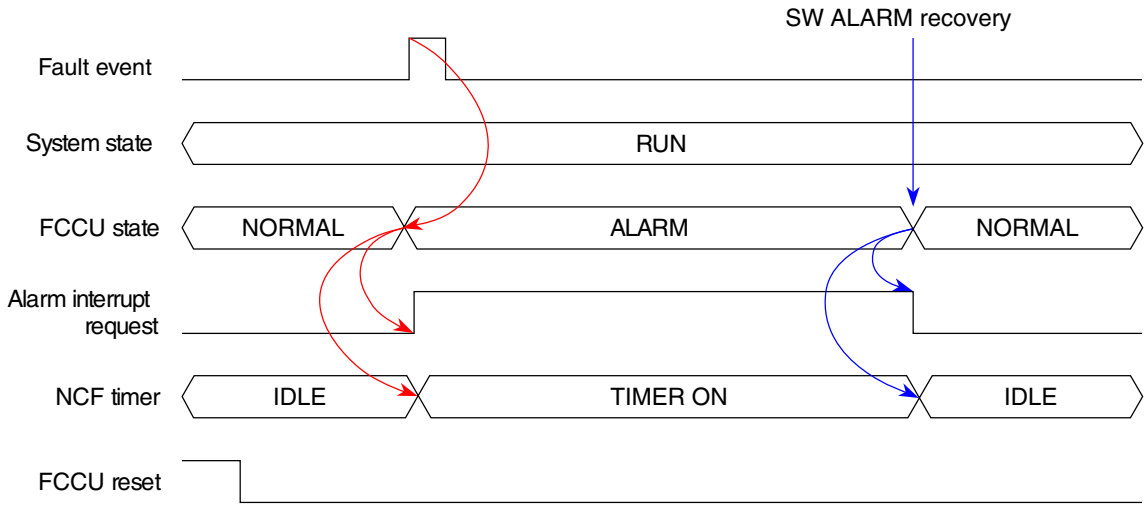

Figure 3-5. Noncritical FAULT (ALARM state) recovery (a)

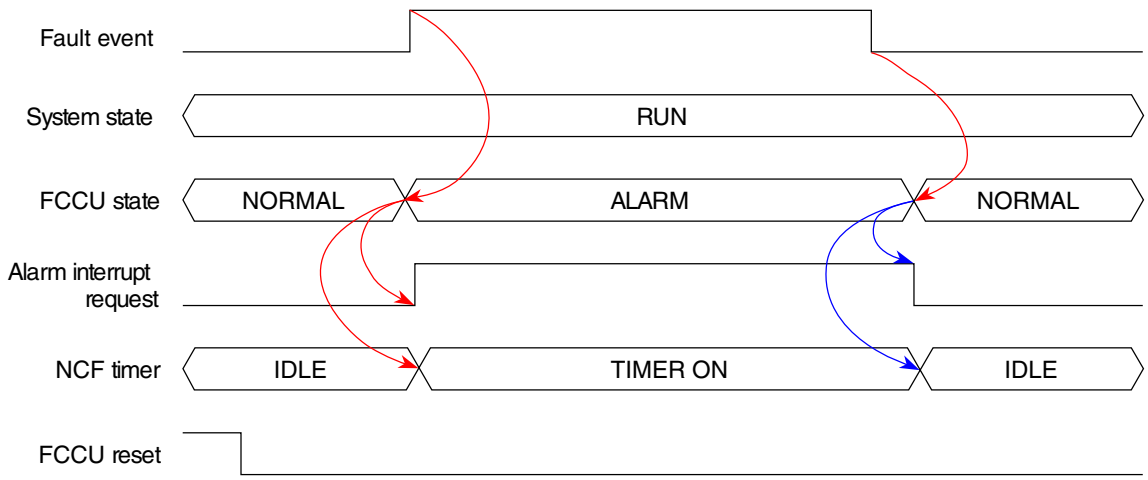

Figure 3-6. Noncritical FAULT (ALARM state) recovery (b)

A typical sequence related to a noncritical FAULT management (ALARM → FAULT state), see Figure 3-7, is as follows:

- Noncritical fault assertion
- FCCU state transition (automatic): NORMAL → ALARM
  - alarm interrupt request (if enabled)
  - time-out running
- FCCU state transition (following the time-out trigger): ALARM → FAULT
  - NMI assertion (if enabled)
- system state transition: RUN → SAFE
- NMI interrupt management (if enabled)

- FAULT recovery (by SW): FCCU state transition FAULT → NORMAL
- system state transition: SAFE → RUN

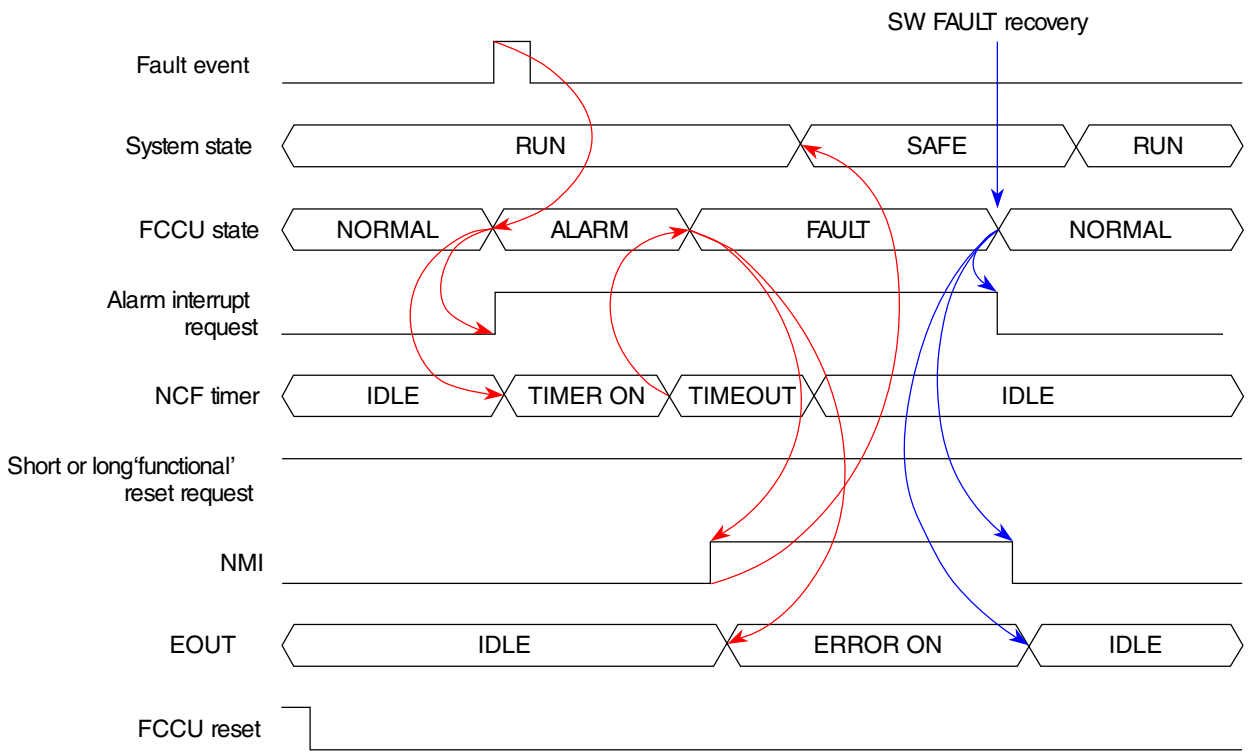

Figure 3-7. FAULT (ALARM → FAULT state) recovery

3.9.6 NMI/WKPU interface

NMIOUT is connected to all processor cores on the chip but is masked when any one of the following is true:

- An FCCU asynchronous reset is in progress.
- The chip is in RESET mode.
- The chip has automatically entered DRUN mode from RESET mode and software has not yet requested another mode change.

This figure shows the logical scheme.

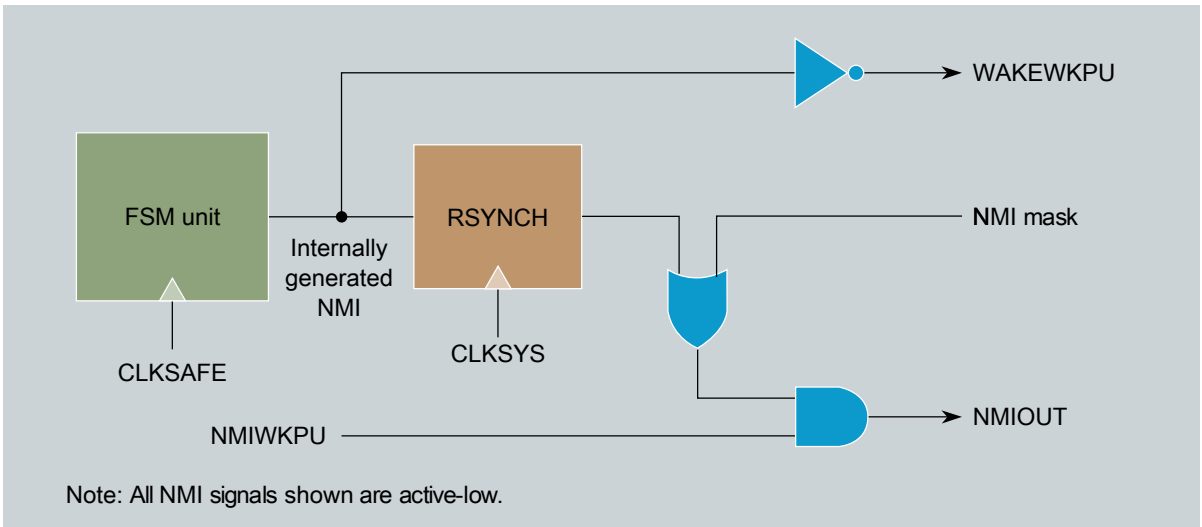

Figure 3-8. NMI/WKPU scheme

3.9.7 STCU interface

The STCU interface includes:

- A set of signals resulting from the self-checking procedure connected externally at the FCCU.

  The STCU fault signals are processed by the FCCU when the SoC is re-booted following the self-testing procedure. The STCU includes a status register that stores the self-testing results (flags).

- a mask that inhibits the EOUT dummy signaling until the STCU self-checking procedure has been completed.

During the self-testing procedure, depending on the STCU results, three cases are applicable:

1. STCU completes the self-testing procedure successfully. The SoC reboots and the FCCU is responsible for fault collection and indication.
2. STCU completes the self-testing procedure with low severity failures. The FCCU records the fault condition but does not, by default, trigger a reset cycle.
3. STCU completes the self-testing procedure with serious failures. The FCCU triggers a reset cycle in response to this fault input from the STCU. Because the fault condition survives reset, new reset cycles are subsequently triggered until the reset escalation feature takes control, freezing the chip in the reset state until a POR. This feature is optionally programmable using MC_RGM.

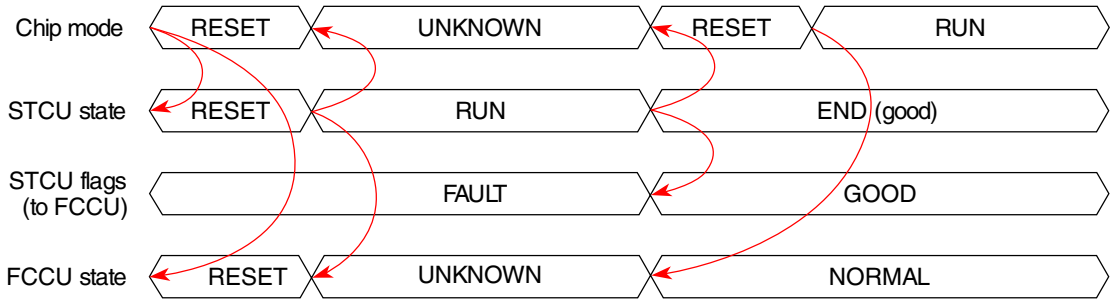

Figure 3-9. STCU-FCCU (case 1)

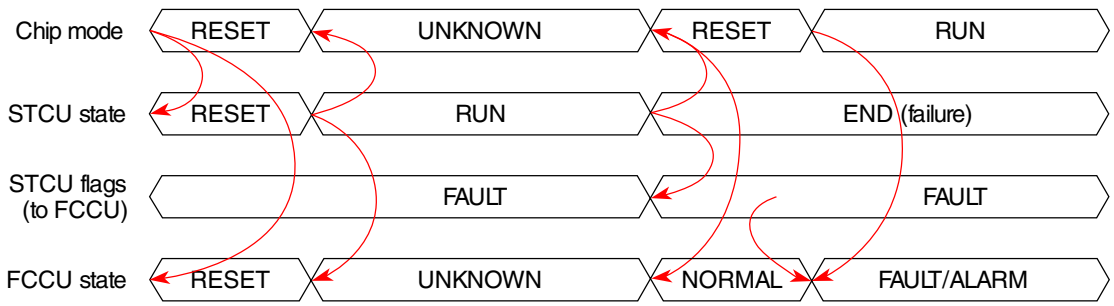

Figure 3-10. STCU-FCCU (case 2)

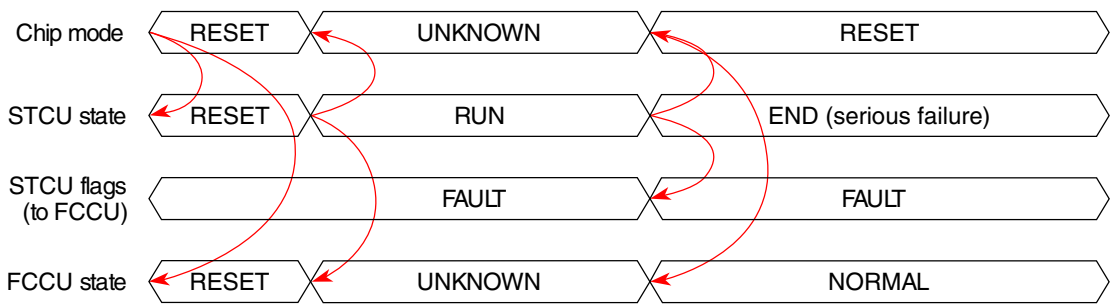

Figure 3-11. STCU-FCCU (case 3)

3.9.8 Nonvolatile memory interface

FCCU includes a nonvolatile memory interface (NVMCFG signals) that provides the values of certain bits in the Configuration (FCCU_CFG) register when certain events occur. See Configuration (FCCU_CFG). Whether any of these signals are actually connected to nonvolatile (flash) memory is chip-specific. Some or all of these signals may be driven by bits in a data record in nonvolatile (flash) memory or may be tied high (1) or low (0). See FCCU_CFG register bit value sources (N and C) by event.

The timing diagram related to the NVM interface is given in Figure 3-12.

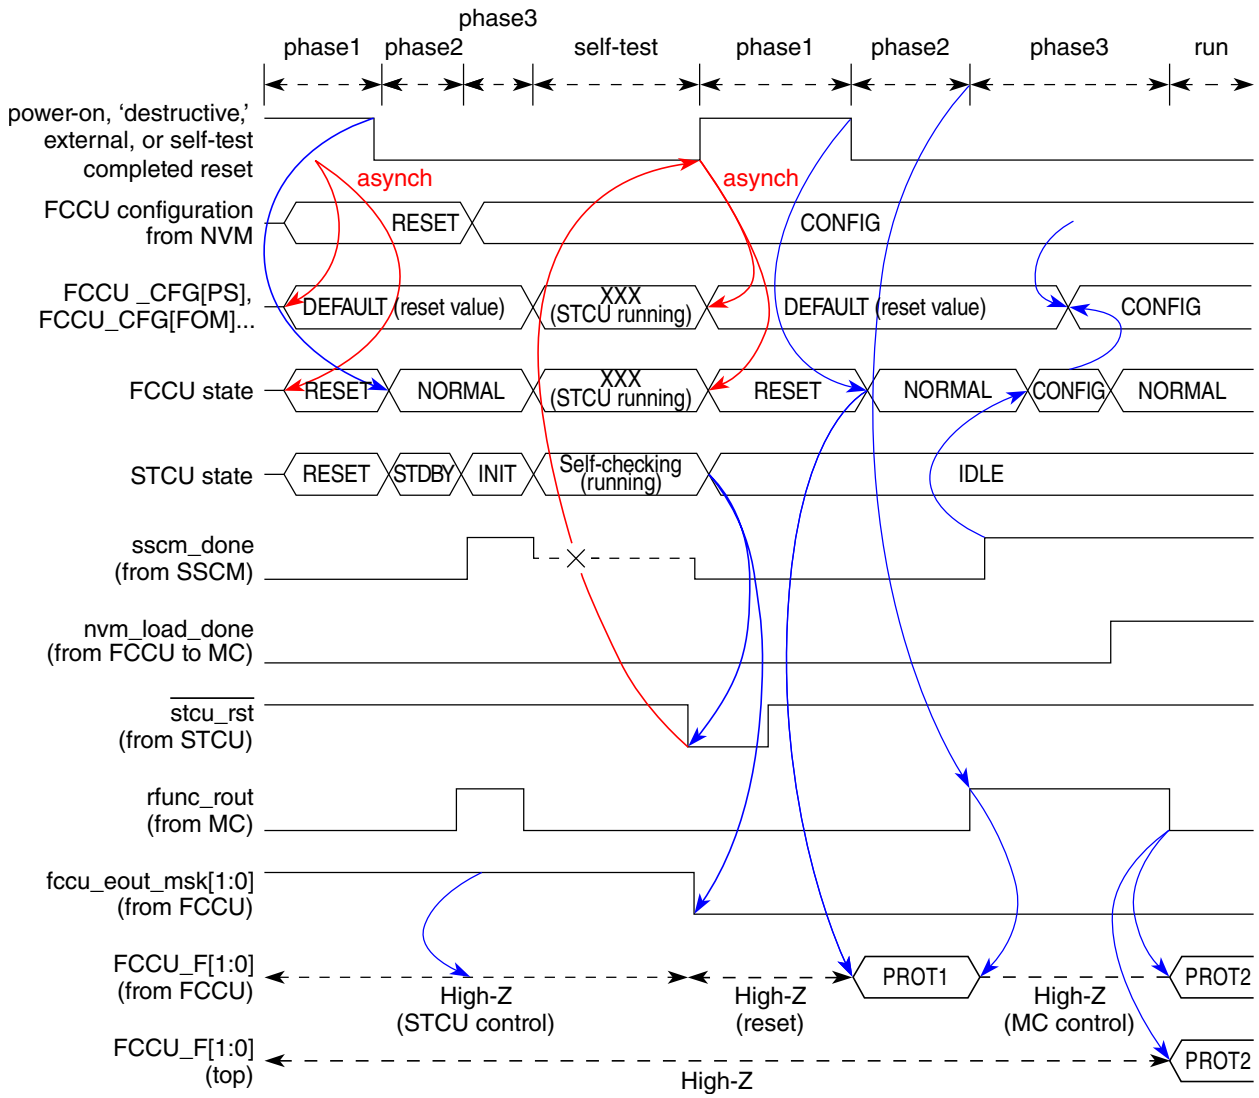

Figure 3-12. NVM interface

3.9.9 EOUT interface

3.9.9.1 Introduction

You use the EOUT[1:0] signals to indicate FCCU's condition to off-chip logic. For information on the availability and names of these FCCU signals on the boundary of this chip, see the chip-specific FCCU information.

3.9.9.2 The FCCU conditions

There are three FCCU conditions:

Condition	Description
Faulty	The fault-output (EOUT) timer is running (see How the fault-output (EOUT) timer works).
Nonfaulty	All of the following are true: • The fault-output (EOUT) timer is not running. • FCCU is in Alarm or Normal state.
Configuration	All of the following are true: • The fault-output (EOUT) timer is not running. • FCCU is in Configuration state.

3.9.9.3 How the fault-output (EOUT) timer works

FCCU starts the fault-output (EOUT) timer when all of the following are true:

- The fault-output (EOUT) signals are not programmed to be always low (FCCU_SET_CLEAR).
- The fault-output (EOUT) timer isn't already running.
- FCCU enters Fault state as the result of a fault.

When the fault-output (EOUT) timer is already running and a new fault occurs:

- When FCCU is in Configuration state: FCCU doesn't restart the fault-output (EOUT) timer.
- When FCCU is in Normal state or Alarm state:
  - And Alarm state is enabled for the fault (noncritical): FCCU enters (or remains in) Alarm state but doesn't restart the fault-output (EOUT) timer.
  - And Alarm state is disabled for the fault (noncritical): FCCU enters Fault state and restarts the fault-output (EOUT) timer.
- When FCCU is in Fault state: FCCU restarts the fault-output (EOUT) timer.

FCCU stops and reinitializes the fault-output (EOUT) timer when all of the following are true:

- If the EOUT signals are in Bistable fault-output mode (FOM), T_min has expired.
- All faults that caused FCCU to enter or remain in Fault state since FCCU started the fault-output (EOUT) timer have been cleared, causing FCCU to return to Normal state.

3.9.9.4 Prepare the EOUT signals to indicate FCCU's condition

Make sure all of the following are true:

- The EOUT signals are active (FCCU_SET_AFTER_RESET).
- The EOUT signals are controlled by FCCU's finite state machine (FCCU_SET_CLEAR).

3.9.9.5 More about the EOUT interface

Different fault-output modes (protocols) for the fault-output (EOUT) interface are supported (FCCU_CFG[FOM]):

- Dual-Rail
- Time-Switching
- Bistable
- Test

You can further configure the fault-output modes using the following attributes:

Attribute	Field	Setting used in the example diagrams and tables that follow
Switching mode	FCCU_CFG[SM]	Slow
Polarity selection	FCCU_CFG[PS]	For the faulty indication, EOUT1 is high, and EOUT0 is low.

The EOUT frequency is generated by dividing the CLKSAFE frequency by a fixed factor of 2^{18}.

With a CLKSAFE frequency of 16 MHz, this drives a signal of 61 Hz on EOUT.

The external monitor of the EOUT protocol should oversample the EOUT signals in order to synchronize periodically the external clock (used by the monitor) and CLKSAFE (which detects the edge transition of the EOUT protocol) in Dual-Rail or Time-Switching fault-output mode.

In case of a failure event or on software request for EOUT indication, the signal(s) are set to the faulty state for a minimum time T_min, even if software tries to release it before. If software configures the error pins to OK(1), and if a fault comes trying to drive the pin to NOK(0), then priority is given to the fault indication and the error signals indicate NOK, such as an incoming fault is not masked when software has set the error signal to high. During the T_min by a non-software fault, the FCCU FSM moves independently of this

signal state (low), and as soon as the timer expires, the pin behavior is dictated by the state in which the FSM finds itself in, and it is not possible to set the signals to OK by software moving FCCU to Configuration state, as long as this timer is running. No software intervention is needed to bring the signal from the low state.

Software can bring the pin back to OK state by clearing the faults and waiting for the T_min interval to expire, after which the FCCU automatically enters Normal state and the error signal indicates OK.

In case another failure event happens within T_min after a first one, the T_min counter is restarted.

NOTE

The transition from Fault to Configuration state is not possible but is shown to display the behavior in all four states—reset, normal, error, and configuration.

NOTE

FCCU remains in Normal state when a fault is disabled; therefore, *NA* (not applicable) appears in the following table.

NOTE

The following table is valid only when the EOUT signals are active (FCCU_SET_AFTER_RESET).

Table 3-5. FCCU error pin behavior on state transitions

Fault signaling state	Transition from Normal to Fault state			Normal+Configuration states			Transition from Normal to Alarm state		
	with Fault disabled | enabled						with Fault disabled | enabled		
	Internal error pin	Error pin enable	Error pad	Internal error pin	Error pin enable	Error pad	Internal error pin	Error pin enable	Error pad
Disabled	NA | OK	NA | 1	NA | OK	OK	1	OK	NA | OK	NA | 1	NA | OK
Enabled	NA | NOK	NA | 1	NA | NOK	OK	1	OK	NA | OK	NA | 1	NA | OK

NOTE

The first time FCCU is in Configuration state, the EOUT pads are in a high-impedance state; thereafter, their states reflect the programmed EOUT protocol.

3.9.9.6 Dual-rail protocol

Dual-rail encoding is an alternate method for encoding bits. In contrast with classical encoding, where each signal carries a single-bit value, dual-rail encoded circuits use two wires to carry each bit. The encoding scheme is given in Table 3-6 and the related timing diagram is given in Figure 3-13 and Figure 3-14.

Table 3-6. Dual-rail encoding

Logical state	Dual-rail encoding (output pins EOUT[1:0])	Note
non-faulty	10	toggling
non-faulty	01	
faulty	00	toggling
faulty	11	
reset	Hi impedence[1]	no toggling
configuration	same as NORMAL	toggling

1. Final value depends on the SoC setting at pad level.

As long as FCCU is in NORMAL or ALARM state, output will show "non-faulty" signal. Output pins EOUT[0:1] will toggle between 01 and 10 with a given frequency of 61 Hz.

In the RESET phase the output pins are set as "high impedance".

Note

Figure 3-13 and Figure 3-14 are formatted to display the behavior in all four phases (reset, normal, error, and config), not to imply transitions between one phase to another. In particular, transition from error phase to config phase is not possible.

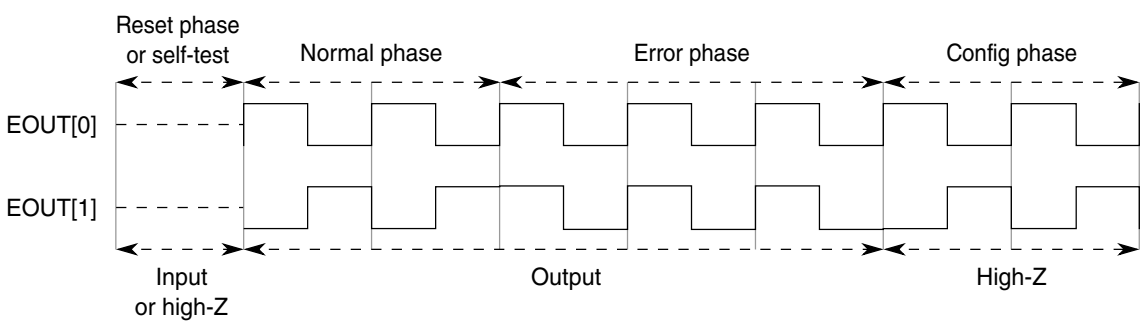

Figure 3-13. Dual-rail protocol (slow switching mode)

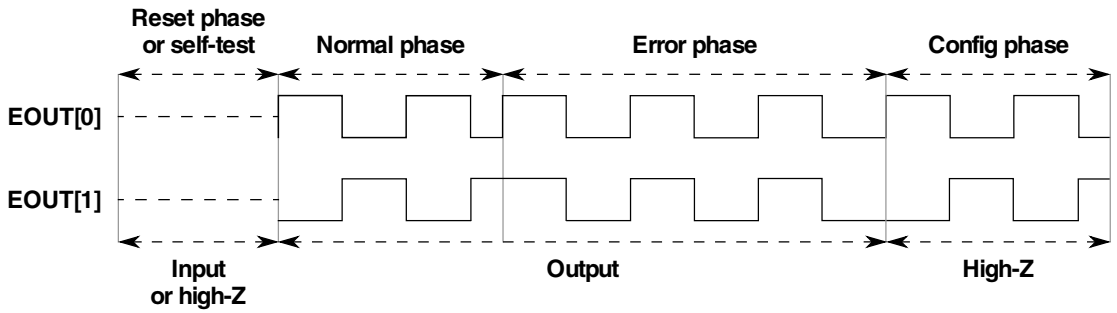

Figure 3-14. Dual-rail protocol (fast switching mode)

3.9.9.7 Time-switching protocol

The encoding scheme is given in Table 3-7 and the related timing diagram is given in Figure 3-15.

Table 3-7. Time-switching encoding

Logical state	Time-switching encoding (output pins EOUT[1:0])	Note
non-faulty	10	toggling
non-faulty	01	
faulty	10	no toggling
reset	high-Z[1]	no toggling
configuration	same as NORMAL	toggling

1. Final value depends on device specific settings at pad level.

As long as FCCU is in NORMAL or ALARM state, outputs will show "non-faulty" signal. Output pins #0, #1 will toggle between 01 and 10 with frequency of 61 Hz.

In the FAULT state, the output pin EOUT[0] is set as low.

In Time Switching mode the second output (EOUT[1]) is the inverted signal of first output (EOUT[0]).

In the RESET phase the output pins are set as "high impedance".[2]

Note

Figure 3-15 is formatted to display the behavior in all four phases (reset, normal, error, and config), not to imply transitions between one phase to another. In particular, transition from error phase to config phase is not possible.

2. Actual value depends on device specific settings at pad level.

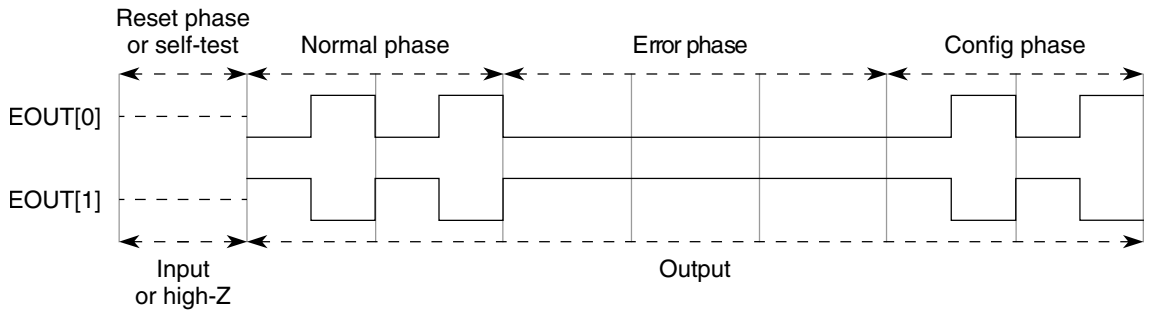

Figure 3-15. Time-switching protocol

3.9.9.8 Bi-stable protocol

The encoding scheme is given in Table 3-8 and the related timing diagram is given in Figure 3-16.

Table 3-8. Bi-stable encoding

Logical state	Bi-stable encoding (output pins EOUT[1:0])	Note
non-faulty	01	no toggling
faulty	10	no toggling
reset	high-Z[1]	no toggling
configuration	same as NORMAL	no toggling

1. Final value depends on device specific settings at pad level.

In the FAULT state, the faulty logical state is indicated. In NORMAL or ALARM state, "no-faulty" state is indicated. In Bi-stable mode the second output (EOUT[1]) is the inverted signal of first output (EOUT[0]).

In the RESET phase the output pins are set as "high impedance".[3]

Note

Figure 3-16 is formatted to display the behavior in all four phases (reset, normal, error, and config), not to imply transitions between one phase to another. In particular, transition from error phase to config phase is not possible.

3. Actual value depends on device specific settings at pad level.

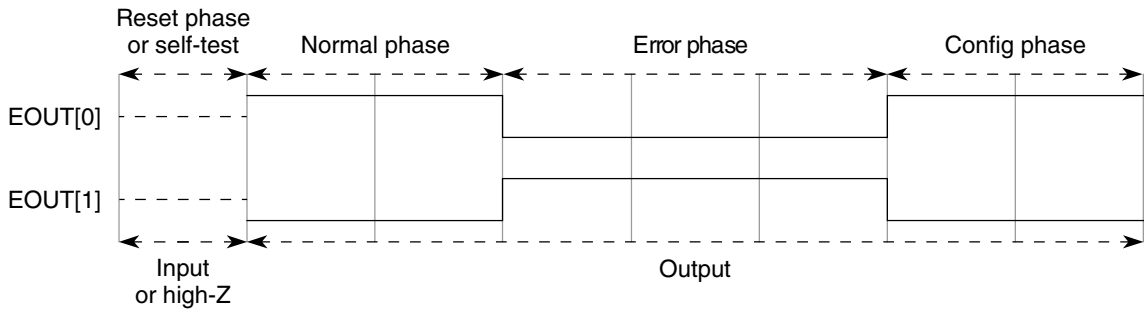

Figure 3-16. Bi-stable protocol

3.9.10 Error signal flow

See the chip-specific FCCU information for the diagram of the signal flow.

3.10 Register descriptions

The FCCU registers are listed in the table below. Any address offset not explicitly mentioned in this table is reserved.

The FCCU supports word (32-bit), half-word (16-bit), and byte (8-bit) read and write accesses.

Follow these register-access guidelines:

- Don't read from or write to any addresses that are not shown in the following table. Doing so may result in a transfer error.
- Don't write to any of the configuration registers unless FCCU is in Configuration state. Doing so results in a transfer error.
- Don't write to FCCU_TRANS_LOCK or FCCU_PERMNT_LOCK unless your code runs in Supervisor mode. Doing so results in a transfer error.

All the registers accessible in write mode only in CONFIG state are referred as configuration registers. These configuration registers return to the default value after configuration watchdog timer expires. These are the registers protected by FCCU_TRANS_LOCK and FCCU_PERMNT_LOCK registers. The configuration register setting has effect only when the FCCU state exits from the CONFIG state.

For each possible NCF failure source, a different reaction—including no reaction—is configurable through the use of NMI, IRQ, and long/short reset selection registers. It is not possible for a single event upset to switch off all reactions on failures as implementation is per fault source (but it will be possible to switch them all off by SW if intended). Failures themselves are not able to disable all reactions and indications.

The FCCU is not reset by short or long functional resets.

3.10.1 Control (FCCU_CTRL)

Initiates and indicates the status of operations, indicates that FCCU successfully loaded configuration data from the NVMCFG signals, controls glitch-filter settings, and enables Debug mode.

Address: 0h base + 0h offset = 0h

FCCU_CTRL field descriptions

Field	Description
0 FILTER_ BYPASS	Filter bypass 0 glitch filter not bypassed 1 glitch filter bypassed
1–2 FILTER_WIDTH	Filter width 00 filters glitches up to 50 µs 01 filters glitches up to 75 µs 10 filters glitches up to 100 µs 11 filters glitches up to 100 µs

Table continues on the next page...

FCCU_CTRL field descriptions (continued)

Field	Description
3–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22 DEBUG	Debug Mode Enable Specifies whether Debug mode is enabled. If so, FCCU enters Debug mode when the Debug signal is asserted. When FCCU enters Debug mode, it halts operation and remains in the state it was in before it entered Debug mode. **NOTE:** FOSU doesn't halt when FCCU enters Debug mode. Therefore, FOSU can still cause a reset if a fault occurs while FCCU is in Debug mode. 0 Disabled 1 Enabled
23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–25 OPS	Operation status. This bit can be read and cleared (via OP15 operation) by the software. 00 Idle 01 In progress 10 Aborted 11 Successful
26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27–31 OPR	Operation Run Initiates operations that perform actions such as putting FCCU in Configuration state or reading a timer. For information on how to run operations, see Run operations. FCCU ignores any write to this field while the operation status (OPS) is In Progress. After completion of an operation, FCCU sets this field to OP0. The following events result in an operation status (OPS) of Aborted: • Writing to a Noncritical Fault Status (FCCU_NCF_S*n*) register (which automatically initiates the OP12 operation) without first successfully unlocking the register (NCFK) • Initiating an OP1 operation when FCCU is not in Normal state or the configuration is locked • Initiating an OP1, OP2, or OP31 operation without first unlocking the operation (CTRLK) 00000 OP0—No operation 00001 OP1—Applies only when the configuration is unlocked, when FCCU is in Normal state, and immediately after you unlock the operation (CTRLK). Put FCCU in Configuration state. 00010 OP2—Applies only immediately after you unlock the operation (CTRLK). Put FCCU in Normal state. 00011 OP3—Capture FCCU's state and the states of the EOUT signals in the Status (FCCU_STAT) register. 00100 OP4—Read the FCCU frozen status flags (NA Freeze Status (FCCU_N2AF_STATUS)). 00101 OP5—Read the FCCU frozen status flags (AF Freeze Status (FCCU_A2FF_STATUS)). 00110 OP6—Read the FCCU frozen status flags (NF Freeze Status (FCCU_N2FF_STATUS)). 00111 OP7—Read the FCCU frozen status flags (FA Freeze Status (FCCU_F2A_STATUS)). 01000 OP8—Read the FCCU frozen status flags (SC Freeze Status (FCCU_SCFS)). 01001 Reserved

Table continues on the next page...

FCCU_CTRL field descriptions (continued)

Field	Description
	01010 OP10—Read the Noncritical Fault Status (FCCU_NCF_S*n*) register. 01011 Reserved 01100 OP12—Do not initiate this operation; it is automatically initiated by FCCU. A Noncritical Fault Status (FCCU_NCF_S*n*) register status clear operation is in progress. 01101 OP13—Clear the freeze status registers (see the freeze registers). 01110 OP14—Do not initiate this operation; it is automatically initiated by FCCU. A Configuration-state timeout is in progress. For more information, see Configuration registers. 01111 OP15—Set the operation status (OPS) to Idle. 10000 Reserved 10001 OP17—Read the Alarm-state timer (XTMR). 10010 Reserved 10011 OP19—Read the Configuration-state timer (XTMR). 10100 Reserved 10101–11110 Forbidden. Writing any of these values returns an operation status (OPS) of Aborted with no side effect. 11111 OP31—Applies only immediately after you unlock the operation (CTRLK). Load configuration data from the NVMCFG signals to certain fields in the Configuration (FCCU_CFG) register, but without resetting FCCU (for testing and debugging). See FCCU_CFG register bit value sources (N and C) by event. The operation status (OPS) for this operation is always Successful.

3.10.2 Control Key (FCCU_CTRLK)

Writable only with a 32-bit write. Unlocks locked operations so you can initiate them (OPR). For information on how to unlock locked operations before you initiate them, see Run an operation.

NOTE

Reading from this register always returns the value 0000_0000h.

Address: 0h base + 4h offset = 4h

FCCU_CTRLK field descriptions

Field	Description
0–31 CTRLK	Locked-Operation Control Key

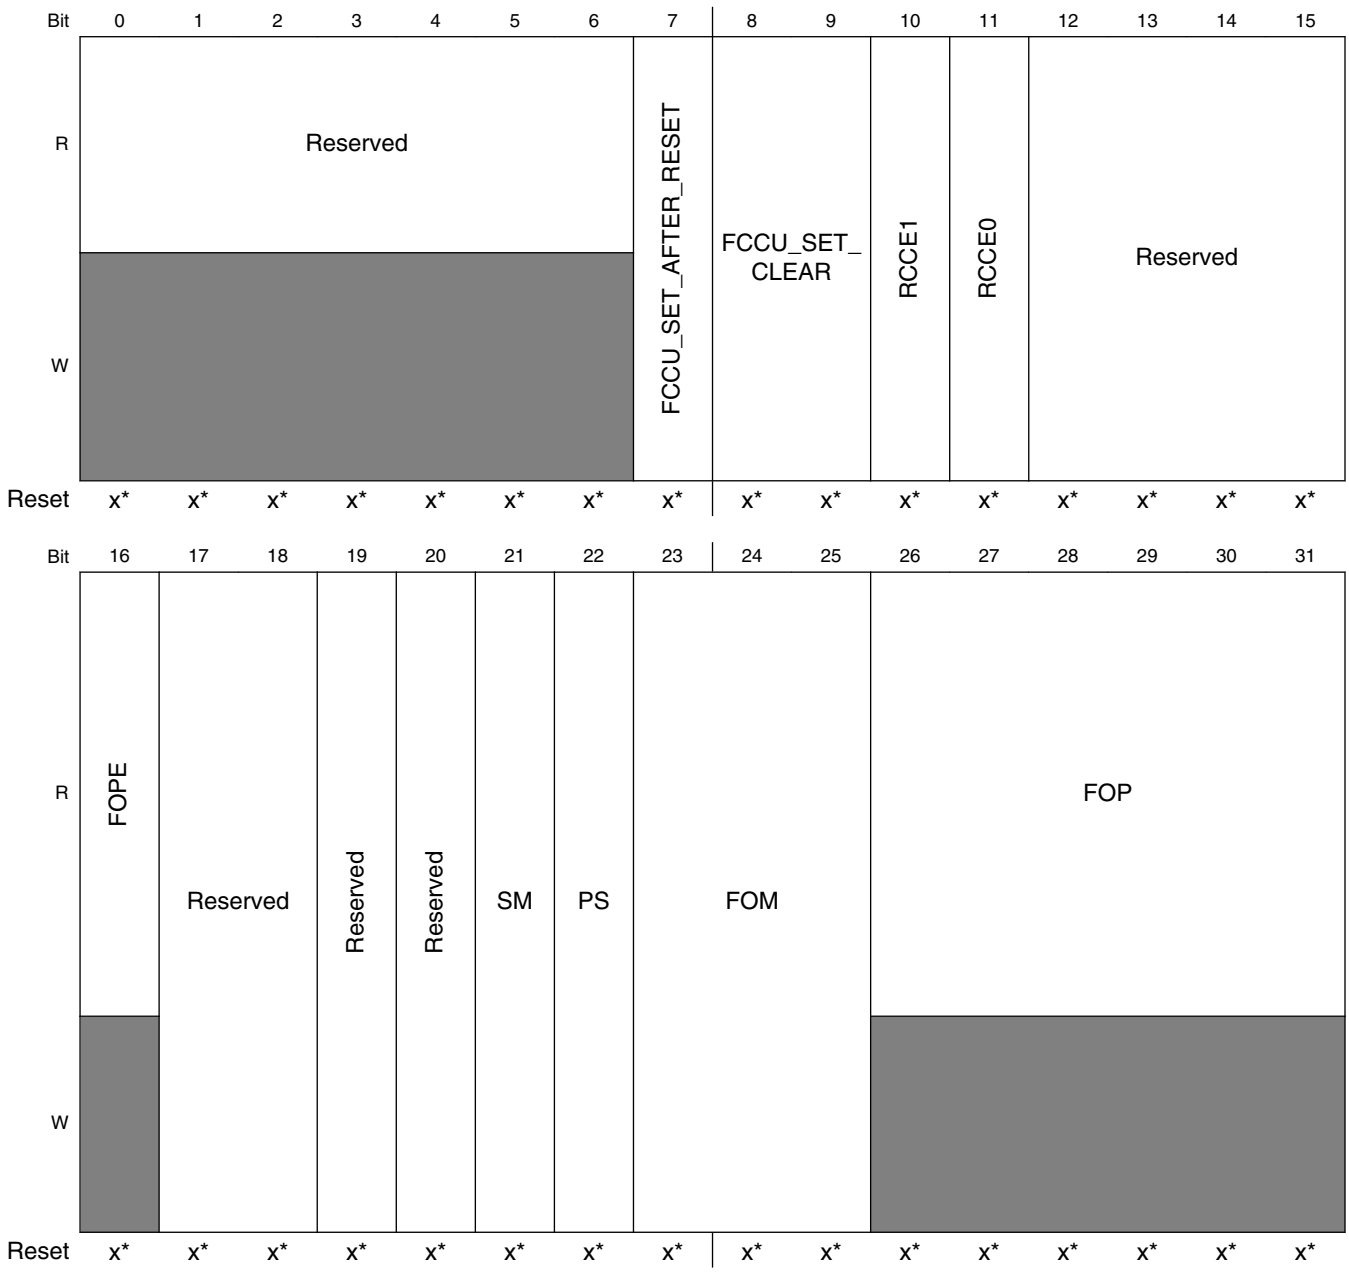
FCCU_CTRLK field descriptions (continued)

Field	Description
	Unlocks locked operations so you can initiate them (OPR). For information on how to unlock locked operations before you initiate them, see Run an operation. **NOTE:** You must initiate an operation in the instruction that immediately follows the instruction that unlocks it; otherwise, the operation is again locked. 9137_56AFh: Unlock OP1. 825A_132Bh: Unlock OP2. 29AF_8752h: Unlock OP31. Any other value: Do nothing.

3.10.3 Configuration (FCCU_CFG)

Writable only when FCCU is in Configuration state. Specifies the global configuration for FCCU.

The values of the bits in this register are affected by writes as well as any of the following events:



- The chip resets FCCU.
- FCCU automatically leaves Configuration state and enters Normal state because the configuration-timer interval (TO) expires. This is called a Configuration-state timeout.
- You run an OP31 operation.

For information on the sources of bit values for these events, see FCCU_CFG register bit value sources (N and C) by event.

NOTE

If you specify a new value for any of the fields in this register that affect the EOUT signals while the fault-output (EOUT) timer is running (FCCU is indicating a fault on the EOUT signals), FCCU doesn't use the new settings you specified until after the fault-output (EOUT) timer expires (FCCU stops indicating a fault on the EOUT signals).

Address: 0h base + 8h offset = 8h

* Notes:

- For information on this register's reset value, see FCCU_CFG register bit value sources (N and C) by event.x = Undefined at reset.

FCCU_CFG field descriptions

Field	Description
0–6 Reserved	This field is reserved.

Table continues on the next page...

FCCU_CFG field descriptions (continued)

Field	Description
7 FCCU_SET_ AFTER_RESET	Fault-Output (EOUT) Activate For fault-output (EOUT) signaling, controls whether the EOUT signals are active. 0 Inactive (the EOUT signals are in a high-impedance state) 1 Active (the EOUT signals indicate FCCU's condition)
8–9 FCCU_SET_ CLEAR	Fault-Output (EOUT) Control Applies only when the EOUT signals are active (FCCU_SET_AFTER_RESET). Controls whether the fault-output (EOUT) signals are controlled by FCCU's finite state machine (FSM). 00 Controlled by the FSM 01 Always low 10 Controlled by the FSM 11 High until a fault occurs on a channel, regardless of whether that fault is disabled; thereafter, controlled by the FSM. Note: FCCU ignores an attempt to write this value if the fault-output (EOUT) timer is already running.
10 RCCE1	Redundancy Control Checker 1 Enable For the self-checking feature, controls whether FCCU's redundancy control checker 1 (RCC1) is enabled. **NOTE:** • Always enable any RCCs in a separate register access after activating the EOUT signals (FCCU_SET_AFTER_RESET). • If only one RCC is enabled and a self-check fails, both RCCs assert an interrupt. 0 Disabled 1 Enabled
11 RCCE0	Redundancy Control Checker 0 Enable For the self-checking feature, controls whether FCCU's redundancy control checker 0 (RCC0) is enabled. **NOTE:** • Always enable any RCCs in a separate register access after activating the EOUT signals (FCCU_SET_AFTER_RESET). • If only one RCC is enabled and a self-check fails, both RCCs assert an interrupt. 0 Disabled 1 Enabled
12–15 Reserved	This field is reserved. Always write the reset value to this field.
16 FOPE	Fault-Output (EOUT) Prescaler Extension For fault-output (EOUT) signaling, specifies the most significant bit of the derived prescaler that controls the signaling frequency. For more information, see the description of the FOP field.
17–18 Reserved	This field is reserved. Always write the reset value to this field.
19 Reserved	This field is reserved. Always write the reset value to this field.
20 Reserved	This field is reserved. Always write the reset value to this field.
21 SM	Fault-Output (EOUT) Switching Mode For fault-output (EOUT) signaling, controls how quickly the signals switch between faulty and nonfaulty indication. Applies only to Dual-Rail and Time-Switching fault-output modes.

Table continues on the next page...

FCCU_CFG field descriptions (continued)

Field	Description
	0 Slow: No EOUT frequency violation during the FCCU state transition (Normal to Fault or vice versa, and Configuration to Normal). The indication transition occurs after a maximum delay equal to the duration of the semiperiod of the EOUT frequency. 1 Fast: The indication transition (Normal to Fault or vice versa, and Configuration to Normal) occurs immediately. A pulse with the minimum duration corresponding to the CLKSAFE period can occur in this mode. It implies a frequency violation of the EOUT protocol.
22 PS	Fault-Output (EOUT) Polarity Selection For fault-output (EOUT) signaling, controls the polarity of the signals for fault-output-mode indications that hold the signals low or high (versus toggling them or placing them in a high-impedance state). Applies only to Time-Switching fault-output mode (for faulty and configuration indications) and Bistable fault-output mode (for all indications). 0 For the faulty indication, EOUT1 is high, and EOUT0 is low. 1 For the faulty indication, EOUT1 is low, and EOUT0 is high.
23–25 FOM	Fault-Output (EOUT) Mode For fault-output (EOUT) signaling, controls the protocol of the signaling. **NOTE:** In the test modes, a simple double-stage resynchronization stage is used to resynchronize the EOUT input/outputs with CLKSAFE. 000 Dual-Rail (default state) [EOUT[1:0]= outputs] 001 Time-Switching [EOUT[1:0]= output to be used] 010 Bistable 011 Reserved 100 Reserved 101 Test 0 (controlled by the FCCU_EINOUT register; EOUT1 is an output; EOUT0 is an input) 110 Test 1 (controlled by the FCCU_EINOUT register; EOUT1 and EOUT0 are both outputs) 111 Test 2 (controlled by the FCCU_EINOUT register; EOUT1 is an input; EOUT0 is an output)
26–31 FOP	Fault-Output (EOUT) Prescaler For fault-output (EOUT) signaling, specifies the least significant bits of the derived prescaler that controls the signaling frequency. The derived prescaler is the concatenation of FOPE and FOP and is represented by *{FOPE, FOP}*. The following equation defines the signaling frequency in terms of the CLKSAFE frequency ($CLKSAFE_{freq}$) and the derived prescaler: $EOUT_{freq} = CLKSAFE_{freq} / ((\{FOPE, FOP\} + 1) \times 2 \times 2048)$ The following example values and meanings are for the derived (7-bit) prescaler, not FOP alone. The meanings show the derived prescaler followed by the corresponding value by which the input clock frequency is then divided. 0000000: 0; divide by 2 × 2048 (4096) 0000001: 1; divide by 4 × 2048 (8192) 0000010: 2; divide by 6 × 2048 (12,288) … 0001000: 8; divide by 18 × 2048 (36,864) … 1111101: 125; divide by 252 × 2048 (516,096)

Table continues on the next page...

FCCU_CFG field descriptions (continued)

Field	Description
	1111110: 126; divide by 254 × 2048 (520,192) 1111111: 127; divide by 256 × 2048 (524,288) **NOTE:** Writing to FCCU_CFG sets FOP to 0.

3.10.4 Noncritical Fault Configuration (FCCU_NCF_CFG*n*)

Contains the configuration of noncritical faults in terms of fault-recovery management. The configuration depends on the type of signaling of a fault event. Hardware-recoverable faults should be configured only if a previous latching stage captures and holds the physical fault; otherwise, the fault can be lost. All other faults should be configured as software faults.

NOTE

These registers are writable only when FCCU is in Configuration state.

Noncritical Fault Configuration (FCCU_NCF_CFG*n*) register (value of n)	Offset	NCFCx fields (value of x)	
		Most significant (leftmost) bit	Least significant (rightmost) bit

FCCU_NCF_CFG*n* field descriptions

Field	Description
0–31 NCFCx	Noncritical Fault Configuration. Defines the fault recovery mode. Hardware-recoverable faults are self-recovered (status flag clearing and related) if the root cause (input fault) has been removed. Software-recoverable faults are recovered (status flag clearing) by software clearing of the related status flag. For the mapping of the NCFCx fields among registers, see the earlier table in this register description.

FCCU_NCF_CFG*n* field descriptions (continued)

Field	Description
	0 Hardware-recoverable fault 1 Software-recoverable fault

3.10.5 Noncritical Fault State Configuration (FCCU_NCFS_CFG*n*)

The FCCU_NCFS_CFGx registers contain the configuration of each noncritical fault in terms of fault reaction (short or long functional reset request pulse) when it is the root cause for the FAULT state transition.

NOTE

These registers are writable only when the FCCU is in the CONFIG state.

Table 3-9 shows FCCU configuration register channels.

Table 3-9. FCCU NCFS configuration register channels

Address offset	Register name	Channel range (x)
4Ch	FCCU_NCFS_CFG0	NCFSCx[15:0]

Field	Description
0–31 NCFSCx	Noncritical fault state configuration See Table 3-9 for register offset to channel number relationship. 00 No reset reaction 01 Short functional reset request pulse (FAULT state reaction) 10 Long functional reset request pulse (FAULT state reaction) 11 No reset reaction

3.10.6 Noncritical Fault Status (FCCU_NCF_S*n*)

The FCCU_NCF_Sx register contains the latched fault indication collected from the noncritical fault sources. Faults are latched also in the CONFIG state and independently from the enabling or reactions programmed for the NCF.

No reactions are executed until the FCCU moves in the NORMAL state.

FCCU reacts and moves from the NORMAL state into the ALARM state only if the respective enable bit for a fault is set in the FCCU_NCF_Ex register and the respective enable bit for the timeout is set in the FCCU_TOEx register.

FCCU reacts and moves from the NORMAL or ALARM state into the FAULT state if the respective enable bit for a fault is set in the FCCU_NCF_Ex register and the respective enable bit for the timeout is disabled in the FCCU_TOEx register.

FCCU reacts and moves from the ALARM state into the FAULT state if the timeout (FCCU_TO register) is elapsed before recovering from the fault.

The timeout is stopped only when the FCCU returns in the NORMAL state.

The FCCU_NCF_Sx register is encoded respectively into the N2FF_STATUS or A2FF_STATUS register to freeze the entry condition in the FAULT state. The status bits of the FCCU_NCF_Sx register, configured as SW recoverable faults, can be cleared by the following locked sequence:

1. Write the proper key into the FCCU_NCFK register.
2. Clear the status (flag) bit NCFSx => the opcode OP12 is automatically set into the FCCU_CTRL.OPR field.
3. Wait for the completion of the operation (FCCU_CTRL.OPS field).
4. Read the FCCU_NCF_Sx register in order to verify the effective deletion and in case of failure to repeat the sequence.

As result of the above sequence, in addition the FAULT interface provides support to clear the external fake FAULT root .

NOTE

There should not be any other operation in between the above steps.

The FCCU moves from the FAULT or ALARM state into the NORMAL state if all the source faults that caused the transition into the FAULT state have been removed (HW recoverable fault) or cleared via SW (SW recoverable fault). In case of nested faults that are not all recovered, the FCCU will remain in the FAULT or ALARM state.

The SW application executes the FCCU_NCF_Sx read operation by the following sequence:

1. Set the OP10 operation into the FCCU_CTRL.OPR field.
2. Wait for the completion of the operation (FCCU_CTRL.OPS field).
3. Read the FCCU_NCF_Sx register.

In case of re-configuration of the FCCU (CONFIG state), before to return in NORMAL state the pending status bits into the FCCU_NCF_Sx must be cleared in order to avoid a false transition in ALARM/FAULT state.

The following faults are ignored:

- to write a wrong key into the FCCU_NCFK register
- to attempt to clear a HW recoverable fault

Noncritical Fault Status (FCCU_NCF_S*n*) register (value of n)	Offset	NCFSx fields (value of x)	
		Most significant (leftmost) bit	Least significant (rightmost) bit
0	80h	31	0

FCCU_NCF_S*n* field descriptions

Field	Description
0–31 NCFSx	Noncritical fault status. The status bits related to the noncritical fault configured as HW recoverable faults are read-only and the flag is self cleared when the fault source is removed. For the mapping of the NCFSx fields among registers, see the earlier table in this register description. 0 No "noncritical" fault latched 1 "Noncritical" fault latched

3.10.7 Noncritical Fault Key (FCCU_NCFK)

The FCCU_NCFK register implements the key access to clear the status flags of the FCCU_NCF_Sx register.

The status bits of the FCCU_NCF_Sx register, configured as SW recoverable faults, can be cleared by the following locked sequence:

1. Write the key into the FCCU_NCFK register.
2. Clear the status (flag) bit NCFSx .

The key must be written for each FCCU_NCF_Sx clear operation.

The FCCU_NCFK register is not readable; a 0000_0000h value is always returned in case of read operation.

Address: 0h base + 90h offset = 90h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

FCCU_NCFK field descriptions

Field	Description
0–31 NCFK	Noncritical fault key = AB34_98FEh

3.10.8 Noncritical Fault Enable (FCCU_NCF_E*n*)

The FCCU_NCF_En registers enable the fault sources to allow a transition from the NORMAL into the FAULT or ALARM state. In case of fault masking, the respective status bit into the FCCU_NCF_Sn register is set (for debugging purposes), only the reaction is masked.

NOTE

These registers are writable only when the FCCU is in the CONFIG state.

NOTE

Any enabled fault should be programmed to result in a defined action. For example, set up an ALARM IRQ action by programming the IRQ Alarm Enable Register (FCCU_IRQ_ALARM_ENn).

Noncritical Fault Enable (FCCU_NCF_E*n*) register (value of n)	Offset	NCFEx fields (value of x)

FCCU_NCF_E*n* field descriptions

Field	Description
0–31 NCFEx	Noncritical fault enable For the mapping of the NCFEx fields among registers, see the earlier table in this register description. 0 No actions following the respective noncritical fault assertion 1 FCCU moves to ALARM or FAULT state

3.10.9 Noncritical Fault Timeout Enable (FCCU_NCF_TOE*n*)

The FCCU_NCF_TOEx registers enable a transition from the NORMAL state into the ALARM state if the respective noncritical fault is enabled (NCFEx and NCFTOEx are set). In case the respective timeout is disabled (NCFTOEx is cleared) and the noncritical fault is enabled (NCFEx is set) the FCCU moves into the FAULT state if the related noncritical fault is asserted. The timer (preset with the timeout value defined by FCCU_TO register) is started when the FCCU moves into the ALARM state. If the fault is not recovered within the timeout the FCCU moves from the ALARM state to the FAULT state.

NOTE

These registers are writable only when the FCCU is in the CONFIG state.

Noncritical Fault Timeout Enable (FCCU_NCF_TOE*n*) register (value of n)	Offset	NCFTOEx fields (value of x)	
		Most significant (leftmost) bit	Least significant (rightmost) bit

FCCU_NCF_TOE*n* field descriptions

Field	Description
0–31 NCFTOEx	Fault timeout enable For the mapping of the NCFTOEx fields among registers, see the earlier table in this register description. 0 FCCU moves into the FAULT state if the respective fault is enabled 1 FCCU moves into the ALARM state if the respective fault is enabled

3.10.10 Noncritical Fault Timeout (FCCU_NCF_TO)

Defines the preset value of the timer for the recovery of enabled noncritical faults. Once FCCU enters Alarm state, following the assertion of a noncritical fault that is enabled (NCFEa and NCFTOEa are set), the timer starts the countdown.

If the fault is not recovered within the timeout period, the FCCU moves from the Alarm state to the Fault state. The alarm timeout value should be programmed to be less than FOSU_COUNT, or destructive resets may be generated by FOSU timeouts.

NOTE

This register is writable only when FCCU is in Configuration state.

Address: 0h base + B4h offset = B4h

FCCU_CFG_TO field descriptions

Field	Description
0–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29–31 TO	Configuration-State Timer Interval Controls the maximum amount of time (T_max) that FCCU can be in Configuration state according to this equation: T_max = $T_{16MHz} \times 2^{(TO + 10)}$ If you put FCCU in Configuration state and this timer interval expires (called a Configuration-state timeout), then FCCU: • Automatically leaves Configuration state and enters Normal state. • Changes the value of the Configuration (FCCU_CFG) register to its Configuration-state-timeout value and the value of each of the other configuration registers to its reset value. For information on the Configuration (FCCU_CFG) register's Configuration-state-timeout value, see FCCU_CFG register bit value sources (N and C) by event. For a list of configuration registers, see Configuration registers.

Table continues on the next page...

FCCU_CFG_TO field descriptions (continued)

Field	Description
	NOTE: Make sure the Configuration-state timer interval is less than the FOSU module's timer interval; otherwise, a fault that occurs while FCCU is in Configuration state can cause FOSU to generate a chip reset. The FOSU timer interval (FOSU_COUNT) is chip-specific. See the chip-specific FCCU information. 000: 64 µs ... 111: 8192 µs

3.10.12 IO Control (FCCU_EINOUT)

The FCCU_EINOUT register allows the following operations typically in NORMAL state:

- to control the EOUT[1] output level when the FCCU is configured in "Test1" or "Test0" fault output mode (FCCU_CFG.FOM)
- to control the EOUT[0] output level when the FCCU is configured in "Test1" or "Test2" fault output mode (FCCU_CFG.FOM)
- to observe the EOUT[1:0] signals in input mode

Table 3-10 shows Bi-stable encoding.

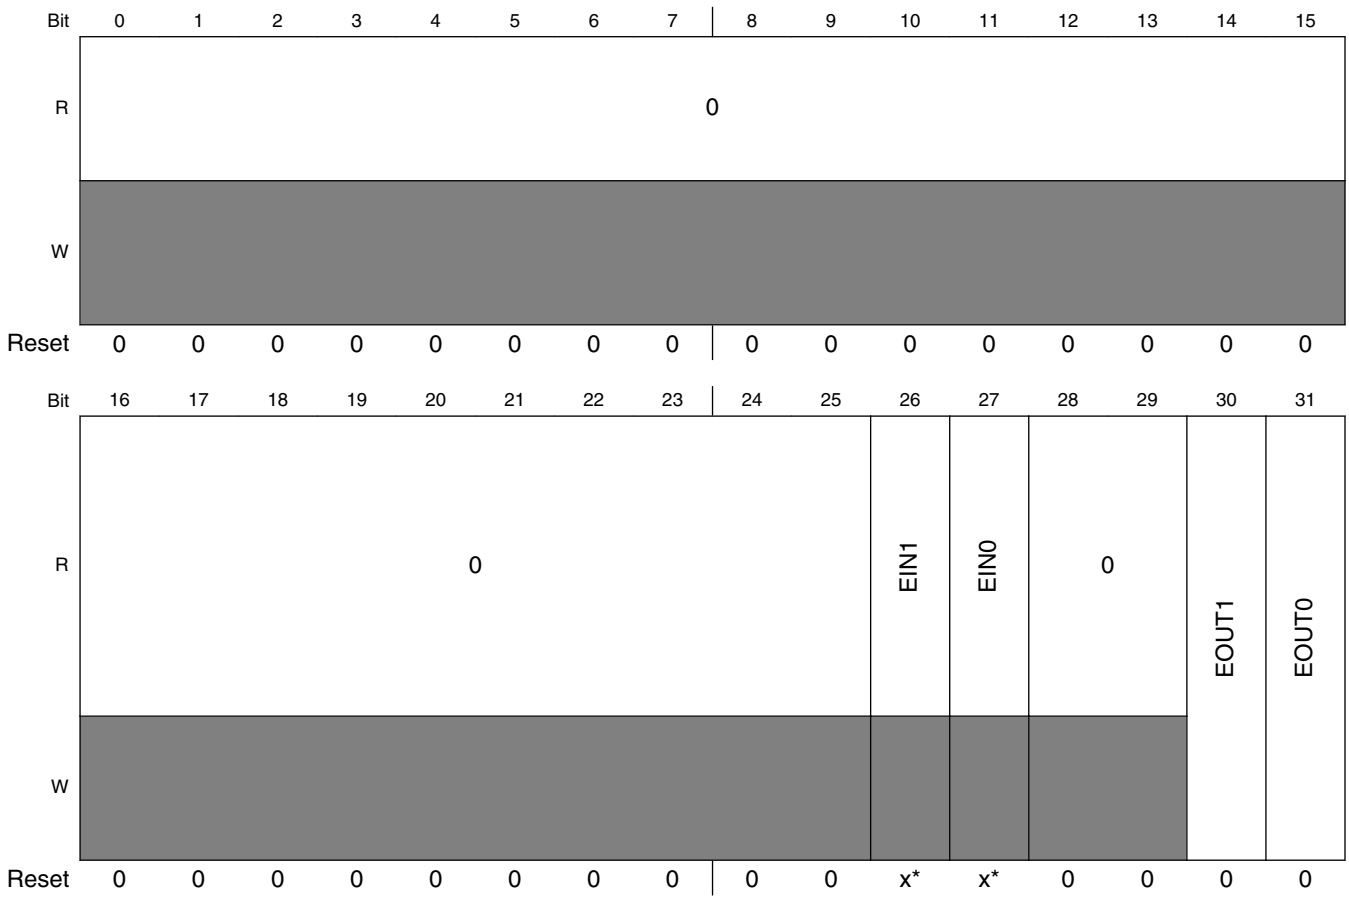

Table 3-10. Bi-stable encoding

Mode = FCCU_CFG.FOM	EOUT[0]	EOUT[1]
Test1	output	output
Test2	output	input
Test0	input	output

NOTE

Due to the resynchronization stage of the EOUT interface, there is a latency of a few CLKSAFE cycles following a write/read operation of the FCCU_EINOUT register.

Address: 0h base + BCh offset = BCh

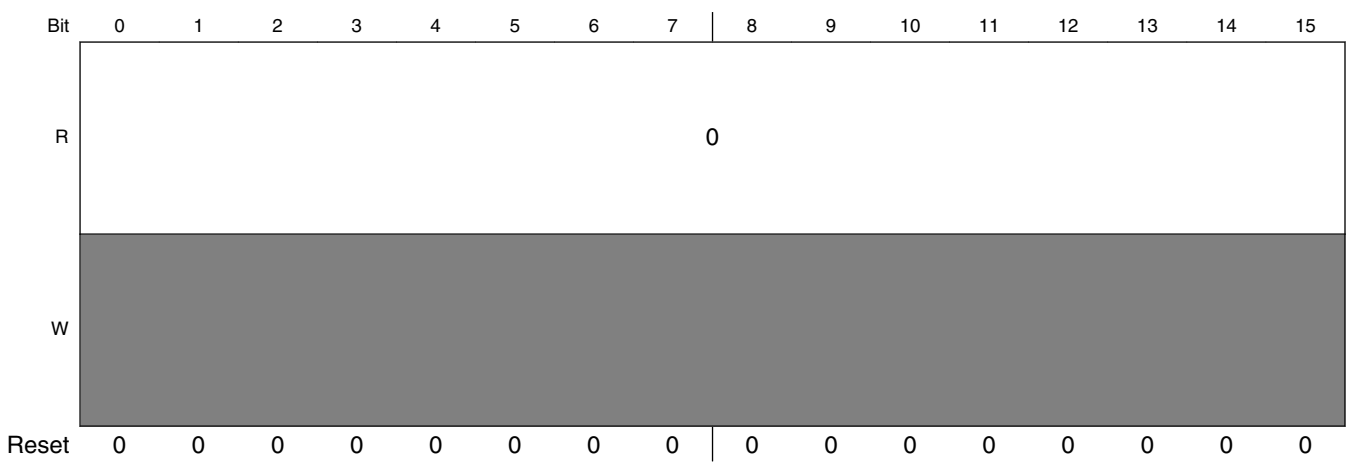
* Notes:
- x = Undefined at reset.

FCCU_EINOUT field descriptions

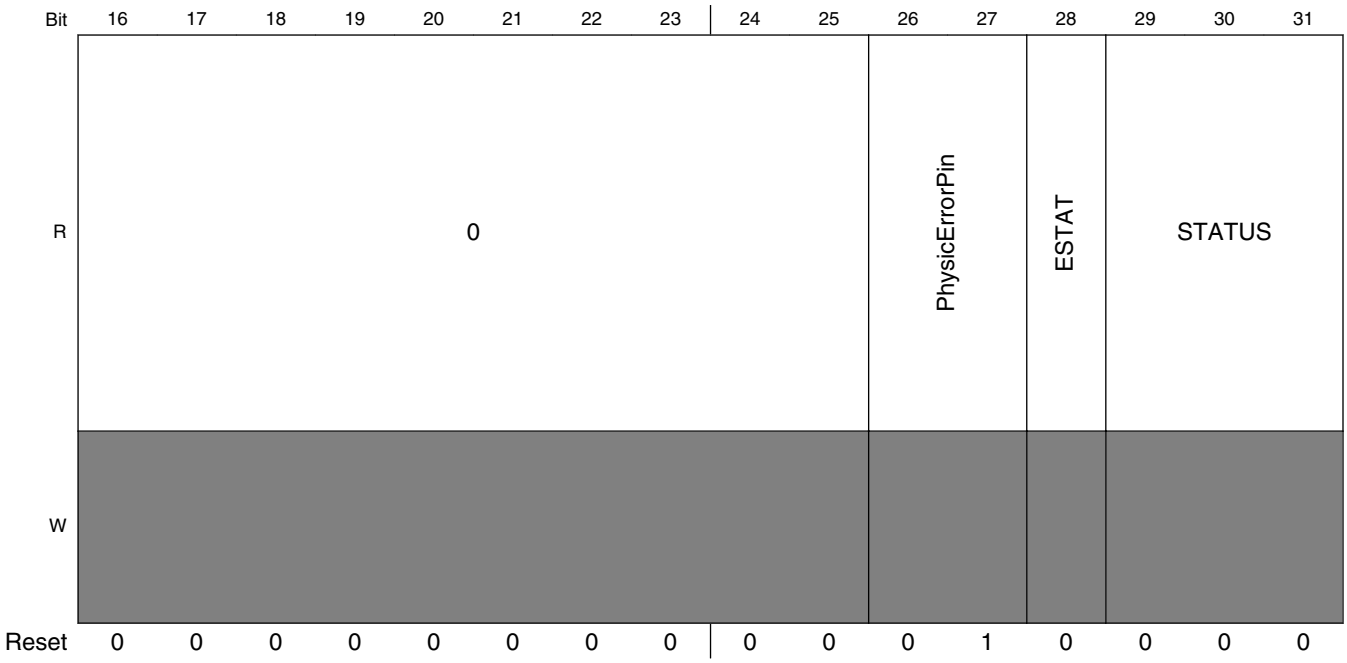
Field	Description
0–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26 EIN1	Error Input 1 Applies only when the EOUT signals are active (FCCU_SET_AFTER_RESET). Indicates the state of the EIN1 signal. 0 Low 1 High
27 EIN0	Error Input 0 Applies only when the EOUT signals are active (FCCU_SET_AFTER_RESET). Indicates the state of the EIN0 signal. 0 Low 1 High
28–29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

FCCU_EINOUT field descriptions (continued)



Field	Description
30 EOUT1	Error out 1 (significant only if the FCCU_CFG.FOM = Test1 or Test0 => EOUT[1] configured in output mode). The EOUT1 set/clear the respective EOUT[1] output signal if FCCU_CFG.FOM = 110 or 101, otherwise it is a "don't-care" value. **NOTE:** When the configuration watchdog timer expires, FCCU changes the value of this field to its reset value. 0 force EOUT[1] = 0 1 force EOUT[1] = 1
31 EOUT0	Error out 0 (significative only if the FCCU_CFG.FOM = Test1 or Test2 => EOUT[0] configured in output mode). The EOUT0 set/clear the respective EOUT[0] output signal if FCCU_CFG.FOM = 110 or 111, otherwise it is a "don't care" value. **NOTE:** When the configuration watchdog timer expires, FCCU changes the value of this field to its reset value. 0 force EOUT[0] = 0 1 force EOUT[0] = 1



3.10.13 Status (FCCU_STAT)

The FCCU_STAT register includes the FCCU status for debugging/test purposes. The FCCU finite state machine operates by the RC oscillator clock asynchronous with the system clock. The FCCU status read operation requires a safe mechanism operated by a HW/SW synchronization sequence. The SW application executes a FCCU status read operation by the following sequence:

1. Set the OP3 operation into the FCCU_CTRL.OPR field.
2. Wait for the completion of the operation (FCCU_CTRL.OPS field).
3. Read the FCCU status (FCCU_STAT register).

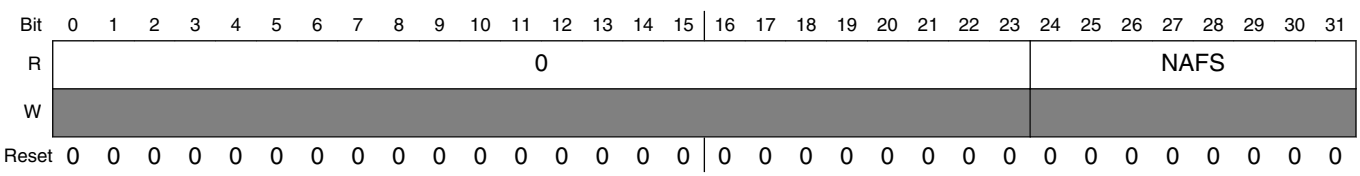
Address: 0h base + C0h offset = C0h

FCCU_STAT field descriptions

Field	Description
0–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26–27 PhysicErrorPin	Fault Output (EOUT) States Applies only after successfully running an OP3 operation (OPR) and only when the EOUT signals are active (FCCU_SET_AFTER_RESET). Indicates the states that FCCU is driving on the EOUT signals. 00 EOUT1 is low; EOUT0 is low. 01 EOUT1 is low; EOUT0 is high. 10 EOUT1 is high; EOUT0 is low. 11 EOUT1 is high; EOUT0 is high.
28 ESTAT	Fault State Applies only after successfully running an OP3 operation (OPR). Indicates whether FCCU is in Fault state. 0 Not in Fault state (in Normal, Alarm, or Configuration state) 1 In Fault state
29–31 STATUS	FCCU State Applies only after successfully running an OP3 operation (OPR). Indicates FCCU's state. 000 Normal 001 Configuration 010 Alarm 011 Fault 100 Reserved 101 Reserved 110 Reserved 111 Reserved

3.10.14 NA Freeze Status (FCCU_N2AF_STATUS)

The N2AF_STATUS register contains a unique code to identify the "noncritical fault" source (fccu_ncf[x]) that caused the state transition from the NORMAL state to the ALARM state. In case of multiple fault conditions the fault source cannot be identified. This register is for test/debug purposes.



The SW application executes the N2AF_STATUS read operation by the following sequence:

1. Set the OP4 operation into the FCCU_CTRL.OPR field.
2. Wait for the completion of the operation (FCCU_CTRL.OPS field).
3. Read the N2AF_STATUS register.

The SW application executes the N2AF_STATUS clear operation by the following sequence:

1. Set the OP13 operation into the FCCU_CTRL.OPR field.
2. Wait for the completion of the operation (FCCU_CTRL.OPS field). (All the freeze registers are cleared by this operation.)

Address: 0h base + C4h offset = C4h

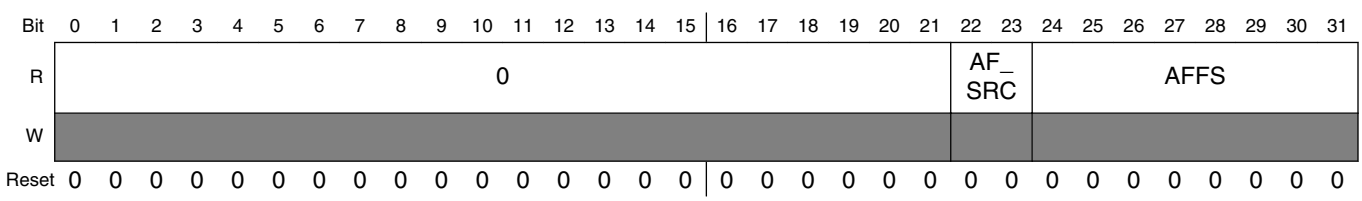
FCCU_N2AF_STATUS field descriptions

Field	Description
0–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–31 NAFS	Normal to Alarm Frozen Status 00000000 No transition from NORMAL to ALARM state 00000001 NORMAL to ALARM state transition cause => fccu_ncf[0] fault 00000010 NORMAL to ALARM state transition cause => fccu_ncf[1] fault 00000011 NORMAL to ALARM state transition cause => fccu_ncf[2] fault ... 10000000 NORMAL to ALARM state transition cause => fccu_ncf[127]/ fault 11111111 NORMAL to ALARM state transition cause => multiple fccu_ncf[]/ faults

3.10.15 AF Freeze Status (FCCU_A2FF_STATUS)

The A2FF_STATUS register contains a unique code to identify the timeout trigger (noncritical fault) that caused the state transition from the ALARM state to the FAULT state. In case of multiple fault conditions the fault source cannot be identified. This register is for test/debug purposes.

The SW application executes the A2FF_STATUS read operation by the following sequence:



1. Set the OP5 operation into the FCCU_CTRL.OPR field.
2. Wait for the completion of the operation (FCCU_CTRL.OPS field).
3. Read the A2FF_STATUS register.

The SW application executes the FCCU_AFFS clear operation by the following sequence:

1. Set the OP13 operation into the FCCU_CTRL.OPR field.
2. Wait for the completion of the operation (FCCU_CTRL.OPS field).

All the freeze registers are cleared by this operation.

Address: 0h base + C8h offset = C8h

FCCU_A2FF_STATUS field descriptions

Field	Description
0–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

3.10.16 NF Freeze Status (FCCU_N2FF_STATUS)

The N2FF_STATUS register contains a unique code to identify the source of the noncritical fault that caused the state transition from the NORMAL state to the FAULT state. In case of multiple fault conditions the fault source cannot be identified. This register is for test/debug purposes. The SW application executes the N2FF_STATUS read operation by the following sequence:

1. Set the OP6 operation into the FCCU_CTRL.OPR field.
2. Wait for the completion of the operation (FCCU_CTRL.OPS field).
3. Read the N2FF_STATUS register.

The SW application executes the N2FF_STATUS clear operation by the following sequence:

1. Set the OP13 operation into the FCCU_CTRL.OPR field.
2. Wait for the completion of the operation (FCCU_CTRL.OPS field). (All the freeze registers are cleared by this operation.)

Address: 0h base + CCh offset = CCh

3.10.17 FA Freeze Status (FCCU_F2A_STATUS)

The F2AF_STATUS register contains a unique code to identify the source of the noncritical fault (fccu_ncf[x]) that caused the state transition from the FAULT state to the ALARM state. In case of multiple fault conditions the fault source cannot be identified. This register is for test/debug purposes.

The SW application executes the F2AF_STATUS read operation by the following sequence:

1. Set the OP7 operation into the FCCU_CTRL.OPR field.
2. Wait for the completion of the operation (FCCU_CTRL.OPS field).
3. Read the F2AF_STATUS register.

The SW application executes the F2AF_STATUS clear operation by the following sequence:

1. Set the OP13 operation into the FCCU_CTRL.OPR field.
2. Wait for the completion of the operation (FCCU_CTRL.OPS field). (All the freeze registers are cleared by this operation.)

Address: 0h base + D0h offset = D0h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

FCCU_F2A_STATUS field descriptions

Field	Description
0–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23–31 FAFS	Fault to Normal Frozen Status 00h: No transition from FAULT to ALARM state 01h: FAULT to ALARM state transition cause => fccu_ncf[0]/ fault 02h: FAULT to ALARM state transition cause => fccu_ncf[1]/ fault 03h: FAULT to ALARM state transition cause => fccu_ncf[2]/ fault ... 80h: FAULT to ALARM state transition cause => fccu_ncf[127]/ fault FFh: FAULT to ALARM state transition cause => multiple fccu_ncf[] faults

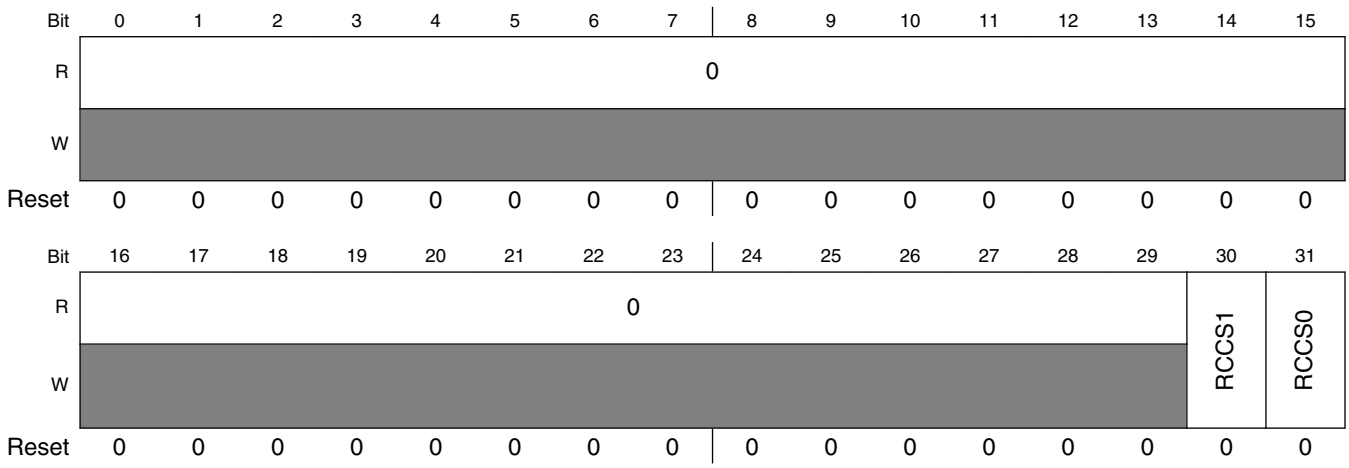
3.10.18 SC Freeze Status (FCCU_SCFS)

The FCCU_SCFS register contains the status of the RCCx checkers. This register is for test/debug purposes.

Two interrupt lines are asserted by the correspondent status bits (FCCU_SCFS.RCCSx).

The SW application executes the FCCU_SCFS read operation by the following sequence:

1. Set the OP8 operation into the FCCU_CTRL.OPR field.
2. Wait for the completion of the operation (FCCU_CTRL.OPS field).
3. Read the FCCU_SCFS register.



The SW application executes the FCCU_SCFS clear operation by the following sequence:

1. Set the OP13 operation into the FCCU_CTRL.OPR field.
2. Wait for the completion of the operation (FCCU_CTRL.OPS field). All the freeze registers are cleared by this operation. The RCCx checkers must be disabled (FCCU_CFG.RCCEx = 00b) during a clear operation otherwise the RCCSx flags are asserted again.

NOTE

The INTC will never attend the second interrupt line since RCCS0 and RCCS1 are always cleared together by the operation above. From SW perspective the INTC should be configured to attend RCCS0 or RCCS1 interrupt line only, not the pair.

Address: 0h base + D4h offset = D4h

FCCU_SCFS field descriptions

Field	Description
0–29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30 RCCS1	RCC1 Status **NOTE:** This field can be read and written but writing 1 has no effect. 0 No miscompares 1 A miscompare has been detected. An interrupt line is asserted.
31 RCCS0	RCC0 Status **NOTE:** This field can be read and written but writing 1 has no effect. 0 No miscompares 1 A miscompare has been detected. The interrupt line is asserted.

3.10.19 Noncritical Fault Fake (FCCU_NCFF)

The FCCU_NCFF register contains a unique code to set a noncritical fault in mutually exclusive mode by the external FAULT interface (signal setting). It allows the SW emulation of the noncritical faults, by the injection of the fault directly in the FAULT root, in order to verify the entire path and reaction. The reaction following a fake noncritical fault cannot be masked. The FCCU_NCFF is a write-only register with a set of codes corresponding to each noncritical fault injection.

Address: 0h base + DCh offset = DCh

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

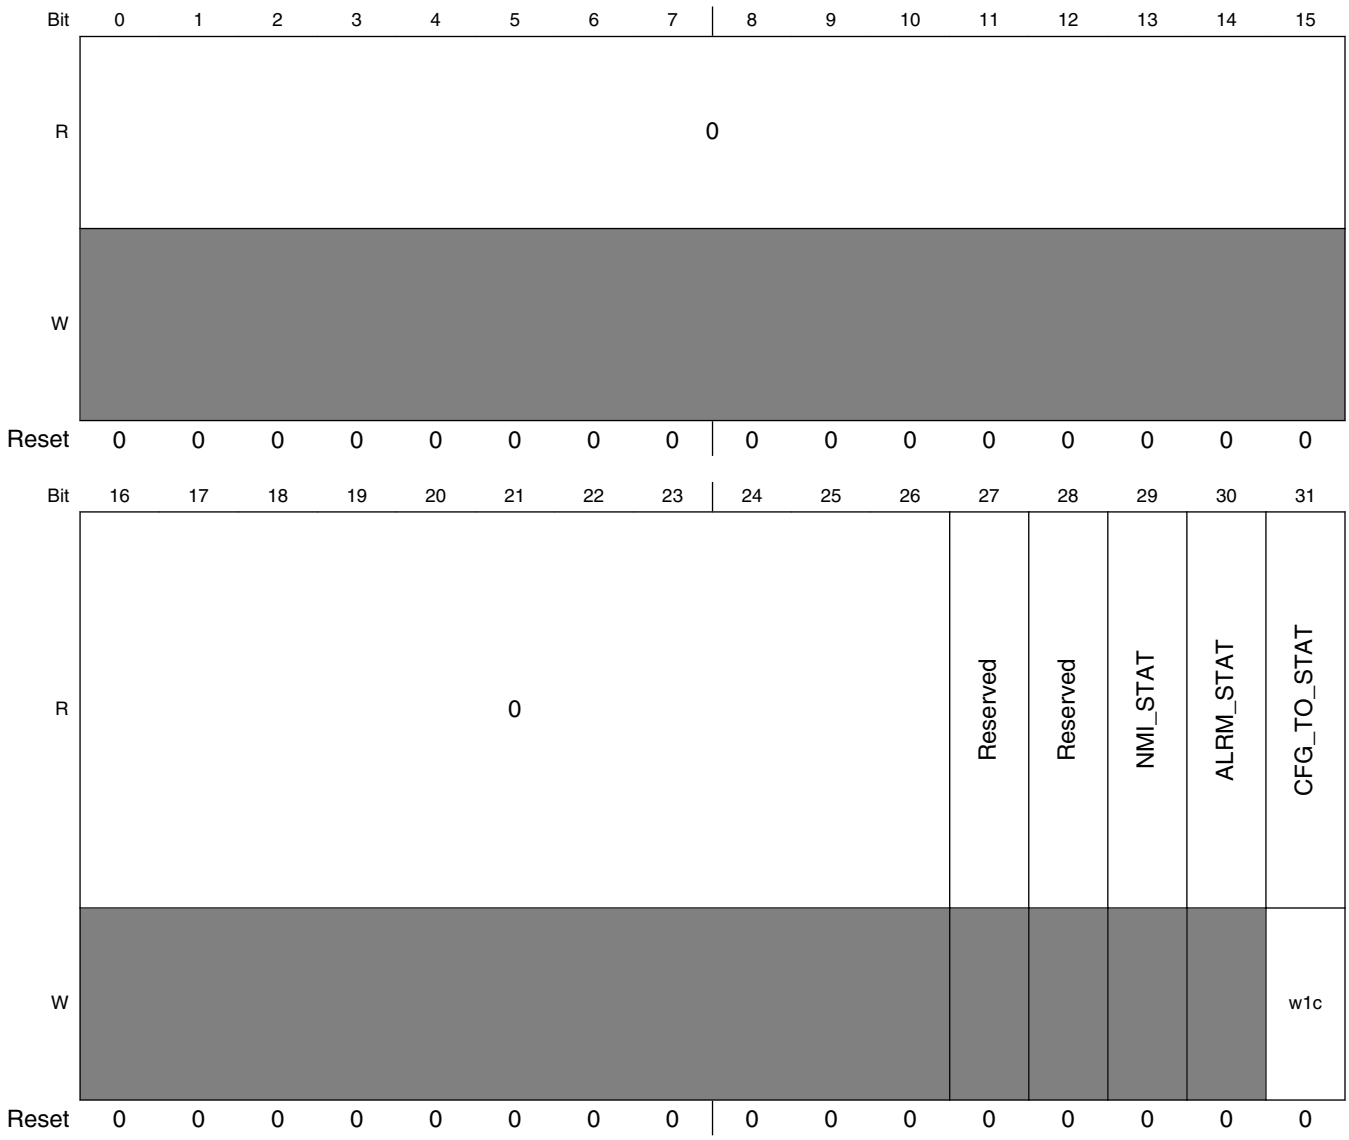
FCCU_NCFF field descriptions

Field	Description
0–24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25–31 FNCFC	FNCFC/ : Fake noncritical fault code **NOTE:** Only writing to this register, fake fault injection occurs, writing 00 and default value being zero give different results. 00h: Fake noncriticalfault injection at noncriticalfault source 0 01h: Fake noncriticalfault injection at noncriticalfault source 1 02h: Fake noncriticalfault injection at noncriticalfault source 2 ... 7Fh: Fake noncriticalfault injection at noncriticalfault source 127

3.10.20 IRQ Status (FCCU_IRQ_STAT)



The FCCU_IRQ_STAT register provides the FCCU interrupt status related to the following events:

- Configuration timeout error
- Alarm interrupt
- NMI interrupt

The configuration timeout interrupt is asserted if the CFG_TO_STAT bit of the FCCU_IRQ_STAT register is set and the CFG_TO_IEN bit of the FCCU_IRQ_EN register is also set. It is cleared when a 1 is written to the CFG_TO_STAT bit.

The NMI and ALARM interrupts are asserted and cleared according to the FCCU state. The status bits of the FCCU_IRQ_STAT trace the status of the related interrupt lines.

Address: 0h base + E0h offset = E0h

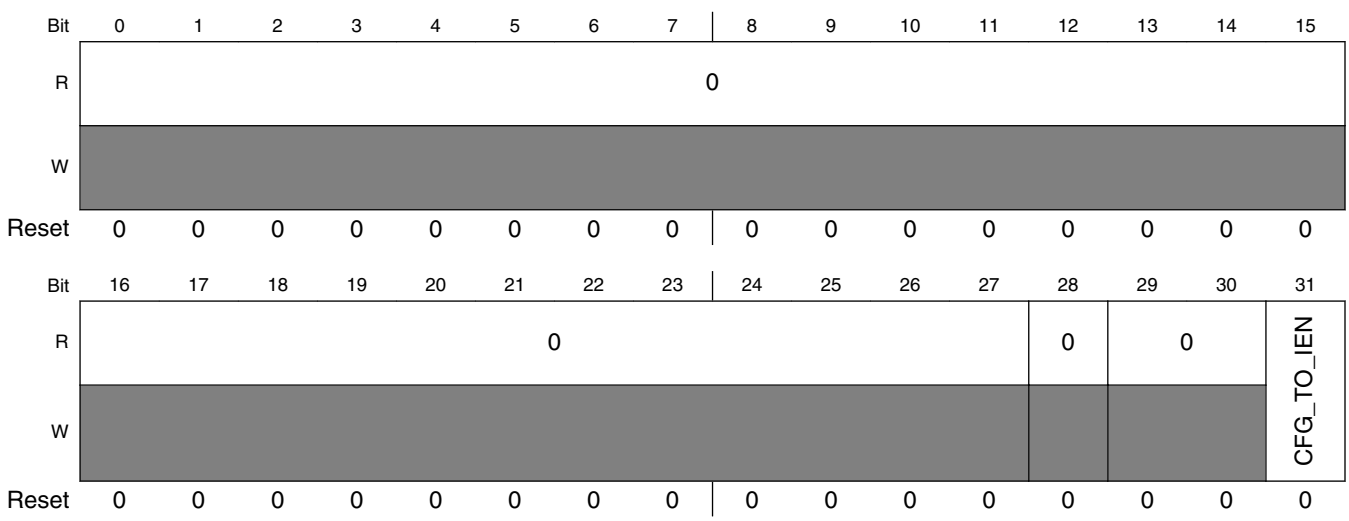
FCCU_IRQ_STAT field descriptions

Field	Description
0–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 Reserved	This field is reserved.

Table continues on the next page...

FCCU_IRQ_STAT field descriptions (continued)

Field	Description
28 Reserved	This field is reserved.
29 NMI_STAT	NMI Interrupt Status 0 NMI interrupt is OFF 1 NMI interrupt is ON
30 ALRM_STAT	Alarm Interrupt Status 0 Alarm interrupt is OFF 1 Alarm interrupt is ON
31 CFG_TO_STAT	Configuration Timeout Status 0 No configuration timeout error 1 Configuration timeout error



3.10.21 IRQ Enable (FCCU_IRQ_EN)

The FCCU_IRQ_EN register defines the FCCU interrupt enable register related to the following event:

- Configuration timeout error

The configuration timeout interrupt is asserted if the CFG_TO_STAT bit of the FCCU_IRQ_STAT register is set and the CFG_TO_IEN bit of the FCCU_IRQ_EN register is also set.

Address: 0h base + E4h offset = E4h

FCCU_IRQ_EN field descriptions

Field	Description
0–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 CFG_TO_IEN	Configuration Timeout Interrupt Enable 0 Configuration timeout interrupt disabled 1 Configuration timeout interrupt enabled

3.10.22 XTMR (FCCU_XTMR)

The FCCU_XTMR register contains the read values of the Alarm or Watchdog Timer. These timers are clocked by CLKSAFE.

The SW application executes the timer read operation by the following sequence:

1. Set any of the following operations into the FCCU_CTRL.OPR field:
   - OP17
   - OP19
2. Wait for the completion of the operation (FCCU_CTRL.OPS field).
3. Read the FCCU_XTMR register.

Table 3-11 shows Timer state/value.

Table 3-11. Timer state/value

TIMER	CONFIG state	NORMAL state	ALARM state	FAULT state
ALARM	00000000h	Initial value	Running	Idle/End of count
CFG	Running	0001FFFFh	0001FFFFh	0001FFFFh

Address: 0h base + E8h offset = E8h

Reset	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	VL1	FS1	0		MCS1				VL0	FS0	0		MCS0			
W																
Reset	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*

* Notes:
- The reset value is chip-specific. See the chip-specific FCCU information. (The MC_ME module changes the value of the register immediately after the chip leaves RESET mode.)

FCCU_MCS field descriptions

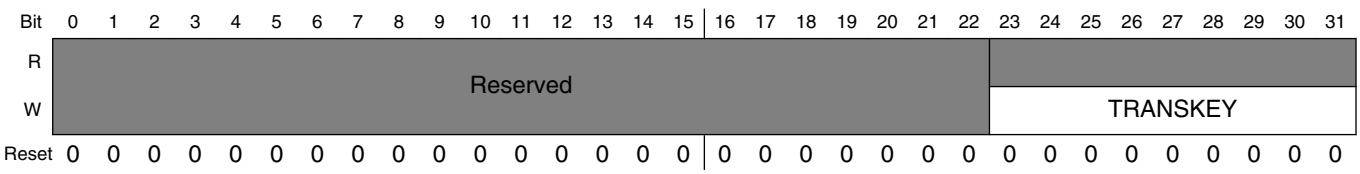
Field	Description
0 VL3	Valid 3—Indicates whether MCS3 and FS3 are valid. 0 Invalid 1 Valid
1 FS3	Fault Status 3 Indicates whether FCCU was in Fault state and NMIOUT was asserted (as the result of a noncritical fault) when FCCU captured MCS3. **NOTE:** This field might occasionally be inaccurate because the MC_ME module provides the chip modes to FCCU in synchronization with CLKSYS, but FCCU captures the chip modes in synchronization with CLKSAFE. 0 Not in Fault state or NMIOUT not asserted 1 In Fault state and NMIOUT asserted

Table continues on the next page...

FCCU_MCS field descriptions (continued)

Field	Description
2–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4–7 MCS3	Mode Controller State 3—Indicates the fourth most recent chip mode.
8 VL2	Valid 2—Indicates whether MCS2 and FS2 are valid. 0 Invalid 1 Valid
9 FS2	Fault Status 2 Indicates whether FCCU was in Fault state and NMIOUT was asserted (as the result of a noncritical fault) when FCCU captured MCS2. **NOTE:** This field might occasionally be inaccurate because the MC_ME module provides the chip modes to FCCU in synchronization with CLKSYS, but FCCU captures the chip modes in synchronization with CLKSAFE. 0 Not in Fault state or NMIOUT not asserted 1 In Fault state and NMIOUT asserted
10–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12–15 MCS2	Mode Controller State 2—Indicates the third most recent chip mode.
16 VL1	Valid 1—Indicates whether MCS1 and FS1 are valid. 0 Invalid 1 Valid
17 FS1	Fault Status 1 Indicates whether FCCU was in Fault state and NMIOUT was asserted (as the result of a noncritical fault) when FCCU captured MCS1. **NOTE:** This field might occasionally be inaccurate because the MC_ME module provides the chip modes to FCCU in synchronization with CLKSYS, but FCCU captures the chip modes in synchronization with CLKSAFE. 0 Not in Fault state or NMIOUT not asserted 1 In Fault state and NMIOUT asserted
18–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20–23 MCS1	Mode Controller State 1—Indicates the second most recent chip mode.
24 VL0	Valid 0—Indicates whether MCS0 and FS0 are valid. 0 Invalid 1 Valid
25 FS0	Fault Status 0 Indicates whether FCCU was in Fault state and NMIOUT was asserted (as the result of a noncritical fault) when FCCU captured MCS0.

Table continues on the next page...



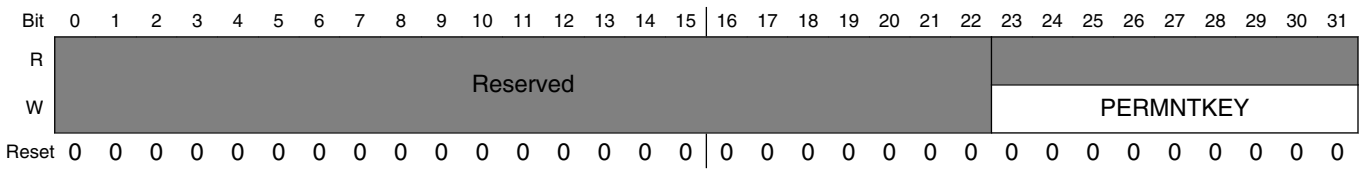
FCCU_MCS field descriptions (continued)

Field	Description
	NOTE: This field might occasionally be inaccurate because the MC_ME module provides the chip modes to FCCU in synchronization with CLKSYS, but FCCU captures the chip modes in synchronization with CLKSAFE. 0 Not in Fault state or NMIOUT not asserted 1 In Fault state and NMIOUT asserted
26–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28–31 MCS0	Mode Controller State 0—Indicates the most recent (current) chip mode.

3.10.24 Transient Configuration Lock (FCCU_TRANS_LOCK)

Writable only by code running in Supervisor mode. Temporarily locks and unlocks the configuration. Locking the configuration prevents FCCU from entering Configuration state.

Address: 0h base + F0h offset = F0h



FCCU_TRANS_LOCK field descriptions

Field	Description
0–22 Reserved	This field is reserved.
23–31 TRANSKEY	Transient Configuration Lock Writable only by code running in Supervisor mode. Temporarily locks and unlocks the configuration. Locking the configuration prevents FCCU from entering Configuration state. BCh: Unlock. Any other value: Lock.

3.10.25 Permanent Configuration Lock (FCCU_PERMNT_LOCK)

Writable only by code running in Supervisor mode. Permanently locks the configuration, which prevents FCCU from entering Configuration state until FCCU is reset.

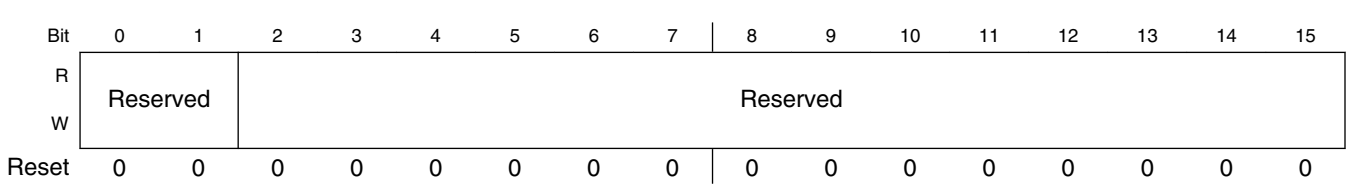
Address: 0h base + F4h offset = F4h

FCCU_PERMNT_LOCK field descriptions

Field	Description
0–22 Reserved	This field is reserved.
23–31 PERMNTKEY	Permanent Configuration Lock Writable only by code running in Supervisor mode. Permanently locks the configuration, which prevents FCCU from entering Configuration state until FCCU is reset. FFh: Lock. Any other value: Do nothing.

3.10.26 Delta T (FCCU_DELTA_T)

The FCCU_DELTA_T register is used for programming the value of delta_T constant, in microseconds.



NOTE

This register can be written only when the FCCU is in CONFIG state.

NOTE

Reserved bits should always be written as all 0's.

Address: 0h base + F8h offset = F8h

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	Reserved		DELTA_T													
W

FCCU_DELTA_T field descriptions

Field	Description
0–1 Reserved	This field is reserved.
2–15 Reserved	This field is reserved.
16–17 Reserved	This field is reserved.
18–31 DELTA_T	Bistable Minimum Fault-Output (EOUT) Faulty Interval Applies only to Bistable fault-output mode (FOM). Controls the minimum amount of time (T_min) that the fault-output (EOUT) timer runs according to this equation: T_min = 250 µs + DELTA_T The following values and meanings are for DELTA_T: 00_0000_0000_0000: 0 µs 00_0000_0000_0001: 1 µs … 11_1111_1111_1110: 16,382 µs 11_1111_1111_1111: 16,383 µs **NOTE:** The durations shown for the DELTA_T values are for CLKSAFE clock signals running at exactly 16 MHz. However, the CLKSAFE signals are sourced from an internal chip clock signal (for example, IRC)—or an integer division of it (see the chip-specific FCCU information)—that has a trimmed frequency variation. Therefore, the DELTA_T durations may vary. See your chip's data sheet for the trimmed frequency variation (for example, δF_{var}).

3.10.27 IRQ Alarm Enable (FCCU_IRQ_ALARM_EN*n*)

These registers enable the corresponding IRQ alarm.

IRQ Alarm Enable (FCCU_IRQ_ALARM_EN*n*) register (value of n)	Offset	IRQENx fields (value of x)	
		Most significant (leftmost) bit	Least significant (rightmost) bit
0	0FCh	31	0
1	100h	63	32
2	104h	95	64

NOTE

These registers can be written only when the FCCU is in CONFIG state.

Address: 0h base + FCh offset + (4d × i), where i=0d to 2d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

FCCU_NMI_EN*n* field descriptions

Field	Description
0–31 NMIENx	NMI enable See Table 3-12 for register offset to channel number relationship. 0 NMI is disabled for error (NCF) source x. 1 NMI is enabled for error (NCF) source x.

3.10.29 Bistable Fault-Output (EOUT) Mode Signaling Enable (FCCU_EOUT_SIG_EN*n*)

Writable only when FCCU is in Configuration state. Applies only when the EOUT signals are active (FCCU_SET_AFTER_RESET). When FCCU is configured for Bistable fault-output mode (FOM), controls whether fault-output (EOUT) signaling is enabled for the associated noncritical fault channel (x). (For other fault-output modes, fault-output signaling is always enabled, regardless of the value of this field.)

When FCCU is configured for a fault-output mode other than Bistable, controls whether FCCU asserts the FIF signal when a fault occurs on the associated noncritical fault channel (x). (When FCCU is configured for Bistable fault-output mode, FCCU always asserts the FIF signal when a fault occurs on the channel, regardless of the value of this field.)

Bistable Fault-Output (EOUT) Mode Signaling Enable (FCCU_EOUT_SIG_EN*n*) register (value of n)	Offset	EOUTENx fields (value of x)	
		Most significant (leftmost) bit	Least significant (rightmost) bit
0	11Ch	31	0
1	120h	63	32
2	124h	95	64

Address: 0h base + 11Ch offset + (4d × i), where i=0d to 2d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

FCCU_EOUT_SIG_EN*n* field descriptions

Field	Description
0–31 EOUTENx	Bistable Fault-Output (EOUT) Mode Signaling Enable x

FCCU_EOUT_SIG_EN*n* field descriptions (continued)

Field	Description
	Writable only when FCCU is in Configuration state. Applies only when the EOUT signals are active (FCCU_SET_AFTER_RESET). When FCCU is configured for Bistable fault-output mode (FOM), controls whether fault-output (EOUT) signaling is enabled for the associated noncritical fault channel (x). (For other fault-output modes, fault-output signaling is always enabled, regardless of the value of this field.) When FCCU is configured for a fault-output mode other than Bistable, controls whether FCCU asserts the FIF signal when a fault occurs on the associated noncritical fault channel (x). (When FCCU is configured for Bistable fault-output mode, FCCU always asserts the FIF signal when a fault occurs on the channel, regardless of the value of this field.) **NOTE:** When FCCU is configured for a fault-output mode other than Bistable, you must set this field to enabled to ensure that FCCU asserts the FIF signal when a fault occurs on the associated noncritical fault channel (x) so the FOSU module doesn't mistakenly generate a destructive chip reset. For the mapping of the EOUTENx fields among registers, see the earlier table in this register description. 0 Disabled 1 Enabled

3.10.30 Configuration registers

3.10.30.1 Definition

Configuration registers are registers that:

- Let you configure FCCU's Alarm-state timer interval, fault channels, and fault-output (EOUT) signals.
- You can write to only when the configuration is not locked (see Lock and unlock the configuration) and FCCU is in Configuration state (see Put FCCU in Configuration or Normal state).
- Save the values you write to them while FCCU is in Configuration state only after you manually put FCCU in Normal state. If FCCU automatically leaves Configuration state and enters Normal state because the configuration-timer interval (TO) expires (called a Configuration-state timeout), FCCU changes the value of the FCCU_CFG register to its Configuration-state-timeout value and the value of each of the other configuration registers to its reset value. For information on the Configuration-state timeout value, see FCCU_CFG register bit value sources (N and C) by event.

3.10.30.2 The configuration registers

The following registers are the configuration registers, listed in offset order from lowest to highest:

- Configuration (FCCU_CFG)
- Noncritical Fault Configuration (FCCU_NCF_CFG*n*)
- Noncritical Fault State Configuration (FCCU_NCFS_CFG*n*)
- Noncritical Fault Enable (FCCU_NCF_E*n*)
- Noncritical Fault Timeout Enable (FCCU_NCF_TOE*n*)
- Noncritical Fault Timeout (FCCU_NCF_TO)
- Delta T (FCCU_DELTA_T)
- IRQ Alarm Enable (FCCU_IRQ_ALARM_EN*n*)
- NMI Enable (FCCU_NMI_EN*n*)
- Bistable Fault-Output (EOUT) Mode Signaling Enable (FCCU_EOUT_SIG_EN*n*)

3.10.31 FCCU_CFG register bit value sources (N and C) by event

Certain events affect the bit values of the Configuration (FCCU_CFG) register; when one of these events occurs, the bit value is either unaffected, or FCCU changes it to one of the following:

- N: a chip-specific (or, for some chips, user-specified) value provided by the bit's associated NVMCFG signal
- C: a chip-specific value provided by the bit's associated constant inside the module

For each bit in the Configuration (FCCU_CFG) register, this table shows the associated NVMCFG signal, if any, and indicates the source of the bit value for the events that affect it. For specific values of *N* and *C* for each bit, see the chip-specific FCCU information.

Bit	NVMCFG signal	FCCU reset	Configuration-state timeout	OP31 operation
0	21	N	C	N
1	20	N	C	N
2	19	N	C	N
3	18	N	C	N
4	17	N	C	N
5	16	N	C	N
6	15	N	C	N
7	—	C	C	(Unaffected)
8	—	C	C	(Unaffected)
9	—	C	C	(Unaffected)
10	—	C	C	(Unaffected)
11	—	C	C	(Unaffected)
12	—	C	C	(Unaffected)

Table continues on the next page...

Bit	NVMCFG signal	FCCU reset	Configuration-state timeout	OP31 operation
13	—	C	C	(Unaffected)
14	—	C	C	(Unaffected)
15	—	C	C	(Unaffected)
16	14	N	C	N
17	13	N	C	N
18	12	N	C	N
19	—	C	C	(Unaffected)
20	11	N	C	N
21	10	N	C	N
22	9	N	C	N
23	8	N	C	N
24	7	N	C	N
25	6	N	C	N
26	5	N	C	N
27	4	N	C	N
28	3	N	C	N
29	2	N	C	N
30	1	N	C	N
31	0	N	C	N

3.11 FCCU Output Supervision Unit

The FOSU provides a supervision of the primary fault notification path by analyzing FCCU behavior for correctness. It waits for any reaction of the FCCU in a fixed time window after a fault is signaled.

The intention of the FOSU is to provide a secondary fault reaction path in most cases when the FCCU fails but not to needlessly propagate a fault which is already handled by the FCCU in a full chip reset. Only a failed primary fault reaction (that is, FCCU's failure) is a reason for the secondary reaction to take over (and generate a destructive reset request).

There is a 'do nothing' input coming from the FCCU that indicates that the FCCU is programmed for no reaction for ALL FAULTS. It is a "static" input in the sense that it does not change after FCCU configuration. The FOSU masks the incoming faults with the 'do nothing' control from the FCCU, meaning that a fault is not captured by the FOSU if the 'do nothing' signal is asserted, (i.e., a disabled fault). There is no minimum pulse

width requirement on the fault indication other than what is required by the technology, which is the same as that of the FCCU. FOSU does not monitor FCCU for the case of faults occurring during CONFIG state.

The FOSU contains a timer with a duration of FOSU_COUNT, driven by CLKSAFE. The timer is initialized and started on any captured, enabled fault. While the timer is running, any subsequent captured fault will neither restart nor reinitialize the timer. The timer is stopped when the FCCU shows any of the following reactions (the FOSU does not check whether the reaction is the configured one for the faults which occurred):

- Reset: Long or short functional reset
- IRQ: NMI or Alarm
- Error out triggered (by FCCU or by SW)

When the timer is stopped, the fault capture logic is cleared in order to ensure that the timer is not restarted due to faults still 'stuck' in the capture logic. The timer will then be restarted by the next new failure indication. When the timer expires, the FOSU's failure indicator output is asserted after it ensures that the fault is enabled and the static "fccu program to do nothing" signal is deasserted. This is because FCCU uses settings after it exits CONFIG state, even if fault captured before the exit.

The FOSU's failure indicator output is connected to one of the MC_RGM's 'destructive' reset inputs, so its assertion will cause a reset sequence to be initiated starting at PHASE0. The FOSU module is reset with the same reset as is used by the FCCU, which is asserted on power-on, 'destructive', and external resets. When this reset is asserted, the FOSU's capture logic is cleared, its timer is kept stopped and in a non-expired state, and its failure indicator output is deasserted.

NOTE

FOSU is triggered on assertion of enabled fault. In case the triggering fault is disabled, FOSU times-out without reaction.

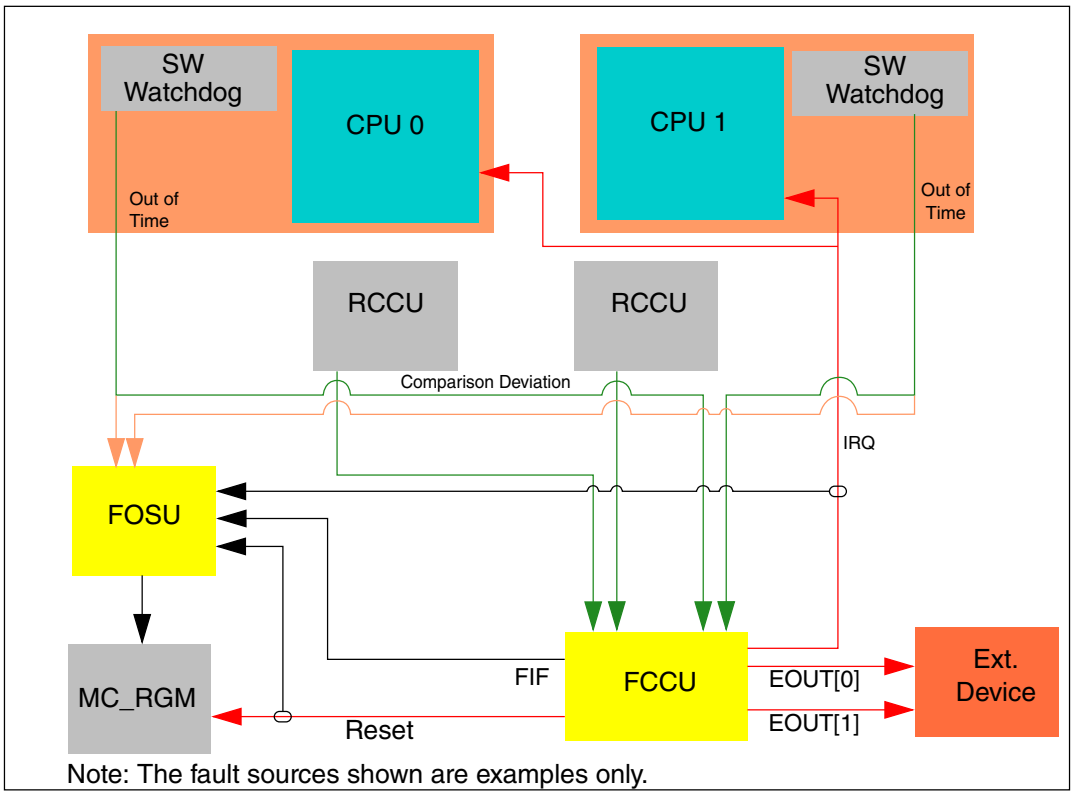

Figure 3-17. FOSU connections to the FCCU and MC_RGM

It is important to remember that there will be no FCCU reaction to a fault while the FCCU is in the CONFIG state. For this reason, the FCCU should not be kept in CONFIG for longer than the FOSU_COUNT duration. Otherwise, there is a risk that an incoming error report causing the FOSU to mistakenly see the FCCU as having failed, and then resets the MCU.

NOTE

FCCU and FOSU timeout counter settings: The FCCU counter value should always be programmed less than the FOSU counter value, FOSU_COUNT, or destructive resets may be generated by an FOSU time-out. This ensures that the FOSU reacts only when the FCCU fails to react to any particular fault.

3.12 Use cases and limitations

3.12.1 Configuration guidelines

Follow these guidelines to configure FCCU:

- If you want FCCU to react to a fault on a noncritical fault channel:
  - Enable the channel (NCFEx).
  - Enable at least one type of Fault-state reaction for the channel: chip reset (NCFSCx), fault-output (EOUT) signaling (EOUTENx), or nonmaskable interrupt (NMIENx).
  - If you enable chip reset as the type of Fault-state reaction for the channel (NCFSCx), enable either Alarm state (NCFTOEx) or at least one other type of Fault-state reaction for the channel: fault-output (EOUT) signaling (EOUTENx) or nonmaskable interrupt (NMIENx).
  - If you enable Alarm state for the channel (NCFTOEx), enable the Alarm-state reaction (IRQENx).
  - If you enable Alarm state for the channel (NCFTOEx), make sure the Alarm-state timer interval (TO) is less than the FOSU module's timer interval; otherwise, FOSU generates a chip reset every time a fault occurs on the channel. The FOSU timer interval (FOSU_COUNT) is chip-specific. See the chip-specific FCCU information.

NOTE

If you enable a noncritical fault channel but disable all reactions for that channel, FCCU changes state if necessary but doesn't perform any reaction because reactions are disabled. If you enable reactions for a noncritical fault channel but disable that channel, and FCCU is in Normal state when a fault occurs on the channel, FCCU doesn't enter Alarm or Fault state and therefore doesn't perform any reaction.

3.12.2 Recommendations to configure FCCU

1. After a power on, 'destructive', or long external reset, where both system and FCCU are reset, the following steps could be followed to configure FCCU:
   a. Check and clear any pending fault status
   b. Verify FCCU is in NORMAL state, else repeat step(a) above
   c. Configure FCCU
2. After a short external or any 'functional' reset of the system, arising out of a reset request from FCCU or other sources, the following steps could be followed to reconfigure FCCU:
   a. If active, wait for the Error out T_min to expire
   b. Check and clear fault status
   c. Error pin moves to "non faulty" state, once fault status is cleared and T_min expires

d. Verify FCCU is in NORMAL state, else repeat step(a) above
e. Read and verify value in FCCU_NCF_Ex
f. Reconfigure FCCU, if necessary

Appendix A
Release Notes for MPC5746RRMAD

A.1 Enhanced Time Processing Unit (eTPU) changes

A.1.1 Chip-specific eTPU2 Plus information changes

- In Register reset values, changed the following:
  - "eTPU System Configuration Registers_MCR" to eTPU_SCR_MCR.
  - "eTPU System Configuration Registers_ECR_ENG1" to eTPU_SCR_ECR_ENG1.
  - "eTPU System Configuration Registers_ECR_ENG2" to eTPU_SCR_ECR_ENG2.
  - "Time Base Registers_TBCR_ENG1" to eTPU_TBR_TBCR_ENG1.
  - "Time Base Registers_TBCR_ENG2" to eTPU_TBR_TBCR_ENG2.
  - "Time Base Registers_STAC_ENG1" to eTPU_TBR_STAC_ENG1.
  - "Time Base Registers_STAC_ENG2" to eTPU_TBR_STAC_ENG2.

A.1.2 eTPU module changes

- Changed the reset value of eTPU Engine 1 Time Base Configuration Register (eTPU_TBR_TBCR_ENG1) and eTPU Engine 2 Time Base Configuration Register (eTPU_TBR_TBCR_ENG2) (was 0000_0000h, is 2000_0000h).

- Editorial changes.
- In Table 2-3, changed the footnote to offsets 0x8000–0xBFFF and 0xC000–0xFFFF (was "Actual sizes of SCM and SDM are MCU-dependent (see Configuration section)", is "Actual sizes of SCM and SDM are MCU-dependent (see the chip-specific eTPU information)").
- In Table 2-4 :
  - Changed the footnote for offsets 0x8000-0xBFFF, 0xC000-0xFFFF, and 0x10000–0x1FFFF (was "The actual SDM size is MCU-dependent (see Configuration section)", is "The actual SDM size is MCU-dependent (see the chip-specific eTPU information). SDM is allocated from the starting value of the given range of offsets.").
  - Changed the footnote for offset 0x10000-1FFFF (was "The actual SCM size is MCU-dependent (see Configuration section). When the size is not the maximum, the unused SCM address range returns the value of the register ETPUSCMOFFDATAR.", is "The actual SCM size is MCU-dependent (see the chip-specific eTPU information). SCM is allocated from the starting value of the given range of offsets. When the size is not the maximum, the unused SCM address range returns the value of the register ETPUSCMOFFDATAR.")
- Changed "Configuration information" to "the chip-specific eTPU information" in:
  - The SCMSIZE field description of eTPU Module Configuration Register (eTPU_SCR_MCR)
  - The note and field descriptions of eTPU Engine 1 Configuration Register (eTPU_SCR_ECR_ENG1)
  - The note and field descriptions of eTPU Engine 2 Configuration Register (eTPU_SCR_ECR_ENG2)
- In eTPU Module Configuration Register (eTPU_SCR_MCR), revised the SCMSIZE reset value (is "See the chip-specific eTPU information for this field's reset value").

- Editorial changes (including the addition of cross-references for improved usability).
- Throughout the chapter, revised register names so that they are always consistent with the official register names as specified in these tables:
  - "eTPU_SCR memory map" in System Configuration memory map and registers
  - "eTPU_TBR memory map" in Timebase memory map and registers
  - "eTPU_ER memory map" in Engine memory map and registers
  - "eTPU_LMR memory map" in Latency Monitor memory map and registers
  - "eTPU_MESR memory map" in Memory Error Support memory map and registers
  - "eTPU_GCR memory map" in Global Channel memory map and registers
  - "eTPU_CCCR memory map" in Channel Configuration Control memory map and registers
  - "eTPU_SSIR memory map" in Shared Subsystem Integration memory map and registers

  So, for example, the chapter now consistently uses:
  - eTPU_MESR_CERDR instead of ETPUCERD
  - eTPU_GCR_CDTRER_ENG1 and eTPU_GCR_CDTRER_ENG2 instead of ETPUCDTRER
  - eTPU_TBR_STAC_ENG1 and eTPU_TBR_STAC_ENG2 instead of ETPUREDCR
- In eTPU Channel n Configuration Register for Engine 1 (eTPU_CCCR_C*n*CR_ENG1), revised the CIE field description.
- In eTPU Channel n Configuration Register for Engine 1 (eTPU_CCCR_C*n*CR_ENG1), in the DTRE field description, changed "This bit is mirrored from eTPU Channel Data Transfer Request Enable Register for Engine 2 (eTPU_GCR_CDTRER_ENG2)" to "This bit is mirrored from eTPU Channel Data Transfer Request Enable Register for Engine 1 (eTPU_GCR_CDTRER_ENG1)."
- In eTPU Channel n Configuration Register for Engine 2 (eTPU_CCCR_C*n*CR_ENG2), in the T4DIS field description, added "For more details, see Channel timing modes."
- In Table 2-34, deleted the footnote "See the eTPU integration guide...".
- In Latency Monitor, in the last bulleted list, changed "after each latency measurement, the value measured is compared with the MAXLAT value in the register ETPULMnMR; and if MAXLAT is not zero and the new measured value is greater." to "After each latency measurement, the value measured is compared with the LATENCY value in eTPU Latency Monitor Measure Register for Engine 1 (eTPU_LMR_LM*n*MR_ENG1) and eTPU Latency Monitor Measure Register for Engine 2 (eTPU_LMR_LM*n*MR_ENG2). If the new measured value is greater, it replaces the old value in eTPU Latency Monitor Measure Register for Engine 1 (eTPU_LMR_LM*n*MR_ENG1) and eTPU Latency Monitor Measure Register for Engine 2 (eTPU_LMR_LM*n*MR_ENG2)."
- In Using Worst-Case Latency estimates to evaluate performance, changed "Refer to Freescale Programming Note" to "See NXP Programming Note".
- In Execution and channel timing, deleted "For timings of eTPU block internal interface signals, consult the eTPU Integration Guide. For timings internal to the eTPU, refer to the eTPU Creation Guide."

A.2 Fault Collection and Control Unit (FCCU) changes

A.2.1 Chip-specific FCCU information changes

- In the FCCU chip-specific register reset values table, changed the reset value of FCCU_CFG to "See FCCU_CFG register bit value sources (N and C) by event."
- Added the FCCU_CFG register event bit values by source (N and C) section/table.
- In the FCCU failure inputs from other modules section, added the following sentence to the second "Note" in this section: "FCCU Fault Channels 22, 23, and 24 may be asserted after reset."
- In Table 3-3, added the following note in the Description column of NCF[17], NCF[19], and NCF[21]: "This input must be mapped only to reset, and must not be mapped to an alarm."

A.2.2 FCCU module changes

• Made the following changes to the Configuration (FCCU_CFG) register description:
  • Added the FOP field, which was previously marked as reserved.
  • Added the FOPE field, which was previously marked as reserved.

• In the Configuration (FCCU_CFG) register description, at the end of the FOP field description, added a Note: *Writing to FCCU_CFG sets FOP to 0.*
• In the Mode Controller Status (FCCU_MCS) register description, changed the footnote for the register reset value from *The MC_ME module changes the value of the register immediately after the chip leaves RESET mode.* to *The reset value is chip-specific. See the chip-specific FCCU information. (The MC_ME module changes the value of the register immediately after the chip leaves RESET mode.)*.
• In the NA Freeze Status (FCCU_N2AF_STATUS) register description, in the NAFS field description, deleted this note: *This field can be read and written but writing 1 has no effect.* • In the AF Freeze Status (FCCU_A2FF_STATUS) register description, changed the access types of the AF_SRC and AFFS fields from read-write to read-only. In the AF_SRC and AFFS field descriptions, deleted this note: *This field can be read and written but writing 1 has no effect.* • In the NF Freeze Status (FCCU_N2FF_STATUS) register description, changed the access types of the NF_SRC and NFFS fields from read-write to read-only. In the NF_SRC and NFFS field descriptions, deleted this note: *This field can be read and written but writing 1 has no effect.* • In the FA Freeze Status (FCCU_F2A_STATUS) register description, in the FAFS field description, deleted this note: *This field can be read and written but writing 1 has no effect.*
• In the Noncritical Fault State Configuration (FCCU_NCFS_CFG*n*) and NMI Enable (FCCU_NMI_EN*n*) register descriptions, removed the following inaccurate note: *Do not configure the same channel for both a RESET reaction in the FCCU_NCFS_CFGn register and an NMI reaction in the FCCU_NMI_ENn register at the same time.*
• In Use cases and limitations, rewrote Configuration guidelines (formerly titled "Misconfigurations") to improve the accuracy and clarity of the material by putting it in terms of guidelines you must follow. Added guidelines about what you must do if you enable chip reset as the type of Fault-state reaction for a noncritical fault channel and if you enable Alarm state for the channel.
• In Fault recovery, added the word *noncritical* before the word *FAULT*.
• In FCCU Output Supervision Unit, deleted *Also, the case of a continuously incoming disabled fault being enabled later, is not monitored*. Also deleted *All intermediate faults are masked (not monitored) during this timeout cycle*.
• In the PhysicErrorPin field description, added the spelled-out name of the field, Fault Output (EOUT) States. Replaced *PhysicErrorPin : Physical Error Pin's state. PhysicErrorPin[0] corresponds to error pin 0 and PhysicErrorPin[1] corresponds to error pin 1. For each of these, the bit values have the following meanings: 0: Error Pin is at logical 0; 1: Error Pin is at logical 1* with *Applies only after successfully running an OP3 operation (OPR) and only when the EOUT signals are active (FCCU_SET_AFTER_RESET). Indicates the states that FCCU is driving on the EOUT signals.* Deleted *During Fault state, a static or toggling value is observed based on selected protocol.* Replaced the list of two values and meanings with a list of four values and meanings.
• In the Mode Controller Status (FCCU_MCS) register description, changed the general description from *and whether FCCU was in Fault state when FCCU captured each mode* to *and whether FCCU was in Fault state and NMIOUT was asserted (as the result of a noncritical fault) when FCCU captured each mode*. In the FS0 field description (and similarly in the FS1, FS2, and FS3 field descriptions), changed *Indicates whether FCCU was in Fault state when FCCU captured MCS0* to *Indicates whether FCCU was in Fault state and NMIOUT was asserted (as the result of a noncritical fault) when FCCU captured MCS0*; changed the meaning for the value 0 from *A state other than Fault state* to *Not in Fault state or NMIOUT not asserted*; changed the meaning for the value 1 from *Fault state* to *In Fault state and NMIOUT asserted*.
• In the Permanent Configuration Lock (FCCU_PERMNT_LOCK) register description, changed the register name from *Permanent Lock* to *Permanent Configuration Lock*; in the general description, changed *The FCCU_PERMNT_LOCK register is used for locking configuration permanently by writing FFh. This register is available only in supervisor mode. The permanent lock can only be removed by applying a reset (not necessarily power on reset). This register is write only.* to *Writable only by code running in Supervisor mode. Permanently locks the configuration, which prevents FCCU from entering Configuration state until FCCU is reset.*; changed the access type of the reserved field from Read-Only Zero to Reserved, Unimplemented. In the PERMNTKEY field description, changed *Transition Locking Key*

value to *Permanent Configuration Lock—Writable only by code running in Supervisor mode. Permanently locks the configuration, which prevents FCCU from entering Configuration state until FCCU is reset.*; changed the meaning for the value FFh from *Configuration Locked* to *Lock.*; changed the meaning for the value *Any other value* from *No Change* to *Do nothing.* • In the Transient Configuration Lock (FCCU_TRANS_LOCK) register description, changed the register name from *Transient Lock* to *Transient Configuration Lock*; in the general description, changed *The FCCU_TRANS register is used for unlocking configuration by writing BCh. This register is available only in supervisor mode. This register is write only.* to *Writable only by code running in Supervisor mode. Temporarily locks and unlocks the configuration. Locking the configuration prevents FCCU from entering Configuration state.*; changed the access type of the reserved field from Read-Only Zero to Reserved, Unimplemented. In the TRANSKEY field description, changed *Transition Unlocking Key value* to *Transient Configuration Lock—Writable only by code running in Supervisor mode. Temporarily locks and unlocks the configuration. Locking the configuration prevents FCCU from entering Configuration state.*; changed the meaning for the value BCh from *Configuration Unlocked* to *Unlock.*; changed the meaning for the value *Any other value* from *FCCU gets transiently locked again.* to *Lock.*
• In the Configuration (FCCU_CFG) register description, in the FCCU_SET_CLEAR field description, added the field name, Fault-Output (EOUT) Control; rewrote the function description and value meanings.
• In the FCCU_SET_AFTER_RESET field description, added the spelled-out name of the field, Fault-Output (EOUT) Activate; rewrote the general description; rewrote the meanings for both values.

• In the Configuration (FCCU_CFG) register description, rewrote the RCCE1 andRCCE0 field descriptions, including their spelled-out names, for clarity.
• In the Delta T (FCCU_DELTA_T) register description, in the DELTA_T field description, added the spelled-out name of the field, Bistable Minimum Fault-Output (EOUT) Faulty Interval; added the following sentence: *Applies only to Bistable fault-output mode (FOM)*; changed *EOUT fault-indication timer* to *fault-output (EOUT) timer*; moved the information that is after the equation to EOUT interface because it's general and not only applicable to DELTA_T.
• Inserted the following new sections in EOUT interface prior to Dual-rail protocol :
  • Introduction. Moved the first paragraph from the previous EOUT interface section into this section. In the moved information, replaced *The FCCU provides up to two bidirectional signals (EOUT[1:0]) as a failure indication to the external world.* with *You use the EOUT[1:0] signals to indicate FCCU's condition to off-chip logic.*
  • The FCCU conditions. Added new content.
  • How the fault-output (EOUT) timer works. Moved general information from the DELTA_T field description to this section. In the moved information, changed *EOUT fault-indication timer* to *fault-output (EOUT) timer*. In the first paragraph of the moved information, added the following new list item to the beginning of the list: *The fault-output (EOUT) signals are not programmed to be always low (FCCU_SET_CLEAR)*. In the third paragraph of the moved information, changed the first list item from *T_min has expired* to *If the EOUT signals are in Bistable fault-output mode (FOM), T_min has expired*. In the second paragraph, deleted *or not applicable*.
  • Prepare the EOUT signals to indicate FCCU's condition. Added new content.
  • More about the EOUT interface. In one of the notes, changed *after software has enabled the EOUT signals (FCCU_CFG[FCCU_SET_AFTER_RESET]* to *when the EOUT signals are active (FCCU_SET_AFTER_RESET)*.
• Revised the Bistable Fault-Output (EOUT) Mode Signaling Enable (FCCU_EOUT_SIG_EN*n*) register description for clarity.

• In Signals, rewrote the description of the EOUT[1:0] signal function for accuracy and clarity. • In the figure in Block diagram, changed the double-headed arrow between *EOUT1 intf* and *EOUT[1]* to a single-headed arrow that indicates that EOUT[1] is an output only.
• In the figure in FCCU Output Supervision Unit, removed the line that connects an FCCU fault output to a FOSU input; added a line that connects the FCCU FIF output to a FOSU input. • In Signals, added a signal description for the FIF signal.
• In the Status (FCCU_STAT) register description, rewrote the ESTAT and STATUS field descriptions for clarity.
• In the IO Control (FCCU_EINOUT) register description, for the EIN1 and EIN0 fields, changed the reset value to indeterminate (x) and rewrote the field descriptions for clarity. • In Signals, added a table row for the EIN[1:0] signals.

• Added the following sections to clarify how to perform certain procedures:
  • Put FCCU in Configuration or Normal state
  • Run operations
  • Lock and unlock the configuration

• In Acronyms and abbreviations, added a row for *NVM*.
In Introduction :

• Replaced the list item that begins with *The FCCU's configuration is lockable* with *Lockable configuration*. • Added the list item *Nonvolatile memory interface (NVMCFG signals) for configuration loading*.
• In Main features, added the list item *Nonvolatile memory interface (NVMCFG signals) for configuration loading*.
• Added FCCU_CFG register bit value sources (N and C) by event.
• Added Configuration registers.
• In Signals, added table rows for the NVMCFG[21:0] and SSCMDONE signals.
• In the Configuration-State Timer Interval (FCCU_CFG_TO) register description, changed its name to *Configuration-State Timer Interval*, and rewrote the description of the register's function and the description of the TO field's function.

• In the Control (FCCU_CTRL) register description:
  • Rewrote the description of the register's function.
  • Rewrote the description of the OPR field.

• Added Nonvolatile memory interface.
• In Introduction, changed *They show operational state only on software request* to *They show operational state only after configuration by software*.
• In More about the EOUT interface, deleted this paragraph: *These resets influence the state of the failure indication pins…Other resets should not influence the state of the failure indication pins*.
• In the Delta T (FCCU_DELTA_T) register description, rewrote the note in the DELTA_T field description to clarify that the variance of the DELTA_T durations is chip-specific.
• In More about the EOUT interface, changed *NA (not applicable) appears in the following table* to *NA (not applicable) appears in the following table*.
• In the Bistable Fault-Output (EOUT) Mode Signaling Enable (FCCU_EOUT_SIG_EN*n*) register description, rewrote the register's function description and the EOUTENx field's function description.
• In Signals, revised the function description for the FIF signal.
• In NMI/WKPU interface, changed *another mode* to *another mode change*.

• Throughout the chapter, changed *non-critical* to *noncritical*.
• In each of the following register descriptions, changed the format of the table in the register function summary and reworded the sentence in the field function summary that refers to the table:
  • Noncritical Fault Configuration (FCCU_NCF_CFG*n*)
  • Noncritical Fault Status (FCCU_NCF_S*n*)
  • Noncritical Fault Enable (FCCU_NCF_E*n*)
  • Noncritical Fault Timeout Enable (FCCU_NCF_TOE*n*)
  • IRQ Alarm Enable (FCCU_IRQ_ALARM_EN*n*)
  • Bistable Fault-Output (EOUT) Mode Signaling Enable (FCCU_EOUT_SIG_EN*n*) (no sentence rewording)

• In Introduction, changed *One of the error out pins is high* to *One of the fault-output (EOUT) signals is high*.

Contents

Section number **Title** **Page**

Chapter 1
Preface

1.1 Overview....91

1.2 Audience....91

1.3 Content....91

1.4 Document organization....92

1.5 Register description conventions....92

1.6 Special terms....93

1.7 Acronyms and abbreviations....93

1.8 References....95

Chapter 2
Introduction

2.1 Introduction....97

2.2 Target applications....97

2.3 Block diagrams....97

2.4 Overall architecture....100

2.5 Core features....100

2.6 Memory hierarchy....100

2.7 Features summary....101

2.8 Feature list....102

2.9 Packaging....103

2.10 Software debug and calibration....104

Chapter 3
Embedded memories

3.1 Overview....105

3.2 SRAM....105

3.2.1 System SRAM....105

3.2.2 Standby SRAM Regulator....106

3.2.3 Overlay SRAM....107
3.2.4 Processor core local SRAM....108
3.3 Flash memory....109
3.4 Flash memory controller....110
3.5 Flash memory array....110
3.5.1 Features....110
3.5.2 Flash organization....111
3.5.3 UTEST memory space....112
3.6 End-to-end Error Correction Code (e2eECC)....112

Chapter 4
Signal Multiplexing and Signal Description

4.1 Generic pins/balls....117
4.1.1 System pin functions....117

Chapter 5
Memory Map

5.1 Introduction....119

Chapter 6
Device Configuration Format (DCF) Records

6.1 Overview....121
6.2 DCF records in boot sequence....122
6.3 DCF records function....122
6.4 DCF records location....122
6.5 DCF record structure....123
6.6 DCF records sequence....124
6.7 DCF clients....126
6.7.1 Miscellaneous DCF clients....136

Chapter 7
e200z4d Core Complex Overview

7.1 Introduction....149
7.2 Overview of the e200z425n3 and e200z424 cores....149

7.3 Features....150
7.4 Microarchitecture summary....151
7.4.1 Instruction unit features....153
7.4.2 Integer unit features....153
7.4.3 Load/Store unit features....154
7.4.4 MPU features....154
7.4.5 Cache features....154
7.4.6 Local memory features....155
7.4.7 e200z425n3 system bus features....155
7.4.8 e200z424 system features....155

Chapter 8
Core description

8.1 Overview of the e200z425n3 core....157
8.2 Register model....158
8.3 Dual-issue operation....162
8.4 Instruction timing....163
8.5 Reservation instructions and cache interactions....174
8.6 Signal Processing Extension/Embedded Floating-point Status and Control Register (SPEFSCR)....175
8.7 Cache....177
8.7.1 Cache overview....177
8.7.2 Cache organization....178
8.7.3 L1 Cache Control and Status Register 0 (L1CSR0)....178
8.7.4 L1 Cache Control and Status Register 1 (L1CSR1)....179
8.7.5 L1 Cache Configuration Register 0 (L1CFG0)....181
8.7.6 L1 Cache Configuration Register 1 (L1CFG1)....182
8.7.7 Cache Invalidate by Set and Way....183
8.7.8 Cache EDC/ECC Parity Protection....184
8.7.9 Cache Error Injection....186

8.8 Exceptions....187
8.8.1 Exception Syndrome Register (ESR)....188
8.8.2 Machine State Register (MSR)....189
8.8.3 Machine Check Syndrome Register (MCSR)....190
8.8.4 Interrupt Vector Prefix Registers (IVPR)....194
8.8.5 Interrupt Definitions....194
8.9 Memory Protection Unit (MPU)....205
8.9.1 MPU Overview....205
8.9.2 Software Interface and MPU Instructions....205
8.9.3 MPU Read Entry Instruction (mpure)....205
8.9.4 MPU Write Entry Instruction (mpuwe)....206
8.9.5 MPU Synchronize Instruction (mpusync)....206
8.9.6 MMU/MPU Configuration Register (MMUCFG)....207
8.9.7 MPU0 Configuration Register (MPU0CFG)....208
8.9.8 MPU0 Control and Status Register 0 (MPU0CSR0)....209
8.9.9 MPU Assist Registers (MAS)....211
8.9.10 MAS Registers Summary....217
8.10 Local memories....217
8.10.1 Local Instruction and Data Memory Overview....217
8.10.2 Local memory control and configuration....218
8.11 End-to-End ECC Support....233
8.11.1 End-to-End ECC control and configuration....233

Chapter 9
System Integration Unit Lite2 (SIUL2)

9.1 System Integration Unit Lite2 (SIUL2) chip-specific module information....237
9.1.1 SIUL2 interrupts....237
9.1.2 Reset values of MIDRn....237
9.2 Introduction....238
9.2.1 Overview....238

9.2.2 Features....239
9.2.3 Register protection....241
9.3 Memory map and register description....241
9.3.1 Memory map....241
9.3.2 SIUL2 MCU ID Register #1 (SIUL2_MIDR1)....275
9.3.3 SIUL2 MCU ID Register #2 (SIUL2_MIDR2)....277
9.3.4 SIUL2 DMA/Interrupt Status Flag Register0 (SIUL2_DISR0)....278
9.3.5 SIUL2 DMA/Interrupt Request Enable Register0 (SIUL2_DIRER0)....280
9.3.6 SIUL2 DMA/Interrupt Request Select Register0 (SIUL2_DIRSR0)....282
9.3.7 SIUL2 Interrupt Rising-Edge Event Enable Register 0 (SIUL2_IREER0)....284
9.3.8 SIUL2 Interrupt Falling-Edge Event Enable Register 0 (SIUL2_IFEER0)....285
9.3.9 SIUL2 Interrupt Filter Enable Register 0 (SIUL2_IFER0)....287
9.3.10 SIUL2 Interrupt Filter Maximum Counter Register (SIUL2_IFMCR*n*)....289
9.3.11 SIUL2 Interrupt Filter Clock Prescaler Register (SIUL2_IFCPR)....289
9.3.12 SoC Configuration Register 0 (SIUL2_SCR0*n*)....290
9.3.13 SIUL2 Multiplexed Signal Configuration Register (SIUL2_MSCR*n*)....291
9.3.14 SIUL2 Input Multiplexed Signal Configuration Register (SIUL2_MSCR*n*)....294
9.3.15 General Purpose Register 0 (SIUL2_GPR0)....295
9.3.16 General Purpose Register 1 (SIUL2_GPR1)....297
9.3.17 General Purpose Register 2 (SIUL2_GPR2)....299
9.3.18 SIUL2 GPIO Pad Data Output Register (SIUL2_GPDO*n*)....300
9.3.19 SIUL2 GPIO Pad Data Input Register (SIUL2_GPDI*n*)....301
9.3.20 SIUL2 Parallel GPIO Pad Data Out Register (SIUL2_PGPDO*n*)....302
9.3.21 SIUL2 Parallel GPIO Pad Data In Register (SIUL2_PGPDI*n*)....302
9.3.22 SIUL2 Masked Parallel GPIO Pad Data Out Register (SIUL2_MPGPDO*n*)....303
9.4 Functional description....304
9.4.1 General....304
9.4.2 Pad Control....304
9.4.3 General Purpose Input and Output Pads (GPIO)....305

9.4.4 External Interrupts/DMA Requests (REQ Pins).....306

Chapter 10
Crossbar Switch (AXBS)

10.1 Crossbar switch configuration.....311
10.1.1 Computational shell crossbar switch configuration.....311
10.1.2 Peripheral Shell Crossbar Switch Configuration.....315
10.2 Introduction.....317
10.2.1 Features.....317
10.3 Memory Map / Register Definition.....317
10.3.1 Priority Registers Slave (XBAR_PRS*n*).....319
10.3.2 Control Register (XBAR_CRS*n*).....321
10.3.3 Master General Purpose Control Register (XBAR_MGPCR*n*).....323
10.4 Functional Description.....324
10.4.1 General operation.....324
10.4.2 Register coherency.....325
10.4.3 Arbitration.....325
10.5 Initialization/application information.....328

Chapter 11
Crossbar Integrity Checker (XBIC)

11.1 Overview.....329
11.2 Features.....329
11.3 Block diagram.....329
11.4 External signal description.....330
11.5 Memory map and register definition.....330
11.5.1 XBIC Module Control Register (XBIC_MCR).....331
11.5.2 XBIC Error Injection Register (XBIC_EIR).....333
11.5.3 XBIC Error Status Register (XBIC_ESR).....333
11.5.4 XBIC Error Address Register (XBIC_EAR).....336
11.6 Functional description.....337

Chapter 12
Peripheral Bridge (AIPS-Lite)

12.1 Peripheral Bridge chip-specific module information....339
12.1.1 Number of peripheral bridges....339
12.1.2 Memory maps....339
12.1.3 MPRA registers....339
12.1.4 PACR registers....340
12.2 Introduction....340
12.2.1 Features....340
12.2.2 General operation....340
12.3 Memory map/register definition....341
12.3.1 Master Privilege Register A (AIPS_MPRA)....343
12.3.2 Peripheral Access Control Register (AIPS_PACR*n*)....346
12.3.3 Off-Platform Peripheral Access Control Register (AIPS_OPACR*n*)....351
12.4 Functional description....357
12.4.1 Access support....357

Chapter 13
System Memory Protection Unit (SMPU)

13.1 System Memory Protection Unit (SMPU) chip-specific module information....359
13.1.1 SMPUx configuration....359
13.2 Overview....360
13.2.1 Block diagram....360
13.2.2 Features....361
13.3 Memory map/register definition....362
13.3.1 Control/Error Status Register 0 (SMPU_CESR0)....365
13.3.2 Control/Error Status Register 1 (SMPU_CESR1)....366
13.3.3 Error Address Register, Bus Master n (SMPU_EAR*n*)....367
13.3.4 Error Detail Register, Bus Master n (SMPU_EDR*n*)....367
13.3.5 Region Descriptor n, Word 0 (SMPU_RGD*n*_WORD0)....368

13.3.6 Region Descriptor n, Word 1 (SMPU_RGD*n*_WORD1)....369
13.3.7 Region Descriptor n, Word 2 (SMPU_RGD*n*_WORD2)....369
13.3.8 Region Descriptor n, Word 3 (SMPU_RGD*n*_WORD3)....371
13.4 Functional description....372
13.4.1 Access evaluation macro....372
13.4.2 Final evaluation and error terminations....373
13.5 Initialization information....374
13.6 Application information....375

Chapter 14
Intelligent AHB Gasket (IAHBG)

14.1 IAHBG chip-specific module information....377
14.1.1 IAHBG implemented operation modes....377
14.1.2 IAHBG clock selection ratios....377
14.1.3 IAHBG features enabled by Platform Configuration Module (PCM)....377
14.2 Introduction....378
14.3 Timing modes....378
14.3.1 1:1....378
14.3.2 2:1....378
14.3.3 1:2....379

Chapter 15
Platform Configuration Module (PCM)

15.1 PCM memory map....381
15.1.1 FEC Burst Optimization Master Control Register (PCM_FBOMCR)....382
15.1.2 Bus Bridge Configuration Register 1 (PCM_IAHB_BE1)....383
15.1.3 Bus Bridge Configuration Register 2 (PCM_IAHB_BE2)....385
15.1.4 IPS Clock Gating Module Enable 0 Register (PCM_IPS_CGM_EN0)....386

Chapter 16
Semaphores2 (SEMA42)

16.1 Introduction....389
16.1.1 Features....389

16.2 Memory map/register definition....391
16.2.1 Gate Register (SEMA42_GATE*n*)....391
16.2.2 Reset Gate Write (SEMA42_RSTGT_W)....392
16.2.3 Reset Gate Read (SEMA42_RSTGT_R)....394
16.3 Functional description....395

Chapter 17
Interrupt Controller (INTC)

17.1 Interrupt Controller (INTC) chip-specific module information....397
17.1.1 INTC configurable parameters....397
17.1.2 Interrupt sources....397
17.2 Introduction....410
17.3 Block diagram....411
17.4 Features....412
17.5 Modes of operation....413
17.5.1 Software vector mode....414
17.5.2 Hardware vector mode....414
17.6 Memory map and register definition....415
17.6.1 INTC Block Configuration Register (INTC_BCR)....444
17.6.2 INTC Master Protection Register (INTC_MPROT)....446
17.6.3 INTC Current Priority Register for Processor 0 (INTC_CPR0)....447
17.6.4 INTC Current Priority Register for Processor 1 (INTC_CPR1)....448
17.6.5 INTC Interrupt Acknowledge Register for Processor 0 (INTC_IACKR0)....449
17.6.6 INTC Interrupt Acknowledge Register for Processor 1 (INTC_IACKR1)....450
17.6.7 INTC End Of Interrupt Register for Processor 0 (INTC_EOIR0)....451
17.6.8 INTC End Of Interrupt Register for Processor 1 (INTC_EOIR1)....451
17.6.9 INTC Software Set/Clear Interrupt Register (INTC_SSCIR*n*)....452
17.6.10 INTC Priority Select Register (INTC_PSR*n*)....454
17.6.11 INTC Monitor Mode Register 0 (INTC_MMRC0)....456
17.6.12 INTC HIPRI Register (INTC_HIPRI*n*C0)....457

17.6.13 INTC LAT Register (INTC_LAT*n*C0)....457
17.6.14 INTC Timer Register (INTC_TIMER*n*C0)....458
17.6.15 INTC Monitor Mode Register 1 (INTC_MMRC1)....458
17.6.16 INTC HIPRI Register (INTC_HIPRI*n*C1)....459
17.6.17 INTC LAT Register (INTC_LAT*n*C1)....459
17.6.18 INTC Timer Register (INTC_TIMER*n*C1)....460
17.7 Functional description....460
17.7.1 Interrupt request sources....460
17.7.2 Priority management....462
17.7.3 Handshaking with processor....464
17.7.4 Interrupt Controller Monitor (INTCM)....467
17.8 Initialization/application information....468
17.8.1 Initialization flow....468
17.8.2 Interrupt exception handler....469
17.8.3 ISR, RTOS, and task hierarchy....470
17.8.4 Order of execution....471
17.8.5 Priority ceiling protocol....472
17.8.6 Selecting priorities according to request rates and deadlines....475
17.8.7 Software-settable interrupt requests....476
17.8.8 Lowering priority within an ISR....477
17.8.9 Negating an interrupt request outside of its ISR....478
17.8.10 Examining LIFO contents....478
17.9 Interrupt sources....479

Chapter 18
Enhanced Direct Memory Access (eDMA)

18.1 Introduction....481
18.2 Overview....482
18.3 Features....482
18.4 Memory map/register definition....488

18.5 Memory Map and Registers....491
18.5.1 Control Register (DMA_CR)....520
18.5.2 Error Status Register (DMA_ES)....523
18.5.3 Enable Request Register High (DMA_ERQH)....526
18.5.4 Enable Request Register Low (DMA_ERQL)....530
18.5.5 Enable Error Interrupt Register High (DMA_EEIH)....533
18.5.6 Enable Error Interrupt Register Low (DMA_EEIL)....537
18.5.7 Set Enable Request Register (DMA_SERQ)....540
18.5.8 Clear Enable Request Register (DMA_CERQ)....541
18.5.9 Set Enable Error Interrupt Register (DMA_SEEI)....542
18.5.10 Clear Enable Error Interrupt Register (DMA_CEEI)....543
18.5.11 Clear Interrupt Request Register (DMA_CINT)....544
18.5.12 Clear Error Register (DMA_CERR)....545
18.5.13 Set START Bit Register (DMA_SSRT)....546
18.5.14 Clear DONE Status Bit Register (DMA_CDNE)....547
18.5.15 Interrupt Request Register High (DMA_INTH)....547
18.5.16 Interrupt Request Register Low (DMA_INTL)....551
18.5.17 Enable Error Interrupt Register High (DMA_ERRH)....555
18.5.18 Enable Error Interrupt RegisterLow (DMA_ERRL)....559
18.5.19 Hardware Request Status Register High (DMA_HRSH)....563
18.5.20 Hardware Request Status Register Low (DMA_HRSL)....566
18.5.21 Channel n Priority Register (DMA_DCHPRI*n*)....569
18.5.22 Channel n Master ID Register (DMA_DCHMID*n*)....571
18.5.23 TCD Source Address (DMA_TCD*n*_WORD_0)....572
18.5.24 TCD Transfer Attributes (DMA_TCD*n*_WORD_1)....573
18.5.25 TCD Number of bytes to be transferred (DMA_TCD*n*_WORD_2_NBYTES)....574
18.5.26 TCD Signed Minor Loop Offset (Minor Loop and Offset Enabled) (DMA_TCD*n*_WORD_2_MLOOP)575
18.5.27 TCD Last Source Address Adjustment (DMA_TCD*n*_WORD_3)....576
18.5.28 TCD Destination Address (DMA_TCD*n*_WORD_4)....576

18.5.29 TCD Current Minor Loop Link, Major Loop Count (Channel Linking Enabled) (DMA_TCD*n*_WORD_5)....577
18.5.30 TCD Last Destination Address Adjustment/Scatter Gather Address (DMA_TCD*n*_WORD_6)....578
18.5.31 TCD Control and Status (DMA_TCD*n*_WORD_7)....579
18.6 Functional description....582
18.6.1 eDMA microarchitecture....582
18.6.2 eDMA basic data flow....583
18.6.3 eDMA performance....587
18.7 Initialization/application information....591
18.7.1 eDMA initialization....591
18.7.2 eDMA programming errors....592
18.7.3 eDMA arbitration mode considerations....593
18.7.4 Transfer....595
18.7.5 TCD status....598
18.7.6 Channel linking....600
18.7.7 Dynamic programming....601

Chapter 19
Direct Memory Access Multiplexer (DMACHMUX)

19.1 DMACHMUX chip-specific module information....607
19.1.1 DMA channel assignment....607
19.1.2 DMA channel multiplexing block diagram....607
19.1.3 DMA request mapping....608
19.1.4 DMAMUX Memory map....611
19.2 Introduction....611
19.2.1 Overview....611
19.2.2 Features....612
19.2.3 Modes of operation....612
19.3 External signal description....613

19.4 Memory map/register definition....613
19.4.1 Channel Configuration register (DMAMUX_CHCFG*n*)....614
19.5 Functional description....615
19.5.1 DMA channels with periodic triggering capability....615
19.5.2 DMA channels with no triggering capability....617
19.5.3 Always-enabled DMA sources....618
19.6 Initialization/application information....619
19.6.1 Reset....619
19.6.2 Enabling and configuring sources....619

Chapter 20
Wakeup Unit (WKPU)

20.1 Introduction....623
20.1.1 Features....624
20.2 External Signal Description....624
20.3 WKPU memory map and registers....624
20.3.1 NMI Status Flag Register (WKPU_NSR)....625
20.3.2 NMI Configuration Register (WKPU_NCR)....627
20.4 Functional Description....629
20.4.1 Non-Maskable Interrupts....629
20.4.2 System Wakeup....629
20.4.3 Glitch Filter....630
20.5 Initialization Information....630
20.5.1 Glitch Filter and Pad Configuration....630
20.5.2 Non-Maskable Interrupts....631

Chapter 21
Error Injection Module (EIM)

21.1 Error Injection Module (EIM) chip-specific module information....633
21.2 Introduction....633
21.2.1 Overview....633

21.2.2 Features....634
21.3 Memory map and register definition....635
21.3.1 Error Injection Module Configuration Register (EIM_EIMCR)....636
21.3.2 Error Injection Channel Enable register (EIM_EICHEN)....637
21.3.3 Error Injection Channel Descriptor, Word0 (EIM_EICHD*n*_WORD0)....638
21.3.4 Error Injection Channel Descriptor, Word1 (EIM_EICHD*n*_WORD1)....639
21.3.5 Error Injection Channel Descriptor, Word2 (EIM_EICHD*n*_WORD2)....639
21.4 Functional description....640

Chapter 22
Clocking

22.1 Introduction....641
22.2 Clock generation....642
22.2.1 MC_CGM registers....644
22.3 System clock frequency limitations....645
22.3.1 JTAG frequencies....646
22.4 Default clock configuration....647
22.5 Clock sources....647
22.5.1 PLL....647
22.5.2 External oscillator (XOSC)....652
22.5.3 Internal 16 MHz RC Oscillator (IRCOSC)....653
22.6 Peripheral Clocks....654
22.6.1 LFAST clocking....655
22.6.2 Ethernet clocking....656
22.6.3 Sigma-Delta ADC clocking....657
22.6.4 LINFlex clocking....658
22.7 Clock monitoring....659
22.7.1 CMU configuration....659
22.7.2 External oscillator (XOSC) monitor....662
22.7.3 Internal RC oscillator (IRCOSC) monitor....662

22.8 Loss of system clock behavior....662
22.8.1 Loss of PLL or XOSC....663
22.8.2 Loss of IRCOSC....663
22.8.3 PLL loss of lock interrupt....663
22.9 Progressive clock switching....664

Chapter 23
Dual PLL Digital Interface (PLLDIG)

23.1 Introduction....665
23.2 Block Diagram....665
23.3 Features....665
23.4 Modes of operation....666
23.4.1 Bypass mode with reference, both PLLs disabled....666
23.4.2 Normal mode with reference, PLL0 or both PLLs enabled....666
23.5 Memory map and register definition....667
23.5.1 PLLDIG PLL0 Control Register (PLLDIG_PLL0CR)....668
23.5.2 PLLDIG PLL0 Status Register (PLLDIG_PLL0SR)....670
23.5.3 PLLDIG PLL0 Divider Register (PLLDIG_PLL0DV)....672
23.5.4 PLLDIG PLL1 Control Register (PLLDIG_PLL1CR)....674
23.5.5 PLLDIG PLL1 Status Register (PLLDIG_PLL1SR)....676
23.5.6 PLLDIG PLL1 Divider Register (PLLDIG_PLL1DV)....677
23.5.7 PLLDIG PLL1 Frequency Modulation Register (PLLDIG_PLL1FM)....679
23.5.8 PLLDIG PLL1 Fractional Divide Register (PLLDIG_PLL1FD)....681
23.6 Register classification for safety requirements....682
23.7 Functional description....682
23.7.1 Input clock frequency....682
23.7.2 Clock configuration....682
23.7.3 Frequency modulation....684
23.8 Maximum lock time....686
23.9 Initialization information....686

Chapter 24
Clock Monitor Unit (CMU)

24.1 Introduction....687
24.1.1 Main features....688
24.2 Block diagram....688
24.3 Signals....688
24.4 Register description and memory map....689
24.4.1 CMU Control Status Register (CMU_CSR)....690
24.4.2 CMU Frequency Display Register (CMU_FDR)....691
24.4.3 CMU High Frequency Reference Register CLKMN1 (CMU_HFREFR)....692
24.4.4 CMU Low Frequency Reference Register CLKMN1 (CMU_LFREFR)....692
24.4.5 CMU Interrupt Status Register (CMU_ISR)....693
24.4.6 CMU Measurement Duration Register (CMU_MDR)....695
24.5 Functional description....695
24.5.1 Frequency meter....695
24.5.2 CLKMN0_RMT supervisor....696
24.5.3 CLKMN1 supervisor....696

Chapter 25
Clock Generation Module (MC_CGM)

25.1 Introduction....699
25.1.1 Overview....699
25.1.2 Features....700
25.2 External Signal Description....701
25.3 MC_CGM Registers....701
25.3.1 PCS Switch Duration (MC_CGM_PCS_SDUR)....704
25.3.2 PCS Divider Change for external crystal oscillator (MC_CGM_PCS_DIVC1)....704
25.3.3 PCS Divider End for external crystal oscillator (MC_CGM_PCS_DIVE1)....705
25.3.4 PCS Divider Start for external crystal oscillator (MC_CGM_PCS_DIVS1)....705
25.3.5 PCS Divider Change for PLL0 PHI (MC_CGM_PCS_DIVC2)....706

25.3.6 PCS Divider End for PLL0 PHI (MC_CGM_PCS_DIVE2)....707
25.3.7 PCS Divider Start for PLL0 PHI (MC_CGM_PCS_DIVS2)....707
25.3.8 PCS Divider Change for PLL1 PHI (MC_CGM_PCS_DIVC4)....708
25.3.9 PCS Divider End for PLL1 PHI (MC_CGM_PCS_DIVE4)....708
25.3.10 PCS Divider Start for PLL1 PHI (MC_CGM_PCS_DIVS4)....709
25.3.11 System Clock Divider Ratio Change Register (MC_CGM_SC_DIV_RC)....710
25.3.12 Divider Update Type (MC_CGM_DIV_UPD_TYPE)....711
25.3.13 Divider Update Trigger (MC_CGM_DIV_UPD_TRIG)....712
25.3.14 Divider Update Status (MC_CGM_DIV_UPD_STAT)....713
25.3.15 System Clock Select Status (MC_CGM_SC_SS)....715
25.3.16 System Clock Divider Configuration 0 (MC_CGM_SC_DC0)....716
25.3.17 System Clock Divider Configuration 1 (MC_CGM_SC_DC1)....717
25.3.18 System Clock Divider Configuration 2 (MC_CGM_SC_DC2)....717
25.3.19 Aux Clock 0 Select Control (MC_CGM_AC0_SC)....718
25.3.20 Aux Clock 0 Select Status (MC_CGM_AC0_SS)....719
25.3.21 Aux Clock 0 Divider Configuration 0 (MC_CGM_AC0_DC0)....720
25.3.22 Aux Clock 0 Divider Configuration 1 (MC_CGM_AC0_DC1)....721
25.3.23 Aux Clock 0 Divider Configuration 2 (MC_CGM_AC0_DC2)....721
25.3.24 Aux Clock 0 Divider Configuration 3 (MC_CGM_AC0_DC3)....722
25.3.25 Aux Clock 0 Divider Configuration 4 (MC_CGM_AC0_DC4)....723
25.3.26 Aux Clock 1 Select Control (MC_CGM_AC1_SC)....724
25.3.27 Aux Clock 1 Select Status (MC_CGM_AC1_SS)....725
25.3.28 Aux Clock 1 Divider Configuration 0 (MC_CGM_AC1_DC0)....726
25.3.29 Aux Clock 2 Select Control (MC_CGM_AC2_SC)....726
25.3.30 Aux Clock 2 Select Status (MC_CGM_AC2_SS)....727
25.3.31 Aux Clock 2 Divider Configuration 0 (MC_CGM_AC2_DC0)....728
25.3.32 Aux Clock 3 Select Control (MC_CGM_AC3_SC)....729
25.3.33 Aux Clock 3 Select Status (MC_CGM_AC3_SS)....730
25.3.34 Aux Clock 4 Select Control (MC_CGM_AC4_SC)....731

25.3.35 Aux Clock 4 Select Status (MC_CGM_AC4_SS)....732
25.3.36 Aux Clock 5 Select Control (MC_CGM_AC5_SC)....732
25.3.37 Aux Clock 5 Select Status (MC_CGM_AC5_SS)....733
25.3.38 Aux Clock 5 Divider Configuration 0 (MC_CGM_AC5_DC0)....734
25.3.39 Aux Clock 5 Divider Configuration 1 (MC_CGM_AC5_DC1)....735
25.3.40 Aux Clock 6 Select Control (MC_CGM_AC6_SC)....736
25.3.41 Aux Clock 6 Select Status (MC_CGM_AC6_SS)....737
25.3.42 Aux Clock 6 Divider Configuration 0 (MC_CGM_AC6_DC0)....737
25.3.43 Aux Clock 8 Select Control (MC_CGM_AC8_SC)....738
25.3.44 Aux Clock 8 Select Status (MC_CGM_AC8_SS)....739
25.3.45 Aux Clock 8 Divider Configuration 0 (MC_CGM_AC8_DC0)....740
25.3.46 Aux Clock 9 Select Control (MC_CGM_AC9_SC)....741
25.3.47 Aux Clock 9 Select Status (MC_CGM_AC9_SS)....742
25.3.48 Aux Clock 9 Divider Configuration 0 (MC_CGM_AC9_DC0)....743
25.3.49 Aux Clock 10 Select Control (MC_CGM_AC10_SC)....743
25.3.50 Aux Clock 10 Select Status (MC_CGM_AC10_SS)....744
25.3.51 Aux Clock 10 Divider Configuration 0 (MC_CGM_AC10_DC0)....745
25.4 Functional Description....746
25.4.1 System Clock Generation....746
25.4.2 Auxiliary Clock Generation....751
25.4.3 Dividers Functional Description....758

Chapter 26
OSC Digital Interface (XOSC)

26.1 Introduction....769
26.2 Functional description....769
26.2.1 Oscillator power-down control and status....770
26.2.2 Oscillator startup delay....770
26.2.3 Oscillator clock available interrupt....770
26.2.4 Oscillator bypass mode....771

26.3 Memory map and register definition....771
26.3.1 XOSC Control Register (XOSC_CTL)....772

Chapter 27
IRCOSC Digital Interface

27.1 Introduction....775
27.2 Functional description....775
27.3 Memory map and register definition....776
27.3.1 IRCOSC Control Register (IRCOSC_CTL)....776
27.3.2 Frequency trimming calculation....777

Chapter 28
RAM Controller (PRAMC)

28.1 Introduction....779
28.2 SRAM controller memory map and register definition....780
28.2.1 Platform RAM Configuration Register 1 (PRAMC_PRCR1)....781
28.3 Functional description....783
28.3.1 Read and Write operations....783
28.3.2 Writes....784
28.4 Initialization/application information....786
28.5 Reliability considerations....786
28.5.1 Hsiao ECC algorithm....786

Chapter 29
Flash memory controller

29.1 Flash memory controller (PFLASH) chip-specific module information....791
29.1.1 PFCR1[RWSC]....791
29.2 Introduction....791
29.3 Features....792
29.4 Block diagrams....792
29.5 Flash memory controller memory map....793
29.5.1 Platform Flash Configuration Register 1 (PFLASH_PFCR1)....798
29.5.2 Platform Flash Configuration Register 2 (PFLASH_PFCR2)....802

29.5.3 Platform Flash Configuration Register 3 (PFLASH_PFCR3)....805
29.5.4 Platform Flash Access Protection Register (PFLASH_PFAPR)....807
29.5.5 Platform Flash Remap Control Register (PFLASH_PFCRCR)....810
29.5.6 Platform Flash Remap Descriptor Enable Register (PFLASH_PFCRDE)....812
29.5.7 Platform Flash Calibration Region Descriptor n Word0 (PFLASH_PFCRD*n*_Word0)....817
29.5.8 Platform Flash Calibration Region Descriptor n Word1 (PFLASH_PFCRD*n*_Word1)....818
29.5.9 Platform Flash Calibration Region Descriptor n Word2 (PFLASH_PFCRD*n*_Word2)....819
29.6 Functional description....824
29.6.1 Basic interface protocol....825
29.6.2 Access protections....825
29.6.3 Access pipelining....827
29.6.4 Line read buffers and prefetch operation....827
29.6.5 Instruction/Data prefetch triggering....828
29.6.6 Per-Master prefetch triggering....829
29.6.7 Buffer allocation....829
29.6.8 PFlash calibration remap support....829
29.6.9 Reliability considerations....836
29.6.10 ECC on data flash accesses....840
29.6.11 Array integrity considerations....841

Chapter 30
Embedded Flash Memory (c55fmc)

30.1 Embedded Flash Memory (c55fmc) chip-specific module information....843
30.2 C55FMC_LOCKn register bit mapping....843
30.3 C55FMC_SELn register bit mapping....843
30.4 Embedded Flash Memory (c55fmc) register reset values....843
30.5 Introduction....844
30.5.1 Overview....845
30.5.2 Features....846
30.5.3 Modes of operation....846

30.6 UTest NVM block....847
30.7 Test mode disable seal....847
30.8 Memory map and register definition....848
30.8.1 Module Configuration Register (C55FMC_MCR)....850
30.8.2 Extended Module Configuration Register (C55FMC_MCRE)....855
30.8.3 Lock 0 register (C55FMC_LOCK0)....858
30.8.4 Lock 1 register (C55FMC_LOCK1)....860
30.8.5 Lock 2 register (C55FMC_LOCK2)....860
30.8.6 Lock 3 register (C55FMC_LOCK3)....861
30.8.7 Select 0 register (C55FMC_SEL0)....862
30.8.8 Select 1 register (C55FMC_SEL1)....863
30.8.9 Select 2 register (C55FMC_SEL2)....864
30.8.10 Select 3 register (C55FMC_SEL3)....865
30.8.11 Address register (C55FMC_ADR)....866
30.8.12 UTest 0 register (C55FMC_UT0)....868
30.8.13 UMISR register (C55FMC_UM*n*)....871
30.8.14 UMISR register (C55FMC_UM9)....872
30.8.15 Over-Program Protection 0 register (C55FMC_OPP0)....873
30.8.16 Over-Program Protection 1 register (C55FMC_OPP1)....874
30.8.17 Over-Program Protection 2 register (C55FMC_OPP2)....875
30.8.18 Over-Program Protection 3 register (C55FMC_OPP3)....875
30.8.19 Test Mode Disable Password Check register (C55FMC_TMD)....876
30.9 Functional Description....877
30.9.1 User Mode....878
30.9.2 UTest mode....886
30.10 Initialization information....890

Chapter 31
Decorated Storage Memory Controller (DSMC)

31.1 Decorated Storage Memory Controller (DSMC) chip-specific module information....893

31.2 Introduction....894
31.3 Decorated stores: st[b,h,w]d{cb}x rS,rA,rB....896
31.3.1 Bit Field Insert (BFINS) into an 8, 16 or 32-bit memory container....897
31.4 DSMC instantiations....902

Chapter 32
Flash Memory Programming and Configuration

32.1 Introduction....903
32.2 Selection of flash memory blocks for erase....905
32.3 Non-secure write protection....907
32.4 Security configuration planning....909
32.4.1 Creating password groups....909
32.5 Secure write protection....910
32.5.1 Implementing secure write protection....911
32.5.2 Overriding secure write protection....915
32.6 Secure read protection....917
32.6.1 Implementing secure read protection....918
32.6.2 Overriding secure read protection....922
32.7 Debug port enable/disable....923
32.8 Tamper detection....923
32.8.1 Implementing tamper detection....924
32.8.2 Creating the tamper detect diary....924
32.8.3 Assigning blocks to Tamper Detection Regions (TDRs)....926
32.8.4 Overriding tamper detection....926
32.9 Implementing OTP....927

Chapter 33
Analog Peripheral Modules

33.1 Analog sub-system overview....929
33.1.1 Block diagram....929

Chapter 34
Sigma Delta Analog-to-Digital Converter (SDADC) Digital Interface

34.1 Sigma Delta Analog-to-Digital Converter (SDADC) digital interface chip-specific information....931
34.1.1 Introduction....931
34.1.2 Sigma-Delta ADC features....931
34.1.3 Sigma-Delta ADC block diagram....932
34.1.4 Sigma-Delta ADC external signal description....933
34.1.5 Sigma-Delta ADC analog input multiplexing....933
34.1.6 Sigma-Delta digital interface....934
34.1.7 Sigma-Delta ADC clock architecture....934
34.1.8 Sigma-Delta ADC starting and triggering....935
34.1.9 Sigma-Delta ADC input biasing....937
34.1.10 Sigma-Delta ADC conversion result processing....937
34.1.11 Sigma-Delta interface to ETPU module....938
34.1.12 Sigma-Delta interface to eMIOS module....939
34.1.13 Sigma-Delta interface to decimation filter modules....940
34.1.14 Sigma-Delta interface to reaction channels....940
34.1.15 Sigma-Delta Interface to the Cross Triggering Unit (CTU)....940
34.2 Sigma Delta Analog-to-Digital Converter (SDADC) digital interface reference....941
34.2.1 Introduction....941
34.2.2 Overview....941
34.2.3 Features....941
34.2.4 Modes of operation....942
34.2.5 External signal description....942

34.2.6 Memory map and register definition....943
34.2.7 Functional description....958
34.2.8 Initialization information....964

Chapter 35
Analog-to-Digital Converter (ADC)

35.1 Analog-to-Digital Converter (ADC) chip-specific information....967
35.1.1 Introduction....967
35.1.2 SAR ADC block diagram....967
35.1.3 SAR ADC external signal description....968
35.1.4 SARADC feature comparison....969
35.1.5 SARADC channel map....969
35.1.6 SARADC control registers....973
35.1.7 SAR ADC trigger inputs....977
35.1.8 SAR ADC externally muxed inputs....977
35.1.9 SAR ADC conversion result processing....979
35.2 Analog-to-Digital Converter (ADC) reference....980
35.2.1 Introduction....980
35.2.2 Overview....980
35.2.3 Features....983
35.2.4 Memory Map/Register Definition....985
35.2.5 Functional description....1102
35.2.6 Clock frequency....1132

Chapter 36
Decimation Filter (DECFILTER)

36.1 Decimation Filter chip-specific module information....1135
36.2 Introduction....1135
36.2.1 Overview....1135
36.2.2 Features....1137

36.2.3 Modes of operation....1137
36.3 External signal description....1139
36.3.1 Integrator enable signal....1139
36.3.2 Integrator halt signal....1139
36.3.3 Integrator reset signal....1139
36.3.4 Integrator output request signal....1139
36.4 Memory map and register definition....1140
36.4.1 Module Configuration Register (DECFILTER_MCR)....1141
36.4.2 Module Status Register (DECFILTER_MSR)....1145
36.4.3 Module Extended Config Register (DECFILTER_MXCR)....1149
36.4.4 Module Extended Status Register (DECFILTER_MXSR)....1152
36.4.5 Interface Input Buffer (DECFILTER_IB)....1155
36.4.6 Interface Output Buffer (DECFILTER_OB)....1156
36.4.7 Filter Coefficient (DECFILTER_COEF*n*)....1157
36.4.8 Filter TAP (DECFILTER_TAP*n*)....1157
36.4.9 Final Integer Value Register (DECFILTER_FINTVAL)....1158
36.4.10 Final Integer Count Register (DECFILTER_FINTCNT)....1159
36.4.11 Current Integer Value Register (DECFILTER_CINTVAL)....1159
36.4.12 Current Integer Count Register (DECFILTER_CINTCNT)....1160
36.5 Functional Description....1160
36.5.1 Overview....1160
36.5.2 Data Interface sub-block description....1160
36.5.3 Input Buffer Description....1161
36.5.4 Output Buffer Description....1162
36.5.5 Bypass Configuration Description....1163
36.5.6 IIR and FIR Filter....1163
36.5.7 Filter Prefill Control Description....1167
36.5.8 Flush Command Description....1168
36.5.9 Soft-Reset Command Description....1169

36.5.10 Interrupts Requests Description....1170
36.5.11 DMA Requests Description....1172
36.5.12 Freeze Mode Description....1173
36.5.13 Integrator....1173
36.5.14 Cascade mode description....1178
36.6 Initialization Information....1182
36.6.1 Initialization Procedure....1182
36.7 Filter Example Simulation....1183
36.7.1 Coefficients Calculation....1183
36.7.2 Input Data Calculation....1184
36.7.3 Filter Results....1185

Chapter 37
Temperature Sensor (TSENS)

37.1 Introduction....1187
37.2 Functional Description....1187
37.2.1 Temperature threshold detection (digital output generation)....1188
37.2.2 Linear temperature sensor (analog output generation)....1189
37.3 Temperature formula....1189
37.4 Calculating device temperature....1190

Chapter 38
Timers Overview

38.1 Timers Overview....1191

Chapter 39
System Timer Module (STM)

39.1 System Timer Module (STM) configuration....1193
39.1.1 STM chip-specific module information....1193
39.2 Introduction....1193
39.2.1 Overview....1193
39.2.2 Features....1194
39.2.3 Modes of operation....1194

39.3 External signal description....1194
39.4 Memory map and registers....1194
39.4.1 STM Control Register (STM_CR)....1195
39.4.2 STM Count Register (STM_CNT)....1196
39.4.3 STM Channel Control Register (STM_CCR*n*)....1197
39.4.4 STM Channel Interrupt Register (STM_CIR*n*)....1197
39.4.5 STM Channel Compare Register (STM_CMP*n*)....1198
39.5 Functional description....1198

Chapter 40
Software Watchdog Timer (SWT)

40.1 Software Watchdog Timer (SWT) chip-specific module information....1201
40.1.1 Implementation....1201
40.1.2 Configuration....1201
40.1.3 SWT_TO register minimum value....1202
40.1.4 SWT time-out events: configuring reset and interrupt requests....1202
40.2 Introduction....1203
40.2.1 Overview....1203
40.2.2 Features....1203
40.2.3 Modes of operation....1203
40.3 External signal description....1204
40.4 Memory Map and Registers....1204
40.4.1 SWT Control Register (SWT_CR)....1205
40.4.2 SWT Interrupt Register (SWT_IR)....1208
40.4.3 SWT Time-out Register (SWT_TO)....1208
40.4.4 SWT Window Register (SWT_WN)....1209
40.4.5 SWT Service Register (SWT_SR)....1209
40.4.6 SWT Counter Output Register (SWT_CO)....1210
40.4.7 SWT Service Key Register (SWT_SK)....1211

40.5 Functional description....1211
40.5.1 Introduction....1211
40.5.2 Configuration locking....1212
40.5.3 Unlock sequence....1213
40.5.4 Servicing operations....1213
40.5.5 Time-out....1215
40.5.6 Initialization....1215

Chapter 41
Periodic Interrupt Timer (PIT-RTI)

41.1 Periodic Interrupt Timer (PIT-RTI) chip-specific module information....1217
41.1.1 Overview....1217
41.1.2 Configuration....1217
41.1.3 General-use PIT....1218
41.2 Introduction....1218
41.2.1 Block diagram....1218
41.2.2 Features....1219
41.3 Modes of operation....1220
41.4 Signal description....1220
41.5 Memory map/register description....1220
41.5.1 PIT Module Control Register (PIT_MCR)....1222
41.5.2 PIT Upper Lifetime Timer Register (PIT_LTMR64H)....1223
41.5.3 PIT Lower Lifetime Timer Register (PIT_LTMR64L)....1224
41.5.4 Timer Load Value Register (PIT_RTI_LDVAL)....1224
41.5.5 Current Timer Value Register (PIT_RTI_CVAL)....1225
41.5.6 Timer Control Register (PIT_RTI_TCTRL)....1225
41.5.7 Timer Flag Register (PIT_RTI_TFLG)....1226
41.5.8 Timer Load Value Register (PIT_LDVAL*n*)....1227
41.5.9 Current Timer Value Register (PIT_CVAL*n*)....1227
41.5.10 Timer Control Register (PIT_TCTRL*n*)....1228

41.5.11 Timer Flag Register (PIT_TFLG*n*)....1229
41.6 Functional description....1229
41.6.1 General operation....1229
41.6.2 Interrupts....1231
41.6.3 Chained timers....1231
41.7 Initialization and application information....1232
41.8 Example configuration for chained timers....1233
41.9 Example configuration for the lifetime timer....1234

Chapter 42
Enhanced Modular IO Subsystem (eMIOS200)

42.1 Enhanced Modular IO Subsystem (eMIOS253) chip-specific module information....1235
42.1.1 Configuration....1235
42.1.2 Global Timebase Enabling....1235
42.1.3 Clocking....1236
42.1.4 STAC bus....1236
42.1.5 Output Disable Inputs....1236
42.2 eMIOS200 Introduction....1236
42.2.1 Overview....1236
42.2.2 Features....1238
42.2.3 Modes of operation....1239
42.3 Memory map / register definition....1240
42.3.1 Memory map....1240
42.4 Control Memory Map and Registers....1242
42.4.1 eMIOS Module Configuration Register (eMIOS_MCR)....1242
42.4.2 eMIOS Global FLAG Register (eMIOS_GFLAG)....1244
42.4.3 eMIOS Output Update Disable register (eMIOS_OUDIS)....1244
42.4.4 eMIOS Disable Channel register (eMIOS_UCDIS)....1245
42.5 Unified Channels Memory Map and Registers....1246
42.5.1 eMIOS UC A register n (eMIOS_A*n*)....1248

42.5.2 eMIOS UC B register n (eMIOS_B*n*)....1249
42.5.3 eMIOS CNT register n (eMIOS_CNT*n*)....1250
42.5.4 eMIOS UC Control register n (eMIOS_C*n*)....1251
42.5.5 eMIOS UC Status register n (eMIOS_S*n*)....1257
42.5.6 eMIOS Alternate Address register n (eMIOS_ALTA*n*)....1259
42.6 Functional Description....1259
42.6.1 Unified Channel (UC)....1261
42.6.2 IP Bus Interface Unit (BIU)....1311
42.6.3 STAC Bus Client submodule....1312
42.6.4 Global Clock Prescaler Submodule (GCP)....1312
42.7 Initialization/Application Information....1313
42.7.1 Considerations....1313
42.7.2 Application Information....1314

Chapter 43
Enhanced Time Processing Unit (eTPU)

43.1 Enhanced Time Processing Unit (eTPU) chip-specific module information....1319
43.1.1 Configuration....1319
43.1.2 Device-specific information....1319
43.1.3 Register reset values....1320
43.1.4 Memory....1320
43.1.5 Clocking....1320
43.1.6 Debug....1321
43.1.7 STAC bus....1321
43.1.8 Input connections....1321
43.1.9 Output connections....1322

43.2 Introduction....1322
43.2.1 Overview....1323
43.2.2 Features....1330
43.2.3 Modes of Operation....1337
43.3 Detailed Signal Descriptions....1339
43.3.1 eTPU Channel Output Signals....1339
43.3.2 eTPU Channel Input Signals....1339
43.3.3 Time Base Clock Signal — TCRCLK....1340
43.3.4 eTPU Channel Output Disable Signals....1340
43.4 Memory Map/Register Definition....1341
43.5 Memory Map....1341
43.6 System Configuration memory map and registers....1346
43.6.1 eTPU Module Configuration Register (eTPU_SCR_MCR)....1347
43.6.2 eTPU Coherent Dual-Parameter Controller Register (eTPU_SCR_CDCR)....1351
43.6.3 eTPU MISC Compare Register (eTPU_SCR_MISCCMPR)....1353
43.6.4 eTPU SCM Off-range Data Register (eTPU_SCR_SCMOFFDATAR)....1353
43.6.5 eTPU Engine 1 Configuration Register (eTPU_SCR_ECR_ENG1)....1354
43.6.6 eTPU Engine 2 Configuration Register (eTPU_SCR_ECR_ENG2)....1358
43.7 Timebase memory map and registers....1362
43.7.1 eTPU Engine 1 Time Base Configuration Register (eTPU_TBR_TBCR_ENG1)....1363
43.7.2 eTPU Engine 1 Time Base 1 (TCR1) Visibility Register (eTPU_TBR_TB1R_ENG1)....1367
43.7.3 eTPU Engine 1 Time Base 2 (TCR2) Visibility Register (eTPU_TBR_TB2R_ENG1)....1367
43.7.4 eTPU Engine 1 STAC Configuration Register (eTPU_TBR_STAC_ENG1)....1368
43.7.5 eTPU Engine 2 Time Base Configuration Register (eTPU_TBR_TBCR_ENG2)....1370
43.7.6 eTPU Engine 2 Time Base 1 (TCR1) Visibility Register (eTPU_TBR_TB1R_ENG2)....1374
43.7.7 eTPU Engine 2 Time Base 2 (TCR2) Visibility Register (eTPU_TBR_TB2R_ENG2)....1374
43.7.8 eTPU Engine 2 STAC Configuration Register (eTPU_TBR_STAC_ENG2)....1375
43.8 Engine memory map and registers....1377
43.8.1 eTPU Watchdog Timer Register for Engine 1 (eTPU_ER_WDTR_ENG1)....1377

43.8.2 eTPU Idle Register for Engine 1 (eTPU_ER_IDLER_ENG1).....1379
43.8.3 eTPU Watchdog Timer Register for Engine 2 (eTPU_ER_WDTR_ENG2).....1380
43.8.4 eTPU Idle Register for Engine 2 (eTPU_ER_IDLER_ENG2).....1381
43.9 Latency Monitor memory map and registers.....1382
43.9.1 eTPU Latency Monitor Configuration Register for Engine 1 (eTPU_LMR_LM*n*CR_ENG1).....1383
43.9.2 eTPU Latency Monitor Measure Register for Engine 1 (eTPU_LMR_LM*n*MR_ENG1).....1385
43.9.3 eTPU Latency Monitor Configuration Register for Engine 2 (eTPU_LMR_LM*n*CR_ENG2).....1386
43.9.4 eTPU Latency Monitor Measure Register for Engine 2 (eTPU_LMR_LM*n*MR_ENG2).....1387
43.10 Memory Error Support memory map and registers.....1388
43.10.1 eTPU Memory Error Control Register (eTPU_MESR_MECR).....1389
43.10.2 eTPU Data Error Injection Address Register (eTPU_MESR_DEIAR).....1392
43.10.3 eTPU Data Error Injection Data Pattern Register (eTPU_MESR_DEIDPR).....1393
43.10.4 eTPU Data Error Injection Parity Pattern Register (eTPU_MESR_DEIPPR).....1393
43.10.5 eTPU Data Error Report Address Register (eTPU_MESR_DERAR).....1395
43.10.6 eTPU Data Error Report Data Register (eTPU_MESR_DERDR).....1396
43.10.7 eTPU Data Error Report Syndrome Register (eTPU_MESR_DERSR).....1397
43.10.8 eTPU Memory Error Status Register (eTPU_MESR_MESR).....1399
43.10.9 eTPU Code Error Injection Address Register (eTPU_MESR_CEIAR).....1402
43.10.10 eTPU Code Error Injection Data Pattern Register (eTPU_MESR_CEIDPR).....1403
43.10.11 eTPU Code Error Injection Parity Pattern Register (eTPU_MESR_CEIPPR).....1403
43.10.12 eTPU Code Error Report Address Register (eTPU_MESR_CERAR).....1404
43.10.13 eTPU Code Error Report Data Register (eTPU_MESR_CERDR).....1405
43.10.14 eTPU Code Error Report Syndrome Register (eTPU_MESR_CERSR).....1406
43.10.15 eTPU Code Error Fix Register (eTPU_MESR_CEFR).....1407
43.11 Global Channel memory map and registers.....1408
43.11.1 eTPU Channel Interrupt Status Register for Engine 1 (eTPU_GCR_CISR_ENG1).....1409
43.11.2 eTPU Channel Interrupt Status Register for Engine 2 (eTPU_GCR_CISR_ENG2).....1409
43.11.3 eTPU Channel Data Transfer Request Status Register for Engine 1 (eTPU_GCR_CDTRSR_ENG1).....1410
43.11.4 eTPU Channel Data Transfer Request Status Register for Engine 2 (eTPU_GCR_CDTRSR_ENG2).....1411

43.11.5 eTPU Channel Interrupt Overflow Status Register for Engine 1 (eTPU_GCR_CIOSR_ENG1).....1412
43.11.6 eTPU Channel Interrupt Overflow Status Register for Engine 2 (eTPU_GCR_CIOSR_ENG2).....1412
43.11.7 eTPU Channel Data Transfer Request Overflow Status Register for Engine 1 (eTPU_GCR_CDTROSR_ENG1).....1413
43.11.8 eTPU Channel Data Transfer Request Overflow Status Register for Engine 2 (eTPU_GCR_CDTROSR_ENG2).....1414
43.11.9 eTPU Channel Interrupt Enable Register for Engine 1 (eTPU_GCR_CIER_ENG1).....1414
43.11.10 eTPU Channel Interrupt Enable Register for Engine 2 (eTPU_GCR_CIER_ENG2).....1415
43.11.11 eTPU Channel Data Transfer Request Enable Register for Engine 1 (eTPU_GCR_CDTRER_ENG1).…1416
43.11.12 eTPU Channel Data Transfer Request Enable Register for Engine 2 (eTPU_GCR_CDTRER_ENG2).…1416
43.11.13 eTPU Watchdog Status Register for Engine 1 (eTPU_GCR_WDSR_ENG1).....1417
43.11.14 eTPU Watchdog Status Register for Engine 2 (eTPU_GCR_WDSR_ENG2).....1417
43.11.15 eTPU Channel Pending Service Status Register for Engine 1 (eTPU_GCR_CPSSR_ENG1).....1418
43.11.16 eTPU Channel Pending Service Status Register for Engine 2 (eTPU_GCR_CPSSR_ENG2).....1419
43.11.17 eTPU Channel Service Status Register for Engine 1 (eTPU_GCR_CSSR_ENG1).....1419
43.11.18 eTPU Channel Service Status Register for Engine 2 (eTPU_GCR_CSSR_ENG2).....1420
43.12 Channel Configuration Control memory map and registers.....1421
43.12.1 eTPU Channel n Configuration Register for Engine 1 (eTPU_CCCR_C*n*CR_ENG1).....1431
43.12.2 eTPU Channel n Status Control Register for Engine 1 (eTPU_CCCR_C*n*SCR_ENG1).....1434
43.12.3 eTPU Channel n Host Service Request Register for Engine 1 (eTPU_CCCR_C*n*HSRR_ENG1).....1436
43.12.4 eTPU Channel n Configuration Register for Engine 2 (eTPU_CCCR_C*n*CR_ENG2).....1437
43.12.5 eTPU Channel n Status Control Register for Engine 2 (eTPU_CCCR_C*n*SCR_ENG2).....1440
43.12.6 eTPU Channel n Host Service Request Register for Engine 2 (eTPU_CCCR_C*n*HSRR_ENG2).....1442
43.13 Shared Subsystem Integration memory map and registers.....1443
43.13.1 eTPU Shared Subsystem n Integration Register (eTPU_SSIR_ETPUSSSIR*n*).....1444

43.14 Functional Description....1444
43.14.1 Functions and Threads....1445
43.14.2 Host Interface....1460
43.14.3 Scheduler....1468
43.14.4 Parameter Sharing and Coherency....1476
43.14.5 Enhanced Channels....1482
43.14.6 Time Bases....1533
43.14.7 EAC - eTPU Angle Counter....1542
43.14.8 Microengine....1564
43.14.9 Microinstruction Set....1583
43.14.10 Shared Subsystems Support....1617
43.14.11 Development Support Features....1620
43.14.12 Safety Features....1628
43.14.13 Performance Monitoring Features....1637
43.15 Initialization/Application Information....1639
43.15.1 Configuration Sequence....1639
43.15.2 Reset Options....1641
43.15.3 Multiple Parameter Coherency Methods....1642
43.15.4 Programming Hints and Caveats....1643
43.15.5 Estimating Worst Case Latency....1645
43.15.6 Endianness....1660
43.15.7 Memory Error Service Procedures....1660
43.16 Appendices....1663
43.16.1 Microcycle and I/O Timing....1663
43.16.2 Channel Mode Summary....1668
43.16.3 MISC Algorithm....1671

Chapter 44
Reaction Module 2 (REACM2)

44.1 Reaction Module 2 chip-specific module information....1673

44.2 Introduction....1674
44.2.1 Features....1675
44.2.2 Modes of Operation....1675
44.2.3 Block Diagram....1677
44.3 Signal Description....1681
44.3.1 REACM2_RCHn — REACM Channel (n) Output Pin a, b and c....1681
44.4 Memory Map and Register Definition....1682
44.4.1 Module Configuration (REACM2_MCR)....1687
44.4.2 Timer Configuration (REACM2_TCR)....1689
44.4.3 Threshold Router Register (REACM2_THRR)....1690
44.4.4 ADC Sensor Input Register (REACM2_SINR)....1691
44.4.5 Period Generator Configuration Register (REACM2_PCR)....1692
44.4.6 Period Shift Delay Configuration Register (REACM2_PSCR)....1693
44.4.7 Global Error Flag Register (REACM2_GEFR)....1694
44.4.8 Channel n Configuration Register (REACM2_CHCR*n*)....1695
44.4.9 Channel n Status Register (REACM2_CHSR*n*)....1699
44.4.10 Channel n Router Register (REACM2_CHRR*n*)....1702
44.4.11 Shared Timer Bank (REACM2_STBK*n*)....1703
44.4.12 Hold Timer Bank (REACM2_HOTBK*n*)....1703
44.4.13 Threshold Bank (REACM2_THBK*n*)....1704
44.4.14 ADC Result Maximum Limit Check (REACM2_ADCMAX)....1705
44.4.15 Modulation Range Pulse Width (REACM2_RANGE_PWD)....1705
44.4.16 Modulation Minimum Pulse Width (REACM2_MIN_PWD)....1706
44.4.17 Modulation Control Word Bank (REACM2_MWBK*n*)....1707
44.5 Functional Description....1709
44.5.1 Reaction Channel....1710
44.5.2 Modulation Control Words Bank....1712
44.5.3 Shared Timer Bank....1713
44.5.4 Hold Time Bank....1715

44.5.5 Threshold Bank and Comparator....1716
44.5.6 ADC Interface....1717
44.5.7 Prescalers....1719
44.5.8 Period / Delay Generator....1720
44.5.9 Banked Mode Support....1721
44.6 Modulation Modes....1722
44.6.1 Threshold/Threshold Mode....1722
44.6.2 Threshold/Hold-off Mode....1723
44.6.3 Threshold/Hold-on Mode....1724
44.6.4 Threshold low/Period Mode....1725
44.6.5 Threshold high/Period Mode....1726
44.6.6 Limitations on the Modulation Process....1727
44.7 Monitored Modulation....1731
44.7.1 Monitoring the ON Pulse Width....1731
44.7.2 Monitoring the OFF State Width and the ADC Maximum Value....1735
44.8 DMA support....1737
44.9 Reset Overview....1738
44.10 Reaction Module Interrupts....1739
44.10.1 Interrupt sources....1739
44.10.2 Global Interrupt and Channel Interrupt....1739
44.11 Use cases....1740
44.11.1 Advancing Modulation Phase on a Threshold level....1747
44.11.2 Controlling the LOOP function....1748
44.11.3 Banked Mode....1749

Chapter 45
Input Glitch Filter (IGF)

45.1 Input Glitch Filter chip-specific module information....1751
45.2 Introduction....1752
45.3 Filter Cluster....1752

45.4 Block Diagram....1753
45.5 Input Glitch Filter overview....1754
45.5.1 Interaction with other peripherals....1754
45.5.2 Mode of operation....1755
45.6 Memory map....1757
45.6.1 Module Configuration Register (IGF_MCR*n*)....1761
45.6.2 Module Status Register (IGF_MSR*n*)....1764
45.6.3 Prescaler Register (IGF_PRESR*n*)....1765
45.6.4 Rising edge Threshold Register (IGF_RTHR*n*)....1766
45.6.5 Falling edge Threshold Register (IGF_FTHR*n*)....1766
45.7 Functional description....1766
45.7.1 Input double sampling....1767
45.7.2 Filter types....1767
45.7.3 Application....1771
45.7.4 Programming guidelines....1774
45.7.5 On-the-fly filter reconfiguration....1774
45.8 Power saving mode....1775
45.8.1 STOP mode....1775

Chapter 46
Body Cross-triggering Unit (BCTU)

46.1 Body Cross-triggering Unit (BCTU) chip-specific module information....1777
46.1.1 Overview....1777
46.1.2 Functional Description Summary....1781
46.2 Introduction....1781
46.3 BCTU overview....1782
46.4 BCTU Interacting with other peripherals....1783
46.5 BCTU Modes of operation....1784
46.5.1 Configuration Mode....1785
46.5.2 Normal Mode....1785

46.5.3 Low Power Mode....1785
46.6 Memory Map....1786
46.6.1 Module Configuration Register (BCTU_MCR)....1789
46.6.2 Module Status register (BCTU_MSR)....1792
46.6.3 Trigger Configuration Register (BCTU_TRGCFG_*n*)....1796
46.6.4 Write Protection register (BCTU_WRPROT)....1798
46.6.5 Software Trigger register 1 (BCTU_SFTRGR1)....1799
46.6.6 Software Trigger register 1 (BCTU_SFTRGR3)....1802
46.6.7 ADC0 Result Data register (BCTU_ADC0DR)....1806
46.6.8 ADC1 result data register (BCTU_ADC1DR)....1807
46.6.9 ADC2 result data register (BCTU_ADC2DR)....1808
46.6.10 ADC3 result data register (BCTU_ADC3DR)....1809
46.6.11 LIST Size Status register (BCTU_LISTSTAR)....1809
46.6.12 LIST Channel Address Register (BCTU_LISTCHR_*n*)....1810
46.6.13 Conversion configuration register (BCTU_CCR_*n*)....1811
46.7 Functional description....1812
46.7.1 Trigger Configuration....1812
46.7.2 Trigger priority and multiplexing....1813
46.7.3 Conversion LIST....1815
46.7.4 ADC conversion results access....1817
46.7.5 Trigger clearing mechanism....1818
46.7.6 On-the-fly reconfiguration of BCTU registers....1819
46.7.7 Multiple Parallel Conversions....1820
46.8 Interrupts and DMA requests....1821

Chapter 47
CAN (FlexCAN)

47.1 CAN chip-specific module information....1823
47.1.1 FlexCAN modules on this chip....1823
47.1.2 Message buffer size....1823

47.1.3 Message buffer address offsets....1824
47.1.4 Reset value of MDIS bit....1826
47.1.5 FlexCAN Clocking....1826
47.1.6 FlexCAN Interrupts....1827
47.1.7 FlexCAN CLKSRC....1827
47.1.8 FlexCAN RAM to memory map address mapping....1827
47.2 Introduction....1828
47.2.1 Overview....1829
47.2.2 FlexCAN module features....1830
47.2.3 Modes of operation....1832
47.3 FlexCAN signal descriptions....1833
47.3.1 CAN Rx....1833
47.3.2 CAN Tx....1833
47.4 Memory map/register definition....1834
47.4.1 FlexCAN memory mapping....1834
47.4.2 Module Configuration Register (CAN_MCR)....1842
47.4.3 Control 1 register (CAN_CTRL1)....1847
47.4.4 Free Running Timer (CAN_TIMER)....1851
47.4.5 Rx Mailboxes Global Mask Register (CAN_RXMGMASK)....1851
47.4.6 Rx 14 Mask register (CAN_RX14MASK)....1853
47.4.7 Rx 15 Mask register (CAN_RX15MASK)....1853
47.4.8 Error Counter (CAN_ECR)....1854
47.4.9 Error and Status 1 register (CAN_ESR1)....1856
47.4.10 Interrupt Masks 2 register (CAN_IMASK2)....1862
47.4.11 Interrupt Masks 1 register (CAN_IMASK1)....1862
47.4.12 Interrupt Flags 2 register (CAN_IFLAG2)....1863
47.4.13 Interrupt Flags 1 register (CAN_IFLAG1)....1864
47.4.14 Control 2 register (CAN_CTRL2)....1867
47.4.15 Error and Status 2 register (CAN_ESR2)....1870

47.4.16 CRC Register (CAN_CRCR)....1872
47.4.17 Rx FIFO Global Mask register (CAN_RXFGMASK)....1872
47.4.18 Rx FIFO Information Register (CAN_RXFIR)....1873
47.4.19 CAN Bit Timing Register (CAN_CBT)....1874
47.4.20 Interrupt Masks 3 Register (CAN_IMASK3)....1876
47.4.21 Interrupt Flags 3 Register (CAN_IFLAG3)....1877
47.4.22 Rx Individual Mask Registers (CAN_RXIMR*n*)....1877
47.4.23 Memory Error Control Register (CAN_MECR)....1878
47.4.24 Error Injection Address Register (CAN_ERRIAR)....1880
47.4.25 Error Injection Data Pattern Register (CAN_ERRIDPR)....1881
47.4.26 Error Injection Parity Pattern Register (CAN_ERRIPPR)....1881
47.4.27 Error Report Address Register (CAN_RERRAR)....1882
47.4.28 Error Report Data Register (CAN_RERRDR)....1884
47.4.29 Error Report Syndrome Register (CAN_RERRSYNR)....1884
47.4.30 Error Status Register (CAN_ERRSR)....1887
47.4.31 Message buffer structure....1888
47.4.32 Rx FIFO structure....1894
47.5 Functional description....1896
47.5.1 Transmit process....1897
47.5.2 Arbitration process....1898
47.5.3 Receive process....1902
47.5.4 Matching process....1904
47.5.5 Move process....1908
47.5.6 Data coherence....1910
47.5.7 Rx FIFO....1914
47.5.8 CAN protocol related features....1917
47.5.9 Clock domains and restrictions....1924
47.5.10 Modes of operation details....1926
47.5.11 Interrupts....1928

47.5.12 Bus interface....1930
47.5.13 Detection and Correction of Memory Errors....1930
47.6 Initialization/application information....1935
47.6.1 FlexCAN initialization sequence....1935

Chapter 48
De-serial Serial Peripheral Interface (DSPI)

48.1 DSPI chip-specific module information....1937
48.1.1 Number of CTARs....1937
48.1.2 Number of PCS signals....1938
48.1.3 IP Instantiation Parameters....1938
48.2 Introduction....1939
48.2.1 Block Diagram....1939
48.2.2 Features....1940
48.2.3 SPI Configuration....1942
48.2.4 DSI Configuration....1943
48.2.5 CSI Configuration....1943
48.2.6 Modes of Operation....1944
48.3 Module signal descriptions....1945
48.3.1 PCS0/SS — Peripheral Chip Select/Slave Select....1946
48.3.2 PCS1 – PCS3 — Peripheral Chip Selects 1 – 3....1946
48.3.3 PCS4/MTRIG — Peripheral Chip Select 4/Master Trigger....1946
48.3.4 PCS5/PCSS — Peripheral Chip Select 5/Peripheral Chip Select Strobe....1946
48.3.5 SIN — Serial Input....1947
48.3.6 SOUT — Serial Output....1947
48.3.7 SCK — Serial Clock....1947
48.4 Memory Map/Register Definition....1947
48.4.1 Module Configuration Register (DSPI_MCR)....1950
48.4.2 Transfer Count Register (DSPI_TCR)....1953
48.4.3 Clock and Transfer Attributes Register (In Master Mode) (DSPI_CTAR*n*)....1954

48.4.4 Clock and Transfer Attributes Register (In Slave Mode) (DSPI_CTAR*n*_SLAVE)....1959
48.4.5 Status Register (DSPI_SR)....1961
48.4.6 DMA/Interrupt Request Select and Enable Register (DSPI_RSER)....1965
48.4.7 PUSH TX FIFO Register In Master Mode (DSPI_PUSHR)....1968
48.4.8 PUSH TX FIFO Register In Slave Mode (DSPI_PUSHR_SLAVE)....1970
48.4.9 POP RX FIFO Register (DSPI_POPR)....1971
48.4.10 Transmit FIFO Registers (DSPI_TXFR*n*)....1971
48.4.11 Receive FIFO Registers (DSPI_RXFR*n*)....1972
48.4.12 DSI Configuration Register 0 (DSPI_DSICR0)....1973
48.4.13 DSI Serialization Data Register 0 (DSPI_SDR0)....1975
48.4.14 DSI Alternate Serialization Data Register 0 (DSPI_ASDR0)....1976
48.4.15 DSI Transmit Comparison Register 0 (DSPI_COMPR0)....1976
48.4.16 DSI Configuration Register 1 (DSPI_DSICR1)....1977
48.4.17 DSI Serialization Source Select Register 0 (DSPI_SSR0)....1979
48.4.18 DSI Serialization Data Register 1 (DSPI_SDR1)....1979
48.4.19 DSI Alternate Serialization Data Register 1 (DSPI_ASDR1)....1980
48.4.20 DSI Transmit Comparison Register 1 (DSPI_COMPR1)....1981
48.4.21 DSI Deserialization Data Register 1 (DSPI_DDR1)....1981
48.4.22 DSI Serialization Source Select Register 1 (DSPI_SSR1)....1982
48.4.23 DSI Deserialized Data Interrupt Mask Register 1 (DSPI_DIMR1)....1983
48.4.24 DSI Deserialized Data Polarity Interrupt Register 1 (DSPI_DPIR1)....1983
48.4.25 Clock and Transfer Attributes Register Extended (DSPI_CTARE*n*)....1984
48.4.26 Status Register Extended (DSPI_SREX)....1985
48.4.27 Trigger Register (DSPI_TRIG)....1986
48.4.28 Time Slot Length Register (DSPI_TSL)....1987
48.4.29 Time Slot Configuration Register (DSPI_TS_CONF)....1988
48.5 Functional description....1990
48.5.1 Start and Stop of module transfers....1991

48.5.2 Serial Peripheral Interface (SPI) configuration....1992
48.5.3 Deserial Serial Interface (DSI) Configuration....1997
48.5.4 Combined Serial Interface (CSI) Configuration....2002
48.5.5 Module baud rate and clock delay generation....2004
48.5.6 Transfer formats....2007
48.5.7 Continuous Serial Communications Clock....2019
48.5.8 Slave Mode Operation Constraints....2021
48.5.9 Timed Serial Bus (TSB)....2021
48.5.10 Interleaved TSB (ITSB) Mode....2024
48.5.11 Parity Generation and Check....2033
48.5.12 Interrupts/DMA requests....2034
48.5.13 Power saving features....2039
48.6 Initialization/application information....2040
48.6.1 How to manage queues....2040
48.6.2 Switching Master and Slave mode....2041
48.6.3 Initializing Module in Master/Slave Modes....2041
48.6.4 Baud rate settings....2041
48.6.5 Delay settings....2042
48.6.6 Calculation of FIFO pointer addresses....2043

Chapter 49
Zipwire

49.1 Introduction....2047
49.2 Block Diagram....2047
49.3 Architecture....2048
49.4 LFAST Clocking....2049
49.5 Zipwire interconnections....2050

49.6 Zipwire performance....2051
49.6.1 Read performance....2051
49.6.2 Write performance....2053
49.7 LFAST/SIPI configuration....2055

Chapter 50
Serial Interprocessor Interface (SIPI)

50.1 Introduction....2057
50.1.1 Scalability....2057
50.2 Overview....2058
50.3 SIPI block diagram....2060
50.4 Feature description....2060
50.4.1 Main features....2060
50.4.2 Standard features....2061
50.5 SIPI operation from reset....2061
50.6 Functional description....2061
50.6.1 External signals....2061
50.6.2 Frame format....2062
50.7 Transfer types....2068
50.7.1 Read transfer....2068
50.7.2 Register read answer transfer....2069
50.7.3 Register Write transfer....2070
50.7.4 Write Acknowledge transfer....2073
50.7.5 ID request response....2073
50.8 Transfer API and flow charts....2075
50.9 DMA programming sequence....2082
50.10 Modes of operation....2083
50.10.1 Initialization mode....2083
50.10.2 Normal mode....2083
50.10.3 Module Disable (MD)....2084

50.11 Errors....2084
50.11.1 Timeout error....2084
50.11.2 CRC error....2084
50.11.3 Maximum count reached error....2085
50.11.4 Transaction ID error....2085
50.11.5 Acknowledge error....2085
50.12 CRC calculation....2085
50.13 Interrupt logic....2086
50.14 SIPI control and status overview....2087
50.15 Memory map and register definition....2088
50.15.1 SIPI Channel Control Register 0 (SIPI_CCR0)....2091
50.15.2 SIPI Channel Status Register 0 (SIPI_CSR0)....2094
50.15.3 SIPI Channel Interrupt Register 0 (SIPI_CIR0)....2095
50.15.4 SIPI Channel Timeout Register 0 (SIPI_CTOR0)....2096
50.15.5 SIPI Channel CRC Register 0 (SIPI_CCRC0)....2097
50.15.6 SIPI Channel Address Register 0 (SIPI_CAR0)....2097
50.15.7 SIPI Channel Data Register 0 (SIPI_CDR0)....2098
50.15.8 SIPI Channel Control Register 1 (SIPI_CCR1)....2098
50.15.9 SIPI Channel Status Register 1 (SIPI_CSR1)....2101
50.15.10 SIPI Channel Interrupt Register 1 (SIPI_CIR1)....2103
50.15.11 SIPI Channel Timeout Register 1 (SIPI_CTOR1)....2104
50.15.12 SIPI Channel CRC Register 1 (SIPI_CCRC1)....2105
50.15.13 SIPI Channel Address Register 1 (SIPI_CAR1)....2105
50.15.14 SIPI Channel Data Register 1 (SIPI_CDR1)....2106
50.15.15 SIPI Channel Control Register 2 (SIPI_CCR2)....2106
50.15.16 SIPI Channel Status Register 2 (SIPI_CSR2)....2109
50.15.17 SIPI Channel Interrupt Register 2 (SIPI_CIR2)....2111
50.15.18 SIPI Channel Timeout Register 2 (SIPI_CTOR2)....2112
50.15.19 SIPI Channel CRC Register 2 (SIPI_CCRC2)....2113

50.15.20 SIPI Channel Address Register 2 (SIPI_CAR2)....2113
50.15.21 SIPI Channel Data Register 2 (SIPI_CDR2_*n*)....2114
50.15.22 SIPI Channel Control Register 3 (SIPI_CCR3)....2114
50.15.23 SIPI Channel Status Register 3 (SIPI_CSR3)....2118
50.15.24 SIPI Channel Interrupt Register 3 (SIPI_CIR3)....2119
50.15.25 SIPI Channel Timeout Register 3 (SIPI_CTOR3)....2120
50.15.26 SIPI Channel CRC Register 3 (SIPI_CCRC3)....2121
50.15.27 SIPI Channel Address Register 3 (SIPI_CAR3)....2121
50.15.28 SIPI Channel Data Register 3 (SIPI_CDR3)....2122
50.15.29 SIPI Module Configuration Register (SIPI_MCR)....2123
50.15.30 SIPI Status Register (SIPI_SR)....2126
50.15.31 SIPI Max Count Register (SIPI_MAXCR)....2128
50.15.32 SIPI Address Reload Register (SIPI_ARR)....2128
50.15.33 SIPI Address Count Register (SIPI_ACR)....2129
50.15.34 SIPI Error Register (SIPI_ERR)....2130

Chapter 51
LVDS Fast Asynchronous Serial Transmission (LFAST) – Interprocessor Communications

51.1 Introduction....2133
51.2 Block diagram....2133
51.3 External signals....2134
51.3.1 LFAST operating data rates....2134
51.4 LFAST frame structure....2134
51.5 Features....2137
51.6 Memory map and register definition....2138
51.6.1 LFAST Mode Configuration Register (LFAST_MCR)....2140
51.6.2 LFAST Speed Control Register (LFAST_SCR)....2142
51.6.3 LFAST Correlator Control Register (LFAST_COCR)....2143
51.6.4 LFAST Test Mode Control Register (LFAST_TMCR)....2145
51.6.5 LFAST Auto Loopback Control Register (LFAST_ALCR)....2146

51.6.6 LFAST Rate Change Delay Control Register (LFAST_RCDCR)....2147
51.6.7 LFAST Wakeup Delay Control Register (LFAST_SLCR)....2147
51.6.8 LFAST ICLC Control Register (LFAST_ICR)....2149
51.6.9 LFAST Ping Control Register (LFAST_PICR)....2150
51.6.10 LFAST Rx FIFO CTS Control Register (LFAST_RFCR)....2150
51.6.11 LFAST Tx Interrupt Enable Register (LFAST_TIER)....2151
51.6.12 LFAST Rx Interrupt Enable Register (LFAST_RIER)....2152
51.6.13 LFAST Rx ICLC Interrupt Enable Register (LFAST_RIIER)....2154
51.6.14 LFAST PLL Control Register (LFAST_PLLCR)....2156
51.6.15 LFAST LVDS Control Register (LFAST_LCR)....2158
51.6.16 LFAST Unsolicited Tx Control Register (LFAST_UNSTCR)....2161
51.6.17 LFAST Unsolicited Tx Data Registers (LFAST_UNSTDR*n*)....2161
51.6.18 LFAST Global Status Register (LFAST_GSR)....2162
51.6.19 LFAST Ping Status Register (LFAST_PISR)....2163
51.6.20 LFAST Data Frame Status Register (LFAST_DFSR)....2164
51.6.21 LFAST Tx Interrupt Status Register (LFAST_TISR)....2165
51.6.22 LFAST Rx Interrupt Status Register (LFAST_RISR)....2166
51.6.23 LFAST Rx ICLC Interrupt Status Register (LFAST_RIISR)....2168
51.6.24 LFAST PLL and LVDS Status Register (LFAST_PLLLSR)....2170
51.6.25 LFAST Unsolicited Rx Status Register (LFAST_UNSRSR)....2171
51.6.26 LFAST Unsolicited Rx Data Register (LFAST_UNSRDR*n*)....2172
51.7 Functional description....2172
51.7.1 Startup procedure....2172
51.7.2 Line Receiver....2176
51.7.3 Transmit Controller....2185
51.7.4 CTS mode support....2190
51.7.5 Frames supported....2191

51.7.6 Frame flow....2192
51.7.7 Test and Debug Support....2199
51.7.8 Interrupts....2208
51.8 Packet memory....2211
51.9 Resets....2212
51.10 Clocks....2213
51.10.1 Clocking strategy....2213
51.10.2 Slow speed clock....2214
51.10.3 Rx Controller Clocks....2217
51.10.4 Clocking Module Requirements for High Speed Phases....2217
51.10.5 Clock module requirements for low speed phases....2218
51.10.6 Tx Controller Clocks....2219

Chapter 52
Fast Ethernet Controller (FEC)

52.1 Fast Ethernet Controller (FEC) chip-specific module information....2221
52.1.1 FEC interface selection....2221
52.2 Introduction....2221
52.2.1 Block diagram....2221
52.2.2 Features....2223
52.2.3 Clocking requirements....2224
52.3 Modes of operation....2225
52.3.1 Full and half duplex operation....2225
52.3.2 Interface options....2225
52.3.3 Address recognition options....2227
52.3.4 Internal loopback....2227
52.4 External signal description....2227
52.5 Memory map and register definition....2229
52.5.1 Interrupt Event Register (FEC_EIR)....2233
52.5.2 Interrupt Mask Register (FEC_EIMR)....2235

52.5.3 Receive Descriptor Active Register (FEC_RDAR)....2237
52.5.4 Transmit Descriptor Active Register (FEC_TDAR)....2238
52.5.5 Ethernet Control Register (FEC_ECR)....2239
52.5.6 MII Management Frame Register (FEC_MMFR)....2240
52.5.7 MII Speed Control Register (FEC_MSCR)....2241
52.5.8 MIB Control Register (FEC_MIBC)....2242
52.5.9 Receive Control Register (FEC_RCR)....2244
52.5.10 Transmit Control Register (FEC_TCR)....2246
52.5.11 Physical Address Low Register (FEC_PALR)....2247
52.5.12 Physical Address High Register and Type Field (FEC_PAUR)....2248
52.5.13 Opcode/Pause Duration (FEC_OPD)....2248
52.5.14 Descriptor Individual Upper Address Register (FEC_IAUR)....2249
52.5.15 Descriptor Individual Lower Address Register (FEC_IALR)....2249
52.5.16 Descriptor Group Upper Address Register (FEC_GAUR)....2250
52.5.17 Descriptor Group Lower Address Register (FEC_GALR)....2250
52.5.18 Transmit FIFO Watermark (FEC_TFWR)....2251
52.5.19 FIFO Receive Bound Register (FEC_FRBR)....2252
52.5.20 FIFO Receive Start Register (FEC_FRSR)....2252
52.5.21 Receive Descriptor Ring Start Register (FEC_ERDSR)....2253
52.5.22 Transmit Buffer Descriptor Ring Start Register (FEC_ETDSR)....2254
52.5.23 Receive Buffer Size Register (FEC_EMRBR)....2254
52.5.24 Count of frames not counted correctly (FEC_RMON_T_DROP)....2255
52.5.25 RMON Tx packet count (FEC_RMON_T_PACKETS)....2256
52.5.26 RMON Tx broadcast packets (FEC_RMON_T_BC_PKT)....2256
52.5.27 RMON Tx multicast packets (FEC_RMON_T_MC_PKT)....2257
52.5.28 RMON Tx packets with CRC/align error (FEC_RMON_T_CRC_ALIGN)....2257
52.5.29 RMON Tx packets < 64 bytes, good CRC (FEC_RMON_T_UNDERSIZE)....2258
52.5.30 RMON Tx packets > MAX_FL bytes, good CRC (FEC_RMON_T_OVERSIZE)....2258
52.5.31 RMON Tx packets < 64 bytes, bad CRC (FEC_RMON_T_FRAG)....2259

52.5.32 RMON Tx packets > MAX_FL bytes, bad CRC (FEC_RMON_T_JAB).....2259
52.5.33 RMON Tx collision count (FEC_RMON_T_COL).....2260
52.5.34 RMON Tx 64 byte packets (FEC_RMON_T_P64).....2260
52.5.35 RMON Tx 65 to 127 byte packets (FEC_RMON_T_P65TO127).....2261
52.5.36 RMON Tx 128 to 255 byte packets (FEC_RMON_T_P128TO255).....2261
52.5.37 RMON Tx 256 to 511 byte packets (FEC_RMON_T_P256TO511).....2262
52.5.38 RMON Tx 512 to 1023 byte packets (FEC_RMON_T_P512TO1023).....2262
52.5.39 RMON Tx 1024 to 2047 byte packets (FEC_RMON_T_P1024TO2047).....2263
52.5.40 RMON Tx packets with > 2048 bytes (FEC_RMON_T_P_GTE2048).....2263
52.5.41 RMON Tx Octets (FEC_RMON_T_OCTETS).....2264
52.5.42 Count of transmitted frames not counted correctly (FEC_IEEE_T_DROP).....2264
52.5.43 Frames transmitted OK (FEC_IEEE_T_FRAME_OK).....2265
52.5.44 Frames transmitted with single collision (FEC_IEEE_T_1COL).....2265
52.5.45 Frames transmitted with multiple collisions (FEC_IEEE_T_MCOL).....2266
52.5.46 Frames transmitted after deferral delay (FEC_IEEE_T_DEF).....2266
52.5.47 Frames transmitted with late collision (FEC_IEEE_T_LCOL).....2267
52.5.48 Frames transmitted with excessive collisions (FEC_IEEE_T_EXCOL).....2267
52.5.49 Frames transmitted with Tx FIFO underrun (FEC_IEEE_T_MACERR).....2268
52.5.50 Frames transmitted with carrier sense error (FEC_IEEE_T_CSERR).....2268
52.5.51 Frames transmitted with SQE error (FEC_IEEE_T_SQE).....2269
52.5.52 Flow control pause frames transmitted (FEC_IEEE_T_FDXFC).....2269
52.5.53 Octet count for frames transmitted without error (FEC_IEEE_T_OCTETS_OK).....2270
52.5.54 Count of received frames not counted correctly (FEC_RMON_R_DROP).....2270
52.5.55 RMON Rx packet count (FEC_RMON_R_PACKETS).....2271
52.5.56 RMON Rx broadcast packets (FEC_RMON_R_BC_PKT).....2271
52.5.57 RMON Rx multicast packets (FEC_RMON_R_MC_PKT).....2272
52.5.58 RMON Rx packets with CRC/Align error (FEC_RMON_R_CRC_ALIGN).....2272
52.5.59 RMON Rx packets < 64 bytes, good CRC (FEC_RMON_R_UNDERSIZE).....2273
52.5.60 RMON Rx packets > MAX_FL bytes, good CRC (FEC_RMON_R_OVERSIZE).....2273

52.5.61 RMON Rx packets < 64 bytes, bad CRC (FEC_RMON_R_FRAG)....2274
52.5.62 RMON Rx packets > MAX_FL bytes, bad CRC (FEC_RMON_R_JAB)....2274
52.5.63 Reserved (FEC_RMON_R_RESVD_0)....2275
52.5.64 RMON Rx 64 byte packets (FEC_RMON_R_P64)....2275
52.5.65 RMON Rx 65 to 127 byte packets (FEC_RMON_R_P65TO127)....2276
52.5.66 RMON Rx 128 to 255 byte packets (FEC_RMON_R_P128TO255)....2276
52.5.67 RMON Rx 256 to 511 byte packets (FEC_RMON_R_P256TO511)....2277
52.5.68 RMON Rx 512 to 1023 byte packets (FEC_RMON_R_P512TO1023)....2277
52.5.69 RMON Rx 1024 to 2047 byte packets (FEC_RMON_R_P1024TO2047)....2278
52.5.70 RMON Rx packets with > 2048 bytes (FEC_RMON_R_P_GTE2048)....2278
52.5.71 RMON Rx octets (FEC_RMON_R_OCTETS)....2279
52.5.72 Count of received frames not counted correctly (FEC_IEEE_R_DROP)....2279
52.5.73 Frames received OK (FEC_IEEE_R_FRAME_OK)....2280
52.5.74 Frames received with CRC error (FEC_IEEE_R_CRC)....2280
52.5.75 Frames received with alignment error (FEC_IEEE_R_ALIGN)....2281
52.5.76 Receive FIFO overflow count (FEC_IEEE_R_MACERR)....2281
52.5.77 Flow control pause frames received (FEC_IEEE_R_FDXFC)....2282
52.5.78 Octet count for frames received without error (FEC_IEEE_R_OCTETS_OK)....2282
52.5.79 Using the RMON and IEEE registers....2282
52.6 Functional description....2283
52.6.1 MII data frame....2283
52.6.2 MII management frame structure....2284
52.6.3 Buffer descriptors....2285
52.6.4 Initialization sequence....2291
52.6.5 User initialization (Prior to Setting ECR[ETHER_EN])....2291
52.6.6 Microcontroller initialization....2292
52.6.7 User initialization (after setting ECR[ETHER_EN])....2293
52.6.8 Network interface options....2293

52.6.9 FEC frame transmission....2294
52.6.10 FEC frame reception....2296
52.6.11 Ethernet address recognition....2297
52.6.12 Hash algorithm....2300
52.6.13 Full duplex flow control....2303
52.6.14 Inter-Packet Gap (IPG) time....2304
52.6.15 Collision managing....2304
52.6.16 MII internal and external loopback....2304
52.6.17 RMII loopback....2305
52.6.18 RMII echo....2305
52.6.19 Ethernet error-managing procedure....2305

Chapter 53
SENT Receiver (SRX)

53.1 SENT chip-specific modules information....2309
53.1.1 SRX_GBL_CTRL[NIB_LEN_VAR_LIMIT] setting....2309
53.2 Introduction....2310
53.2.1 Features....2310
53.2.2 Modes of operation....2311
53.2.3 Block diagram....2314
53.2.4 Design overview....2316
53.3 External signal description....2317
53.3.1 SENT_RX [(CH-1):0]....2317
53.4 Memory map and register definition....2318
53.4.1 Global Control Register (SRX_GBL_CTRL)....2322
53.4.2 Channel Enable Register (SRX_CHNL_EN)....2323
53.4.3 Global Status Register (SRX_GBL_STATUS)....2325
53.4.4 Fast Message Ready Status Register (SRX_FMSG_RDY)....2326
53.4.5 Slow Serial Message Ready Status Register (SRX_SMSG_RDY)....2327
53.4.6 Data Control Register 1 (SRX_DATA_CTRL1)....2328

53.4.7 Fast Message DMA Control Register (SRX_FDMA_CTRL)....2330
53.4.8 Slow Serial Message DMA Control Register (SRX_SDMA_CTRL)....2330
53.4.9 Fast Message Ready Interrupt Control Register (SRX_FRDY_IE)....2331
53.4.10 Slow Serial Message Ready Interrupt Enable Register (SRX_SRDY_IE)....2332
53.4.11 DMA Fast Message Data Read Register (SRX_DMA_FMSG_DATA)....2332
53.4.12 DMA Fast Message CRC Read Register (SRX_DMA_FMSG_CRC)....2333
53.4.13 DMA Fast Message Time Stamp Read Register (SRX_DMA_FMSG_TS)....2334
53.4.14 DMA Slow Serial Message Bit3 Read Register (SRX_DMA_SMSG_BIT3)....2334
53.4.15 DMA Slow Serial Message Bit2 Read Register (SRX_DMA_SMSG_BIT2)....2335
53.4.16 DMA Slow Serial Message Time Stamp Read Register (SRX_DMA_SMSG_TS)....2336
53.4.17 Channel 'n' Clock Control Register (n = 0 to (CH-1)) (SRX_CH*n*_CLK_CTRL)....2337
53.4.18 Channel 'n' Status Register (n=0 to (CH-1)) (SRX_CH*n*_STATUS)....2339
53.4.19 Channel 'n' Configuration Register (n=0 to (CH-1)) (SRX_CH*n*_CONFIG)....2342
53.4.20 Channel 'n' Fast Message Data Read Register (n=0 to (CH-1)) (SRX_CH*n*_FMSG_DATA)....2345
53.4.21 Channel 'n' Fast Message CRC Read Register (n=0 to (CH-1)) (SRX_CH*n*_FMSG_CRC)....2346
53.4.22 Channel 'n' Fast Message Time Stamp Read Register (n=0 to (CH-1)) (SRX_CH*n*_FMSG_TS)....2346
53.4.23 Channel 'n' Serial Message Read Register (Bit 3) (n=0 to (CH-1)) (SRX_CH*n*_SMSG_BIT3)....2347
53.4.24 Channel 'n' Serial Message Read Register (Bit 2)(n=0 to (CH-1)) (SRX_CH*n*_SMSG_BIT2)....2348
53.4.25 Channel 'n' Serial Message Time Stamp Read Register (n=0 to (CH-1)) (SRX_CH*n*_SMSG_TS)....2349
53.5 Functional description....2349
53.5.1 Initialization sequence....2349
53.5.2 DMA read logic....2350
53.5.3 Message reading via interrupts....2355
53.5.4 Overflow behavior....2357
53.5.5 Adjustment for variation in sensor (Tx) clock....2358
53.5.6 Input programmable filter....2359
53.5.7 Receiver diagnostics....2360
53.5.8 Time stamp logic....2365
53.5.9 Bus Idle Diagnostic....2366

53.6 Clocks and resets....2367
53.6.1 Clocking strategy....2367
53.6.2 System bus clock requirements....2368
53.6.3 High frequency receiver clock (protocol clock) requirements....2369

Chapter 54
LINFlexD

54.1 LinFlexD chip-specific module information....2371
54.2 Introduction....2372
54.2.1 Glossary and acronyms....2372
54.2.2 References....2372
54.3 Main features....2374
54.3.1 LIN mode features....2374
54.3.2 UART mode features....2375
54.4 Functional description....2376
54.4.1 LIN protocol....2376
54.4.2 LINFlexD features....2378
54.4.3 Timer....2398
54.4.4 UART mode....2398
54.4.5 DMA interface....2404
54.5 Memory map and register description....2423
54.5.1 LIN Control Register 1 (LINFlexD_LINCR1)....2425
54.5.2 LIN Interrupt enable register (LINFlexD_LINIER)....2428
54.5.3 LIN Status Register (LINFlexD_LINSR)....2430
54.5.4 LIN Error Status Register (LINFlexD_LINESR)....2434
54.5.5 UART Mode Control Register (LINFlexD_UARTCR)....2435
54.5.6 UART Mode Status Register (LINFlexD_UARTSR)....2441
54.5.7 LIN Time-Out Control Status Register (LINFlexD_LINTCSR)....2444
54.5.8 LIN Output Compare Register (LINFlexD_LINOCR)....2445
54.5.9 LIN Time-Out Control Register (LINFlexD_LINTOCR)....2446

54.5.10 LIN Fractional Baud Rate Register (LINFlexD_LINFBRR)....2446
54.5.11 LIN Integer Baud Rate Register (LINFlexD_LINIBRR)....2447
54.5.12 LIN Checksum Field Register (LINFlexD_LINCFR)....2448
54.5.13 LIN Control Register 2 (LINFlexD_LINCR2)....2449
54.5.14 Buffer Identifier Register (LINFlexD_BIDR)....2451
54.5.15 Buffer Data Register Least Significant (LINFlexD_BDRL)....2452
54.5.16 Buffer Data Register Most Significant (LINFlexD_BDRM)....2453
54.5.17 Identifier Filter Enable Register (LINFlexD_IFER)....2453
54.5.18 Identifier Filter Match Index (LINFlexD_IFMI)....2454
54.5.19 Identifier Filter Mode Register (LINFlexD_IFMR)....2454
54.5.20 Identifier Filter Control Register (LINFlexD_IFCR*n*)....2455
54.5.21 Global Control Register (LINFlexD_GCR)....2456
54.5.22 UART Preset Timeout Register (LINFlexD_UARTPTO)....2458
54.5.23 UART Current Timeout Register (LINFlexD_UARTCTO)....2459
54.5.24 DMA Tx Enable Register (LINFlexD_DMATXE)....2460
54.5.25 DMA Rx Enable Register (LINFlexD_DMARXE)....2460
54.6 Programming considerations....2461
54.6.1 Master node....2461
54.6.2 Slave node....2463
54.6.3 Extended frames....2468
54.6.4 Timeout....2469
54.6.5 UART mode....2470
54.6.6 Interrupts....2470
54.6.7 LINFlexD Clock Tolerance....2472

Chapter 55
Reset and Boot

55.1 Introduction....2475
55.2 Flash memory boot overview....2475
55.3 Device Configuration Format (DCF) records....2476

55.4 Reset sequence....2477
55.4.1 RSTOUT functionality....2477
55.4.2 POWERUP Phase: power stabilization....2478
55.4.3 PHASE0 Phase: analog supply initial configuration....2478
55.4.4 PHASE1[DEST] Phase: temporization and monitoring setup....2478
55.4.5 PHASE2[DEST] Phase: flash initial configuration....2479
55.4.6 PHASE3[DEST] Phase: device configuration....2479
55.4.7 IDLE[DEST] Phase: self-test execution....2480
55.4.8 PHASE1[FUNC] Phase: temporization and monitoring setup....2480
55.4.9 PHASE2[FUNC] Phase: flash initial configuration....2480
55.4.10 PHASE3[FUNC] Phase: device configuration monitoring....2481
55.4.11 IDLE[FUNC] Phase....2481
55.5 Module status during reset sequence....2482

Chapter 56
Reset Generation Module (MC_RGM)

56.1 Introduction....2485
56.1.1 Overview....2485
56.1.2 Features....2486
56.1.3 Reset Sources....2487
56.2 External Signal Description....2488
56.3 MC_RGM Registers....2489
56.3.1 ‘Destructive’ Event Status (MC_RGM_DES)....2490
56.3.2 ‘Destructive’ Event Reset Disable (MC_RGM_DERD)....2492
56.3.3 ‘Destructive’ Event Alternate Request (MC_RGM_DEAR)....2494
56.3.4 ‘Destructive’ Bidirectional Reset Enable (MC_RGM_DBRE)....2496
56.3.5 ‘Functional’ Event Status (MC_RGM_FES)....2498
56.3.6 ‘Functional’ Event Reset Disable (MC_RGM_FERD)....2500
56.3.7 ‘Functional’ Event Alternate Request (MC_RGM_FEAR)....2501
56.3.8 ‘Functional’ Bidirectional Reset Enable (MC_RGM_FBRE)....2502

56.3.9 'Functional' Event Short Sequence (MC_RGM_FESS).....2504
56.3.10 Functional Reset Threshold (MC_RGM_FRET).....2506
56.3.11 'Destructive' Reset Threshold (MC_RGM_DRET).....2507
56.4 Functional Description.....2508
56.4.1 Reset State Machine.....2508
56.4.2 'Destructive' Resets.....2511
56.4.3 External Reset.....2511
56.4.4 'Functional' Resets.....2512
56.4.5 Alternate Event Generation.....2513
56.4.6 'Functional' Reset Escalation.....2514
56.4.7 'Destructive' Reset Escalation.....2515

Chapter 57
Boot Assist Flash (BAF)

57.1 BAF chip-specific module information.....2517
57.1.1 Search boot header and boot options.....2517
57.1.2 LinFLEXD_1 and FlexCAN_1 pin configuration.....2518
57.1.3 BAF memory map.....2519
57.1.4 Reset values on BAF exit.....2520
57.1.5 Serial boot password behavior.....2520
57.2 Introduction.....2520
57.3 BAF image header.....2521
57.3.1 BAF image version.....2521
57.4 Functional description.....2521
57.4.1 Boot modes.....2521
57.4.2 Device initialization.....2522
57.4.3 Flow of control.....2522
57.4.4 Optionally remap calibration RAM.....2523
57.4.5 BAF SAFE mode event handling.....2524
57.4.6 BAF NMI Event Handling.....2525

57.4.7 Initialization of BAF DCF clients....2526
57.4.8 Optionally perform serial boot....2535
57.4.9 Serial boot configuration....2540
57.5 Resources....2543

Chapter 58
System Status and Configuration Module (SSCM)

58.1 System Status and Configuration Module (SSCM) chip-specific module information....2545
58.2 Introduction....2546
58.2.1 Overview....2546
58.2.2 Glossary....2547
58.2.3 Features....2547
58.2.4 Modes of operation....2548
58.3 External signal description....2548
58.4 Memory map and register definition....2548
58.4.1 SSCM System Status (SSCM_STATUS)....2549
58.4.2 SSCM System Memory and ID Register (SSCM_MEMCONFIG)....2551
58.4.3 Processor Start Address Register (SSCM_PSA)....2551
58.4.4 Life Cycle Status Register (SSCM_LCSTAT)....2552
58.5 Functional description....2553
58.5.1 CERS-DCF Mechanism....2553
58.5.2 ECC error monitoring....2554
58.5.3 Boot mode functionality....2554
58.5.4 BAF configuration....2554
58.5.5 Life Cycle....2554
58.6 Initialization and application information....2556
58.6.1 Reset....2556
58.7 Additional safety measures....2556
58.7.1 Spurious reset protection....2556

Chapter 59
Power Management

59.1 Overview....2559
59.1.1 Power Management Controller (PMC)....2560
59.1.2 Supply Concept....2560
59.1.3 Power Modes....2561
59.1.4 External Supply....2562
59.1.5 Voltage Monitoring....2562
59.1.6 PMC Power-on Reset....2564
59.1.7 SoC Power-on Reset....2565
59.1.8 Power-up Sequence....2565
59.1.9 ADC Interface....2567
59.1.10 Safety Measures....2569

Chapter 60
Power Management Controller digital interface (PMC_dig)

60.1 PMC_dig chip-specific module information....2571
60.1.1 PMC registers whose reset values can be defined by DCF clients....2571
60.1.2 PMC registers with chip-specific reset values....2571
60.1.3 Self test bit definition....2572
60.2 PMC introduction....2572
60.2.1 Features....2573
60.3 Memory Map and Registers....2573
60.3.1 Temperature Sensor Interrupt Enable Register (PMC_TS_IER)....2575
60.3.2 Temperature Event Status register (PMC_ESR_TD)....2577
60.3.3 Temperature Reset Event Enable register (PMC_REE_TD)....2579
60.3.4 Temperature Reset Event Selection register (PMC_RES_TD)....2580
60.3.5 Temperature detector configuration register (PMC_CTL_TD)....2582
60.3.6 Temperature Fault Injection Register (PMC_TS_FIR)....2583
60.3.7 Voltage Detect User Mode Test Register (PMC_SELF_TEST_UM_VD_REG)....2584

60.3.8 FCCU Fault Injection Register (PMC_FIR)....2586
60.3.9 LVD HVD Interrupt Enable Control Register (PMC_LVD_HVD_INTR_ENB)....2587
60.3.10 LVD HVD Event Status Register (PMC_LVD_HVD_EVENT_STATUS)....2590
60.3.11 Reset Enable Control Register (PMC_REE)....2592
60.3.12 Reset Type (Destructive / Functional) Selection Register (PMC_RES)....2595
60.3.13 ADC Channel Select Register (PMC_ADC_CS)....2599
60.4 Functional description....2600
60.4.1 Analog PMC interface....2600
60.4.2 Temperature sensor interface logic....2600
60.4.3 POR RGM phase gates....2600
60.4.4 Flash interface to DCF....2601
60.4.5 FCCU interface....2601
60.4.6 LVD-HVD self test mechanism....2602

Chapter 61
Power Control Unit (MC_PCU)

61.1 Introduction....2607
61.2 Memory map and register definition....2607
61.2.1 Power Domain Status Register (MC_PCU_PSTAT)....2608
61.3 Functional description....2608

Chapter 62
Mode Entry Module (MC_ME)

62.1 Introduction....2609
62.1.1 Overview....2609
62.1.2 Features....2610
62.1.3 Modes of Operation....2611
62.2 External Signal Description....2613
62.3 MC_ME Registers....2613
62.3.1 Global Status (MC_ME_GS)....2618
62.3.2 Mode Control (MC_ME_MCTL)....2620

62.3.3 Mode Enable (MC_ME_ME)....2622
62.3.4 Interrupt Status (MC_ME_IS)....2624
62.3.5 Interrupt Mask (MC_ME_IM)....2625
62.3.6 Invalid Mode Transition Status (MC_ME_IMTS)....2627
62.3.7 Debug Mode Transition Status (MC_ME_DMTS)....2628
62.3.8 RESET Mode Configuration (MC_ME_RESET_MC)....2633
62.3.9 TEST Mode Configuration (MC_ME_TEST_MC)....2635
62.3.10 SAFE Mode Configuration (MC_ME_SAFE_MC)....2636
62.3.11 DRUN Mode Configuration (MC_ME_DRUN_MC)....2638
62.3.12 RUN0 Mode Configuration (MC_ME_RUN0_MC)....2640
62.3.13 RUN1 Mode Configuration (MC_ME_RUN1_MC)....2641
62.3.14 RUN2 Mode Configuration (MC_ME_RUN2_MC)....2643
62.3.15 RUN3 Mode Configuration (MC_ME_RUN3_MC)....2645
62.3.16 HALT0 Mode Configuration (MC_ME_HALT0_MC)....2646
62.3.17 STOP0 Mode Configuration (MC_ME_STOP0_MC)....2648
62.3.18 Peripheral Status 0 (MC_ME_PS0)....2650
62.3.19 Peripheral Status 1 (MC_ME_PS1)....2652
62.3.20 Peripheral Status 2 (MC_ME_PS2)....2654
62.3.21 Peripheral Status 3 (MC_ME_PS3)....2656
62.3.22 Peripheral Status 4 (MC_ME_PS4)....2658
62.3.23 Peripheral Status 5 (MC_ME_PS5)....2659
62.3.24 Peripheral Status 6 (MC_ME_PS6)....2661
62.3.25 Peripheral Status 7 (MC_ME_PS7)....2663
62.3.26 Run Peripheral Configuration 0 (MC_ME_RUN_PC*n*)....2665
62.3.27 Low-Power Peripheral Configuration 0 (MC_ME_LP_PC*n*)....2666
62.3.28 LFAST_0 Control (MC_ME_PCTL9)....2667
62.3.29 SIPI_0 Control (MC_ME_PCTL11)....2668
62.3.30 DECFILT_1 Control (MC_ME_PCTL28)....2669
62.3.31 DECFILT_0 Control (MC_ME_PCTL29)....2669

62.3.32 PIT_RTI_0 Control (MC_ME_PCTL30)....2670
62.3.33 PIT_RTI_1 Control (MC_ME_PCTL31)....2670
62.3.34 DMA_CH_MUX_0-2 Control (MC_ME_PCTL36)....2671
62.3.35 CRC_0 Control (MC_ME_PCTL38)....2671
62.3.36 JTAGM Control (MC_ME_PCTL45)....2672
62.3.37 ADCSD_2 Control (MC_ME_PCTL59)....2672
62.3.38 ADCSD_0 Control (MC_ME_PCTL60)....2673
62.3.39 ADCSAR_2 Control (MC_ME_PCTL69)....2673
62.3.40 ADCSAR_0 Control (MC_ME_PCTL71)....2674
62.3.41 FLEXCAN_2 Control (MC_ME_PCTL81)....2674
62.3.42 FLEXCAN_0 Control (MC_ME_PCTL83)....2675
62.3.43 LINFLEX_M0 Control (MC_ME_PCTL85)....2675
62.3.44 LINFLEX_2 Control (MC_ME_PCTL91)....2676
62.3.45 LINFLEX_0 Control (MC_ME_PCTL92)....2677
62.3.46 DSPI_M0 Control (MC_ME_PCTL96)....2677
62.3.47 DSPI_4 Control (MC_ME_PCTL97)....2678
62.3.48 DSPI_2 Control (MC_ME_PCTL98)....2678
62.3.49 DSPI_0 Control (MC_ME_PCTL99)....2679
62.3.50 EMIOS Control (MC_ME_PCTL102)....2680
62.3.51 SENT_0 Control (MC_ME_PCTL104)....2680
62.3.52 DMA_CH_MUX_3 Control (MC_ME_PCTL143)....2681
62.3.53 CRC_1 Control (MC_ME_PCTL166)....2681
62.3.54 ADCSD_1 Control (MC_ME_PCTL188)....2682
62.3.55 ADCSAR_3 Control (MC_ME_PCTL196)....2682
62.3.56 IGF Control (MC_ME_PCTL197)....2683
62.3.57 ADCSAR_1 Control (MC_ME_PCTL198)....2683
62.3.58 ETPU_SCRAM Control (MC_ME_PCTL202)....2684
62.3.59 ETPU_SCRAM Control (MC_ME_PCTL203)....2685
62.3.60 ETPU_SPRAM Control (MC_ME_PCTL204)....2685

62.3.61 ETPU_SPRAM Control (MC_ME_PCTL205)....2686
62.3.62 REACM Control (MC_ME_PCTL206)....2686
62.3.63 ETPU Control (MC_ME_PCTL207)....2687
62.3.64 FLEXCAN_3 Control (MC_ME_PCTL208)....2688
62.3.65 FLEXCAN_1 Control (MC_ME_PCTL210)....2688
62.3.66 LINFLEX_M1 Control (MC_ME_PCTL213)....2689
62.3.67 LINFLEX_3 Control (MC_ME_PCTL219)....2689
62.3.68 LINFLEX_1 Control (MC_ME_PCTL220)....2690
62.3.69 DSPI_M1 Control (MC_ME_PCTL225)....2690
62.3.70 DSPI_3 Control (MC_ME_PCTL226)....2691
62.3.71 DSPI_1 Control (MC_ME_PCTL227)....2691
62.3.72 EMIOS_1 Control (MC_ME_PCTL230)....2692
62.3.73 SENT_1 Control (MC_ME_PCTL232)....2692
62.3.74 BCTU Control (MC_ME_PCTL251)....2693
62.3.75 Core Status (MC_ME_CS)....2693
62.3.76 CORE1 Control (MC_ME_CCTL0)....2695
62.3.77 CORE0 Control (MC_ME_CCTL1)....2696
62.3.78 CORE2 Control (MC_ME_CCTL2)....2697
62.3.79 CORE1 Address (MC_ME_CADDR0)....2699
62.3.80 CORE0 Address (MC_ME_CADDR1)....2700
62.3.81 CORE2 Address (MC_ME_CADDR2)....2700
62.4 Functional Description....2701
62.4.1 Mode Transition Request....2701
62.4.2 Modes Details....2703
62.4.3 Mode Transition Process....2708
62.4.4 Software Considerations for Preventing the Blocking of Mode Transitions....2717
62.4.5 Protection of Mode Configuration Registers....2720
62.4.6 Mode Transition Interrupts....2721
62.4.7 Peripheral Clock Gating....2724

62.4.8 Initialization / Application Information....2725

Chapter 63
Calibration and Debug

63.1 Introduction....2727
63.2 Core debug support....2727
63.3 Run control and memory access....2728
63.3.1 Debug and Calibration Interface (DCI)....2729
63.3.2 JTAG Data Communication (JDC)....2734
63.3.3 Sequence Processing Unit (SPU)....2734
63.4 Calibration interface....2751
63.4.1 JTAG Master (JTAGM)....2751
63.4.2 Development Trigger Semaphore (DTS)....2752
63.5 Flash calibration support....2752
63.6 Nexus Trace Aurora interface....2753
63.6.1 Nexus Aurora overview....2755
63.6.2 Nexus Aurora Router (NAR)....2756
63.6.3 Nexus Aurora Link (NAL)....2759
63.6.4 Nexus Aurora PHY (NAP)....2759
63.7 Nexus clients....2761
63.7.1 Enhanced Time Processing Unit (eTPU)....2761
63.7.2 e200z4 Nexus 3....2761
63.7.3 Nexus Crossbar Multi-master Client (NXMC)....2762

Chapter 64
Core Debug Support

64.1 Overview....2765
64.1.1 Software Debug Facilities....2765
64.1.2 Additional Debug Facilities....2766
64.1.3 Hardware Debug Facilities....2767

64.1.4 Sharing Debug Resources by Software/Hardware....2768
64.2 Software Debug Events and Exceptions....2769
64.2.1 Instruction Address Compare Event....2771
64.2.2 Data Address Compare Event....2771
64.2.3 Linked Instruction Address Compare and Data Address Compare Events....2781
64.2.4 Trap Debug Event....2782
64.2.5 Branch Taken Debug Event....2782
64.2.6 Instruction Complete Debug Event....2783
64.2.7 Interrupt Taken Debug Event....2783
64.2.8 Critical Interrupt Taken Debug Event....2784
64.2.9 Return Debug Event....2784
64.2.10 Critical Return Debug Event....2784
64.2.11 External debug event....2785
64.2.12 Unconditional debug event....2785
64.2.13 Performance Monitor Interrupt debug event....2785
64.3 Debug registers....2786
64.3.1 Debug Address and Value Registers....2786
64.3.2 Debug Control and Status registers....2787
64.3.3 External Debug Resource Allocation Control Register (EDBRAC0)....2812
64.3.4 Debug Event Select Register (DEVENT)....2819
64.3.5 Debug Data Acquisition Message Register (DDAM)....2821
64.4 Using Debug Resources for Stack Limit Checking....2822
64.5 External Debug Support....2824
64.5.1 External Debug Registers....2826
64.5.2 OnCE Introduction....2832
64.5.3 JTAG/OnCE Pins....2835

64.5.4 OnCE Internal Interface Signals....2835
64.5.5 OnCE Interface Signals....2836
64.5.6 OnCE Controller and serial interface....2839
64.5.7 Access to Debug Resources....2847
64.5.8 Methods of Entering Debug Mode....2849
64.5.9 CPU Status and Control Scan Chain Register (CPUSCR)....2850
64.5.10 Reserved Registers (Reserved)....2857
64.6 Watchpoint Support....2857
64.7 MPU Operation During Debug....2860
64.8 Cache Array Access During Debug....2861
64.9 Basic Steps for Enabling, Using, and Exiting External Debug Mode....2861

Chapter 65
Debug and Calibration Interface (DCI)

65.1 Introduction....2865
65.1.1 Features....2865
65.1.2 Overview....2865
65.1.3 Operating modes....2868
65.2 External signal description....2875
65.3 Register description....2875
65.3.1 DCI control register (DCI_CR)....2875
65.3.2 DCI EVTx pin multiplexing control register (DCI_PINCR)....2877

Chapter 66
JTAG Controller (JTAGC)

66.1 Introduction....2879
66.1.1 Block diagram....2879
66.1.2 Features....2880
66.1.3 Modes of operation....2880
66.2 External signal description....2881
66.2.1 TCK—Test clock input....2882

66.2.2 TDI—Test data input....2882
66.2.3 TDO—Test data output....2882
66.2.4 TMS—Test mode select....2882
66.2.5 JCOMP—JTAG compliancy....2882
66.3 Register description....2883
66.3.1 Instruction register....2883
66.3.2 Bypass register....2883
66.3.3 Device identification register....2883
66.3.4 JTAG_PASSWORD register....2884
66.3.5 Boundary scan register....2885
66.4 Functional description....2885
66.4.1 JTAGC reset configuration....2885
66.4.2 IEEE 1149.1-2001 (JTAG) Test Access Port....2885
66.4.3 TAP controller state machine....2886
66.4.4 JTAGC block instructions....2888
66.4.5 Boundary scan....2891
66.5 Initialization/Application information....2892

Chapter 67
IEEE 1149.7 Compact JTAG Test Access Port Controller (CJTAG)

67.1 References....2893
67.2 Abbreviations....2893
67.3 Introduction....2894
67.3.1 Types of operation....2895
67.3.2 Deployment by class....2895
67.3.3 1149.7 TAP signals....2896
67.3.4 TAP.7 architecture....2897
67.3.5 Protocols....2898
67.4 Operating models....2900

67.5 CJTAG implementation summary....2900
67.5.1 T0 functions....2900
67.5.2 T1 functions....2901
67.5.3 T2 functions....2901
67.5.4 T3 functions....2901
67.5.5 T4 functions....2901
67.6 Ancillary services....2901
67.6.1 Overview....2901
67.6.2 Resets....2902
67.6.3 Start-up Options....2905
67.6.4 RSU operation....2906
67.6.5 TAPC State Machine....2908
67.7 EPU (Extended Protocol Unit) Operation....2909
67.7.1 EPU Operation....2909
67.7.2 EPU Registers....2912
67.7.3 EPU Commands....2924
67.7.4 EPU operating states....2932
67.7.5 System and EPU Paths....2933
67.8 APU (Advanced Protocol Unit) Operation....2933
67.8.1 Overview....2933
67.8.2 Operation....2936
67.8.3 Escape sequences....2938
67.8.4 Signal behaviors....2938
67.8.5 APU Functions....2939
67.8.6 Configuration Change Packets (CP)....2945
67.8.7 Scan Packet....2946
67.8.8 SP Format....2946
67.9 Functional Description....2953
67.9.1 Switching from Standard Protocol to Advanced Protocol....2953

Chapter 68
JTAG Data Communication (JDC)

68.1 Introduction....2955

68.2 Overview....2955

68.3 Memory mapped registers....2956

68.3.1 Module Configuration Register (JDC_MCR)....2957

68.3.2 Module Status Register (JDC_MSR)....2958

68.3.3 JTAG Output Data Register (JDC_JOUT_IPS)....2959

68.3.4 JTAG Input Data Register (JDC_JIN_IPS)....2960

68.4 Non-Memory mapped register definition....2960

68.4.1 JTAG output data register (JOUT)....2960

68.4.2 JTAG input data register (JIN)....2961

68.5 Functional description....2961

68.5.1 JTAG register access....2962

Chapter 69
Sequence Processing Unit (SPU)

69.1 Sequence Processing Unit (SPU) chip-specific module information....2963

69.2 Introduction....2963

69.2.1 SPU block diagram....2963

69.2.2 Overview....2964

69.2.3 Features....2965

69.3 SPU actions....2968

69.4 SPU enable/disable mode....2969

69.5 SPU module interface....2969

69.6 Register definition....2970

69.6.1 Level1 input Mux configurations registers....2974

69.6.2 Level2 input Mux configurations registers....2981

69.6.3 Sequence unit registers....2988

69.6.4 SLU status (SS) register....2995

69.6.5 SPU enable (SE) register....2997
69.6.6 Sample and hold mechanism....2998
69.6.7 SLU action unit registers....2999
69.6.8 Counters control n (CCTRLn) registers....3006
69.6.9 Counters compare n (CCMPn) registers....3007
69.6.10 Status registers....3008
69.7 Functional description....3010
69.7.1 Input Mux unit....3010
69.7.2 Processor exception vector encoding....3012
69.7.3 State logic unit (SLU)....3013
69.7.4 Sequence formation....3014
69.7.5 Performance counters/timers unit....3017
69.7.6 Action unit....3020
69.7.7 Optional trace group....3020
69.7.8 CKSRC and CKDATA format....3020

Chapter 70
JTAG Master (JTAGM)

70.1 Introduction....3023
70.1.1 Overview....3023
70.1.2 Feature description....3024
70.2 Functional description....3025
70.2.1 JTAGM Ready signal....3025
70.2.2 JTAGM to DCI serial interface....3026
70.2.3 Software interface....3026
70.3 Modes of operation....3026
70.4 Memory mapped registers....3027
70.4.1 Module Configuration Register (JTAGM_MCR)....3027
70.4.2 Status Register (JTAGM_SR)....3029
70.4.3 Data Out Register 0 (JTAGM_DOR0)....3030

70.4.4 Data Out Register 1 (JTAGM_DOR1)....3031
70.4.5 Data Out Register 2 (JTAGM_DOR2)....3031
70.4.6 Data Out Register 3 (JTAGM_DOR3)....3032
70.4.7 Data Input Register 0 (JTAGM_DIR0)....3032
70.4.8 Data Input Register 1 (JTAGM_DIR1)....3033

Chapter 71
Development Trigger Semaphore (DTS)

71.1 Introduction....3035
71.2 Overview....3035
71.3 DTS device connections....3037
71.3.1 DTS register access....3038
71.4 Memory mapped registers....3039
71.4.1 Output Enable Register (DTS_ENABLE)....3039
71.4.2 Startup Register (DTS_STARTUP)....3040
71.4.3 Semaphore Register (DTS_SEMAPHORE)....3041
71.4.4 Semaphore Extension (DTS_SEMAPHORE_B)....3042
71.5 Example application....3042

Chapter 72
Nexus Aurora Router (NAR)

72.1 Nexus Aurora Router (NAR) chip-specific information....3045
72.1.1 NAR DID value....3045
72.2 Introduction....3045
72.3 Overview....3047
72.4 Features....3047
72.5 Register definition....3048
72.5.1 NAR control register (NAR_CR)....3048
72.5.2 NAR status register (NAR_ST)....3050

72.5.3 Message filtering registers....3052
72.5.4 Trace memory bus configuration registers....3055
72.5.5 Suppress mode triggers registers (NAR_STCR)....3058
72.5.6 Client suppress status register (NAR_CSSR)....3059
72.5.7 Receive queue client disable register (NAR_CDR)....3060
72.5.8 Trace Memory fill level and partition configuration register (NAR_AHFPAR)....3062
72.6 Functional description....3063
72.6.1 Reset/Startup....3063
72.6.2 Operation modes....3064
72.6.3 Data reception and arbitration....3066
72.6.4 Suppress mode....3069
72.6.5 Stall detection....3070
72.6.6 Message translation and formatting....3071
72.6.7 Trace memory bus output port usage....3071
72.6.8 Internal message generation....3073
72.6.9 Timestamp function....3077
72.6.10 Overlay and internal trace memory full status generation....3078
72.6.11 Configuration/debug interface JTAG....3079
72.6.12 Trace memory bus controller....3082
72.6.13 Legacy client interface controller....3084
72.7 Application information....3086

Chapter 73
Nexus Module

73.1 Introduction....3089
73.1.1 General Description....3089
73.1.2 Terms and Definitions....3089
73.1.3 Feature List....3090
73.1.4 Functional Block Diagram....3092

73.2 Enabling Nexus 3 Operation....3093
73.2.1 Interaction with Low Power Modes....3094
73.3 TCODEs supported....3095
73.4 Nexus 3 Programmer's Model....3100
73.4.1 Client Select Control (CSC) register....3102
73.4.2 Port Configuration Register (PCR) - reference only....3102
73.4.3 Nexus Development Control Register 1 (DC1)....3103
73.4.4 Nexus Development Control Registers 2 & 3 (DC2, DC3)....3105
73.4.5 Nexus Development Control Register 4 (DC4)....3111
73.4.6 Development Status Register (DS)....3112
73.4.7 Watchpoint Trigger (WT, PTSTC, PTETC, DTSTC, DTETC) registers....3113
73.4.8 Nexus Watchpoint Mask (WMSK) register....3122
73.4.9 Nexus Overrun Control Register (OVCR)....3124
73.4.10 Data Trace Control Register (DTC) register....3125
73.4.11 Data Trace Start Address Registers (DTSA1-4)....3128
73.4.12 Data Trace End Address (DTEA1-4) registers....3128
73.4.13 Read/Write Access Control/Status (RWCS) register....3129
73.4.14 Read/Write Access Data (RWD) register....3131
73.4.15 Read/Write Access Address (RWA)....3133
73.5 Nexus 3 Register Access via JTAG/OnCE....3133
73.6 Nexus 3 Register Access via Software....3134
73.7 Nexus Message Fields....3135
73.7.1 TCODE Field....3135
73.7.2 Source ID Field (SRC)....3135
73.7.3 Relative Address Field (U-ADDR)....3135
73.7.4 Full Address Field (F-ADDR)....3136
73.8 Nexus Message Queues....3137
73.8.1 Message Queue Overrun....3137
73.8.2 CPU Stall....3137

73.8.3 Message Suppression....3138
73.8.4 Nexus Message Priority....3138
73.8.5 Data Acquisition Message Priority Loss Response....3139
73.8.6 Ownership Trace Message Priority Loss Response....3140
73.8.7 Program Trace Message Priority Loss Response....3140
73.8.8 Program Trace Sync Message Priority Loss Response....3140
73.8.9 Data Trace Message Priority Loss Response....3140
73.9 Debug Status messages....3141
73.10 Error messages....3141
73.11 Ownership trace....3142
73.11.1 Overview....3142
73.11.2 Ownership Trace Messaging (OTM)....3142
73.12 Program trace....3144
73.12.1 Branch Trace Messaging types....3144
73.12.2 BTM Message For mats....3146
73.12.3 Program Trace Message Fields....3147
73.12.4 Resource Full Messages....3149
73.12.5 Program Correlation Messages....3150
73.12.6 Program Trace Overflow Error messages....3151
73.12.7 Program Trace Synchronization messages....3151
73.12.8 Program Trace Direct/Indirect Branch with Sync messages....3153
73.12.9 Enabling Program Trace....3154
73.12.10 Program Trace Timing Diagrams (2 MDO / 1 MSEO configuration)....3155
73.13 Data Trace....3156
73.13.1 Data Trace Messaging (DTM)....3156
73.13.2 DTM Message formats....3157
73.13.3 DTM Operation....3160
73.13.4 Data Trace Timing Diagrams (8 MDO / 2 MSEO configuration)....3161

73.14 Data Acquisition messaging....3162
73.14.1 Data Acquisition ID Tag field....3162
73.14.2 Data Acquisition Data field....3163
73.14.3 Data Acquisition Trace event....3163
73.15 Watchpoint Trace messaging....3164
73.15.1 Watchpoint Timing Diagram (2 MDO / 1 MSEO configuration)....3165
73.16 External Hardware Trigger Controls....3166
73.17 Nexus 3 Read/Write access to memory-mapped resources....3167
73.17.1 Single write access....3168
73.17.2 Block write access....3169
73.17.3 Single read access....3170
73.17.4 Block read access....3171
73.17.5 Error handling....3172
73.17.6 Read/Write access error message....3173
73.18 Nexus 3 pin interface....3173
73.18.1 Pins implemented....3173
73.18.2 Pin protocol....3176
73.19 Rules for output messages....3178
73.20 Auxiliary port arbitration....3179
73.21 Examples....3179
73.22 Electrical characteristics....3182
73.23 IEEE 1149.1 (JTAG) RD/WR sequences....3182
73.23.1 JTAG sequence for accessing internal Nexus registers....3183
73.23.2 JTAG sequence for read access of memory-mapped resources....3183
73.23.3 JTAG sequence for write access of memory-mapped resources....3183

Chapter 74
Nexus Crossbar Multi-Master Client (NXMC)

74.1 NXMC chip-specific module information....3185
74.1.1 Generating In Circuit Trace Messages (ICTM)....3185

74.2 Introduction....3186
74.2.1 Features....3186
74.3 External signal description....3187
74.4 Supported messages and TCODEs....3188
74.5 Register description....3191
74.5.1 Development control register 1 (DC1)....3192
74.5.2 Development control register 2 (DC2)....3193
74.5.3 Watchpoint trigger register (WT)....3194
74.5.4 Data trace control register (DTC)....3195
74.5.5 Data trace start address registers 1 and 2 (DTSA1 and DTSA2)....3196
74.5.6 Data trace end address registers 1 and 2 (DTEA1 and DTEA2)....3196
74.5.7 Breakpoint/watchpoint control register 1 (BWC1)....3197
74.5.8 Breakpoint/watchpoint control register 2 (BWC2)....3198
74.5.9 Breakpoint/watchpoint address registers 1 and 2 (BWA1 and BWA2)....3199
74.5.10 Unimplemented registers....3199
74.6 Programming considerations (RESET)....3200
74.6.1 IEEE 1149.1 (JTAG) Test Access Port....3200
74.6.2 Enabling NXMC operation....3200
74.6.3 Enabling NXMC TAP controller....3200
74.6.4 NXMC register access via JTAG....3200
74.7 Functional description....3201
74.7.1 Data trace....3202
74.7.2 Watchpoint support....3207
74.7.3 Peripheral interface....3209
74.7.4 Timestamping feature....3210

Chapter 75
Functional Safety

75.1 Introduction....3213
75.2 Safety overview....3213

75.3 Module categorization....3213
75.4 System implementation....3214
75.4.1 General concept....3214
75.4.2 Dual-core lockstep....3222
75.4.3 Common Cause Failure measures....3225
75.4.4 ECC....3225

Chapter 76
Cyclic Redundancy Check (CRC) Unit

76.1 Introduction....3229
76.2 Main features....3229
76.2.1 Standard features....3229
76.3 Block diagram....3230
76.4 External signal description....3230
76.4.1 Peripheral bus interface....3230
76.5 CRC memory map and registers....3231
76.5.1 Configuration Register (CRC_CFG)....3232
76.5.2 Input Register (CRC_INP)....3233
76.5.3 Current Status Register (CRC_CSTAT)....3234
76.5.4 Output Register (CRC_OUTP)....3234
76.6 Functional description....3235
76.7 Use cases....3237
76.7.1 Programming example....3237
76.7.2 Register programming....3238

Chapter 77
Memory Error Management Unit (MEMU)

77.1 Memory Error Management Unit (MEMU) chip-specific module information....3241
77.1.1 MEMU system connections....3241
77.1.2 MEMU error sources....3241
77.1.3 Reporting table implementation....3242

77.1.4 Concurrent overflow register (OFLW) implementation....3242
77.1.5 Uncorrectable error in flash memory can cause uncorrectable error in SRAM....3244
77.2 Introduction....3244
77.3 Features....3246
77.4 Block diagram....3247
77.5 Design overview....3247
77.6 External signal description....3251
77.7 Memory map and register definition....3252
77.7.1 Overview....3252
77.7.2 Control register (MEMU_CTRL)....3256
77.7.3 Error flag register (MEMU_ERR_FLAG)....3256
77.7.4 Debug register (MEMU_DEBUG)....3260
77.7.5 System RAM correctable error reporting table status register (MEMU_SYS_RAM_CERR_STS*n*)....3262
77.7.6 System RAM correctable error reporting table address register (MEMU_SYS_RAM_CERR_ADDR*n*)..3263
77.7.7 System RAM uncorrectable error reporting table status register (MEMU_SYS_RAM_UNCERR_STS). 3263
77.7.8 System RAM uncorrectable error reporting table address register (MEMU_SYS_RAM_UNCERR_ADDR)....3264
77.7.9 System RAM concurrent overflow register (MEMU_SYS_RAM_OFLW*n*)....3264
77.7.10 Peripheral RAM correctable error reporting table status register (MEMU_PERIPH_RAM_CERR_STS*n*)....3265
77.7.11 Peripheral RAM correctable error reporting table address register (MEMU_PERIPH_RAM_CERR_ADDR*n*)....3266
77.7.12 Peripheral RAM uncorrectable error reporting table status register (MEMU_PERIPH_RAM_UNCERR_STS)....3266
77.7.13 Peripheral RAM uncorrectable error reporting table address register (MEMU_PERIPH_RAM_UNCERR_ADDR)....3267
77.7.14 Peripheral RAM concurrent overflow register (MEMU_PERIPH_RAM_OFLW*n*)....3267
77.7.15 Flash memory correctable error reporting table status register (MEMU_FLASH_CERR_STS*n*)....3268
77.7.16 Flash memory correctable error reporting table address register (MEMU_FLASH_CERR_ADDR*n*)....3269
77.7.17 Flash memory uncorrectable error reporting table status register (MEMU_FLASH_UNCERR_STS)....3269

77.7.18 Flash memory uncorrectable error reporting table address register (MEMU_FLASH_UNCERR_ADDR)....3270
77.7.19 Flash memory concurrent overflow register (MEMU_FLASH_OFLW*n*)....3270
77.8 Functional description....3271
77.8.1 Initializing MEMU....3271
77.8.2 Reading the reporting table....3272
77.8.3 Handling overflows (Multiple error reporting)....3272

Chapter 78
Fault Collection and Control Unit (FCCU)

78.1 FCCU chip-specific module information....3275
78.1.1 FCCU fault recovery after NMI reaction....3275
78.1.2 FCCU chip-specific register reset values....3275
78.1.3 Available FCCU output signals....3276
78.1.4 Error signal flow diagram....3276
78.1.5 FCCU failure inputs from other modules....3278
78.1.6 Lockstep Status....3287
78.1.7 FOSU Count Value....3287
78.1.8 FCCU_CFG[FCCU_SET_AFTER_RESET]....3287
78.2 Introduction....3287
78.2.1 Acronyms and abbreviations....3289
78.3 Main features....3289
78.4 Block diagram....3290
78.5 Signal description....3291
78.5.1 Signals....3291
78.6 Functional description....3293
78.6.1 Definitions....3293
78.6.2 FSM description....3293
78.6.3 Self-checking capabilities....3296
78.6.4 Fault priority scheme and nesting....3297

78.6.5 Fault recovery....3298
78.6.6 NMI/WKPU interface....3300
78.6.7 STCU interface....3301
78.6.8 EOUT interface....3302
78.6.9 Error signal flow....3307
78.7 Register descriptions....3308
78.7.1 Control (FCCU_CTRL)....3310
78.7.2 Control Key (FCCU_CTRLK)....3313
78.7.3 Configuration (FCCU_CFG)....3314
78.7.4 Noncritical Fault Configuration (FCCU_NCF_CFG*n*)....3317
78.7.5 Noncritical Fault State Configuration (FCCU_NCFS_CFG*n*)....3318
78.7.6 Noncritical Fault Status (FCCU_NCF_S*n*)....3319
78.7.7 Noncritical Fault Key (FCCU_NCFK)....3321
78.7.8 Noncritical Fault Enable (FCCU_NCF_E*n*)....3321
78.7.9 Noncritical Fault Timeout Enable (FCCU_NCF_TOE*n*)....3323
78.7.10 Noncritical Fault Timeout (FCCU_NCF_TO)....3324
78.7.11 Configuration-State Timeout (FCCU_CFG_TO)....3324
78.7.12 IO Control (FCCU_EINOUT)....3325
78.7.13 Status (FCCU_STAT)....3327
78.7.14 NA Freeze Status (FCCU_N2AF_STATUS)....3329
78.7.15 AF Freeze Status (FCCU_A2FF_STATUS)....3330
78.7.16 NF Freeze Status (FCCU_N2FF_STATUS)....3331
78.7.17 FA Freeze Status (FCCU_F2A_STATUS)....3332
78.7.18 SC Freeze Status (FCCU_SCFS)....3333
78.7.19 Noncritical Fault Fake (FCCU_NCFF)....3335
78.7.20 IRQ Status (FCCU_IRQ_STAT)....3335
78.7.21 IRQ Enable (FCCU_IRQ_EN)....3337
78.7.22 XTMR (FCCU_XTMR)....3338
78.7.23 Mode Controller Status (FCCU_MCS)....3339

78.7.24 Transient Lock (FCCU_TRANS_LOCK)....3341
78.7.25 Permanent Lock (FCCU_PERMNT_LOCK)....3341
78.7.26 Delta T (FCCU_DELTA_T)....3342
78.7.27 IRQ Alarm Enable (FCCU_IRQ_ALARM_EN*n*)....3343
78.7.28 NMI Enable (FCCU_NMI_EN*n*)....3344
78.7.29 Fault-Output (EOUT) Signaling Enable (FCCU_EOUT_SIG_EN*n*)....3345
78.8 FCCU Output Supervision Unit....3346
78.9 Use cases and limitations....3348
78.9.1 Misconfigurations....3348
78.9.2 Recommendations to configure FCCU....3348

Chapter 79
Self-Test Control Unit (STCU2)

79.1 STCU2 chip-specific module information....3351
79.1.1 STCU2 register reset values....3351
79.1.2 Chip-specific STCU2 registers....3352
79.1.3 MBIST Partitions....3354
79.1.4 MBIST Test Cycles....3355
79.1.5 Running Offline MBIST....3356
79.1.6 Off-line LBIST....3357
79.1.7 On-line LBIST....3358
79.1.8 LBIST Partitions....3358
79.1.9 LBIST Configuration....3361
79.1.10 AUTOLOCK_VALUE for register write access via STCU2_SKC....3362
79.1.11 Wait time for writing to the online registers....3362
79.1.12 On-Line reset generation (only MBIST)....3362
79.1.13 On-Line reset generation (LBIST enabled)....3362
79.2 Introduction....3363
79.3 Main features....3363
79.4 Block diagram....3365

79.5 IPS bus interface....3366
79.6 Functional description....3368
79.6.1 FSM description....3368
79.6.2 Reset management....3368
79.6.3 Built-in self-test scheduling....3368
79.6.4 ABORT management....3369
79.6.5 PLL interface....3370
79.6.6 Interrupt interface....3370
79.6.7 FCCU interface....3371
79.6.8 Watchdogs....3371
79.6.9 SSCM interface....3372
79.7 Register description....3373
79.7.1 STCU2 Run Register (STCU2_RUN)....3378
79.7.2 STCU2 Run Software Register (STCU2_RUNSW)....3379
79.7.3 STCU2 SK Code Register (STCU2_SKC)....3381
79.7.4 STCU2 Configuration Register (STCU2_CFG)....3382
79.7.5 STCU2 PLL Configuration Register (STCU2_PLL_CFG)....3385
79.7.6 STCU2 Watchdog Register Granularity (STCU2_WDG)....3386
79.7.7 STCU2 Interrupt Flag Register (STCU2_INT_FLG)....3388
79.7.8 STCU2 Error Register (STCU2_ERR_STAT)....3389
79.7.9 STCU2 Error FM Register (STCU2_ERR_FM)....3392
79.7.10 STCU2 Off-Line LBIST Status Register (STCU2_LBS)....3393
79.7.11 STCU2 Off-Line LBIST End Flag Register (STCU2_LBE)....3394
79.7.12 STCU2 On-Line LBIST Status Register (STCU2_LBSSW)....3395
79.7.13 STCU2 On-Line LBIST End Flag Register (STCU2_LBESW)....3397
79.7.14 STCU2 On-Line LBIST Reset Management (STCU2_LBRMSW)....3398
79.7.15 STCU2 LBIST Unrecoverable FM Register (STCU2_LBUFM)....3399
79.7.16 STCU2 Off-Line MBIST Status Low Register (STCU2_MBSL)....3400
79.7.17 STCU2 Off-Line MBIST Status Medium Register (STCU2_MBSM)....3405

79.7.18 STCU2 Off-Line MBIST Status High Register (STCU2_MBSH).....3408
79.7.19 STCU2 Off-Line MBIST End Flag Low Register (STCU2_MBEL).....3409
79.7.20 STCU2 Off-Line MBIST End Flag Medium Register (STCU2_MBEM).....3412
79.7.21 STCU2 Off-Line MBIST End Flag High Register (STCU2_MBEH).....3414
79.7.22 STCU2 On-Line MBIST Status Low Register (STCU2_MBSLSW).....3415
79.7.23 STCU2 On-Line MBIST Status Medium Register (STCU2_MBSMSW).....3419
79.7.24 STCU2 On-Line MBIST Status High Register (STCU2_MBSHSW).....3421
79.7.25 STCU2 On-Line MBIST End Flag Low Register (STCU2_MBELSW).....3421
79.7.26 STCU2 On-Line MBIST End Flag Medium Register (STCU2_MBEMSW).....3425
79.7.27 STCU2 On-Line MBIST End Flag High Register (STCU2_MBEHSW).....3427
79.7.28 STCU2 MBIST Unrecoverable FM Low Register (STCU2_MBUFML).....3428
79.7.29 STCU2 MBIST Unrecoverable FM Medium Register (STCU2_MBUFMM).....3431
79.7.30 STCU2 MBIST Unrecoverable FM High Register (STCU2_MBUFMH).....3434
79.7.31 STCU2 LBIST Control Register (STCU2_LB_CTRL*n*).....3434
79.7.32 STCU2 LBIST PC Stop Register (STCU2_LB_PCS*n*).....3437
79.7.33 STCU2 LBIST PRPG Low Register (STCU2_LB_PRPGL*n*).....3438
79.7.34 STCU2 LBIST PRPG High Register (STCU2_LB_PRPGH*n*).....3439
79.7.35 STCU2 Off-Line LBIST MISR Expected Low Register (STCU2_LB_MISREL*n*).....3439
79.7.36 STCU2 Off-Line LBIST MISR Expected High Register (STCU2_LB_MISREH*n*).....3440
79.7.37 STCU2 Off-Line LBIST MISR Read Low Register (STCU2_LB_MISRRL*n*).....3441
79.7.38 STCU2 Off-Line LBIST MISR Read High Register (STCU2_LB_MISRRH*n*).....3441
79.7.39 STCU2 On-Line LBIST MISR Expected Low Register (STCU2_LB_MISRELSW*n*).....3442
79.7.40 STCU2 On-Line LBIST MISR Expected High Register (STCU2_LB_MISREHSW*n*).....3443
79.7.41 STCU2 On-Line LBIST MISR Read Low Register (STCU2_LB_MISRRLSW*n*).....3444
79.7.42 STCU2 On-Line LBIST MISR Read High Register (STCU2_LB_MISRRHSW*n*).....3444
79.7.43 STCU2 MBIST Control Register (STCU2_MB_CTRL*n*).....3445
79.8 Use cases and limitations.....3446
79.8.1 Offline self-test sequence.....3446
79.8.2 Online self-test sequence.....3448

83.7.4 Specifying the diary base address....3532
83.7.5 TDR lock status....3533
83.7.6 TDR override....3533
83.7.7 One time programmable (OTP)....3534

Chapter 1
Preface

1.1 Overview

The primary objective of this document is to define the functionality of the MPC5746R microcontroller for use by software and hardware developers.

The information in this book is subject to change without notice, as described in the disclaimers on the back cover. As with any technical documentation, it is the reader's responsibility to be sure he or she is using the most recent version of the documentation.

To locate any published errata or updates for this document, visit the Freescale Web site at http://www.freescale.com.

1.2 Audience

This manual is intended for system software and hardware developers and applications programmers who want to develop products with the MPC5746R device. It is assumed that the reader understands operating systems, microprocessor system design, basic principles of software and hardware, and basic details of the Power Architecture.

1.3 Content

Please note the following about this version of this document, and use it with a complete understanding of its limitations.

- This is a preliminary draft.
- Its content is subject to change without notice.

1.4 Document organization

This document includes two major sets of chapters:

- Chapters in the first set, SoC Specific Chapters, describe the device as a whole or device-specific information.
- Chapters in the second set describe the functionality of the individual modules on the device. These chapters are organized into the following groups:
  - System modules
  - Clocking
  - Memories and Memory Interfaces
  - Analog modules
  - Timers
  - Communication Interface Modules
  - Reset and Boot Modules
  - Power Management Modules
  - Calibration and Debug Modules
  - Safety Modules
  - Security modules

Within a module chapter, module information that is specific to the chip appears in the Configuration section at the beginning of the chapter.

1.5 Register description conventions

The register information for this chip is presented in:

- Memory maps containing:
  - An offset from the module's base address
  - The name and acronym/abbreviation of each register
  - The page number on which each register is described
- Register figures
- Field-description tables
- Associated text

The register figures show the field structure using the conventions in the following figure.

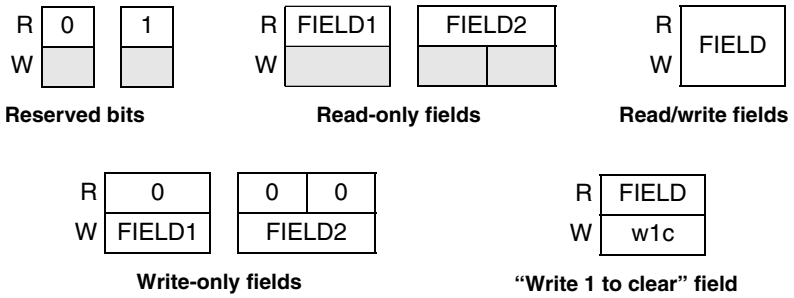

Figure 1-1. Register figure conventions

The numbering of register bits and fields on this chip is as follows:

- Register bit numbers, shown at the top of each figure, use the standard Power Architecture bit ordering (0, 1, 2, ...) where bit 0 is the most significant bit (MSB).
- Multi-bit fields within a register use conventional bit ordering (..., 2, 1, 0) where bit 0 is the least significant bit (LSB).

1.6 Special terms

The following terms have special meanings:

Term	Meaning
asserted	Refers to the state of a signal as follows: • An active-high signal is asserted when high (1). • An active-low signal is asserted when low (0).
deasserted	Refers to the state of a signal as follows: • An active-high signal is deasserted when low (0). • An active-low signal is deasserted when high (1). In some cases, deasserted signals are described as *negated*.
reserved	Refers to a memory space, register, field, or programming setting. Writes to a reserved location can result in unpredictable functionality or behavior. • Do not modify the default value of a reserved programming setting, such as the reset value of a reserved register field. • Consider undefined locations in memory to be reserved.
w1c	Write 1 to clear: Refers to a register bitfield that must be written as 1 to be "cleared."

1.7 Acronyms and abbreviations

Term	Meaning
ATX	Analog Test Module
AUTOSAR	Automotive Open System Architecture

Table continues on the next page...

Term	Meaning
BAF	Boot Assist Flash
CAN	Controller Area Network
CGM	Clock Generation Module
CMU	Clock Monitoring Unit
CRC	Cyclic Redundancy Check
DMA	Direct Memory Access
DMAMUX	Direct Memory Access Controller Multiplexer
DSPI	Deserial Serial Peripheral interface
DTS	Development Tool Semaphore
FCCU	Fault Control and Collection Unit
FEC	Fast Ethernet controller
GPIO	General-purpose I/O
IEEE	Institute for Electrical and Electronics Engineers
INTC	Interrupt Controller
JDC	JTAG Data Communication
JEDEC	Joint Electron Device Engineering Council
JTAG	Joint Test Action Group
Zipwire (LFAST/SIPI)	LVDS Fast Asynchronous Serial Transmission
LINFlex	Local Interconnect Network controller
ME	Mode Entry Module (MC_ME)
MEMU	Memory Error Management Unit
Mux	Multiplex
OSC	Oscillator
PASS	Password and Device Security Module
PCM	Platform Configuration Module
PCU	Power Control Unit
PFLASH	Flash controller
PIT	Periodic Interrupt Timer
PMC	Power Management Controller
PRAM	RAM controller
RCOSC	RC Oscillator
RGM	Reset Generation Module
RTL	Register transfer language
Rx	Receive
SD	ADC Sigma Delta Analog to Digital Converter
SAR	ADC Successive Approximation Register Analog to Digital Converter
SEMA4	Semaphore
SENT	Single Edge Nibble Transmission
SIUL	System Integration Unit Lite
SMPU	System Memory Protection Unit

Table continues on the next page...

Term	Meaning
SoC	System on Chip
SSCM	System Status and Configuration Module
STAC	Shared Time and Angle Count Bus
STCU	Self-Test Control Unit
STM	System Timer module
SWT	Software Watchdog Timer
TSENS	Temperature Sensor
Tx	Transmit
UART	Universal asynchronous/synchronous receiver transmitter
WKPU	Wakeup Unit
XBAR	Crossbar

1.8 References

In addition to this reference manual, the following documents provide additional information on the operation of the MPC5746R:

- IEEE-ISTO 5001-2003 Standard for a Global Embedded Processor Interface (Nexus)
- IEEE 1149.1-2001 standard - IEEE Standard Test Access Port and Boundary-Scan Architecture

Chapter 2
Introduction

2.1 Introduction

The MPC5746R microcontroller is a member of a family of powertrain devices based on the eTPU timer. The device builds on the legacy of the family, while introducing new features coupled with higher throughput to provide substantial reduction of cost per feature and significant performance improvement.

2.2 Target applications

The MPC5746R is targeted for mid-range automotive powertrain controller applications.

Many of the target applications are considered to be functionally safe and are designed to achieve ISO26262 ASIL-D compliance.

2.3 Block diagrams

The figures below are the top-level block diagrams. They show the general interconnection of functional modules through the crossbar switch and provide an indication of the modules that connect to external pins.

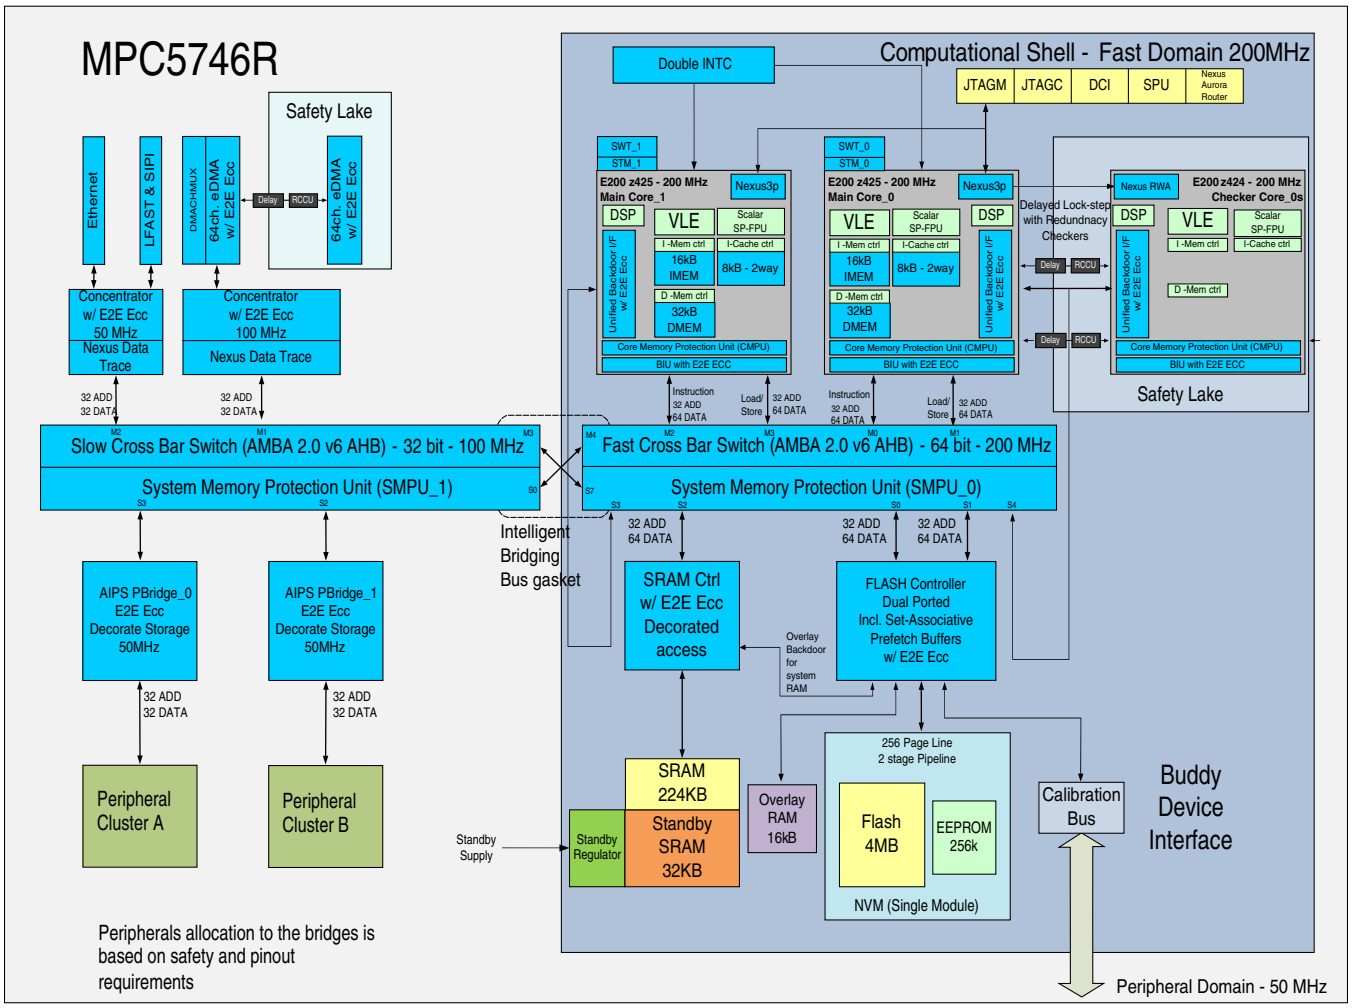

Figure 2-1. Core block diagram

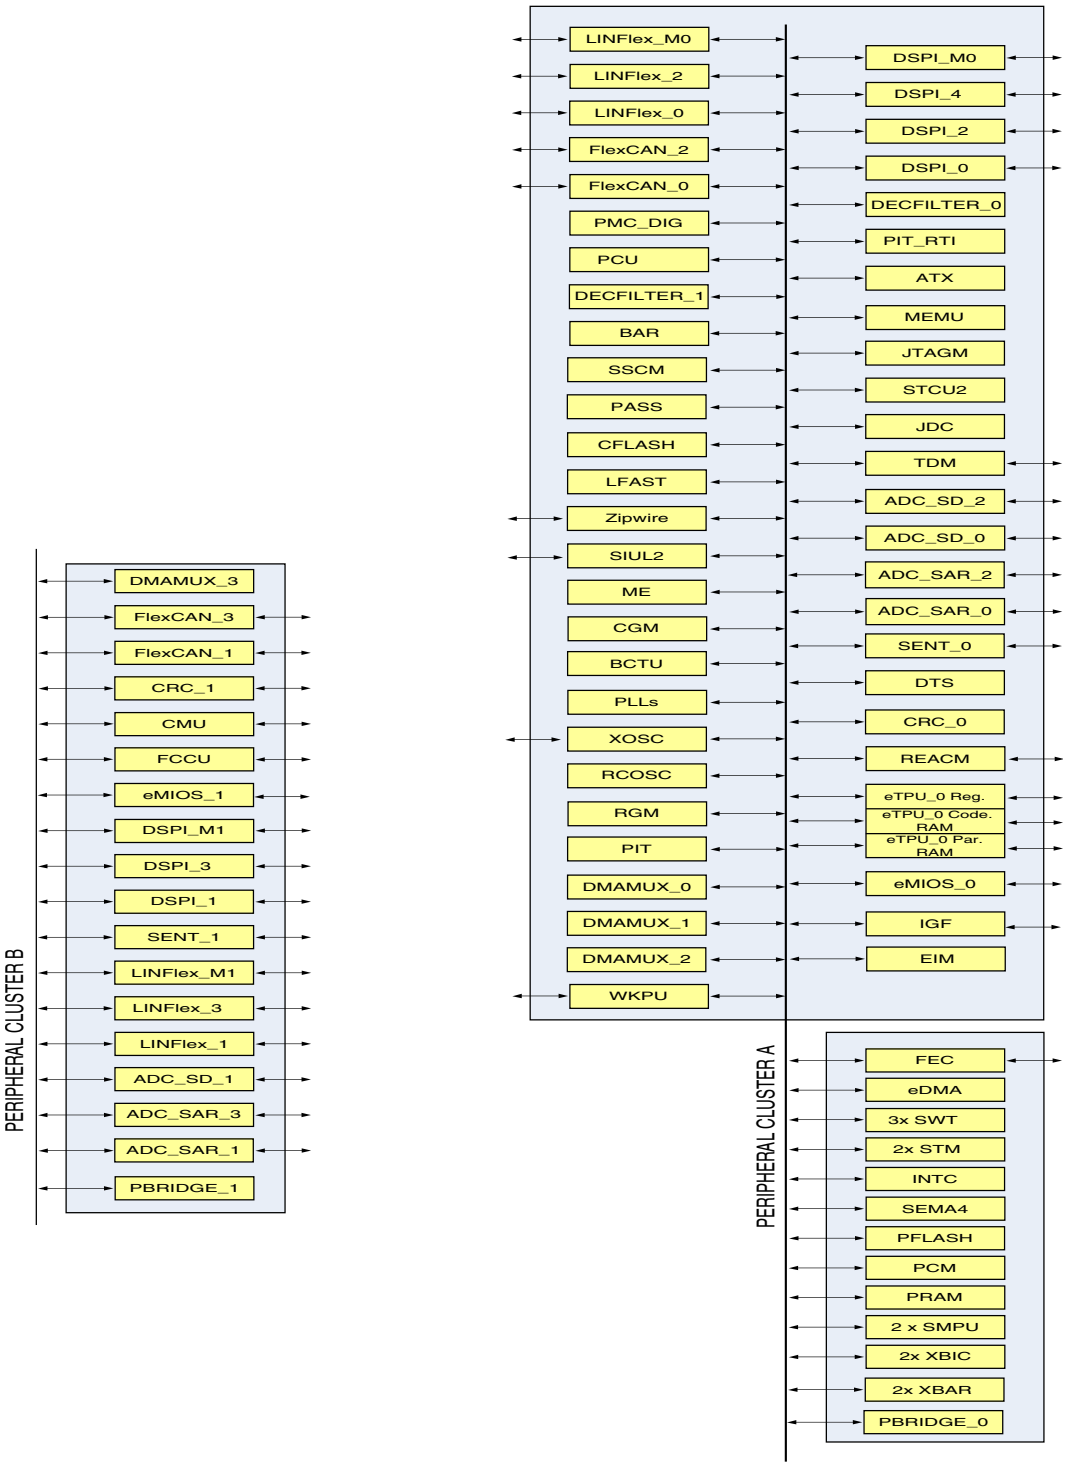

Figure 2-2. Peripherals allocation

2.4 Overall architecture

The architecture is split into two distinct regions: the computational shell and the I/O subsystem.

The computational shell consists of two CPUs, one additional core in lock-step for safety, fast local memories inside the CPUs, and fast system memory. All components of the computational shell are connected through a fast crossbar switch.

The I/O subsystem consists of the DMA and all other peripherals connected through a slow crossbar switch.

The computational shell is optimized for performance and the I/O subsystem is optimized for low power.

2.5 Core features

The device includes two user programmable CPU cores and one safety core. The two e200z425 CPUs operate at 200 MHz and include enhancements to implement Digital Signal Processing (DSP) algorithms. The third core is an e200z424 which runs as a safety checker in delayed lockstep mode with one of the e200z425 CPUs.

All CPUs are compatible with the Power Architecture™ VLE instruction set, which supports code size reduction. The Power Architecture has enhancements that improve the architecture's fit in embedded applications.

2.6 Memory hierarchy

The device computational shell has three levels of memory hierarchy.

- At the top level is a combination of 8 KB instruction cache, 16 KB Local Instruction RAM, and 32 KB Local Data RAM. These RAM arrays are embedded into the CPU's pipeline to provide the fastest possible access time.
- The second level of memory is the system RAM and flash.They are connected via a 200 MHz, 64-bit wide crossbar.
- The third level of memory system is the I/O subsystem. All the I/O peripherals are connected together via a 100 MHz, 32-bit wide crossbar switch. Peripherals are connected at either 100 MHz or 50 MHz depending on their need. The reduced speed for the peripherals helps to reduce power.

2.7 Features summary

On-chip modules available within the MPC5746R include the following features:

- Main CPUs:
  - Three dual issue, 32-bit CPU core complexes (e200z4), one of which is a dedicated lockstep core
  - Power Architecture embedded specification compliance
  - Instruction set enhancement with variable length encoding (VLE, encoding of mixed 16-bit and 32-bit instructions) for code size footprint reduction
  - Single-precision floating point operations
  - 16 KB local instruction RAM and 32 KB local data RAM
  - 8 KB I-Cache
- 4272 KB on-chip flash including 16 KB UTEST
  - Supports reads during program and erase operations, and multiple blocks allowing EEPROM emulation
- 256 KB on-chip general-purpose SRAM
  - 32 KB Standby RAM powered by a separate supply so the contents of this portion can be preserved when the main MCU is powered down
- 64-channel direct memory access controller (eDMA)
- Interrupt controller (INTC)
- Dual Phase-locked loops with stable clock domain for peripherals and FM modulation domain for computational shell
- Dual Crossbar switch architecture for concurrent access to peripherals, flash, or RAM from multiple bus masters
- System Integration Unit Lite 2 (SIUL2)
- Boot Assist Flash module (BAF) supports serial bootload via LINFlex and FlexCAN
- Seven deserial serial peripheral interface (DSPI) modules
- Six UART communication interface modules with LIN support (LINFlex)

    - LINFlexD_0 is a Master/Slave
    - LINFlexD_1, LINFlexD_2,LINFLEXD_3, LINFlexD_M0 and LINFlexD_M1 are Masters only
- Four FlexCAN modules
    - Two modules with 96 Message Buffers
    - Two modules with 64 Message Buffers
- Enhanced analog-to-digital converter system with
    - Four separate 12 bit SAR analog converters
    - Three separate 16 bit Sigma-Delta analog converters
- Two 32 channel enhanced time processing units (eTPU)
- 32 channel Input Glitch Filter (IGF) connected to eTPU and eMIOS inputs
- Two 16 channel timed IOs (eMIOS)
- 10 channel Reaction Moduile (REACM)
- Nexus development interface (NDI) per IEEE-ISTO 5001-2003 standard, with some support for 2010 standard
- Device and board test support per Joint Test Action Group (JTAG) (IEEE 1149.1)
- Self Test capability

See section Feature list for feature differences in the MPC5745R, MPC5743R, and MPC5742R.

2.8 Feature list

The following table lists a summary of major features of the device.

Table 2-1. Features list

Feature	MPC5746R	MPC5745R	MPC5743R
Main core	2	2	1[1]
Locked step core	1	1	1
Flash	4256KB + 16KB	3232KB + 16KB	2208KB + 16KB
EEPROM	2x64KB + 8x16KB	2x64KB + 8x16KB	2x64KB + 8x16KB

Table continues on the next page...

Table 2-1. Features list (continued)

Feature	MPC5746R	MPC5745R	MPC5743R
System RAM	256KB (including standby RAM)	192KB (including standby RAM)	128KB (including standby RAM)
I-CACHE	8KB/core	8KB/core	8KB/core
Local IRAM	16KB/core	16KB/core	16KB/core
Local DRAM	32KB/core	32KB/core	32KB/core
Stby RAM	32KB	32KB	32KB
Overlay RAM	16KB	16KB	16KB
Core freq	200MHz	150MHz[2]	200MHz
SAR	4	4	4
SD ADC	3	3	3
Decimation Filters	2	2	2
eTPU	32ch x 2	32ch x 2	32ch x 2
Reaction module	10ch	10ch	10ch
DMA controller	64ch	64ch	64ch
FlexCAN	4	4	4
LINFlex	4+2MSB support	4+2MSB support	3+2MSB support[3]
DSPI	5+2MSB support	5+2MSB support[4]	4+2MSB support[5]
Ethernet	10/100MBPS	10/100MBPS	10/100MBPS
SENT	6ch	6ch	6ch
Package	MAPBGA252 MAPBGA292 Emulation Device	LQFP176 or MAPBGA252	LQFP176 or LQFP144

1. Core0 + Locked step core will be supported. Core 1 will be used for BAF execution at start-up only.
2. 256 BGA package supports 200MHz operation.
3. LINFlex 3 is not supported.
4. For 176 LQFP DSPI 4 is not supported.
5. DSPI 4 is not supported. For 144 LQFP, DSPI M1 is also not supported.

2.9 Packaging

The device will be available in three production packages:

- 144 LQFP
- 176 LQFP
- 252 MAPBGA

The device uses a MAPBGA292 as the Emulation Device.

2.10 Software debug and calibration

The Production Device (PD) includes many features to facilitate software development and calibration of constant data. These features include:

- Nexus code execution trace on all CPUs and eTPUs
- Nexus data trace on all bus masters (DMA, Zipwire, CPUs, and others) and eTPUs
- Performance monitors for each CPU
- Sequence Processing Unit for complex trace triggering
- 16 KB overlay RAM

The microcontroller has a comprehensive feature set to assist debug and calibration. Specialized variants, referred to as Emulation and Debug Devices (EDs), include additional calibration and debug features. An ED consists of the normal production die plus an additional die, called a Buddy die or Buddy Device (BD), bonded together in the same package. A Production Device (PD) includes a production die only and no buddy die.

The Emulation and Debug Device (ED) will:

- Provide all of the features and modules that are included in the Production Device (PD)
- Be available in the MAPBGA292 package
- Have additional overlay RAM (up to 1 Mbytes)
- Have a high-speed Nexus trace output port consisting of four lanes of Aurora (LVDS) running at up to 1.25 Gbits/second

Chapter 3
Embedded memories

3.1 Overview

The embedded memory architecture for MPC5746R devices is a significant departure from previous-generation devices. Features include:

- On-chip SRAM, including system SRAM, local instruction and data memory for each processor core, and overlay SRAM
- On-chip system error correction code (ECC) flash memory
- End-to-end ECC (e2eECC) error detection and correction [1]
- Embedded memories in the peripherals [2] :
  - FlexCAN
  - eDMA
  - FEC
  - eTPU2
  - NAR

3.2 SRAM

3.2.1 System SRAM

MPC5746R includes 256 KB of general-purpose on-chip ECC SRAM, including 32 KB standby RAM. The SRAM can be configured for either zero- or one-wait state read operation latency using the PFCR1 register in the SRAM controller.

- See the RAM controller (PRAM) chapter for details on configuring the SRAM controller.

1. Not all modules support e2eECC.
2. Refer to the respective module chapter for details.

3.2.2 Standby SRAM Regulator

A total of 32 KB of the system SRAM on the device can remain powered when the rest of the device is powered down. This is achieved with the dedicated VDDSTBY pin in the packages. When the standby RAM is powered by VDDSTBY, the RAM is not operational, but the contents are retained.

The Standby RAM regulator has the following key features:

- Automatic, safe switching between operational (VDD_LV) and standby (VDDSTBY) supplies
- Internal regulation of the high voltage VDDSTBY supply to the low voltage standby RAM supply
- Brownout detection (minimum RAM data retention voltage violation) and reporting via a S/W clearable register bit

The Standby RAM regulator block diagram is given in Figure 3-1.

There are two primary modes of operation with the standby RAM feature:

- Standby RAM feature is not required in the application - in this case, the VDDSTBY pin is connected to ground, and the standby RAM on the device is supplied by VDD_LV and will behave as normal RAM for all conditions.
- Standby RAM feature is required in the application - in this case, the VDDSTBY pin is connected to a voltage within the range given in the device data sheet. The VDDSTBY pin is assumed to be connected to a constant supply, and present before and after the power up/down of the device LV and HV supplies. When the VDD_LV supply to the RAM is above the LV operational voltage threshold, the standby RAM is fully operational and behaves exactly the same as the non-standby system RAM. When the VDD_LV supply falls below the LV Detect threshold, the RAM low voltage supply is switched to the standby supply. See the device data sheet for min/max VDDSTBY values, LV supply thresholds, and the operational and brownout detection voltages.

The brownout detection feature of the standby RAM regulator informs the user if any voltage dip caused a RAM retention failure in standby mode. The brownout detector monitors the supply to the RAM array, and sets a latch in the PMC digital interface, when the voltage falls below the minimum RAM retention voltage given in the device data sheet. The latch is set on power up of the device. S/W then clears the latch by following the instructions in PMC_ADC_CS[STND_BY_RAM_BR_DETCT] description in the Power Management Controller digital interface (PMC_dig) chapter. If the minimum

RAM retention voltage is violated, the latch will be set again. The latch is set on every power-up of VDD_LV unless VDDSTBY is present and within the specified ranges in the data sheet.

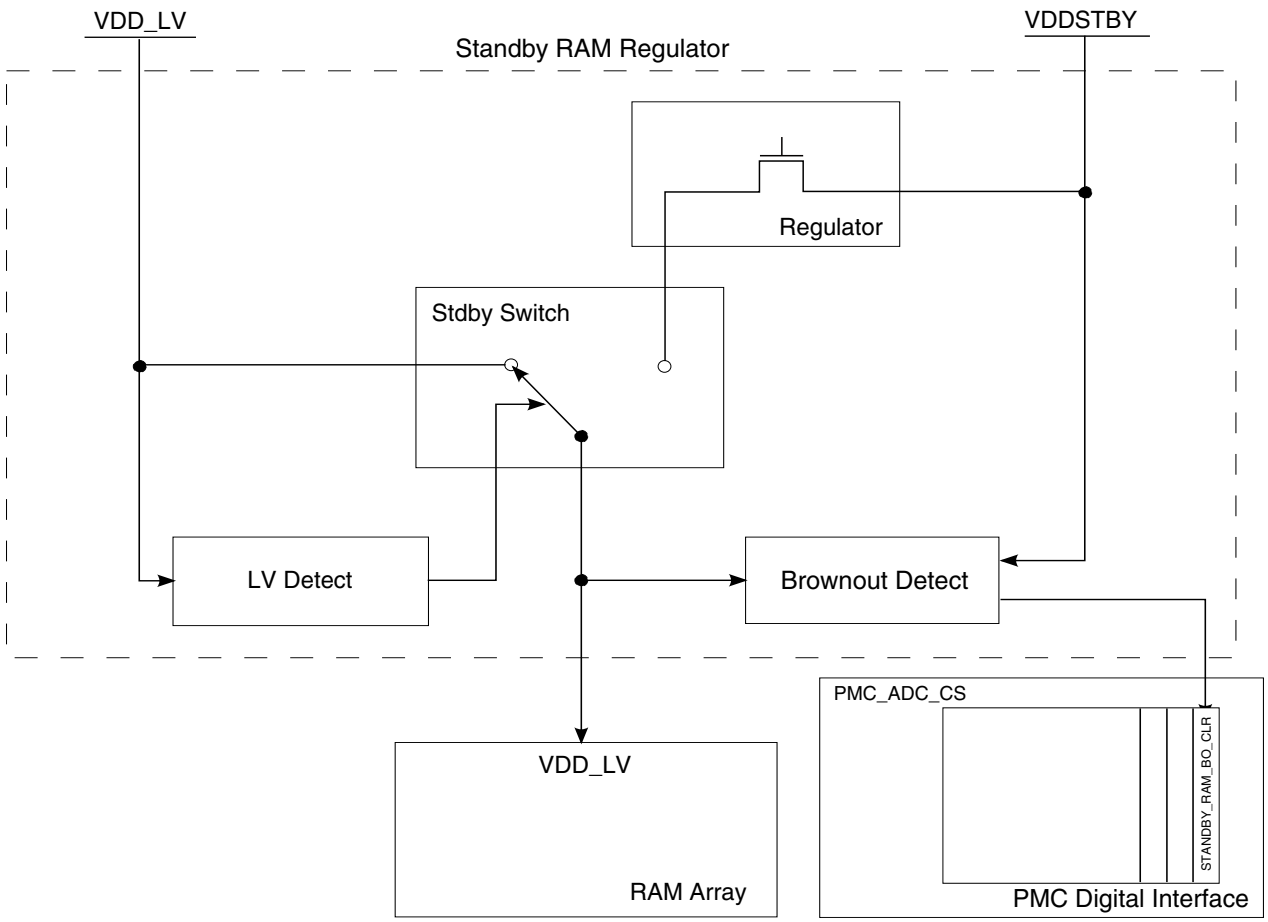

Figure 3-1. Standby RAM regulator block diagram

3.2.3 Overlay SRAM

Overlay SRAM is included in the MPC5746R family of devices as part of a comprehensive set of calibration and debug features. Overlay SRAM can be mapped over specific regions of on-chip flash memory so that any access to an overlaid flash address is routed to the overlay SRAM instead. This enables the calibration of constant data without requiring additional external RAMs and calibration memory interfaces.The microcontroller has two 8 KB banks of 8-bit ECC-protected RAM, for a total of 16 KB.

NOTE

All read/write accesses to Overlay RAM must be 32bit aligned.

NOTE

Overlay SRAM is normally used for system development purposes only. Code can be executed from internal overlay RAM and extended overlay RAM where available. Execution from overlay RAM remapped over Flash can be enabled or disabled by use of PFCRCR[IRMEM]. Code can be executed directly from Extended Overlay RAM (address range beginning 0x0C000000) on the ED device or internal Overlay RAM (address range beginning 0x0D000000) on the PD regardless of the PFCRCR[IRMEM] setting.

Overlay memory can also be used to hold the device debug trace stream without requiring complex debug tool hardware and access to a high-speed trace port. Timing for calibration accesses to a particular overlay SRAM is the same as access to the underlying flash memory if the overlay SRAM is not being used as a destination for trace streaming at the same time.

The calibration remap function supports three different types of overlay SRAM:

- An internal overlay RAM is included on all standard production devices.
- An extended overlay RAM is an additional memory that is available only on special emulation and debug devices.
- A portion of the system RAM can be used as the overlay RAM.

The overlay function is implemented using registers in the flash memory controller.

1. Using PFlash Calibration Region Descriptors (PFCRDn) define one or more (up to 32) overlay regions.
2. Enable individual regions using the appropriate bits in the PFLASH Remap Descriptor Enable Register (PFDCRDE).
3. Enable overlay using the PFCRCR[GRMEN] field.

See PFlash calibration remap support for details on memory overlay (remapping).

3.2.4 Processor core local SRAM

MPC5746R devices include local instruction and data SRAM (I-MEM and D-MEM) for each processor core to provide enhanced performance. Each main processor core has 16 KB of instruction SRAM and 32 KB of data SRAM.

The core SRAM supports zero wait-state, single-cycle latency on processor local accesses.

Each area of core SRAM is accessible by other processor cores and bus mastering peripheral devices.

3.3 Flash memory

Flash memory on the MPC5746R microcontroller consists of a flash memory controller and a flash memory array module. The flash controller provides flash configuration and control functions and manages the interface between the flash memory array and the device crossbar switch. Figure 3-2 shows the memory architecture.

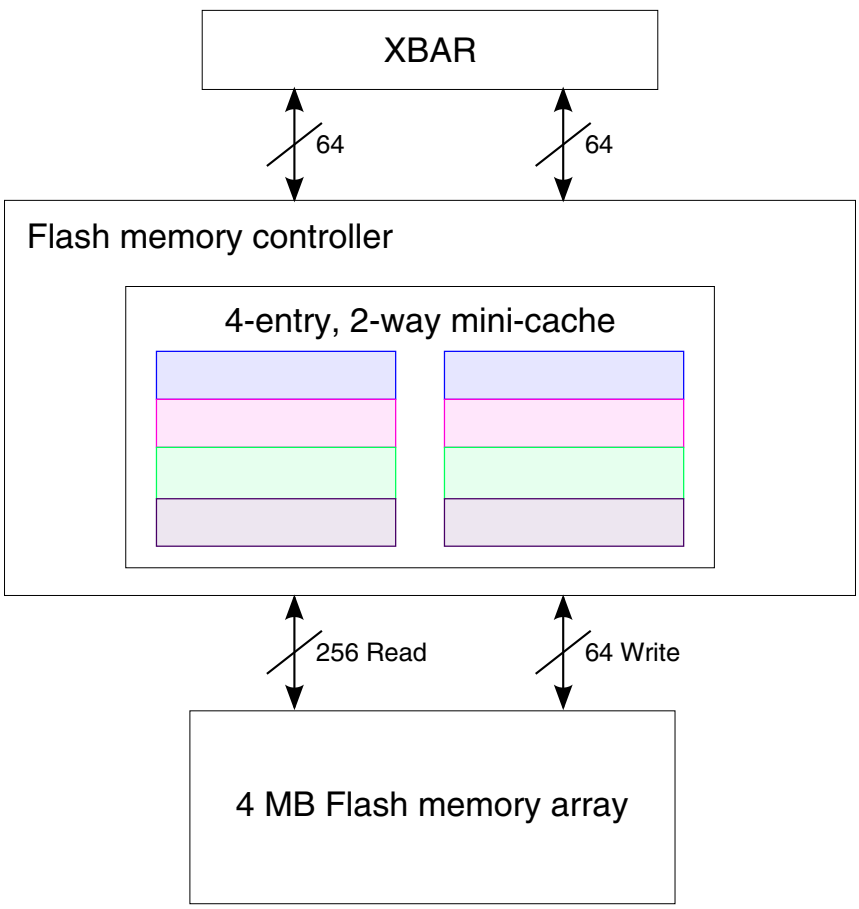

Figure 3-2. Flash memory block diagram

The remaining sections give the functional details of the flash controller and flash array, followed by the memory maps.

3.4 Flash memory controller

The MPC5746R flash memory controller acts as an interface between the system bus and the flash memory array and serves as the interface to the on-chip overlay RAM and off-chip Buddy Device. [3]

The flash memory controller contains a four-entry, two-way set-associative mini-cache that delivers flash read data with a zero-wait state response on lines that reside in the cache. Each entry contains one flash page, a 256-bit (32-byte) memory value. Read requests that miss the cache generate the needed flash memory array access.

The flash memory controller contains configuration registers that manage flash functionality such as read buffering in the mini-cache, access control, calibration RAM overlay remapping, and read wait state management of the flash memory.

See the flash memory controller chapter for details.

3.5 Flash memory array

MPC5746R devices include a single 4256 KB flash memory array, referred to as “main space,” plus an independent 16 KB block of one-time-programmable (OTP) flash memory included to support systems that require non-volatile memory for security features or system initialization information. The independent 16 KB block is referred to as “UTEST space.”

Reads of the embedded flash memory return a 256-bit page of data that may be buffered in the mini-cache in the flash memory controller. Programming of the flash may be done by double word (64-bits), page (256-bits), or quad-page (1024-bits). Erase of the flash memory is done on a block by block basis.

3.5.1 Features

- Flash segmentation
  - 16 KB, 32 KB, 64 KB, and 256 KB blocks provided for code or data
  - Eight 16 KB blocks and two 64 KB blocks provided for EEPROM emulation
  - Support for reading-while-writing when the accesses are to different partitions

3. The Buddy Device is an optional companion chip with additional memory and debug features. A Buddy Device is combined with a Production Device to form an Emulation and Debug Device (ED) for use during system development. It is not used in production systems.

- Flash memory protection: write protection and one-time-programmable (OTP) function available for each block
- Test and initialization data stored in a non-volatile 16 KB OTP UTEST block
- ECC with double bit detection, single bit correction
- Erase suspend, program suspend, and erase-suspended program all supported

3.5.2 Flash organization

The embedded flash memory consists of six address spaces in three groupings:

- 16 KB low address space, 32 KB low address space, and 64 KB low address space
- 16 KB mid address space and 64 KB mid address space
- 256 KB address space

Address space group (low-, mid-, or 256 KB address space) determines which registers/fields are used to select blocks for modify operations or lock them from modify operations. Each address space is independent.

The flash module is further divided into six partitions that determine locations for valid read-while-write (RWW) operations. While the embedded flash memory is performing a “write” (program or erase) to a given partition, it can simultaneously perform a read from any other partition.

- For program operations, only the address specified by an interlock write determines the partition being written (block locking and block select registers do not determine the RWW partitions being written).
- For erase operations, only blocks that are selected and unlocked determine the RWW partitions being written.

Figure 3-3 shows the flash block segmentation and read-while-write partitioning for MPC5746R devices.

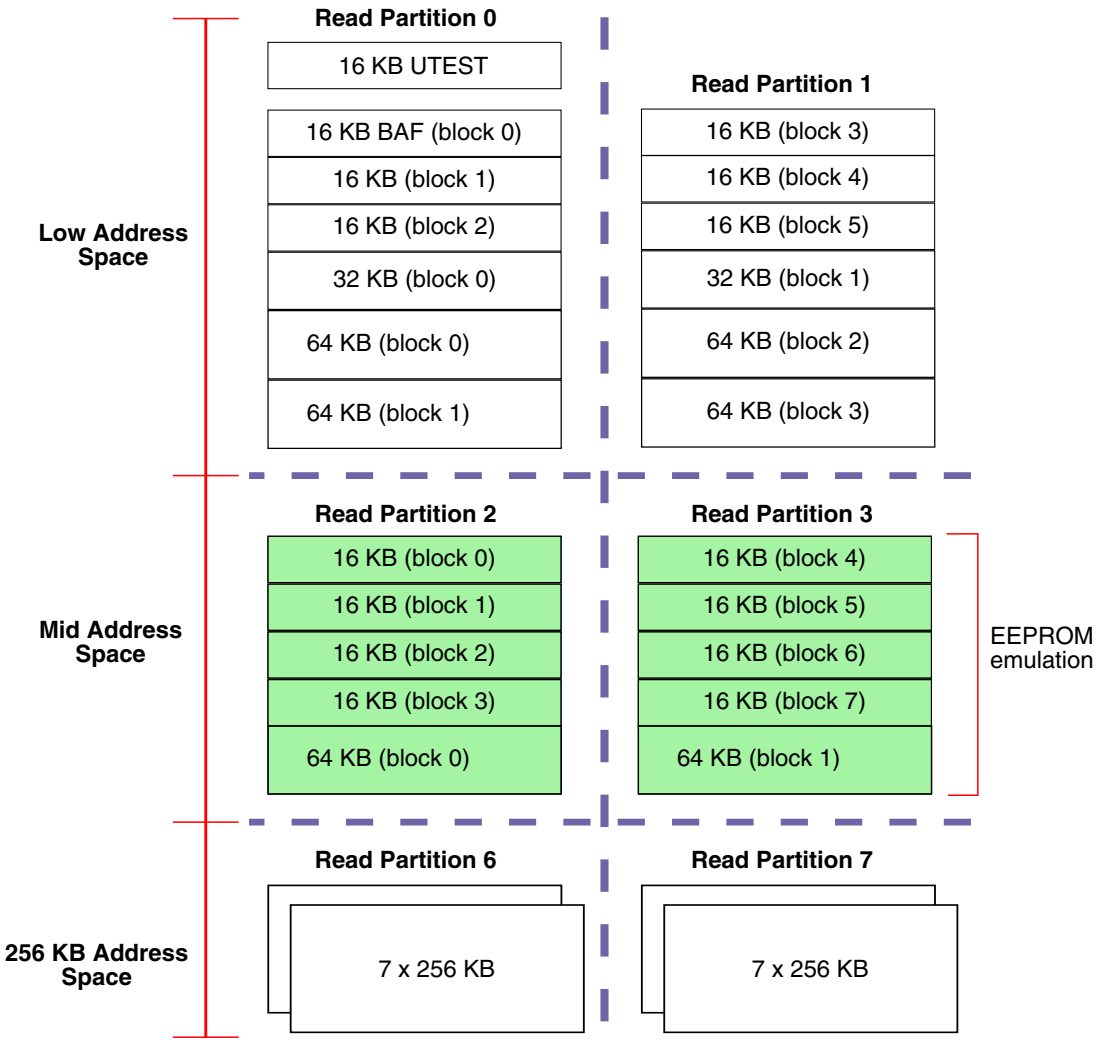

Figure 3-3. Flash memory segmentation and read-while-write partitioning

3.5.3 UTEST memory space

Devices in the MPC5746R family contain a 16 KB area of One-Time Programmable (OTP) flash memory for storing test information and device configuration data.

3.6 End-to-end Error Correction Code (e2eECC)

To support market requirements related to improved functional and transient fault detection capabilities, this family of automotive microcontrollers includes end-to-end ECC (e2eECC) support. This e2eECC is structurally different to traditional “ECC at

memory" functionality because it provides robust error detection capabilities from one endpoint of an information transfer to another endpoint, with temporary information storage in one or more intermediate components.

Memory protected by ECC/EDC traditionally generates and checks additional error parity information local to the memory unit to detect and/or correct errors that have occurred on data stored in the memory. On the other hand, e2eECC generates error protection codes at the source of data generation. It sends the encoded data and error protection codes to intermediate storage when a memory write is initiated by a bus master and performs a data integrity check using the previously stored error protection codes at a data memory when a read of stored information is requested by a bus master. The intermediate storage may transform the generated error protection codes into another format for storage and then regenerate the codes for provision when a request is made to read the stored information or it may simply store the original protection codes unaltered, depending on the particular unit.

Additionally, the error protection codes are generated on the basis of more than just the data associated with a storage location to protect additional information associated with an access. In particular, address information corresponding to the access location of the stored information is combined with the stored data at the data source to generate error protection codes that cover certain types of addressing errors in the system interconnect or in the memory unit. The error protection codes may be checked at the memory unit on a store to ensure that no address information or data has been corrupted while the request has transitioned through the device from the bus master source. The error protection codes may also be checked to ensure that address decoding within the storage memory was performed properly (although not all address decoding errors can be detected this way) or it may simply store the received data and protection codes at the address it receives.

On a read request from a bus master, the memory unit retrieves the data information and error protection codes corresponding to the received address from the storage location or locations and supplies the data along with the error protection codes to the requesting device. The requesting device uses a locally stored address value corresponding to the read request to check the returning data and error protection codes to ensure that no errors have occurred in either addressing the memory or in the retrieved data. This ensures that the address sent for the request was not corrupted, the addressed location was actually accessed (to the extent it is possible to ensure) and the stored data was error free, to the extent the ECC coding scheme is able to detect. As a result, the fault coverage provided by the end-to-end check is considerably more robust than the previous implementation of locally generated and checked/corrected error protection at each memory unit.

A comparison of the traditional and e2eECC approaches is shown in Table 3-1.

Table 3-1. ECC comparison of data write-then-read sequence

Traditional ECC	End-to-End ECC (e2eECC)
Bus master initiates data write	Bus master initiates data write and generates ECC checkbits based on 29-bit address and 64-bit data fields for the computational shell, or based on 30-bit address and 32-bit data field for the peripheral shell
Data write transfer routed from bus master to appropriate bus slave	Data write transfer (including checkbits) routed from bus master to appropriate bus slave
For a bus memory slave, generate the ECC checkbits based on the data value and store data + checkbits into the memory	For a bus memory slave, store data and checkbits into the memory
Bus master initiates data read of previously written memory location	Bus master initiates data read of previously written memory location
Data read transfer routed from bus master to appropriate bus slave	Data read transfer routed from bus master to appropriate bus slave
For a bus memory slave, the memory array is accessed, the controller performs the ECC checkbit decode and syndrome generation, performs any needed single-bit correction and drives the read data onto the system bus interconnect	For a bus memory slave, the memory array is accessed, and the controller passes the read data and associated checkbits onto the system bus interconnection
The bus master captures the read data and continues	The bus master captures the read data and associated checkbits, performs the ECC checkbit decode and syndrome generation, performs any needed single-bit correction and continues

The scope of differences in the operations “covered” by the ECC checks is readily apparent with the e2eECC concept providing improved fault detection capabilities in two important aspects:

- The entire data transaction; from the initiating bus master, through the entire platform crossbar steering mechanism, to the destination slave target is covered during write accesses. Likewise, a read is checked from the initiating bus master, through the crossbar steering mechanism, through the actual memory read and transmission of the data plus checkbits back to the bus master, where the integrity and correctness of the entire transaction is checked.
- The selected ECC provides protection of both the address field as well as the data field, again for improved fault coverage.

Additionally, this particular structure also provides a significant implementation improvement. The traditional ECC at the memory approach places the checkbit decode and error syndrome generation with the error/no_error state, affecting whether the system bus transfer must be stalled (to correct a single bit error or report a noncorrectable event) or is allowed to complete (for error-free transfers) in a critical timing arc which often sets the upper limit of the operating frequency of the microcontroller. With the e2eECC scheme, the checkbit decode and error syndrome logic is located in the requesting bus master where there are generally more degrees of implementation freedom and the error/no_error state determination is removed from the system bus cycle termination logic; producing an improved timing arc and generally higher operating speeds.

Errors that occur within the system interconnect are typically manifested as an incorrect address, incorrect write data, or incorrect read data to be presented to the slave or back to the master. Errors occurring within the storage typically manifest themselves eventually in corrupted read data or checkbits being returned to a requester. While not all possible errors can be detected this way, this approach provides a substantial improvement versus traditional methods. Additional on-line diagnostics, or additional hardware, or both should be able to catch a majority of the errors not covered directly by the e2eECC scheme.

Chapter 4
Signal Multiplexing and Signal Description

4.1 Generic pins/balls

The I/O Signal Description Table contains information on pins/balls of this device. See the device I/O Signal Description and Input Multiplexing Tables (Excel file) attached to this document. Locate the paperclip symbol on the left side of the PDF window, and click it. Double-click on the Excel file to open it and select the I/O Signal Table tab.

Multi-function pins are programmable via their respective Multiplexed Signal Configuration Register (MSCR) Source Signal Select (SSS) values. The SSS value selects which source signal is connected to the associated destination. For additional information, refer to System Integration Unit Lite2 (SIUL2) chapter.

The I/O Signal Table provides the port pin, SIUL MSCR number, MSCR SSS, function, module, signal description, direction, pad type, and package pin/ball numbers for each I/O pin on the device.

4.1.1 System pin functions

The following table describes the functions of the system pins.

Table 4-1. System pin functions

Function	Description	Direction	Active State	144QFP	176QFP	252MAP BGA	292MAP BGA (ED)
XTAL	External Oscillator Output Analog output of the oscillator amplifier circuit needs to be grounded if oscillator is used in bypass mode.	O		7	7	G1	G1
EXTAL	External Oscillator Input Analog input of the oscillator amplifier circuit when oscillator is not in bypass mode. Analog input for the clock generator when oscillator is in bypass mode.	I		6	6	F1	F1

Table continues on the next page...

Table 4-1. System pin functions (continued)

Function	Description	Direction	Active State	144QFP	176QFP	252MAP BGA	292MAP BGA (ED)
RESET	Functional Reset Ouput External functional reset with Schmitt trigger characteristics and noise filter. RESET is active low.	I/O	low	8	8	F3	F4
PORST	Power On Reset Input Power on reset with Schmitt trigger characteristics and noise filter. PORST is active low.	I/O	low	9	9	G3	G4
TESTMODE	Test Mode Enable Input Pin for testing purpose only. An internal pull-down is implemented on the TESTMODE pin to prevent the device from entering TESTMODE. It is recommended to connect the TESTMODE pin to VSS_HV_IO on the board. The value of the TESTMODE pin is latched at the negation of reset and has no affect afterward. The device will not exit reset with the TESTMODE pin asserted during power-up.	I	high	23	24	M2	M2

Chapter 5
Memory Map

5.1 Introduction

The memory map is provided as an Excel file attached to this document with the file name *Memory_Map_Table.xslx*. Locate the paperclip symbol on the left side of the PDF window, and click it. Double-click on the Excel file to open it.

The Excel file contains six memory maps.

- Overview memory map
- Peripheral memory map
- NVM and overlay memory map
- Buddy device memory map
- RAM memory map
- UTEST flash memory map

All addresses on the chip, including those that are reserved, are identified in the tables. The addresses represent the physical addresses assigned to each region or module name.

The **Overview memory map** summarizes the complete 32-bit address map. A memory access, either read or write, to any region marked as 'Reserved' will result in a Transfer Error. This error can generate an interrupt request in the CPU.

The **Peripheral memmory map** lists the memory map of the peripheral region. This region is sub-divided into 16 KB regions or 'slots'. A peripheral occupies one or more slots. A memory access, either read or write, to any slot marked as 'Reserved' will result in a Transfer Error. This error can generate an interrupt request in the CPU.

Within a 16 KB peripheral slot, it is normal for the peripheral registers to only occupy part of that 16 KB slot, normally from the lowest address upwards. The individual chapters for each block define all the registers within that contiguous group of registers.

Any memory access outside the range of the defined register map will result in a Transfer Error. This error can generate an interrupt request in the CPU.

The other tables define the embedded memory maps and the buddy memory map. A memory access, either read or write, to any region marked as 'Reserved' in these tables, will result in a Transfer Error. This error can generate an interrupt request in the CPU.

Chapter 6
Device Configuration Format (DCF) Records

6.1 Overview

Device Configuration Format (DCF) records are used by the System Status and Configuration Module (SSCM) to configure certain registers in the device during system boot while the reset signal is asserted.

There are two kinds of DCF records:

- Factory-written DCF records: written to UTEST flash by the factory.
- User-supplied DCF records: written to UTEST flash by the user.

The following figure is a conceptual representation of the functionality of DCF records which is described in this chapter.

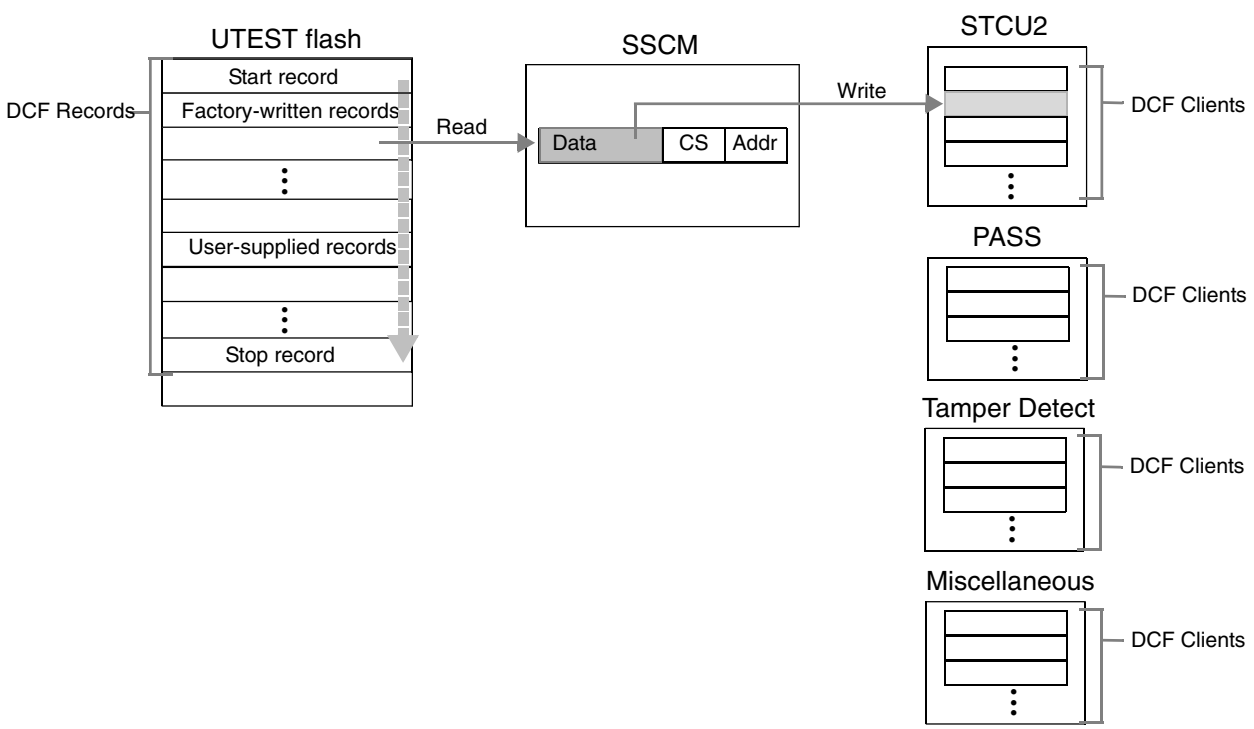

Figure 6-1. Conceptual representation of DCF records functionality

6.2 DCF records in boot sequence

For the device to be used in a user application, the system boot process must properly program the following to the respective flash memories before releasing reset.

- User application code
- Reset vectors for all CPUs
- DCF records

The following is a high-level summary of the boot sequence leading to the use of DCF records:

1. When power is applied to a properly programmed device, the Power Management Controller (PMC) takes control of the device.
2. After the system power supplies have reached predefined levels, the Power Management Controller signals the Reset Generation Module (RGM) to begin the boot sequence.
3. During the boot sequence, the RGM enables the System Status and Control Module (SSCM) to read the Device Configuration Format records.
4. SSCM writes the configuration information to the specified registers.
5. After registers are initialized, the SSCM passes the control of the boot sequence back to the RGM, which directs the STCU2 to start the memory and logic built in self tests (MBIST and LBIST).

6.3 DCF records function

User-supplied DCF records define the following:

- Setup of the initial memory map
- Tests the Self-Test Control Unit (STCU2) runs during the boot sequence
- Memory blocks assigned as OTP
- Flash memory block association with specific password groups
- Flash memory block association with specific tamper detect regions

6.4 DCF records location

Factory-written DCF records start at the first address in the UTEST flash memory area. See the UTEST flash memory map in the Memory map chapter.

User-supplied UTEST DCF records may be added at the next location in the UTEST memory map immediately following the factory-written UTEST DCF records.

6.5 DCF record structure

A DCF record is a double-word (64-bit) entry consisting of the following:

- Control word: Information to locate the corresponding DCF client internal to the device (pointer to the location of a register internal to the device)
- Data word: Data to be written to that client

DCF Records select the target DCF client by a 30-bit field in the DCF Record consisting of a 15-bit ‘Chip Select’ field and a 15-bit Address field. Each module that includes DCF clients is assigned a Chip Select during chip definition. The address field is only relevant to the address decoding within that module and may not necessarily relate to the address of a register visible to software.

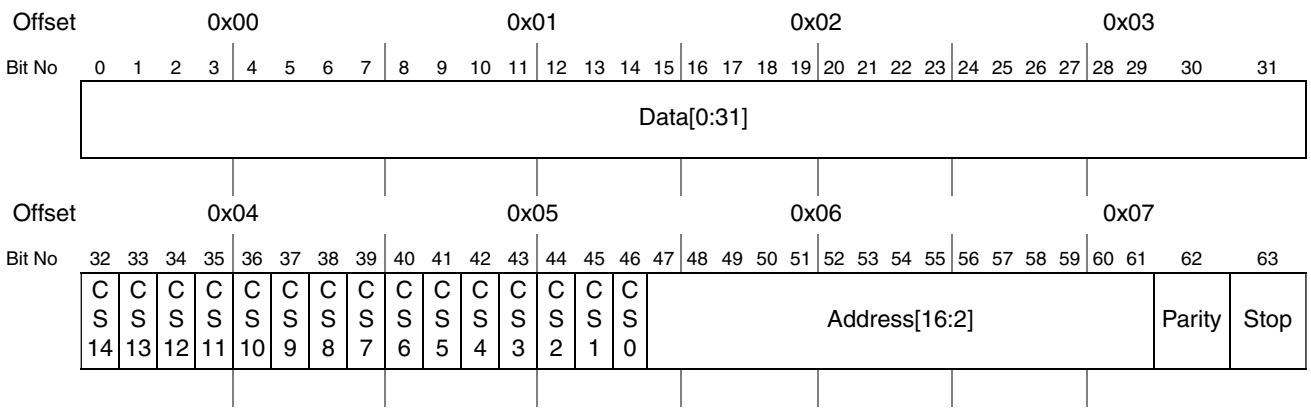

Figure 6-2. DCF Record Structure

Table 6-1. DCF Record Field Description

Field	Name	Description
0-31	Data[0:31]	32 bits of data that is to be written to the DCF Client
32-46	CS*n*	Chip Select *n* One Chip select is asserted (‘1’) per DCF record to select the target module for the DCF client. All other Chip Selects should be negated (‘0’).
47-61	Address[16:2]	Address of the DCF client within the selected module Note: Address decoding for DCF clients may not match the standard software address map decoding. Details of DCF Client addresses are defined in each module chapter.
62	Parity	Parity Bit for the DCF Record. Even parity.

Table continues on the next page...

Table 6-1. DCF Record Field Description (continued)

Field	Name	Description
63	Stop	Stop bit. Indicates the end of the list of DCF Records. Stop = '0' - NOT the end of the list Stop = '1' - End of the list Note: The Erased state of flash is 0xFFFF_FFFF_FFFF_FFFF. Therefore the list ends with the first unprogrammed double word. This location can be programmed with a new record to extend the list.

6.6 DCF records sequence

DCF records must appear as a contiguous series of entries programmed from the beginning of the UTEST flash memory area in the following order.

1. **Start DCF record**: The first DCF record must be a start record. This record must be found at the beginning of a DCF area in flash memory to indicate to the device that the following records must be processed.
2. **DCF records containing configuration data**: DCF records containing configuration data must immediately follow the start record with no blank records in between.
3. **Stop DCF record**: The end of the configuration records is indicated by the stop record. A record with the stop bit set is a stop record. All other bits are ignored. No DCF records following the stop record are processed.

SSCM recognizes the following record as a start record.

Table 6-2. DCF start record

0x00 (0:31)	0x04 (32:63)
0x05AA_55AF	0x0000_0000

The start bit is set by the factory at the beginning of the UTEST flash memory area.

SSCM recognizes the following record as a stop record.

Table 6-3. DCF stop record

0:31	32:62	63
Ignored	Ignored	1

The stop bit is never set by the factory, since this would not allow the user to add DCF records. The flash memory location following the last factory-written UTEST DCF record is unprogrammed, with the content of 0xFFFF_FFFF. This is interpreted as the stop record, since the stop bit is set.

User-supplied DCF records may be added in a contiguous manner immediately following the factory-written DCF records. There must never be an unprogrammed record in the series of DCF records as it will be interpreted as a stop record.

The following table shows the series of DCF records when *n* data records are stored in the UTEST flash.

Table 6-4. Series of DCF records in UTEST flash memory

Record type	ADDR offset	DATA			
Start record	0x00	0x05AA_55AF			
	0x04	0x0000_0000			STOP=0
Data records	0x08	WDATA[31:0]			
	0x0C	CS[14:0]	ADDR[16:2]	PRTY	STOP=0
	0x10	WDATA[31:0]			
	0x14	CS[14:0]	ADDR[16:2]	PRTY	STOP=0
	...	...			
Stop record	8*n*-1 + 0x0	Reserved			
	8*n*-1 + 0x4	Reserved			1
	8*n* + 0x0				
	8*n* + 0x4				

It is possible for more than one DCF Record to write to the same DCF client. In this case the later record usually overrides a DCF client value set by a previous record. However, not all DCF clients allow overwrites; this depends on the DCF client implementation.

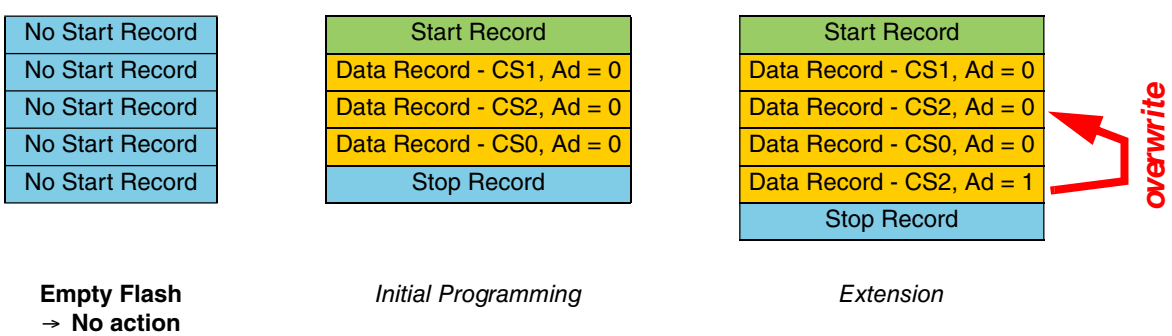

Figure 6-3. Appending DCF records

6.7 DCF clients

DCF clients are 32-bit wide hardware registers inside a module that receive and store the data from a DCF record. This stored data is used to initialize registers and to configure features.

DCF clients have the following characteristics:

- Have a default value before any DCF Records are written.
- Need not implement all 32 bits.

The table below shows the DCF clients available in this device. The meaning of the table columns are as follows:

- **DCFCS[14:0]**
  A 15-bit field with each bit in the field assigned to a particular module. These bits act as chip select signals for the internal modules. Only one bit in this field is be set in a DCF record.
- **DCF Address [16:2]**
  A 15-bit field that specifies an internal address for a DCF client. These addresses are used only by the SSCM when interpreting DCF records and writing the data to specified modules.
- **DCF Client Description**
  Name of the DCF clients
- **Reset Value of DCF Client**
  The reset value of DCF client before being written by the SSCM with the associated DCF record.
- **Typical Value of DCF Client**
  A typical value that you might program into the various DCF clients. This field is for information only.
- **IPS Read Direct Access**
  Whether or not a DCF client can be read by user software after the release of reset.
- **DCF Client Special Strategy**
  Though all DCF records have the same format, they can be used in different ways. As the device is being designed, registers must be designated as Device Configuration Format clients if they need to be written with a DCF record. There are other features that must be designated for DCF clients. For instance, DCF clients can have several different write strategies—Parity, Write Once, Triple Voted + Parity + Check with second write, Triple voted + Check with second write, or no strategy at all. The SSCM examines the DCF client to determine the correct special

strategy to use and then appropriately write a DCF record to that client. The following list defines the special strategies.

- None: No special DCF strategy is used.
- Parity: Parity Bit for the DCF Record. Even parity is expected of all DCFs which require parity evaluation. To confirm which UTEST DCFs require parity specification, refer to the DCF Client Special Strategy column in the table below.
- Write Once: A register using the Write Once strategy can only be written once. The DCF client ignores subsequent writes.
- Triple voting: These clients have three copies of the register. The SSCM will write to all three registers in a single write cycle. The outputs of the three registers are majority-voted to determine the correct data value. Triple voting allows for a ‘bit-flip’ error to occur without changing the DCF client output data.
- Triple Voting with second write: DCF clients that use the Triple Voted with 2nd write strategy have three copies of the register. The SSCM will write to all three registers in a single write cycle. The outputs of the three registers are majority-voted to determine the correct data value. During the second execution of Phase 3 of the reset sequence, the SSCM attempts to write the DCF client again. At this time, the DCF client checks to see that the register contains the same data that is being written again.
- Write 0 only: A bit in a DCF client can only be written from a logic 1 to a logic 0. An attempt to write a bit with this attribute to a logic 1 is ignored.
- Write 1 only: A bit in a DCF client can only be written from a logic 0 to a logic 1. An attempt to write a bit with this attribute to a logic 0 is ignored.
- Spread address (SPRD): This parameter is only available on safe_clients and dcf_safe_mclients. This parameter decides if the three instances share one address, or if they are addressable separately on three different addresses (i.e. spread out). If SPRD_ADR is instantiated as 1, the three dcf_clients are accessible at CFG_ADR + 0x04, CFG_ADR+0x08 and CFG_ADR+0x10. The lower 5 bits of CFG_ADR must be set to 0. In addition to spreading the addresses to three separate locations, SPRD_ADR also activates data transformation. Data transformation is used only in conjunction with triple-voting in the safe clients. It means that the data in the three sub-instances is not the same, but is stored in a transformed format. If the normal payload data is X, then the three sub-instances will store the data as a0=X, a1=~X and a2=shift_rotate_right(X). (So for e.g. X = 1011, a2 = 1101.)

- **DCF Order Dependency**

  Whether or not there are special conditions on the location of a particular DCF record in flash memory.

- **UTEST Flash Memory Space**

Estimated UTEST flash memory space the client occupies, in bytes

DCF clients are found in the following modules:

- STCU
- PASS
- Tamper Detect

Some other DCF clients are classified as Miscellaneous. See description of the individual clients in the table.

Table 6-5. DCF Clients

DCF CS[14:0]	DCF Address [16:2]	DCF Client Description	Reset Value of DCF Client	IPS Read Direct Access	DCF Client Special Strategy	Flash Special Strategy	DCF Order Dependency	UTEST Flash Memory Space

1. Can be updated from DCF Bus (FLASH DCF records or SSCM test access port).
2. Can be accessed only from IPS. Password group has to be unlocked.

6.7.1 Miscellaneous DCF clients

This section describes the DCF clients classified in the Miscellaneous category.

The DCF_SELFTEST_CONFIG_IPS_n DCF clients are memory-mapped. All other DCF clients here are not memory-mapped.

6.7.1.1 DCF_UTEST_Miscellaneous DCF client

The DCF_UTEST_Miscellaneous register controls miscellaneous functionalities.

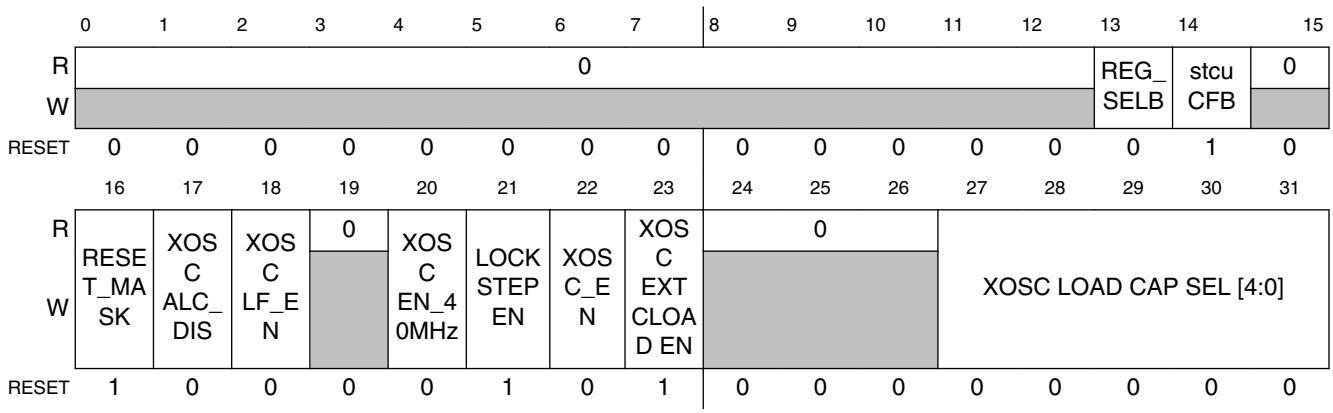

Table 6-7. DCF_UTEST_Miscellaneous Field Description

Field	Name	Description
0-12	Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13	REG_SELB	If this bit is set to 0, internal regulation will be selected. If not external regulation is selected.
14	stcu CFB	If this is set to 1, critical fault during offline LBIST run will generate a destructive reset.
15	Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16	RESET_MASK	Active Low reset Mask bit. 1- RESET PIN enabled, 0-RESET Pin Disabled Level Controller
17	XOSC ALC_DIS	Active high to disable Automatic Level Controller
18	XOSC LF_EN	Active high when oscillator is used for low frequency (~8MHz)
19	Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20	XOSC EN_40MHz	Selects 20MHz against 40MHz XOSC. Set this bit to enable the 40Mhz mode.
21	LOCKSTEP EN	Enables Safety Core to be in lockstep with Checker Core. Value 0 = Lockstep disabled, Value 1 = Lockstep enabled
22	XOSC_EN	Enables XOSC.
23	XOSC EXT CLOAD EN	Selects XOSC internal capacitor (ok for 20-40MHz operation) or external (required for 4-16MHz operation). Set to 1 if external capacitors are used.
24-26	Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27-31	XOSC LOAD CAP SEL [4:0]	5 Trim bits to program the load capacitance at crystal pins

6.7.1.2 DCF_PMC_REE_CTRL DCF client

The DCF_PMC_REE_CTRL register controls whether or not the voltage detect signal causes a reset.

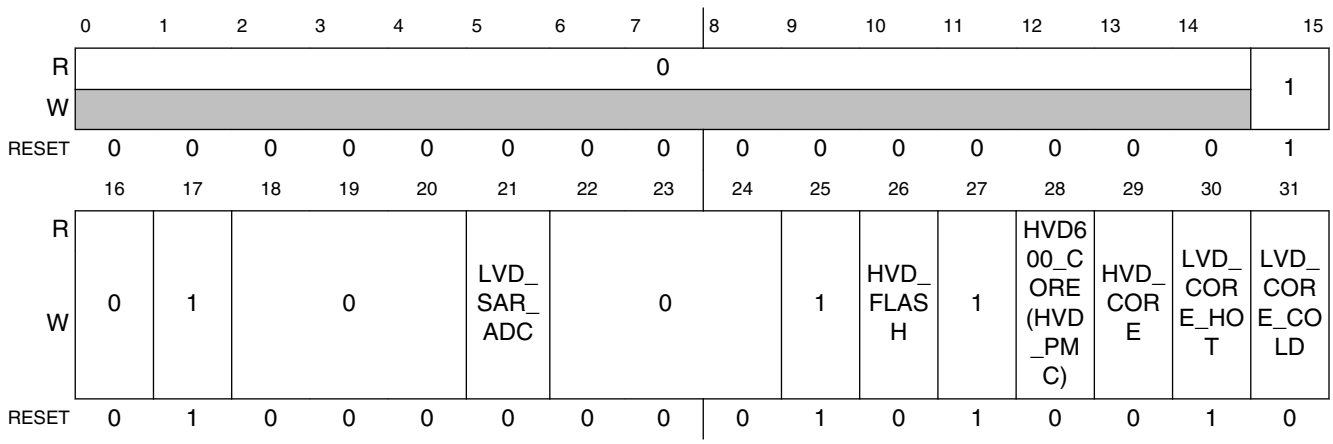

Table 6-9. DCF_PMC_REE_CTRL Field Description

Field	Name	Description
0-14	Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15-20	Reserved	This field is reserved. **NOTE:** Always write the reset value to this field.
21	LVD_SAR_ADC	• 0: Disabled (The voltage detect signal does not cause a reset) • 1: Enabled (The voltage detect signal causes a reset)
22-24	Reserved	This field is reserved. **NOTE:** Always write the reset value to this field.
25	Reserved	This field is reserved. **NOTE:** Always write the reset value to this field.
26	HVD_FLASH	• 0: Disabled (The voltage detect signal does not cause a reset) • 1: Enabled (The voltage detect signal causes a reset)
27	Reserved	This field is reserved. **NOTE:** Always write the reset value to this field.
28	HVD600_CORE (HVD_PMC)	• 0: Disabled (The voltage detect signal does not cause a reset) • 1: Enabled (The voltage detect signal causes a reset)
29	HVD_CORE	• 0: Disabled (The voltage detect signal does not cause a reset) • 1: Enabled (The voltage detect signal causes a reset)
30	LVD_CORE_HOT	• 0: Disabled (The voltage detect signal does not cause a reset) • 1: Enabled (The voltage detect signal causes a reset)
31	LVD_CORE_COLD	• 0: Disabled (The voltage detect signal does not cause a reset) • 1: Enabled (The voltage detect signal causes a reset)

6.7.1.3 DCF_PMC_RES_CTRL DCF client

The DCF_PMC_RES_CTRL register controls whether voltage detect signal causes a destructive reset or a functional reset.

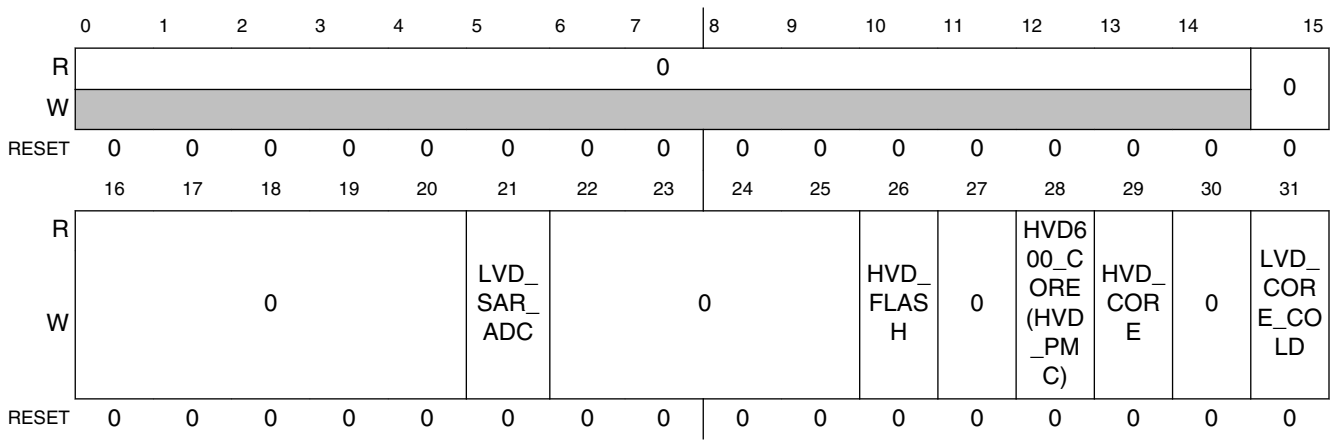

Table 6-11. DCF_PMC_RES_CTRL Field Description

Field	Name	Description
0-14	Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15-20	Reserved	This field is reserved. **NOTE:** Always write the reset value to this field.
21	LVD_SAR_ADC	• 0: The voltage detect signal causes a destructive reset • 1: The voltage detect signal causes a functional reset
22-25	Reserved	This field is reserved. **NOTE:** Always write the reset value to this field.
26	HVD_FLASH	• 0: The voltage detect signal causes a destructive reset • 1: The voltage detect signal causes a functional reset
27	Reserved	This field is reserved. **NOTE:** Always write the reset value to this field.
28	HVD600_CORE (HVD_PMC)	• 0: The voltage detect signal causes a destructive reset • 1: The voltage detect signal causes a functional reset
29	HVD_CORE	• 0: The voltage detect signal causes a destructive reset • 1: The voltage detect signal causes a functional reset
30	Reserved	This field is reserved. **NOTE:** Always write the reset value to this field.
31	LVD_CORE_COLD	• 0: The voltage detect signal causes a destructive reset • 1: The voltage detect signal causes a functional reset

6.7.1.4 DCF_PMC_REE_TD DCF client

The DCF_PMC_REE_TD register controls whether the temperature detect signal event causes a reset.

If the desired flag bit is enabled, the temperature detect event causes a reset to be generated when the selected temperature passes the trigger event.

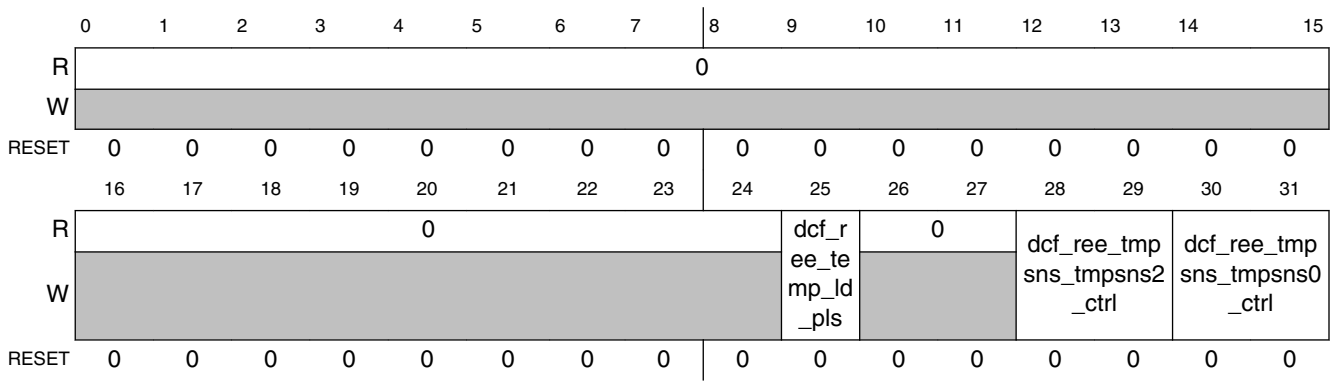

Table 6-13. DCF_PMC_REE_TD Field Description

Field	Name	Description
0-24	Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25	dcf_ree_temp_ld_pls	Set this bit to 1 so that values uploaded becomes effective.
26-27	Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28-29	dcf_ree_tmpsns_tmpsns2_ctrl	Defines whether a temperature detect assertion generates a system reset. This is associated with the temperature for the temperature sensor point (150C). • 00: Temperature sensor detect event does not cause system reset. • 01: Temperature sensor 0 detect causes system reset. • 10: Temperature sensor 1 detect causes system reset. • 11: Temperature sensor 0 and 1 detect causes system reset.
30-31	dcf_ree_tmpsns_tmpsns0_ctrl	Defines whether a temperature detect assertion generates a system reset. This is associated with the temperature for the cold temperature sensor,when the temperature exceeds its corresponding threshold. • 00: Temperature sensor detect event does not cause system reset. • 01: Temperature sensor 0 detect causes system reset. • 10: Temperature sensor 1 detect causes system reset. • 11: Temperature sensor 0 and 1 detect causes system reset.

6.7.1.5 DCF_IVPR0 DCF client

The DCF_IVPR0 is the reset interrupt vector prefix register DCF client for Main Core_0.

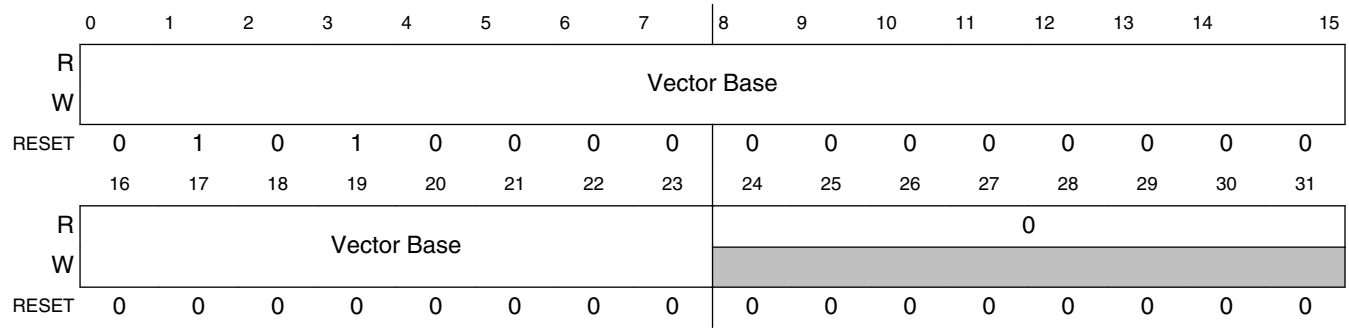

Table 6-15. DCF_IVPR0 Field Description

Field	Name	Description
0-23	Vector Base	This field is used to define the base location of the vector table, aligned to a 256 byte boundary. This field provides the high-order 24 bits of the location of all interrupt handlers (unless hardware vectoring is used). The vector offset value appropriate for the type of exception being processed is concatenated with the IVPR Vector Base to form the address of the handler in memory. For hardware-vectored interrupts, the value of the supplied interrupt vector is logically OR'ed with the low order bits of the Vec Base Field to determine the interrupt handler address. **NOTE:** dcf_ivpr[23:0] -> core.ivpr[0:23]
24-31	Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

6.7.1.6 DCF_IVPR1 DCF client

The DCF_IVPR1 is the reset interrupt vector prefix register DCF client for Main Core_1.

NOTE

- This DCF client is put into effect only after BAF is executed and the application code starts executing.
- The value in this DCF client is left-shifted by 8 bits before programmed to the Core_1 IVPR.

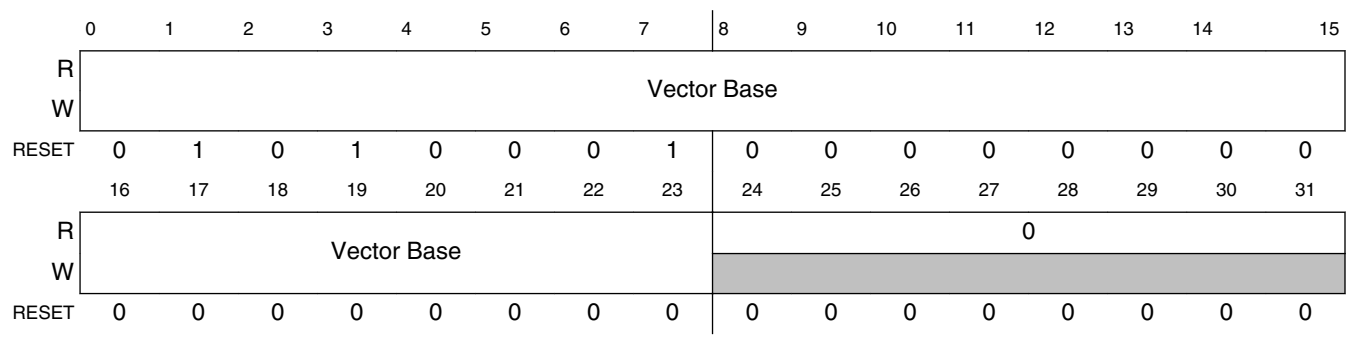

Table 6-17. DCF_IVPR1 Field Description

Field	Name	Description
0-23	Vector Base	This field is used to define the base location of the vector table, aligned to a 256 byte boundary. This field provides the high-order 24 bits of the location of all interrupt handlers (unless hardware vectoring is used). The vector offset value appropriate for the type of exception being processed is concatenated with the IVPR Vector Base to form the address of the handler in memory. For hardware-vectored interrupts, the value of the supplied interrupt vector is logically OR'ed with the low order bits of the Vec Base Field to determine the interrupt handler address. **NOTE:** dcf_ivpr[23:0] -> core.ivpr[0:23]
24-31	Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

6.7.1.7 DCF_SELFTEST_CONFIG_IPS_1 DCF client

The DCF_SELFTEST_CONFIG_IPS_1 register controls the fault Model for LBIST and selects which PLL would be used for LBIST testing if any.

Address: 0x11_1111_1110_0000 base + 0x0 offset

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0									PLL_LOCK 1	PLL_LOCK 0	0			1
W																
RESET	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0			config[1]	0											
W																
RESET	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 6-19. DCF_SELFTEST_CONFIG_IPS_1 Field Description

Field	Name	Description
0	Reserved	This field is reserved. Set this bit when running LBIST.
1-9	Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
10	PLL_LOCK1	Program this bit to "1" if PLL1 is to be used for Selftest. Only one of bits 20 and 21 should be programmed "1".
11	PLL_LOCK0	Program this bit to "1" if PLL0 is to be used for Selftest . Only one of bits 20 and 21 should be programmed "1".
12-14	Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15	Reserved	This field is reserved. This read-only field is reserved and always has the value 1.
16-18	Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

Table 6-19. DCF_SELFTEST_CONFIG_IPS_1 Field Description (continued)

Field	Name	Description
19	config[1]	Program this bit to "1" if stuck-At LBIST is required to be run. In this mode PLL is locked at 200 Mhz but all partitions are run at 50 Mhz at 4 seperate edges of 200 Mhz so as to reduce the peak power.
20-31	Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

6.7.1.8 DCF_SELFTEST_CONFIG_IPS_2 DCF client

The DCF_SELFTEST_CONFIG_IPS_2 register controls the division values for the dividers.

The division value set by these fields is the bit value + 1. (0b000 sets the division value to 1, 0b001 sets the division value to 2, and so on.)

Address: 0x11_1111_1110_0000 base + 0x100 offset

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

W																
RESET	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	(Aux_MUX_0_Divider_0_Division_Value)	0			System_MUX_Divider_3_Division_Value		System_MUX_Divider_2_Division_Value		System_MUX_Divider_1_Division_Value			System_MUX_Divider_0_Division_Value				
W																
RESET	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 6-21. DCF_SELFTEST_CONFIG_IPS_2 Field Description

Field	Name	Description
0-1	Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2-5	Aux_MUX_0_Divider_4_Division_Value	Sets the division value of the divider.
6-7	Aux_MUX_0_Divider_3_Division_Value	Sets the division value of the divider.
8-10	Aux_MUX_0_Divider_2_Division_Value	Sets the division value of the divider.

Table continues on the next page...

Table 6-21. DCF_SELFTEST_CONFIG_IPS_2 Field Description (continued)

Field	Name	Description
11-13	Aux_MUX_0_Divider_1_Division_Value	Sets the division value of the divider.
14-16	Aux_MUX_0_Divider_0_Division_Value	Sets the division value of the divider.
17-19	Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20-22	System_MUX_Divider_3_Division_Value	Sets the division value of the divider.
23-25	System_MUX_Divider_2_Division_Value	Sets the division value of the divider.
26-28	System_MUX_Divider_1_Division_Value	Sets the division value of the divider.
29-31	System_MUX_Divider_0_Division_Value	Sets the division value of the divider.

6.7.1.9 DCF_SELFTEST_CONFIG_IPS_3 DCF client

The DCF_SELFTEST_CONFIG_IPS_3 register controls the division values for the dividers.

The division value set by these fields is the bit value + 1. (0b000 sets the division value to 1, 0b001 sets the division value to 2, and so on.)

Address: 0x11_1111_1110_0000 base + 0x1000 offset

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Field	Name	Description
0-4	Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5-7	Aux_Mux_10_Divider_0_Division_Value	Sets the division value of the divider.

Table continues on the next page...

Table 6-23. DCF_SELFTEST_CONFIG_IPS_3 Field Description (continued)

Field	Name	Description
8-10	Aux_Mux_9_Divider_0_Division_Value	Sets the division value of the divider.
11-13	Aux_Mux_8_Divider_0_Division_Value	Sets the division value of the divider.
14-16	Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
17-19	Aux_Mux_6_Divider_0_Division_Value	Sets the division value of the divider.
20-22	Aux_Mux_5_Divider_1_Division_Value	Sets the division value of the divider.
23-25	Aux_Mux_5_Divider_0_Division_Value	Sets the division value of the divider.
26-28	Aux_Mux_2_Divider_0_Division_Value	Sets the division value of the divider.
29-31	Aux_Mux_1_Divider_0_Division_Value	Sets the division value of the divider.

6.7.1.10 DCF_SELFTEST_CONFIG_IPS_4 DCF client

The DCF_SELFTEST_CONFIG_IPS_4 register controls the LBIST shift length for each partition.

Address: 0x11_1111_1110_0000 base + 0x1100 offset

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Table 6-25. DCF_SELFTEST_CONFIG_IPS_4 Field Description

Field	Name	Description
0-7	Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8-13	LBIST_W1_Shift_Length	Sets the LBIST shift length of the W1 partition.
14-19	LBIST_W0_Shift_Length	Sets the LBIST shift length of the W0 partition.

Table continues on the next page...

Table 6-25. DCF_SELFTEST_CONFIG_IPS_4 Field Description (continued)

Field	Name	Description
20-25	LBIST_L1_Shift_Length	Sets the LBIST shift length of the L1 partition.
26-31	LBIST_L0_Shift_Length	Sets the LBIST shift length of the L0 partition.

6.7.1.11 DCF_ERROR0_PAD_SELECT DCF client

The DCF_ERROR0_PAD_SELECT_CONTROL register selects either the functional muxing or the EOUT functionality on pads PJ[11], PJ[1], PI[0], and PH[0]. This is done at boot time according to the SELn bits of this DCF client:

- If ERROR0 OUT is selected (i.e., the SELn bits are set), the PAD controls of the pad are governed by this DCF client.
- If functional muxing is selected (i.e., the SELn bits are not set), the PAD controls are governed by the SIUL2_MSCRn register.

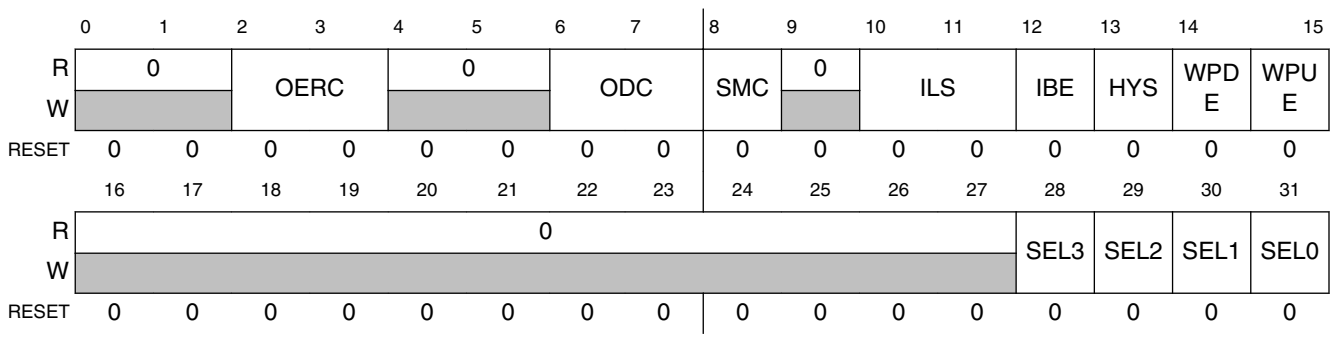

Table 6-27. DCF_ERROR0_PAD_SELECT_CONTROL Field Descriptions

Field	Name	Description
0-1	Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2-3	OERC	Sets the Output Edge Rate Control when ERROR0 OUT is enabled. The function is the same as the corresponding field in SiUL2_MSCRn.
4-5	Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6-7	ODC	Sets the Output Drive Control when ERROR0 OUT is enabled. The function is the same as the corresponding field in SiUL2_MSCRn.
8	SMC	Sets the Safe Mode Control when ERROR0 OUT is enabled. The function is the same as the corresponding field in SiUL2_MSCRn.
9	Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
10-11	ILS	Sets the Input Level Selection when ERROR0 OUT is enabled. The function is the same as the corresponding field in SiUL2_MSCRn.
12	IBE	Sets the Input Buffer Enable when ERROR0 OUT is enabled. The function is the same as the corresponding field in SiUL2_MSCRn.

Table continues on the next page...

Table 6-27. DCF_ERROR0_PAD_SELECT_CONTROL Field Descriptions (continued)

Field	Name	Description
13	HYS	Sets the Input Hysteresis when ERROR0 OUT is enabled. The function is the same as the corresponding field in SiUL2_MSCRn.
14	WPDE	Sets the Weak Pulldown Enable when ERROR0 OUT is enabled. The function is the same as the corresponding field in SiUL2_MSCRn.
15	WPUE	Sets the Weak Pullup Enable when ERROR0 OUT is enabled. The function is the same as the corresponding field in SiUL2_MSCRn.
16-27	Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28	SEL3	Enable ERROR0 OUT on PJ[11] irrespective of SIUL2_MSCRn[SSS] settings and override the pad setting as defined in this register.
29	SEL2	Enable ERROR0 OUT on PJ[1] irrespective of SIUL2_MSCRn[SSS] settings and override the pad setting as defined in this register
30	SEL1	Enable ERROR0 OUT on PI[0] irrespective of SIUL2_MSCRn[SSS] settings and override the pad setting as defined in this register
31	SEL0	Enable ERROR0 OUT on PH[0] irrespective of SIUL2_MSCRn[SSS] settings and override the pad setting as defined in this register

There is no hardware restriction on the programming of the SELn bits. All the four pads can be simultaneously be programmed as ERROR0 OUT Pins.

6.7.1.12 DCF_ERROR1_PAD_SELECT DCF client

The DCF_ERROR1_PAD_SELECT_CONTROL register selects either the functional muxing or the EOUT functionality on pads PJ[0], PI[1], and PH[3]. This is done at boot time according to the SELn bits of this DCF client:

- If ERROR1 OUT is selected (i.e., the SELn bits are set), the PAD controls of the pad are governed by this DCF client.
- If functional muxing is selected (i.e., the SELn bits are not set), the PAD controls are governed by the SIUL2_MSCR register.

9	Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
10-11	ILS	Sets the Input Level Selection when ERROR0 OUT is enabled. The function is the same as the corresponding field in SiUL2_MSCRn.
12	IBE	Sets the Input Buffer Enable when ERROR0 OUT is enabled. The function is the same as the corresponding field in SiUL2_MSCRn.
13	HYS	Sets the Input Hysteresis when ERROR0 OUT is enabled. The function is the same as the corresponding field in SiUL2_MSCRn.
14	WPDE	Sets the Weak Pulldown Enable when ERROR0 OUT is enabled. The function is the same as the corresponding field in SiUL2_MSCRn.
15	WPUE	Sets the Weak Pullup Enable when ERROR0 OUT is enabled. The function is the same as the corresponding field in SiUL2_MSCRn.
16-28	Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29	SEL2	Enable ERROR1 OUT on PJ[0] irrespective of SIUL2_MSCRn[SSS] settings and override the pad setting as defined in this register.
30	SEL1	Enable ERROR1 OUT on PI[1] irrespective of SIUL2_MSCRn[SSS] settings and override the pad setting as defined in this register.
31	SEL0	Enable ERROR1 OUT on PH[3] irrespective of SIUL2_MSCRn[SSS] settings and override the pad setting as defined in this register.

There is no hardware restriction on the programming of the SELn bits. All three pads can be simultaneously be programmed as ERROR1 OUT Pins.

Chapter 7
e200z4d Core Complex Overview

7.1 Introduction

The main computational shell consists of Main Core_0 and Main Core_1. Both cores use an e200z425n3 core. A third core, referred to as Checker Core_0s, is an e200z424 core that is a true subset of the e200z425n3 core. When enabled, Checker Core_0s operates in lock step mode with Main Core_0, executing exactly the same instructions as Main Core_0. Thus, Checker Core_0s checks to insure that Main Core_0 is executing correctly. This chapter provides overviews of the e200z425n3 core and the e200z424 core.

The e200z425n3 and the e200z424 cores are very similar. The register set for these cores is identical. The e200z424 core differs in hardware from the e200z425n3 in that no cache or D-memory is implemented.

7.2 Overview of the e200z425n3 and e200z424 cores

The e200z processor family is a set of CPU cores that implement low-cost versions of the Power architecture.

The e200z425n3 and e200z424 are dual-issue, 32-bit Power VLE compliant designs with 32-bit general purpose registers (GPRs).

An Embedded Floating-point (EFPU2) APU is provided to support real-time single-precision embedded numeric operations using the general-purpose registers.

The e200z425n3 and e200z424 cores implement the VLE (variable-length encoding) ISA, providing improved code density. The VLE ISA is further documented in PowerISA 2.06, a separate document.

Note that Data Cache is not implemented on any core on this device.

The e200z425n3 and e200z424 processor cores integrate a pair of integer execution units, a branch control unit, instruction fetch unit, load/store unit, and a multi-ported register file capable of sustaining six read and three write operations per clock. Most integer instructions execute in a single clock cycle. Branch target prefetching is performed by the branch unit to allow single-cycle branches in many cases.

A Nexus Class 3+ module is integrated into each e200z425n3 and e200z424 processor core.

A Memory Protection Unit is integrated in each e200z425n3 and e200z424 processor core.

7.3 Features

The following is a list of some of the key features of the e200z425n3 and e200z424 processor cores:

- Dual issue, 32-bit *PowerISA 2.06*-VLE compliant CPU
- In-order execution and retirement
- Precise exception handling
- Branch processing unit
  - Dedicated branch address calculation adder
  - Branch target prefetching using BTB
- Load/store unit
  - 2 cycle load latency
  - Fully pipelined
  - Misaligned access support
- 32-bit General Purpose Register (GPR) file
- Dual AHB 2.v6 64-bit System buses
- Local Instruction (IMEM) and Data Memory (DMEM) with shared AHB 2.v6 64-bit slave interface
  - e200z425n3 core—16 KB IMEM, 32 KB DMEM
  - e200z424 core does not contain either IMEM or DMEM
- Memory Protection Unit (MPU) implementing a 24-entry region descriptor table with support for 6 arbitrary-sized instruction memory regions, 12 arbitrary-sized data memory regions, and 6 additional arbitrary-sized instruction or data memory regions
- 2-Way Set Associative Harvard Instruction Cache (ICache)
  - e200z425n3 core—8 KB ICache
  - e200z424 core does not contain ICache
- Embedded Floating-point APU (EFPU2) supporting single-precision floating-point operations
- Performance Monitor APU supporting execution profiling
- Nexus Class 3-plus Real-time Development Unit

- Power management
  - Low power design with extensive clock gating
  - Power saving mode: wait
  - Dynamic power management of execution units, caches and Local memories
- Testability
  - Synthesizeable, MuxD scan design
  - ABIST/MBIST for arrays
  - Built-in LBIST unit

7.4 Microarchitecture summary

The e200z425n3 and e200z424 processor cores utilize a five stage instruction pipeline with two stages for execution. The Instruction Fetch, Instruction Decode/Register File Read/ EA Calc, Execute 0/ Memory Access0, Execute1/Memory Access1, and Register Writeback stages operate in an overlapped fashion allowing single clock instruction execution for most instructions. The following figure shows a block diagram of the e200z architecture.

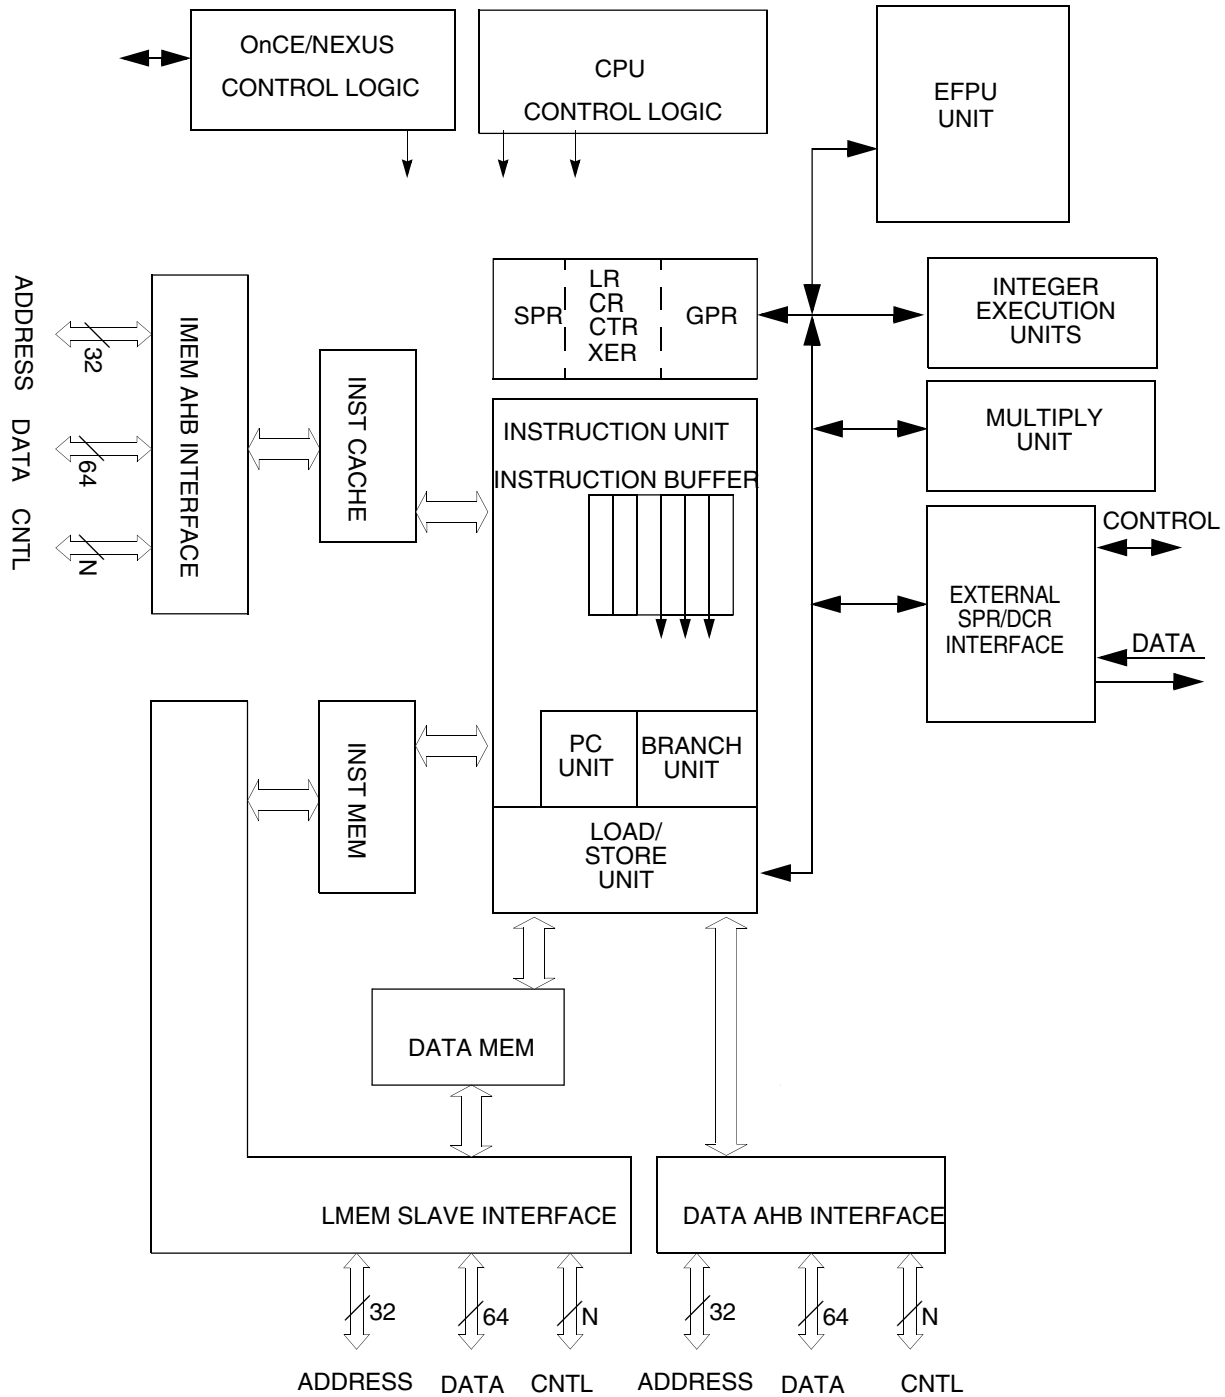

Figure 7-1. e200z block diagram

The integer execution units each consists of a 32-bit Arithmetic Unit (AU), a Logic Unit (LU), a 32-bit Barrel shifter (Shifter), a Mask-Insertion Unit (MIU), a Condition Register manipulation Unit (CRU), a Count-Leading-Zeros unit (CLZ), and result feed-forward hardware. Integer EU1 also supports hardware division and a 32x32 Hardware Multiplier array.

Most arithmetic and logical operations are executed in a single cycle with the exception of multiply, which is implemented with a pipelined hardware array, and the divide instructions. A Count-Leading-Zeros unit operates in a single clock cycle.

The Instruction Unit contains a PC incrementer and dedicated Branch Address adders to minimize delays during change of flow operations. Sequential prefetching is performed to ensure a supply of instructions into the execution pipeline. Branch target prefetching is performed to accelerate taken branches. Prefetched instructions are placed into an instruction buffer.

Branch target addresses are calculated in parallel with branch instruction decode, resulting in an execution time of two clocks for correctly predicted branches. Conditional branches which are not taken execute in a single clock. Branches with successful BTB target prefetching have an effective execution time of one clock if correctly predicted.

Memory load and store operations are provided for byte, halfword, word (32-bit), and doubleword data with automatic zero or sign extension of byte and halfword load data as well as optional byte reversal of data. These instructions can be pipelined to allow effective single cycle throughput. Load and store multiple word instructions allow low overhead context save and restore operations. The load/store unit contains a dedicated effective address adder to allow effective address generation to be optimized.

The Condition Register unit supports the condition register (CR) and condition register operations defined by the Power architecture. The condition register consists of eight 4-bit fields that reflect the results of certain operations, such as move, integer and floating-point compare, arithmetic, and logical instructions, and provide a mechanism for testing and branching.

Vectored and autovectored interrupts are supported by the CPU. Vectored interrupt support is provided to allow multiple interrupt sources to have unique interrupt handlers invoked with no software overhead.

7.4.1 Instruction unit features

The features of the e200z425n3 and e200z424 Instruction units are:

- 64-bit path to cache supports fetching of two 32-bit instructions per clock
- Instruction buffer holds up to eight 32-bit instructions
- Dedicated PC incrementer supporting instruction prefetches
- Branch unit with dedicated branch address adder and branch lookahead logic (BTB) supporting single cycle execution of successfully predicted branches

7.4.2 Integer unit features

The e200z425n3 and e200z424 integer units support single cycle execution of most integer instructions:

- 32-bit AU for arithmetic and comparison operations
- 32-bit LU for logical operations
- 32-bit priority encoder for the count leading zero's function
- 32-bit single cycle barrel shifter for static shifts and rotates
- 32-bit mask unit for data masking and insertion
- Divider logic for signed and unsigned divide in 4-14 clocks with minimized execution timing (EU1 only)
- Pipelined 32x32 hardware multiplier array supports 32x32->32 multiply with 2 clock latency, 1 clock throughput (EU1 only)

7.4.3 Load/Store unit features

The e200z425n3 and e200z424 load/store units support load, store, and the load multiple / store multiple instructions:

- 32-bit effective address adder for data memory address calculations
- Pipelined operation supports throughput of one load or store operation per cycle
- Dedicated 64-bit interface to memory supports saving and restoring of up to two registers per cycle for load multiple and store multiple word instructions and context save/restore instructions

7.4.4 MPU features

The features of the MPU are as follows:

- 24-entry fully-associative Range Table
- Arbitrary range size support from 1 byte to 4 GB
- 8-bit Process Identifier
- Bypass capability for individual access types
- Maskable Address and Process Identifier
- Programmable Memory Attributes
- Entry Invalidation Protection
- Write-Once Option
- Alternate Debug Breakpoint/Watchpoint function

7.4.5 Cache features

The features of the Caches are as follows:

- 2-Way Set Associative Harvard Instruction Cache
  - e200z425n3—8 KB ICache
  - e200z424—No ICache
- Writethrough support
- 8-entry store buffer
- Linefill buffer
- 32-bit address bus plus attributes and control
- Separate uni-directional 64-bit read data bus and 64-bit write data bus
- Support for Way locking
- Support for Write allocation policies
- Support for multi-bit EDC with Correction/Auto-invalidation capability for the ICache
- Software and Hardware Debug access to cache tag, status and data storage via dedicated control registers

7.4.6 Local memory features

The features of the Local Instruction and Data Memories are as follows:

- Local instruction and data memories (IMEM, DMEM) with shared AHB 2.v6 64-bit slave interface
  - e200z425n3—16 KB IMEM, 32 KB DMEM
  - e200z424—No IMEM, No DMEM
- Support for zero wait-state access relative to cache hit timings
- Support for multi-bit (SECDED) ECC with correction/scrubbing capability
- 4-entry ECC R-M-W Store Buffer for DMEM
- 32-bit address bus plus attributes and control
- Separate uni-directional 64-bit read data bus and (for DMEM only) 64-bit write data bus

7.4.7 e200z425n3 system bus features

The features of the e200z425n3 System Bus interface are as follows:

- Independent instruction and data interfaces
- Advanced microcontroller bus architecture (AMBA) AHB2.v6 protocol
- 32-bit address bus, 64-bit data bus, plus attributes and control
- Data interface provides separate uni-directional 64-bit read and write data buses
- Support for HCLK running at a slower rate than CPU clock

7.4.8 e200z424 system features

Checker Core_0s is implemented using an e200z424 core. When enabled, Checker Core_0s is used in Lock Step with Main_Core_0. The e200z424 core can only be enabled or disabled by the user. For this device, the Checker Core_0s has no system bus and cannot independently execute user code. The core is only used to execute the same instruction stream as Main Core 0.

The e200z424 core is identical to the e200z425n3 with these exceptions:

- IMEM memory array is not present
- ICache memory array is not present
- DMEM memory array is not present
- The e200z424 has a pair of system bus interfaces, which are driven/sampled by the delayed lockstep logic.

Chapter 8
Core description

8.1 Overview of the e200z425n3 core

The e200z425n3 is a dual-issue 32-bit *PowerISA 2.06* VLE compliant design with 32-bit general-purpose registers (GPRs). The e200z425n3 core implements the VLE (variable-length encoding) ISA, providing improved code density. The VLE ISA is further documented in *PowerISA 2.06*, a separate document.

An Embedded Floating-point (EFPU2) APU is provided to support real-time single-precision floating-point embedded numerics operations using the general-purpose registers.

A Lightweight Signal Processing Extension (LSP) APU is provided to support real-time SIMD fixed-point embedded numerics operations using the general-purpose registers. All arithmetic instructions that execute in the core operate on data in the general purpose registers (GPRs). The GPRs support register pairing in order to support vector instructions defined by the LSP APU. These instructions operate on a vector pair of 16-bit or 32-bit data types, and deliver 16-bit vector and 32-bit scalar results. A wide variety of data manipulation, multiply, multiply/accumulate, and dot product instructions along with specialized memory access instructions allow a sustained throughput of up to two 16x16-bit multiply/accumulate operations per cycle.

The e200z425n3 processor integrates a pair of integer execution units, a branch control unit, instruction fetch unit, load/store unit, and a multi-ported register file capable of sustaining six read and three write operations per clock cycle. Most integer instructions execute in a single clock cycle. Branch target prefetching is performed by the branch unit to allow single-cycle branches in many cases.

e200z425n3 contains an 8 KB Instruction Cache, as well as a Nexus Class 3+ real-time debug module with support for program and data trace features as well as extensive trace controls. Data cache is not supported on any of the cores on this device.

A Memory Protection Unit that protects various instruction and data memory areas is also included.

For details on the instruction sets supported by this core, refer to the following documents:

- Basic 32-bit instruction set: EREF_RM.pdf – EREF 2.0: A Programmer's Reference Manual for Freescale Power Architecture Processors.
- VLE instruction set: VLEPEM.pdf – Variable-Length Encoding (VLE) Programming Environments Manual: A Supplement to the EREF
- LSP instruction set: LSPAPURM.pdf – Lightweight Signal Processing APU (LSP APU) Reference Manual
- Decorated storage instructions: This Reference Manual

8.2 Register model

This section describes the registers implemented in the e200z425n3 core. The *PowerISA 2.06* architecture defines register-to-register operations for all computational instructions.

e200z425n3 extends usage of the general purpose registers to support EFPU /LSP APU operations on the 32-bit GPR registers.

Figure 8-1 and Figure 8-2 show the complete e200z425n3 register set, all of which are accessible in supervisor mode. Figure 8-3 and Figure 8-4 show the subset of registers accessible in user mode. The number to the right of the special-purpose registers (SPRs) is the decimal number used in the instruction syntax to access the register (for example, the integer exception register (XER) is SPR 1).

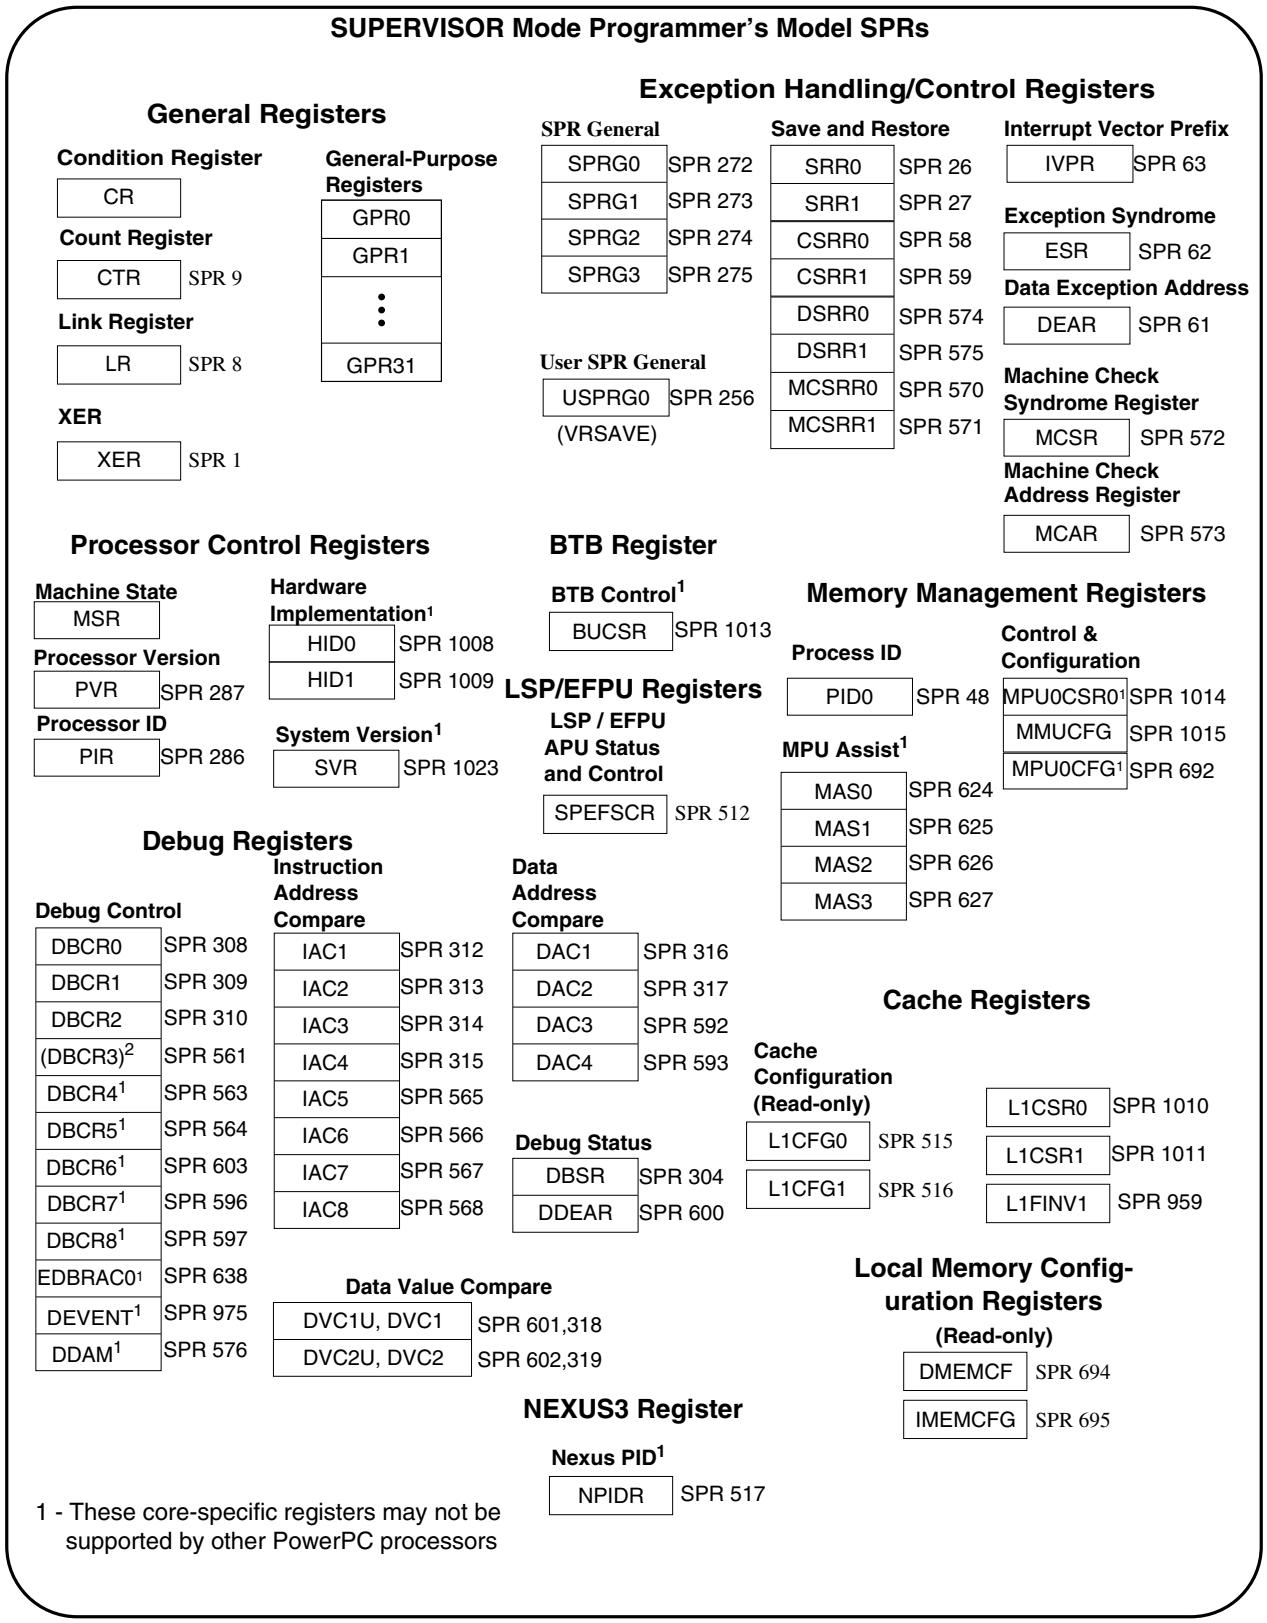

Figure 8-1. e200z425n3 Supervisor Mode Programmer's Model SPRs

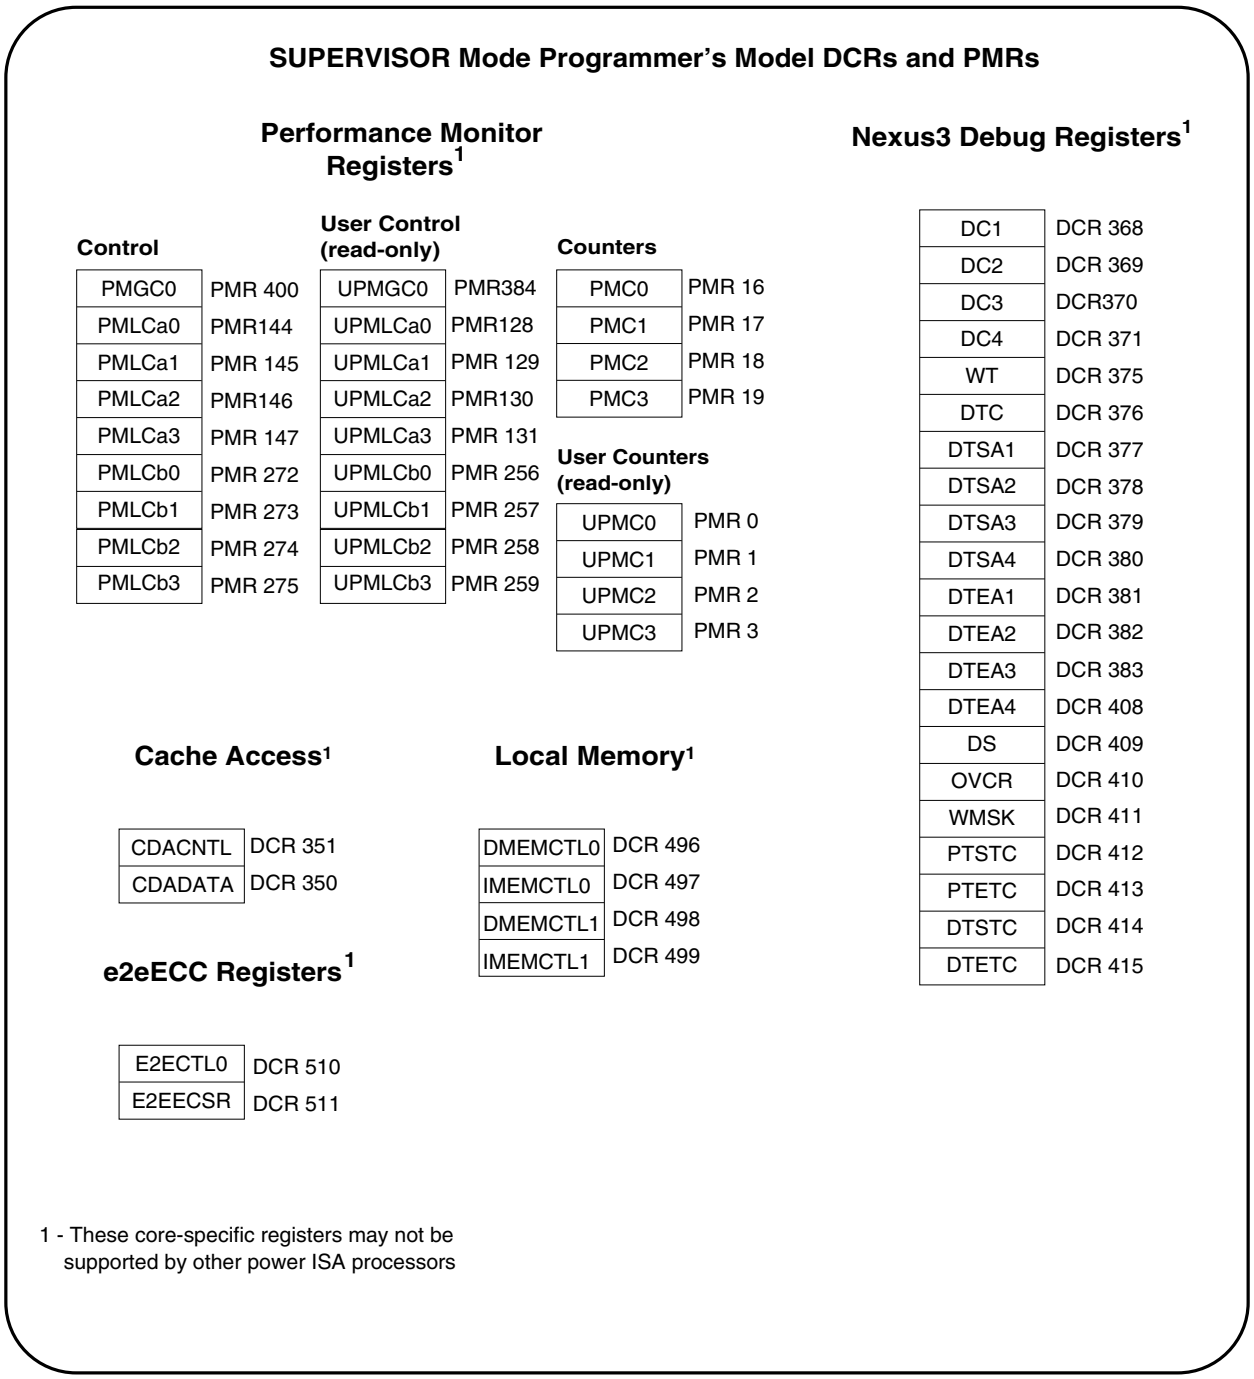

Figure 8-2. e200z425n3 Supervisor Mode Programmer's Model DCRs and PMRs

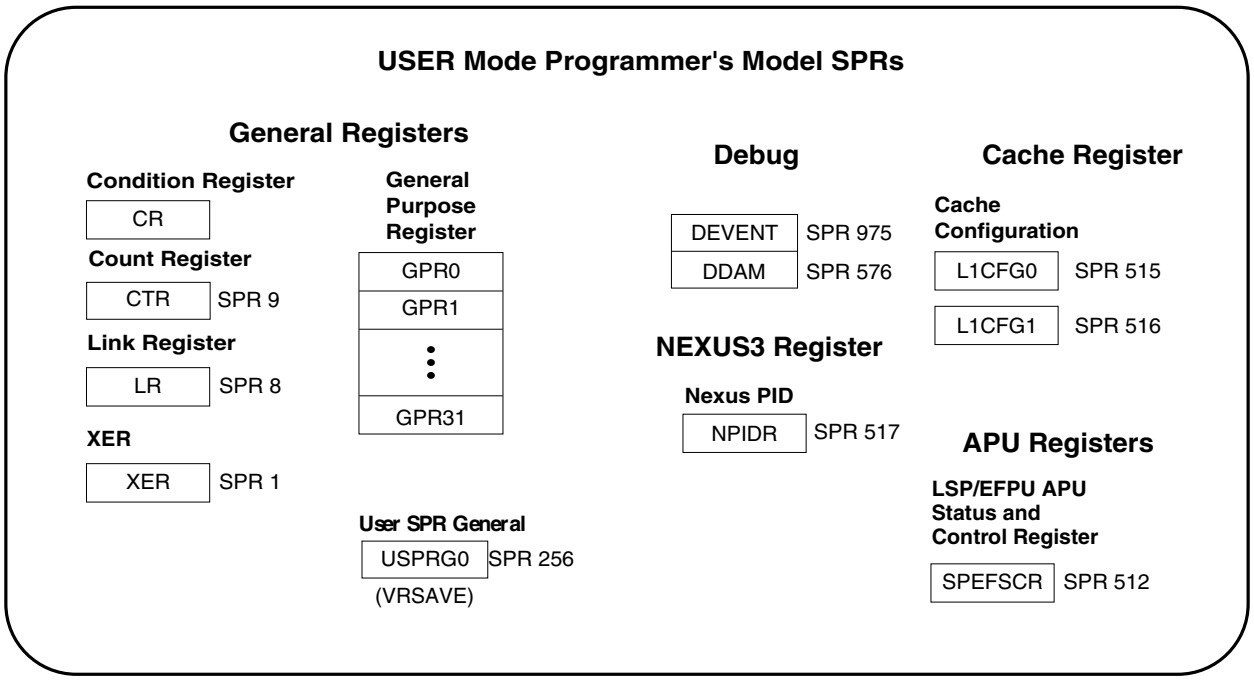

Figure 8-3. e200z425n3 User Mode Programmer's Model SPRs

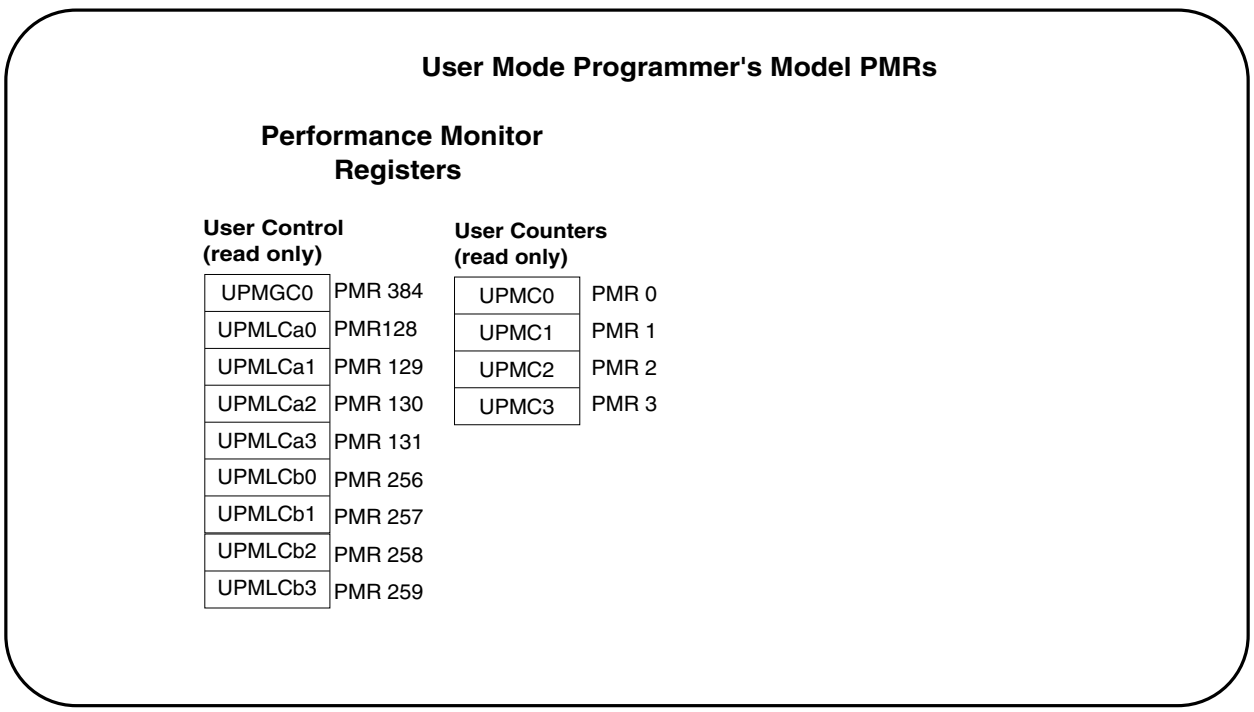

Figure 8-4. e200z425n3 User Mode Programmer's Model PMRs

8.3 Dual-issue operation

The instruction issue unit attempts to issue a pair of instructions to the execution units each cycle. Source operands for each of the instructions are provided from the GPRs or from the operand feed-forward muxes. Data or resource hazards may create stall conditions that cause instruction issue to be stalled for one or more cycles until the hazard is eliminated.

The execution units write the result of a finished instruction onto the proper result bus and into the destination registers. The writeback logic retires an instruction when the instruction has finished execution. Up to three results can be simultaneously written.

Two execution units are provided to allow dual issue of most instructions. Only a single load/store unit is provided. Only a single integer multiply and divide unit is provided, thus a pair of multiply or divide instructions cannot issue simultaneously. In addition, the divide unit is blocking.

The following table shows the concurrent instruction issue capabilities. Note that data dependencies between instructions will generally preclude dual-issue of those instructions.

Table 8-1. Concurrent instruction issue capabilities for e200z425n3

Class of instruction	Branch	Load/ Store	Scalar integer	Scalar float	Vector integer non-MAC	Vector integer MAC	Special
Branch	—	yes	yes	yes	yes	yes	—
Load/Store	yes	—	yes	yes	yes	yes	—
Scalar integer	yes	yes	yes[1]	yes	yes	yes[2, 2]	—
Scalar float	yes	yes	yes	—	yes	yes	—
Vector integer non-MAC	yes	yes	yes	yes	yes	yes	—
Vector integer MAC	yes	yes	yes[2]	yes	yes	—	—
Special	—	—	—	—	—	—	—

1. Excludes multiply or divide class instructions occurring in both issue slots.
2. Excludes vector MAC/multiply class instructions occurring with scalar multiply, or divide class instructions.

8.4 Instruction timing

Instruction timing in number of processor clock cycles for various instruction classes is shown in Table 8-2. Pipelined instructions are shown with cycles of total latency and throughput cycles. Divide instructions are not pipelined and block other instructions from executing during execution. Timing for EFPU instructions is detailed in Table 8-5. Timing for LSP instructions is detailed in:

- LSP simple instruction timing—Table 8-6
- LSP complex instruction timing—Table 8-7
- LSP shift/rotate instruction timing—Table 8-8
- LSP vector compare instruction timing—Table 8-9
- LSP vector select instruction timing—Table 8-10
- LSP vector data arrangement instruction timing—Table 8-11
- LSP multiply and multiply/accumulate instruction timing—Table 8-12
- LSP dot product instruction timing—Table 8-13
- LSP miscellaneous vector instruction timing—Table 8-14
- LSP load and store instruction timing—Table 8-15

Load/store multiple instruction cycles are represented as a fixed number of cycles plus a variable number of cycles where *n* is the number of words accessed by the instruction. In addition, cycle times marked with & require variable number of additional cycles due to serialization.

Table 8-2. Instruction class cycle counts

Class of Instructions	Latency	Description	Special notes
integer: **add**, **sub**, **shift**, **rotate**, **logical**, **cntlzw**	1	1	—
integer: **compare**			—
Branch	3/2/1	3/2/1	Correct branch lookahead allows single-cycle execution. Worst-case mispredicted branch is 3 cycles.
multiply	2	1	—
divide	4–14	4–14	Data-dependent timing
CR logical	1	1	—
loads (non-multiple)	2	1	—
load multiple	2 + *n*/2 (max)	1 + *n*/2 (max)	Actual timing depends on *n* and address alignment.
stores (non-multiple)	2	1	—
store multiple	2 + *n*/2 (max)	2 + *n*/2 (max)	Actual timing depends on *n* and address alignment.
mtmsr, **wrtee**, **wrteei**	3&	3&	—

Circular increment	**zcircinc**	1	1
Bit reversed increment	**zbrminc**	1	1

Instruction timing for LSP load and store instructions instructions is shown in Table 8-15.

Table 8-15. LSP load and store instruction timing

Instruction	Latency	Throughput
all **zv** loads	—	1
all **zv** stores	—	1

8.5 Reservation instructions and cache interactions

If the CPU supports reservation instruction functionality, the CPU treats reservation instruction (**lbarx**, **lharx**, **lwarx**, **stbcx**, **sthcx**, and **stwcx**) accesses as though they were cache-inhibited, and forces a cache miss. A reservation access is always issued to the bus. This is done to allow external reservation logic to be built that properly signals a reservation failure. The bus access will be treated as a single-beat transfer.

8.6 Signal Processing Extension/Embedded Floating-point Status and Control Register (SPEFSCR)

Status and control for embedded floating-point operations use the SPEFSCR. This register is also used by the LSP APU. The SPEFSCR is implemented as special-purpose register (SPR) number 512 and is read and written by the mfspr and mtspr instructions. The SPEFSCR is shown in the following figure.

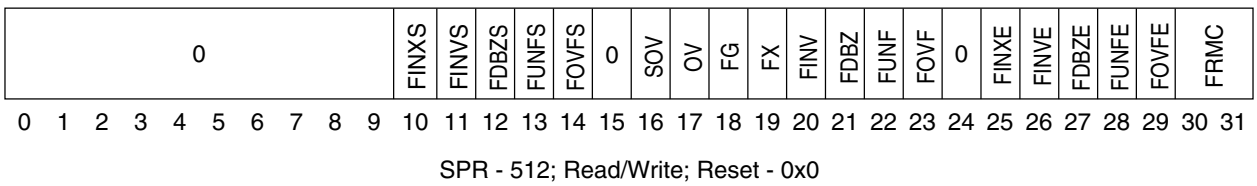

Figure 8-5. LSP/EFPU Status and Control Register (SPEFSCR)

The SPEFSCR bits are defined in the following table.

Table 8-16. LSP/EFPU Status and Control Register field descriptions

Bits	Name	Description
0:9 (32:41)	—	Reserved
10 (42)	FINXS	Embedded Floating-point Inexact Sticky Flag The FINXS bit is set to 1 whenever the execution of a floating-point instruction delivers an inexact result and no Floating-point Data exception is taken, or if the result of a Floating-point instruction results in overflow (FOVF = 1), but Floating-point Overflow exceptions are disabled (FOVFE = 0), or if the result of a Floating-point instruction results in underflow (FUNF = 1), but Floating-point Underflow exceptions are disabled (FUNFE = 0), and no Floating-point Data exception occurs. The FINXS bit remains set until it is cleared by a **mtspr** instruction specifying the SPEFSCR.
11 (43)	FINVS	Embedded Floating-point Invalid Operation Sticky Flag The FINVS bit is set to a 1 when a floating-point instruction sets the FINV bit to 1. The FINVS bit remains set until it is cleared by a **mtspr** instruction specifying the SPEFSCR.
12 (44)	FDBZS	Embedded Floating-point Divide by Zero Sticky Flag The FDBZS bit is set to 1 when a floating-point divide instruction sets the FDBZ bit to 1. The FDBZS bit remains set until it is cleared by a **mtspr** instruction specifying the SPEFSCR.
13 (45)	FUNFS	Embedded Floating-point Underflow Sticky Flag The FUNFS bit is set to 1 when a floating-point instruction sets the FUNF bit to 1. The FUNFS bit remains set until it is cleared by a **mtspr** instruction specifying the SPEFSCR.
14 (46)	FOVFS	Embedded Floating-point Overflow Sticky Flag The FOVFS bit is set to 1 when a floating-point instruction sets the FOVF bit to 1. The FOVFS bit remains set until it is cleared by a **mtspr** instruction specifying the SPEFSCR.
15 (47)	—	Reserved

Table continues on the next page...

Table 8-16. LSP/EFPU Status and Control Register field descriptions (continued)

Bits	Name	Description
16 (48)	SOV	Summary integer overflow Defined by LSP APU.
17 (49)	OV	Integer overflow Defined by LSP APU.
18 (50)	FG	Embedded Floating-point Guard bit FG is supplied for use by the Floating-point Round exception handler. FG is zeroed if a Floating-point Data Exception occurs.
19 (51)	FX	Embedded Floating-point Sticky bit FX is supplied for use by the Floating-point Round exception handler. FX is zeroed if a Floating-point Data Exception occurs.
20 (52)	FINV	Embedded Floating-point Invalid Operation / Input error In mode 0, the FINV bit is set to 1 if the A or B operand of a floating-point instruction is Infinity, NaN, or Denorm, or if the operation is a divide and the dividend and divisor are both 0. In mode 1, the FINV bit is set on an IEEE754 invalid operation (IEEE754-1985 sec7.1).
21 (53)	FDBZ	Embedded Floating-point Divide by Zero The FDBZ bit is set to 1 when a floating-point divide instruction executed with divisor of 0, and the l dividend is a finite non-zero number.
22 (54)	FUNF	Embedded Floating-point Underflow The FUNF bit is set to 1 when the execution of a floating-point instruction results in an underflow.
23 (55)	FOVF	Embedded Floating-point Overflow The FOVF bit is set to 1 when the execution of a floating-point instruction results in an overflow.
24 (56)	—	Reserved
25 (57)	FINXE	Embedded Floating-point Inexact Exception Enable If the exception is enabled, a Floating-point Round exception is taken if the result of a Floating-point instruction does not result in overflow or underflow, and the result is inexact (FG l FX = 1), or if the result of a Floating-point instruction does result in overflow (FOVF = 1) but Floating-point Overflow exceptions are disabled (FOVFE = 0), or if the result of a Floating-point instruction results in underflow (FUNF = 1 or FUNFH = 1) but Floating-point Underflow exceptions are disabled (FUNFE = 0), and no Floating-point Data exception occurs. 0 Exception disabled 1 Exception enabled
26 (58)	FINVE	Embedded Floating-point Invalid Operation / Input Error Exception Enable If the exception is enabled, a Floating-point Data exception is taken if the FINV bit is set by a floating-point instruction. 0 Exception disabled 1 Exception enabled

Table continues on the next page...

Table 8-16. LSP/EFPU Status and Control Register field descriptions (continued)

Bits	Name	Description
27 (59)	FDBZE	Embedded Floating-point Divide by Zero Exception Enable If the exception is enabled, a Floating-point Data exception is taken if the FDBZ bit is set by a floating-point instruction. 0 Exception disabled 1 Exception enabled
28 (60)	FUNFE	Embedded Floating-point Underflow Exception Enable If the exception is enabled, a Floating-point Data exception is taken if the FUNF bit is set by a floating-point instruction. 0 Exception disabled 1 Exception enabled
29 (61)	FOVFE	Embedded Floating-point Overflow Exception Enable If the exception is enabled, a Floating-point Data exception is taken if the FOVF bit is set by a floating-point instruction. 0 Exception disabled 1 Exception enabled
30:31 (62:63)	FRMC	Embedded Floating-point Rounding Mode Control 00 Round to Nearest 01 Round toward Zero 10 Round toward +Infinity 11 Round toward -Infinity

8.7 Cache

This section describes the cache registers, cache control instructions, and various cache operations.

8.7.1 Cache overview

The e200z425n3 processor supports an 8 KB 2-way set-associative instruction cache with a 32-byte line size. The cache improves system performance by providing low-latency data to the e200z425n3 instruction pipeline, which decouples processor performance from system memory performance.

The e200z425n3 processor also contains an 8-entry store buffer to decouple store completion to the processor from store completion on the data interface to further improve system performance.

Instruction addresses from the processor are used to index the cache arrays. If the access address matches a valid cache tag entry, the access hits in the cache.

8.7.2 Cache organization

The e200z425 cache is organized as two ways of 64 sets with each line containing 32 bytes (four doublewords) of storage. Figure 8-6 illustrates the cache organization along with the cache line format.

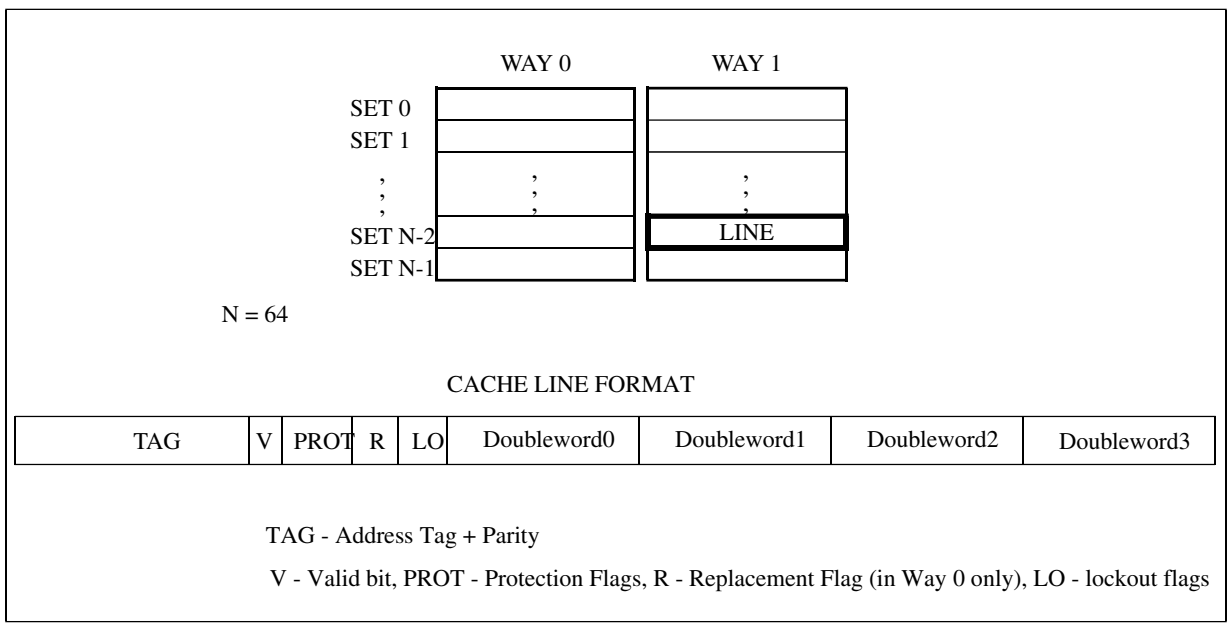

Figure 8-6. Cache organization and line format

Address bits A[20:26] provide an index to select a set. Ways are selected according to the rules of set association.

Each line consists of a address tag, protection bit(s), status bits, and four doublewords of data. Address bits A[27:29] select the word within the line. The address tag consists of the upper address of the access value used to fill the cache line. The protection field (PROT) contains a Supervisor Protect bit (SP). The protection bits are used to enforce access protection provided from an external SoC-level memory protection unit (MPU). Lockout bits (LO) are provided to support the cache line lockout functionality when errors are encountered.

8.7.3 L1 Cache Control and Status Register 0 (L1CSR0)

L1CSR0 implements the WID control field for instruction cache way disabling. The other fields are reserved. The L1CSR0 register is accessed using a **mfspr** or **mtspr** instruction. The L1CSR0 register is shown in the following figure.

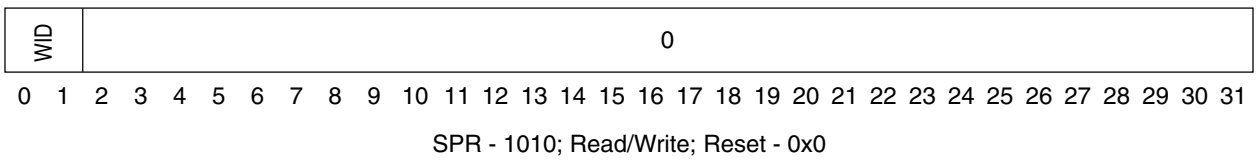

Figure 8-7. L1 Cache Control and Status Register 0 (L1CSR0)

The L1CSR0 fields are described in the following table.

Table 8-17. L1CSR0 field descriptions

Bits	Name	Description
0:1	WID	Way Instruction Disable Bit 0 corresponds to way 0. Bit 1 corresponds to way 1. The WID bits may be used for locking ways of the instruction cache, and also affect the replacement policy of the instruction cache. 0 The corresponding way in the instruction cache is available for replacement by instruction miss line fills. 1 The corresponding way instruction cache is not available for replacement by instruction miss line fills.
2:31	—	Reserved[1]

1. These bits are not implemented and should be written with zero for future compatibility.

8.7.4 L1 Cache Control and Status Register 1 (L1CSR1)

The L1 Cache Control and Status Register 1 (L1CSR1) is a 32-bit register used for general control of the instruction cache. The L1CSR1 register is accessed using a **mfspr** or **mtspr** instruction. The L1CSR1 register is shown in the following figure.

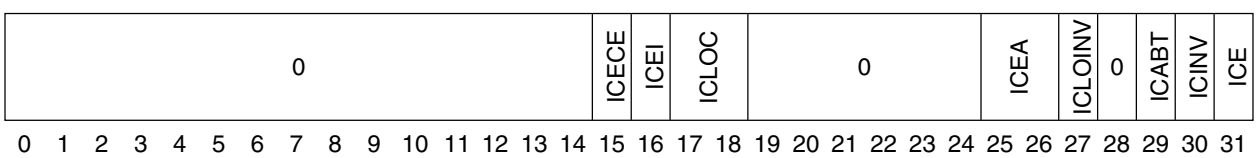

Figure 8-8. L1 Cache Control and Status Register 1 (L1CSR1)

The L1CSR1 fields are described in the following table.

Table 8-18. L1CSR1 field descriptions

Bits	Name	Description
0:14	—	Reserved[1, 1]
15	ICECE	Instruction Cache Error Checking Enable 0 Error Checking is disabled 1 Error Checking is enabled
16	ICEI	Instruction Cache Error Injection Enable ICEI will cause injection of errors regardless of the setting of ICECE, although reporting of errors will be masked when ICECE = 0. 0 Cache Error Injection is disabled 1 A double-bit error will be injected into each doubleword written into the cache by inverting the two uppermost parity check bits.
17:18	ICLOC	Instruction Cache Lockout Control **Note:** For the **icbi** instruction, no lockout operation is performed, regardless of the occurrence of EDC/ECC error conditions, and errors are handled in the same manner as when lockout is disabled. See ECC/EDC Error Handling for Cache Control Operations and Instructions. **Note:** When operating in MC mode (ICEA = 00), detected errors on cache-inhibited accesses will not cause an instruction cache line to be locked out, instead the cache line contents are ignored. 00 Cache line lockout is disabled (and array LO indicators are ignored). 01 Cache line lockout is enabled. Cache lines with any tag errors or any data errors will have the corresponding lockout indicators set. A Machine check will not be generated for the error if the operation would have normally generated one unless a locked line is locked out. 10 Cache line lockout is enabled. Cache lines with any tag or data errors will have the corresponding lockout indicators set. A Machine check will still be generated for an error if the operation would have normally generated one. 11 Cache line lockout is enabled. Cache lines with uncorrectable tag errors or any data errors will have the corresponding lockout indicators set. A Machine check will not be generated for the error if the operation would have normally generated one unless a locked line is locked out. If a correctable tag error occurs, and is re-detected on recycling the access after a correction cycle for the tag is performed, the line is locked out regardless of detecting a single-bit or multi-bit error.
19:24	—	Reserved[1]
25:26	ICEA	Instruction Cache Error Action 00 Error Detection causes Machine Check exception. 01 Error Detection causes Correction/Auto-invalidation. No machine check is generated for most cases. Correction is performed for single-bit tag errors, and lines with multi-bit tag errors are invalidated. Correction is performed for single or multi-bit data errors on cache hits by reloading of the line. 10 Reserved 11 Reserved

Table continues on the next page...

Table 8-18. L1CSR1 field descriptions (continued)

Bits	Name	Description
27	ICLOINV	Instruction Cache Lockout Indicator Invalidate When written to a 1 in conjunction with writing ICINV to a 1, a cache lockout indicator invalidation operation is initiated by hardware, and the LO bits are cleared, removing all line lockout status. Once complete, this bit is reset to 0. Writing a 1 while an invalidation operation is in progress will result in an undefined operation. Writing a 0 to this bit while an invalidation operation is in progress will be ignored. Cache lockout bit invalidation operations require approximately 66 cycles to complete. Invalidation occurs regardless of the instruction cache enable (ICE) value. When ICINV = 0: Reserved, do not set to 1 When ICINV = 1: 0 No cache lockout bit invalidate 1 Cache lockout indicator invalidation operation
28	—	Reserved[1]
29	ICABT	Instruction Cache Operation Aborted Indicates a Cache Invalidate operation was aborted prior to completion. This bit is set by hardware on an aborted condition, and will remain set until cleared by software writing 0 to this bit location.
30	ICINV	Instruction Cache Invalidate When written to a 1, a cache invalidation operation is initiated by hardware. Once complete, this bit is reset to 0. Writing a 1 while an invalidation operation is in progress will result in an undefined operation. Writing a 0 to this bit while an invalidation operation is in progress will be ignored. Cache invalidation operations require approximately 130 cycles to complete. Invalidation occurs regardless of the enable (ICE) value. 0 No cache invalidate 1 Cache invalidation operation
31	ICE	Instruction Cache Enable When disabled, cache lookups are not performed for instruction accesses. Other L1CSR1 cache control operations are still available and are not affected by ICE. 0 Cache is disabled 1 Cache is enabled

1. These bits are not implemented and should be written with zero for future compatibility.

8.7.5 L1 Cache Configuration Register 0 (L1CFG0)

The L1 Cache Configuration Register 0 (L1CFG0) is a 32-bit read-only register. L1CFG0 provides information about the configuration of the e200z425n3 L1 data cache design. The contents of the L1CFG0 register can be read using a **mfspr** instruction. The L1CFG0 register is shown in the following figure.

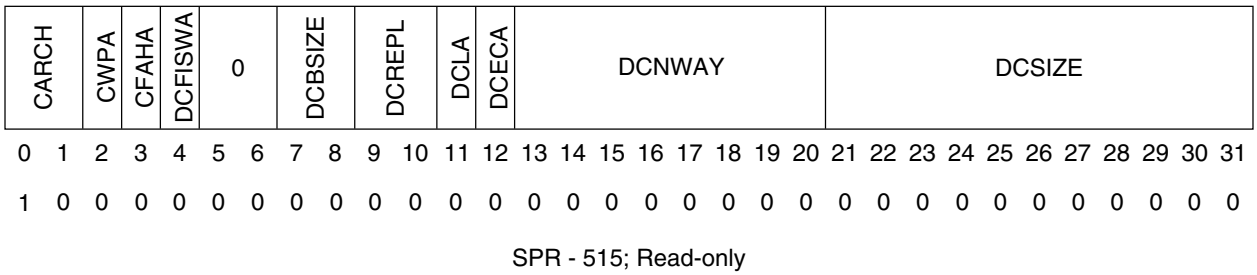

Figure 8-9. L1 Cache Configuration Register 0 (L1CFG0)

Table 8-19. L1CFG0 field descriptions

Bits	Name	Description
0:1	CARCH	Cache Architecture 00 The cache architecture is Harvard 10 An I-Cache but no D-Cache is present
2	CWPA	Cache Way Partitioning Available 0 The caches do not support partitioning of way availability for I/D accesses
3	DCFAHA	Data Cache Flush All by Hardware Available 0 The data cache does not support Flush All in Hardware
4	DCFISWA	Data Cache Flush/Invalidate by Set and Way Available 0 The data cache does not support invalidation by Set and Way via L1FINV0
5:6	—	Reserved - read as zeros
7:8	DCBSIZE	Data Cache Block Size 00 The data cache implements a block size of 32 bytes
9:10	DCREPL	Data Cache Replacement Policy 00 The data cache does not implement a replacement policy
11	DCLA	Data Cache Locking APU Available 0 The data cache does not implement the line locking APU
12	DCECA	Data Cache Error Checking Available 0 The data cache does not implement error checking
13:20	DCNWAY	Data Cache Number of Ways 0x00 The data cache is 0-way set-associative
21:31	DCSIZE	Data Cache Size 0x000 No data cache is present

8.7.6 L1 Cache Configuration Register 1 (L1CFG1)

The L1 Cache Configuration Register 1 (L1CFG1) is a 32-bit read-only register. L1CFG1 provides information about the configuration of the e200z425n3 L1 instruction cache design. The contents of the L1CFG1 register can be read using a **mfspr** instruction. The L1CFG1 register is shown in the following figure.

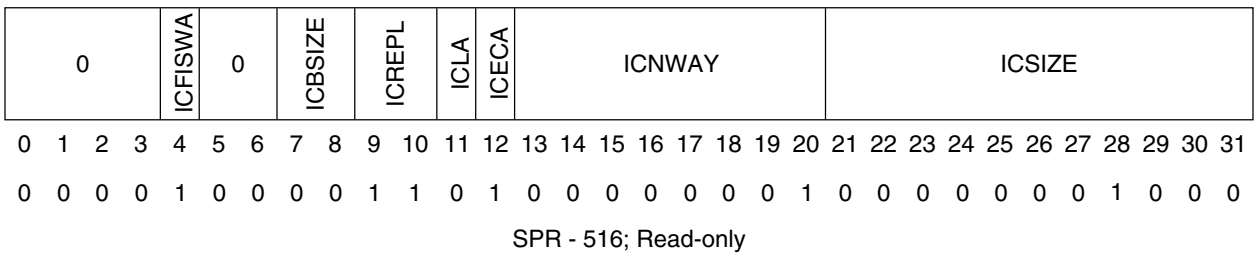

Figure 8-10. L1 Cache Configuration Register 1 (L1CFG1)

The L1CFG1 fields are described in the following table.

Table 8-20. L1CFG1 field descriptions

Bits	Name	Description
0:3	—	Reserved - read as zeros
4	ICFISWA	Instruction Cache Flush/Invalidate by Set and Way Available 1 The instruction cache supports invalidation by Set and Way via L1FINV1
5:6	—	Reserved - read as zeros
7:8	ICBSIZE	Instruction Cache Block Size 00 The instruction cache implements a block size of 32 bytes
9:10	ICREPL	Instruction Cache Replacement Policy 11 The instruction cache implements a FIFO replacement policy
11	ICLA	Instruction Cache Locking APU Available 0 The instruction cache does not implement the line locking APU
12	ICECA	Instruction Cache Error Checking Available 1 The instruction cache implements error checking
13:20	ICNWAY	Instruction Cache Number of Ways 0x01 The instruction cache is 2-way set-associative
21:31	ICSIZE	Instruction Cache Size 0x008 The size of the instruction cache is 8 KB

8.7.7 Cache Invalidate by Set and Way

e200z425n3 supports cache set/way invalidation under software control. The instruction cache may be invalidated by index and way through a **mtspr l1finv1** instruction.

The L1 Flush and Invalidate Control Registers (L1FINV1) are 32-bit SPRs used to select a cache set and way to be invalidated. This function is available even when the instruction cache is disabled.

8.7.7.1 L1FINV1

The L1FINV1 register is shown in following figure.

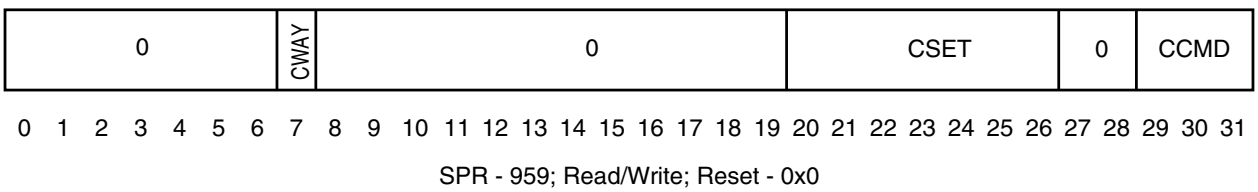

Figure 8-11. L1 Flush/Invalidate Register 1 (L1FINV1)

The L1FINV1 bits are described in the following table.

Table 8-21. L1FINV1 field descriptions

Bits	Name	Description
0:6	—	Reserved
7	CWAY	Cache Way Specifies the instruction cache way to be selected
8:19	—	Reserved
20:26	CSET	Cache Set Specifies the instruction cache set to be selected
27:28	—	Reserved
29:31	CCMD	Cache Command 000 The data contained in this entry is invalidated. LO bits are unaffected 001 Reserved 01x Reserved 100 Reserved 101 The data contained in this entry is invalidated. LO bits are cleared 11x Reserved

For invalidation operations via L1FINV1, tag ECC errors and data EDC errors are ignored, and the selected line will be invalidated regardless of any error. Invalidations conditionally affect the state of the lockout bits (LO).

8.7.8 Cache EDC/ECC Parity Protection

Cache parity protection is supported for both the tag and data arrays of the instruction cache. Seven parity check bits are provided for each tag entry for the tag array to support error detection and correction (ECC - SECDED). Eight parity check bits are provided for each doubleword in the data arrays of the I-Cache, which are used for single- and double-bit error detection (EDC - DED, double error detection). Utilizing ECC/EDC protection, many multi-bit errors are also detected.

The error detection codes also cover the cache index address of the cache line, providing additional protection against addressing errors. If any type of error (including a single-bit error in one of the index bits) is encountered in one of the index address bits, it is treated as an uncorrectable tag ECC error to protect against internal addressing failures. No attempt will be made to correct single-bit errors where the syndrome indicates an index address bit.

Tag ECC and data EDC checking is controlled by the L1CSR1[ICECE] control field. When error checking is enabled, checking is performed on each cache access. Errors are not signaled by the instruction cache when cache error checking is disabled (L1CSR1[ICECE] = 0).

If an uncorrectable tag ECC error is detected on any portion of a tag accessed during cache lookups performed because of instruction fetching, a tag ECC error is signaled, regardless of whether a cache hit or miss occurs. Otherwise, if a cache hit for an instruction fetch occurs and a data EDC error is detected on any portion of the accessed data, a parity error is also signaled.

Signaling of an ECC error or EDC error may cause a Machine Check exception to occur. One or more syndrome bits may be set in the Machine Check Syndrome register, or may instead result in a correction/auto-invalidation operation and not result in an exception being signaled. Both may occur, depending on the error action control setting in the appropriate cache control register.

8.7.8.1 Cache Line Lockout

In addition to the ECC/EDC protection employed for the cache, each cache line in the I-Cache has a lockout indicator composed of a redundant set of lockout bits. These lockout bits can selectively be set when certain errors occur in either the tag or the data portion of the cache line. Use of the lockout function and control over error conditions that cause a lockout to occur are controlled by $L1CSR1_{ICLOC}$. When the lockout function is enabled, lines that encounter selected tag ECC or data EDC errors on instruction fetch, accesses will have their lockout bits set. When the lockout indicator is set, the line will not be

replaced and will remain in an invalid state, effectively disabling it. Also, future tag ECC or data EDC errors on the line are ignored. Cache-inhibited accesses will only set lockout indicators on lines not in a locked way. In addition, no lockout indicators are set by cache-inhibited accesses when operating in machine check mode.

When operating in machine check mode, if lockout controls are enabled via $L1CSR1_{ICLOC}$, lockout bit parity errors on any line detected on a cacheable cache lookup will generate a machine check exception.

If correction/auto-invalidation is instead enabled, on each cache lookup operation for an instruction fetch, if a single- or double-bit lockout bit parity error is detected in one or more ways and lockout controls are enabled, the lockout error(s) will be corrected by rewriting all lockout bits to the asserted state, and no machine check is generated, unless the line is in a locked way. If a line in a locked way incurs a LO bit parity error, a machine check will be generated to ensure that any possible new lockout of the line is reported. For non-cacheable accesses, lockout bit parity errors will only be corrected for lines not in a locked way. Lockout bit parity errors do not generate a machine check for non-cacheable accesses in either error action mode, thus lockout bit correction is not performed for lockout bit parity errors detected on a line in a locked way.

In addition, cache contents are ignored for lines with those errors. Cache invalidate instructions do not report or correct lockout bit parity errors. For both of these cases, a future cacheable access will perform the lockout function if required.

8.7.9 Cache Error Injection

Cache error injection provides a way to test error recovery by intentionally injecting parity errors into the instruction cache.

Error injection into the instruction cache operates as follows:

- If $L1CSR1_{ICEI}$ is set, any instruction cache line fill to the instruction cache data has the associated two most significant parity check bits inverted in the instruction cache data array for each doubleword loaded.

Cache parity error injection is not performed for cache debug write accesses, since parity bit values written can be directly controlled.

In order to clear the parity errors, a cache invalidation or an invalidation of the lines that could have had an injected parity error may be performed. Line invalidation may be performed by an **icbi** instruction or an L1FINV1 invalidation operation.

8.8 Exceptions

Interrupts implemented in e200z425n3 and the exception conditions that cause them are listed in the following table.

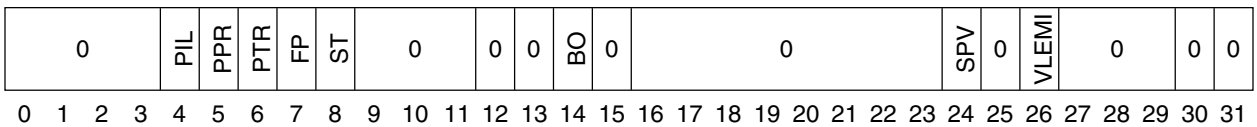

Table 8-22. Exceptions and Conditions

Interrupt type	Interrupt vector offset value	Causing conditions
System reset	none, vector to [p_rstbase[0:29]] || 2'b00	Reset
Critical Input	0x00[1, 1]	**p_critint_b** is asserted and MSR_{CE} = 1.
Machine check	0x10	1. **p_mcp_b** transitions from negated to asserted 2. ISI or Bus Error on first instruction fetch for an exception handler 3. Parity Error signaled on Cache access 4. Parity Error signaled on Local Memory access 5. External bus error 6. Stack limit check failure
Machine check (NMI)	0x10	Non-Maskable Interrupt
Data Storage	0x20	Access control
Instruction Storage	0x30	Access control
External Input	0x40[2]	Interrupt Controller interrupt and MSR_{EE} = 1
Alignment	0x50	1. **lmw**, **stmw** not word aligned 2. **lwarx** or **stwcx.** not word aligned, **lharx** or **sthcx.** not halfword aligned 3. LSP ld and st instructions not properly aligned 4. **dcbz**
Program	0x60	Illegal, Privileged, Trap
Performance Monitor	0x70	Performance Monitor Enabled Condition or Event w/$PMGC0_{UDI}$ = 0
System call	0x80	Execution of the System Call (**se_sc**) instruction
Debug	0x90	Trap, Instruction Address Compare, Data Address Compare, Instruction Complete, Branch Taken, Return from Interrupt, Interrupt Taken, Debug Counter, External Debug Event, Unconditional Debug Event, Performance Monitor Enabled Condition or Event w/$PMGC0_{UDI}$ = 1, MPU
EFPU Data Exception	0xA0	Embedded Floating-point Data Exception
EFPU Round Exception	0xB0	Embedded Floating-point Round Exception
TBD	0xC0–0xF0	Reserved for future processor use

1. Autovectored Critical Input interrupts use this offset value. Vectored interrupts supply an interrupt vector offset directly.
2. Autovectored External Input interrupts use this offset value. Vectored interrupts supply an interrupt vector offset directly.

8.8.1 Exception Syndrome Register (ESR)

The Exception Syndrome Register (ESR) provides a *syndrome* to differentiate between exceptions that can generate the same interrupt type.

SPR - 62; Read/Write; Reset - 0x0

Figure 8-12. Exception Syndrome Register (ESR)

The ESR bits are defined in the following table.

Table 8-23. ESR field descriptions

Bit(s)	Name	Description	Associated interrupt type
0:3	—	Reserved	—
4	PIL	Illegal Instruction exception For e200z425n3, PIL is used for both illegal and unimplemented instructions.	Program
5	PPR	Privileged Instruction exception	Program
6	PTR	Trap exception	Program
7	FP	Floating-point operation	Program
8	ST	Store operation	Alignment Data Storage
9:11	—	Reserved	—
12	—	Reserved	—
13	—	Reserved	—
14	BO	Byte Ordering exception Mismatched Instruction Storage exception	Instruction Storage
15	—	Reserved	—
16:23	—	Reserved	—
24	SPV	LSP/EFPU APU Operation	EFPU Floating-point Data Exception EFPU Floating-point Round Exception Alignment Data Storage
25	—	Reserved	—

Table continues on the next page...

Table 8-23. ESR field descriptions (continued)

Bit(s)	Name	Description	Associated interrupt type
26	VLEMI	VLE Mode Instruction	EFPU Floating-point Data Exception EFPU Floating-point Round Exception Data Storage Instruction Storage Alignment Program System Call
27:29	—	Reserved	—
30	—	Reserved	—
31	—	Reserved	—

8.8.2 Machine State Register (MSR)

The Machine State Register defines the state of the processor. The e200z425n3 MSR is shown in the following figure.

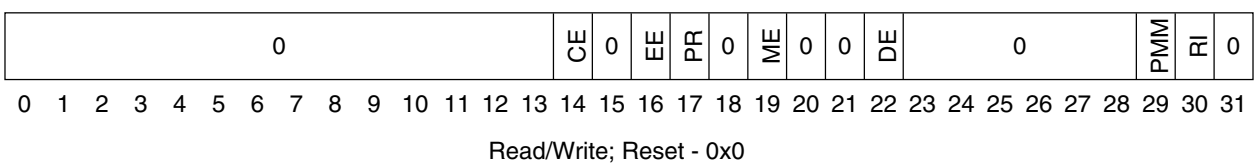

Figure 8-13. Machine State Register (MSR)

The MSR bits are defined in the following table.

Table 8-24. MSR field descriptions

Bit(s)	Name	Description
0:13	—	Reserved
14	CE	Critical Interrupt Enable 0 Critical Input interrupts are disabled. 1 Critical Input interrupts are enabled.
15	—	Reserved
16	EE	External Interrupt Enable 0 External Input interrupts are disabled. 1 External Input interrupts are enabled.

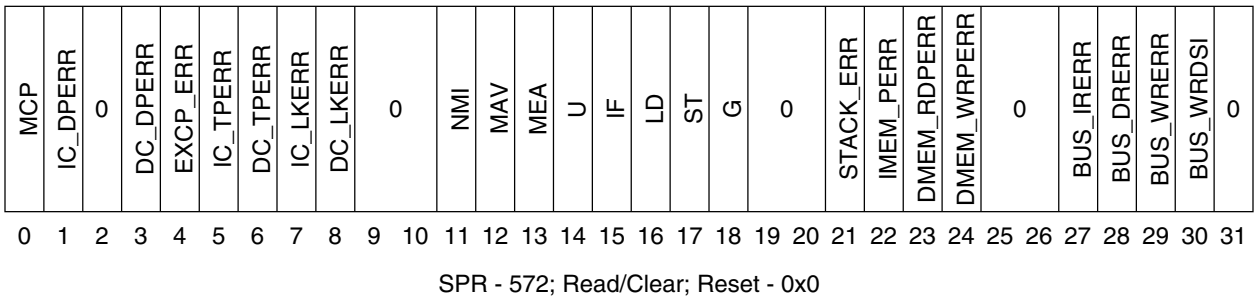

Table continues on the next page...

Table 8-24. MSR field descriptions (continued)

Bit(s)	Name	Description
17	PR	Problem State 0 The processor is in supervisor mode, can execute any instruction, and can access any resource (e.g. GPRs, SPRs, MSR, etc.). 1 The processor is in user mode, cannot execute any privileged instruction, and cannot access any privileged resource.
18	—	Reserved
19	ME	Machine Check Enable 0 Asynchronous Machine Check interrupts are disabled. 1 Asynchronous Machine Check interrupts are enabled.
20	—	Reserved
21	—	Reserved
22	DE	Debug Interrupt Enable 0 Debug interrupts are disabled. 1 Debug interrupts are enabled.
23:28	—	Reserved
29	PMM	PMM Performance monitor mark bit System software can set PMM when a marked process is running to enable statistics to be gathered only during the execution of the marked process. MSR_{PR} and MSR_{PMM} together define a state that the processor (supervisor or user) and the process (marked or unmarked) may be in at any time. If this state matches an individual state specified in the PMLCa*n* Performance Monitor registers, the state for which monitoring is enabled, counting is enabled.
30	RI	Recoverable Interrupt This bit is provided for software use to detect nested machine check exception conditions. This bit is cleared by hardware when a Machine Check interrupt is taken.
31	—	Reserved

8.8.3 Machine Check Syndrome Register (MCSR)

When the processor takes a machine check interrupt, it updates the Machine Check Syndrome Register (MCSR) to differentiate between machine check conditions. The MCSR is shown in the following figure.

SPR - 572; Read/Clear; Reset - 0x0

Figure 8-14. Machine Check Syndrome Register (MCSR)

The following table describes MCSR fields. The MCSR indicates the source of a machine check condition.

All bits in the MCSR are implemented as "write 1 to clear." Software in the machine check handler is expected to clear the MCSR bits it has sampled prior to re-enabling MSR_{ME} to avoid a redundant machine check exception and to prepare for updated status bit information on the next machine check interrupt.

Note that any set bit in the MCSR other than status-type bits will cause a subsequent machine check interrupt once $MSR_{ME} = 1$.

Table 8-25. Machine Check Syndrome Register (MCSR) field descriptions

Bit	Name	Description	Exception type[1, 1]	Recoverable
0	MCP	Machine check input pin	Async Mchk	Maybe
1	IC_DPERR	Instruction Cache data array parity error	Async Mchk	Precise
2	—	Reserved	—	—
3	DC_DPERR	Data Cache data array parity error Will not be set by e200z425n3 since no data cache is present.	Async Mchk	Maybe
4	EXCP_ERR	ISI or Bus Error on first instruction fetch for an exception handler	Async Mchk	Precise
5	IC_TPERR	Instruction Cache Tag parity error	Async Mchk	Precise
6	DC_TPERR	Data Cache Tag parity error Will not be set by e200z425n3 since no data cache is present.	Async Mchk	Maybe
7	IC_LKERR	Instruction Cache Lock error Indicates a cache control operation or invalidation operation invalidated one or more lines in a locked way of the I-Cache for certain situations. May also be set on locked line refill error.	Async Mchk	—

Table continues on the next page...

Table 8-25. Machine Check Syndrome Register (MCSR) field descriptions (continued)

Bit	Name	Description	Exception type[1, 1]	Recoverable
8	DC_LKERR	Data Cache Lock error Indicates a cache control operation or invalidation operation invalidated one or more lines in a locked way of the D-Cache for certain situations. May also be set on locked line refill error. Will not be set by e200z425n3 since no data cache is present.	Async Mchk	—
9:10	—	Reserved	—	—
11	NMI	NMI input pin	NMI	—
12	MAV	MCAR Address Valid Indicates that the address contained in the MCAR was updated by hardware to correspond to the first detected Async Mchk error condition	Status	—
13	MEA	MCAR holds Effective Address If MAV = 1, MEA = 1 indicates that the MCAR contains an effective address and MEA = 0 indicates that the MCAR contains a physical address. Note that since no address translation mechanism is present on e200z425n3, the MEA value is always set to \0'.	Status	—
14	U	User Indicates the value captured in MCAR was generated in user mode.	Status	—
15	IF	Instruction Fetch Error Report An error occurred during the fetch of an instruction and the instruction attempted to execute. This could be due to an internal parity error, or an external bus error. MCSRR0 contains the instruction address.	Error Report	Precise
16	LD	Load type instruction Error Report An error occurred during the attempt to execute the load type instruction located at the address stored in MCSRR0. This could be due to an internal parity error, stack limit check error, or an external bus error.	Error Report	Precise
17	ST	Store type instruction Error Report An error occurred during the attempt to execute the store type instruction located at the address stored in MCSRR0. This could be due to an internal parity error, stack limit check error, or on certain external bus errors.	Error Report	Precise

Table continues on the next page...

Table 8-25. Machine Check Syndrome Register (MCSR) field descriptions (continued)

Bit	Name	Description	Exception type[1, 1]	Recoverable
18	G	Guarded instruction Error Report An error occurred during the attempt to execute the load or store type instruction located at the address stored in MCSRR0 and the access was guarded and encountered an error on the external bus, or an uncorrectable DMEM error.	Error Report	Precise
19:20	—	Reserved	—	—
21	STACK_ERR	Stack Access Limit Check Error Indicates a limit check failure on a CPU data access using R1 in the <EA> calculation.	Async Mchk	Precise
22	IMEM_PERR	Instruction Mem (IMEM) Parity Error Indicates an uncorrectable error in the IMEM on a CPU port access.	Async Mchk	Precise
23	DMEM_RDPERR	Data Mem (DMEM) Parity Error Indicates an uncorrectable error in the DMEM on a CPU port read access.	Async Mchk	Precise
24	DMEM_WRPERR	Data Mem (DMEM) Write Parity Error Indicates an uncorrectable error in the DMEM on a CPU port write access.	Async Mchk	Maybe
25:26	—	Reserved	—	—
27	BUS_IRERR	Read bus error on Instruction recovery linefill	Async Mchk	Precise if data used
28	BUS_DRERR	Read bus error on data load	Async Mchk	Precise if data used
29	BUS_WRERR	Write bus error on store to bus or DMEM imprecise write error	Async Mchk	Unlikely
30	BUS_WRDSI	Write bus error on buffered store to bus with DSI signaled. Set concurrently with BUS_WRERR for this case	Async Mchk	Unlikely
31	—	Reserved	—	—

1. The Exception Type indicates the exception type associated with a given syndrome bit.
   - "Error Report" indicates that this bit is only set for error report exceptions which cause machine check interrupts. These bits are only updated when the machine check interrupt is actually taken. Error report exceptions are not gated by MSR_{ME}. These are synchronous exceptions. These bits will remain set until cleared by software writing a '1' to the bit position(s) to be cleared.
   - "Status" indicates that this bit is provides additional status information regarding the logging of a machine check exception. These bits will remain set until cleared by software writing a '1' to the bit position(s) to be cleared.
   - "NMI" indicates that this bit is only set for the non-maskable interrupt type exception which causes a machine check interrupt. This bit is only updated when the machine check interrupt is actually taken. NMI exceptions are not gated by MSR_{ME}. This is an asynchronous exception. This bit will remain set until cleared by software writing a '1' to the bit position.
   - "Async Mchk" indicates that this bit is set for an asynchronous machine check exception. These bits are set immediately upon detection of the error. Once any "Async Mchk" bit is set in the MCSR, a machine check interrupt will occur if $MSR_{ME} = 1$. If $MSR_{ME} = 0$, the machine check exception will remain pending. These bits will remain set until cleared by software writing a '1' to the bit position(s) to be cleared.

8.8.4 Interrupt Vector Prefix Registers (IVPR)

The Interrupt Vector Prefix Register is used during interrupt processing for determining the starting address of a software handler used to handle an interrupt. The value of the Vector Offset selected for a particular interrupt type is concatenated with the Vector Base value held in the IVPR to form an instruction address from which execution is to begin. The format of IVPR is shown in the following figure.

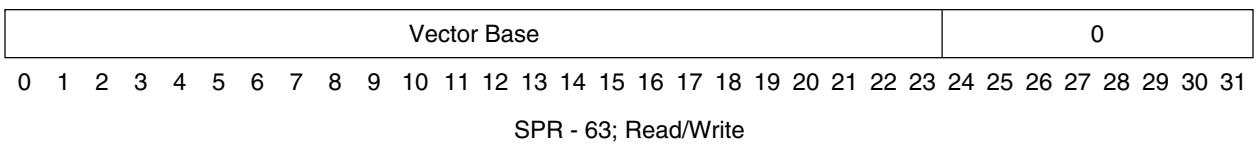

Figure 8-15. Interrupt Vector Prefix Register (IVPR)

The IVPR fields are defined in the following table.

Table 8-26. IVPR field descriptions

Bit(s)	Name	Description
0:23 (32:55)	Vector Base	Vector Base This field is used to define the base location of the vector table, aligned to a 256 byte boundary. This field provides the high-order 24 bits of the location of all interrupt handlers (unless hardware vectoring is used). The vector offset value appropriate for the type of exception being processed is concatenated with the IVPR Vector Base to form the address of the handler in memory. For hardware-vectored interrupts, the value of the supplied interrupt vector is logically OR'ed with the low order bits of the Vec Base Field to determine the interrupt handler address.
24:31 (56:63)	—	Reserved

8.8.5 Interrupt Definitions

8.8.5.1 Critical Input Interrupt (offset 0x00)

A Critical Input exception is signaled to the processor by the assertion of the critical interrupt pin. If the exception is enabled by MSR_{CE}, the Critical Input interrupt is taken.

A Critical Input interrupt may be delayed by other higher priority exceptions or if MSR_{CE} is cleared when the exception occurs.

The following table lists register settings when a Critical Input interrupt is taken.

Table 8-27. Critical Input Interrupt—register settings

Register	Setting description					
CSRR0	Set to the effective address of the instruction that the processor would have attempted to execute next if no exception conditions were present.					
CSRR1	Set to the contents of the MSR at the time of the interrupt					
MSR	SPV	0	FP	0	FE1	0
	WE	0	ME	—	IS	0
	CE	0	FE0	0	DS	0
	EE	0	DE	—/0[1]	PMM	0
	PR	0			RI	—
ESR	Unchanged					
MCSR	Unchanged					
DEAR	Unchanged					
Vector	$IVPR_{0:23}$ || 0x00 (autovectored)					
	$IVPR_{0:15}$ || (IVPR16:29 | **p_voffset[0:13]**) || 2'b00 (non-autovectored)					

1. Clearing of DE is optionally supported by control in HID0.

The MSR_{DE} bit is not automatically cleared by a Critical Input interrupt, but it can be configured to be cleared via the HID0 register ($HID0_{CICLRDE}$).

8.8.5.2 Machine Check Interrupt (offset 0x10)

The EIS Machine Check APU defines a separate set of save/restore registers (MCSRR0/1), a Machine Check Syndrome Register (MCSR) to record the source(s) of machine checks, and a Machine Check Address Register (MCAR) to hold an address associated with a machine check for certain classes of machine checks. Return from Machine Check instructions (**se_rfmci**) are also provided to support returns using MCSRR0/1.

The MSR_{DE} bit is not automatically cleared by a Machine Check exception, but it can be configured to be cleared or left unchanged via the HID0 register ($HID0_{MCCLRDE}$).

When a Machine Check interrupt is taken, registers are updated as shown in the following table.

Table 8-28. Machine Check Interrupt—register settings

Register	Setting description
MCSRR0	On a best-effort basis, set to the address of some instruction that was executing or about to be executing when the machine check condition occurred.
MCSRR1	Set to the contents of the MSR at the time of the interrupt

Table continues on the next page...

Table 8-28. Machine Check Interrupt—register settings (continued)

Register	Setting description					
MSR	SPV	0	FP	0	FE1	0
	WE	0	ME	0	IS	0
	CE	0	FE0	0	DS	0
	EE	0	DE	0/—[1]	PMM	0
	PR	0			RI	0
ESR	Unchanged					
MCSR	Updated to reflect the source(s) of a machine check. Hardware only sets appropriate bits, no previously set bits are cleared by hardware.					
Vector	$IVPR_{0:23}$ || 0x10					

1. Clearing of DE is optionally supported by control in HID0.

8.8.5.3 Data Storage Interrupt (offset 0x20)

A Data Storage interrupt (DSI) may occur if no higher priority exception exists and a Read or Write Access Control exception condition exists.

The following table lists register settings when a DSI is taken.

Table 8-29. Data Storage Interrupt—register settings

Register	Setting description					
SRR0	Set to the effective address of the excepting load/store instruction.					
SRR1	Set to the contents of the MSR at the time of the interrupt					
MSR	SPV	0	FP	0	FE1	0
	WE	0	ME	—	IS	0
	CE	—	FE0	0	DS	0
	EE	0	DE	—	PMM	0
	PR	0			RI	—
ESR	Access:		[ST], [SPV], VLEMI. All other bits cleared.			
MCSR	Unchanged					
DEAR	For Access Control exceptions, set to the effective address of the access that caused the violation.					
Vector	$IVPR_{0:23}$ || 0x20					

8.8.5.4 Instruction Storage Interrupt (offset 0x30)

An Instruction Storage interrupt (ISI) occurs when no higher priority exception exists and an Execute Access Control exception occurs.

The following table lists register settings when an ISI is taken.

Table 8-30. Instruction Storage Interrupt—register settings

Register	Setting description					
SRR0	Set to the effective address of the excepting instruction.					
SRR1	Set to the contents of the MSR at the time of the interrupt

	PR	0			RI	—
ESR	VLEMI. All other bits cleared.					
MCSR	Unchanged					
DEAR	Unchanged					
Vector	$IVPR_{0:23}$ || 0x30					

8.8.5.5 External Input Interrupt (offset 0x40)

An External Input exception is signaled to the processor by the assertion of an interrupt from the interrupt controller. The input is a level-sensitive signal expected to remain asserted until the core acknowledges the external interrupt. If the input is negated early, recognition of the interrupt request is not guaranteed. When the core detects the exception, if the exception is enabled by MSR_{EE}, it takes the External Input interrupt.

An External Input interrupt may be delayed by other higher priority exceptions or if MSR_{EE} is cleared when the exception occurs.

The following table lists register settings when an External Input interrupt is taken.

Table 8-31. External Input Interrupt—Register Settings

Register	Setting description					
SRR0	Set to the effective address of the instruction that the processor would have attempted to execute next if no exception conditions were present.					
SRR1	Set to the contents of the MSR at the time of the interrupt					
MSR	SPV	0	FP	0	FE1	0
	WE	0	ME	—	IS	0
	CE	—	FE0	0	DS	0
	EE	0	DE	—	PMM	0
	PR	0			RI	—
ESR	Unchanged					

Table continues on the next page...

Register	Setting description
MCSR	Unchanged
DEAR	Unchanged
Vector	$IVPR_{0:23}$ || 0x40 (autovectored) IVPR0:15 || (IVPR16:29 | **p_voffset[0:13]**) || 2'b00 (non-autovectored)

8.8.5.6 Alignment Interrupt (offset 0x50)

An Alignment exception is generated when any of the following occurs:

- The operand of **lmw** or **stmw** is not word aligned.
- The operand of **lwarx** or **stwcx.** is not word aligned.
- The operand of **lharx** or **sthcx.** is not halfword aligned.
- Execution of a **dcbz** instruction is attempted.
- Execution of an LSP APU load or store instruction that is not properly aligned.

The following table lists register settings when an alignment interrupt is taken.

Table 8-32. Alignment Interrupt—register settings

Register	Setting description					
SRR0	Set to the effective address of the excepting load/store/dcbz instruction.					
SRR1	Set to the contents of the MSR at the time of the interrupt					
MSR	SPV	0	FP	0	FE1	0
	WE	0	ME	—	IS	0
	CE	—	FE0	0	DS	0
	EE	0	DE	—	PMM	0
	PR	0			RI	—
ESR	[ST], [SPV], VLEMI. All other bits cleared.					
MCSR	Unchanged					
DEAR	Set to the effective address of a byte of the load or store access causing the violation.					
Vector	$IVPR_{0:23}$ || 0x50					

8.8.5.7 Program Interrupt (offset 0x60)

A program interrupt occurs when no higher priority exception exists and one or more of the following exception conditions occur:

- Illegal Instruction exception
- Privileged Instruction exception
- Trap exception

The e200z425n3 will invoke an Illegal Instruction program exception on attempted execution of the following instructions:

- Unimplemented instructions
- An instruction from the illegal instruction class
- **mtspr** and **mfspr** instructions with an undefined SPR specified
- **mtdcr** and **mfdcr** instructions with an undefined DCR specified

The e200z425n3 will invoke a Privileged Instruction program exception on attempted execution of the following instructions when $MSR_{PR} = 1$ (user mode):

- A privileged instruction
- **mtspr** and **mfspr** instructions that specify a SPRN value with $SPRN_5 = 1$ (even if the SPR is undefined)

The e200z425n3 will invoke an Trap exception on execution of the **tw** instruction if the trap conditions are met and the exception is not also enabled as a Debug interrupt.

The core will invoke an Illegal instruction program exception on attempted execution of the instructions **lswi**, **lswx**, **stswi**, **stswx**, **mfapidi**, **mfdcrx**, **mtdcrx**, or on any *PowerISA 2.06* floating-point instruction. All other defined or allocated instructions that are not implemented by core will cause an illegal instruction program exception.

The following table lists register settings when a Program interrupt is taken.

Table 8-33. Program Interrupt—register settings

Register	Setting description
SRR0	Set to the effective address of the excepting instruction.
SRR1	Set to the contents of the MSR at the time of the interrupt

	Trap:		PTR, VLEMI. All other bits cleared.			
MCSR	Unchanged					
DEAR	Unchanged					
Vector	$IVPR_{0:23}$ || 0x60					

8.8.5.8 Performance Monitor Interrupt (offset 0x70)

A performance monitor interrupt that may be generated by an enabled condition or event. An enabled condition or event is as follows:

A PMC*x* register overflow condition occurs with the following settings:

- PMLCax_{CE} = 11; that is, for the given counter the overflow condition is enabled.
- PMCx_{OV} = 11; that is, the given counter indicates an overflow.

For a performance monitor interrupt to be signaled on an enabled condition or event, $PMGC0_{PMIE}$ must be set.

Although an exception condition may occur with MSR_{EE} = 0, the interrupt cannot be taken until MSR_{EE} = 1.

The priority of the performance monitor interrupt is below all other asynchronous interrupts.

The following table lists register settings when an performance monitor interrupt is taken.

Table 8-34. Performance Monitor Interrupt—Register Settings

Register	Setting description
SRR0/ DSRR0[1, 1]	Set to the effective address of the next instruction to be executed.

Table continues on the next page...

Table 8-34. Performance Monitor Interrupt—Register Settings (continued)

Register	Setting description					
SRR1/ DSRR1[1]	Set to the contents of the MSR at the time of the interrupt.

8.8.5.9 System Call Interrupt (offset 0x80)

A System Call interrupt occurs when a System Call (**se_sc**) instruction is executed and no higher priority exception exists.

The following table lists register settings when a System Call interrupt is taken.

Table 8-35. System Call Interrupt—register settings

Register	Setting description					
SRR0	Set to the effective address of the instruction *following* the system call instruction.					
SRR1	Set to the contents of the MSR at the time of the interrupt

8.8.5.10 Debug Interrupt (offset 0x90)

There are multiple sources that can signal a Debug exception. A Debug interrupt occurs when no higher priority exception exists, a Debug exception exists in the Debug Status Register, and Debug interrupts are enabled (both $DBCR0_{IDM} = 1$ (internal debug mode) and $MSR_{DE} = 1$).

The following table lists register settings when a Debug interrupt is taken.

Table 8-36. Debug Interrupt—register settings

Register	Setting description					
DSRR0[1]	Set to the effective address of the excepting instruction for IAC, BRT, RET, CRET, and TRAP.Set to the effective address of the next instruction to be executed *following* the excepting instruction for DAC (usually) and ICMP. For a UDE, IRPT, CIRPT, DCNT, or DEVT type exception, set to the effective address of the instruction that the processor would have attempted to execute next if no exception conditions were present.

8.8.5.11 Embedded Floating-point Data Interrupt (offset 0xA0)

The Embedded Floating-point Data interrupt is taken if no higher priority exception exists and an EFPU Floating-point Data exception is generated. When a Floating-point Data exception occurs, the processor suppresses execution of the instruction causing the exception.

The following table lists register settings when an EFPU Floating-point Data interrupt is taken.

Table 8-37. Embedded Floating-point Data Interrupt—register settings

Register	Setting description					
SRR0	Set to the effective address of the excepting EFPU instruction.

8.8.5.13 System Reset Interrupt

The System Reset exception is a non-maskable, asynchronous exception signaled to the processor through the assertion of system-defined signals.

A System Reset may be initiated by either a software reset or during power-on reset.

When a reset request occurs, the processor branches to the system reset exception vector without attempting to reach a recoverable state. If reset occurs during normal operation, all operations cease and the machine state is lost.

The following table lists register settings when a System Reset interrupt is taken.

Table 8-39. System Reset Interrupt—register settings

8.9 Memory Protection Unit (MPU)

8.9.1 MPU Overview

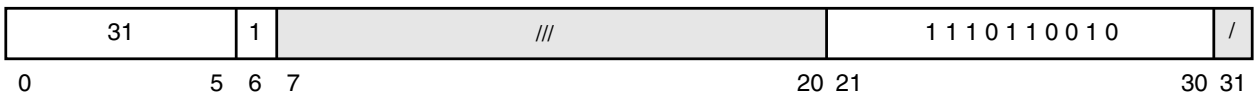
The e200z425n3 Memory Protection Unit (MPU) protects regions of memory, with the following feature set:

- 24-entry region descriptor table with support for 6 arbitrary-sized instruction memory regions, 12 arbitrary-sized data memory regions, and 6 additional arbitrary-sized regions programmable as instruction or data memory regions
- Ability to set access permissions and memory attributes on a per-region basis
- Process ID aware, with per-bit masking of TID values
- Capability for masking upper address bits in the range comparison
- Capability of bypassing permissions checking for selected access types
- Per-entry write-once logic for entry protection
- Hardware flash invalidation support and per-entry invalidation protection controls
- Ability to optionally utilize region descriptors for generating debug events and watchpoints
- Software managed by **mpure** and **mpuwe** instructions

8.9.2 Software Interface and MPU Instructions

The MPU entries are accessed indirectly through several MPU Assist (MAS) registers. Software can write and read the MAS registers with **mtspr** and **mfspr** instructions. These registers contain information related to reading and writing a given entry within the MPU. Data is read from the MPU into the MAS registers with an **mpure** (MPU read entry) instruction. Data is written to the MPU from the MAS registers with an **mpuwe** (MPU write entry) instruction.

The **mpure**, **mpuwe**, and **mpusync** instructions are privileged.



8.9.3 MPU Read Entry Instruction (mpure)

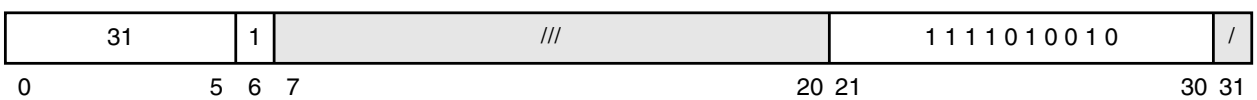
The MPU read entry instruction causes the content of a single MPU entry to be placed in the MPU assist registers. The entry is specified by the INST, SHD, and ESEL fields of the MAS0 register. The entry contents are placed in the MAS0, MAS1, MAS2, and MAS3 registers.

mpure

mpu read entry

mpure

```
mpu_entry_id = MAS0(INST, SHD, ESEL)
result = MPU(mpu_entry_id)
MAS0, MAS1, MAS2, MAS3 = result
```



8.9.4 MPU Write Entry Instruction (mpuwe)

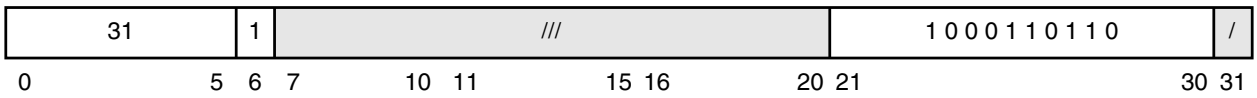
The MPU write entry instruction causes the contents of certain fields within the MPU assist registers MAS0, MAS1, MAS2, and MAS3 to be written into a single MPU entry in the MPU. The entry written is specified by the INST, SHD, and ESEL fields of the MAS0 register.

mpuwe

mpu write entry

mpuwe

```
mpu_entry_id = MAS0(INST, SHD, ESEL)
MPU(mpu_entry_id) = MAS0, MAS1, MAS2, MAS3
```



8.9.5 MPU Synchronize Instruction (mpusync)

The MPU Synchronize instruction is treated as a privileged no-op by the core.

mpusync

MPU Synchronize
mpusync

mpusync

8.9.6 MMU/MPU Configuration Register (MMUCFG)

The MMU/MPU Configuration Register (MMUCFG) is a 32-bit read-only register. The SPR number for MMUCFG is 1015 in decimal. MMUCFG provides information about the configuration of the e200z425n3 MPU design. The MMUCFG register is shown in the following figure.

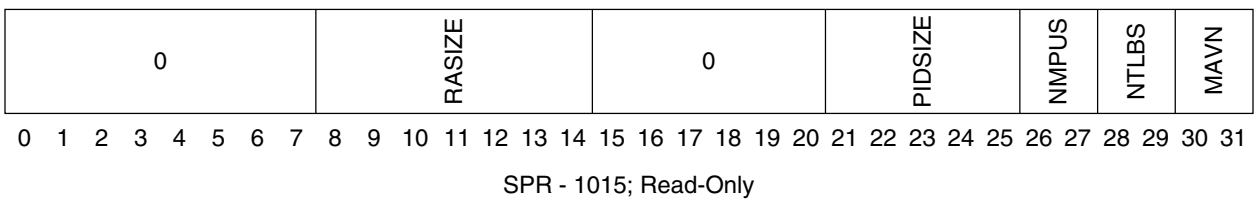


Figure 8-16. MMU/MPU Configuration Register (MMUCFG)

The MMUCFG bits are described in the following table.

Table 8-40. MMUCFG field descriptions

Bits	Name	Function
0:7	—	Reserved
8:14	RASIZE	Number of Bits of Real Address supported 0100000 This version of the MPU implements 32 real address bits
15:16	—	Reserved
17:20	—	Reserved
21:25	PIDSIZE	PID Register Size 00111 PID registers contain 8 bits in this version of the MPU
26:27	NMPUS	Number of MPUs 01 This version of the MMU implements one MPU structure: a fully associative MPU for MPU0
28:29	NTLBS	Number of TLBs 00 This version of the MMU implements no TLB structures
30:31	MAVN	MMU Architecture Version Number 11 This version of the MMU implements Version 3.1 of the EIS MMU Architecture

8.9.7 MPU0 Configuration Register (MPU0CFG)

The MPU0 Configuration Register (MPU0CFG) is a 32-bit read-only register. The SPR number for MPU0CFG is 692 in decimal. MPU0CFG provides information about the configuration of MPU0 in the e200z425n3 MPU. The MPU0CFG register is shown in following figure.

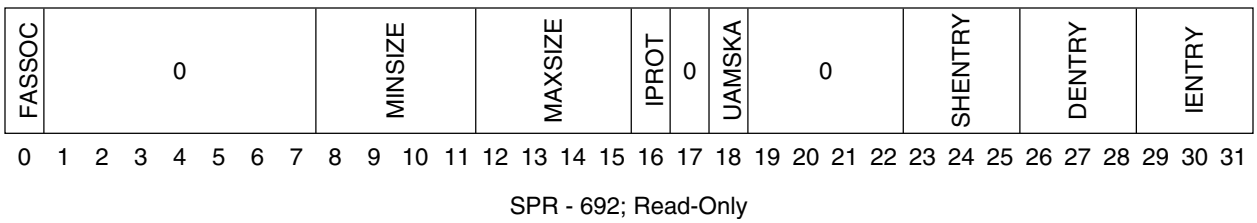

Figure 8-17. MPU0 Configuration Register (MPU0CFG)

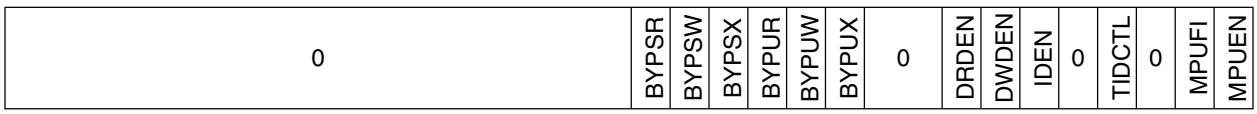

The MPU0CFG bits are described in the following table.

Table 8-41. MPU0CFG field descriptions

Bits	Name	Function
0	FASSOC	Fully Associative 1 Indicates that MPU0 is fully associative
1:7	—	Reserved for non-fully associative implementation use
8:11	MINSIZE	Minimum Region Size Due to the use of access address matching, the effective smallest region size is 8 bytes 0x0 Smallest region size is 1 byte
12:15	MAXSIZE	Maximum Region Size 0xB Largest region size is 4 GB
16	IPROT	Invalidate Protect Capability 1 Invalidate Protect Capability is supported in MPU0
17	—	Reserved
18	UAMSKA	Upper Address Masking Availability 1 Upper Address Masking is Available
19:22	—	Reserved
23:25	SHENTRY	Number of Shared (configurable for I or D) Entries 0x2 Indicates that MPU0 contains six shared entries
26:28	DENTRY	Number of Data Entries 0x4 Indicates that MPU0 contains 12 dedicated data entries
29:31	IENTRY	Number of Instruction Entries 0x2 Indicates that MPU0 contains six dedicated Instruction entries

8.9.8 MPU0 Control and Status Register 0 (MPU0CSR0)

The MPU0 Control and Status Register 0 (MPU0CSR0) is a 32-bit register. The SPR number for MPU0CSR0 is 1014 in decimal. MPU0CSR0 controls the operation of the MPU. The MPU0CSR0 register is shown in the following figure.

SPR - 1014; Read/ Write; Reset - 0x0[1]

Figure 8-18. MPU0 Control and Status Register 0 (MPU0CSR0)

Note

[1] Reset by processor reset **p_reset_b** if EDBCR0[EDM] = 0, as well as unconditionally by an internal power-on reset signal. If EDBCR0[EDM] = 1, EDBRAC0 masks off hardware-owned resources from reset by **p_reset_b** and only software-owned resources indicated by EDBRAC0 will be reset by **p_reset_b**. Specifically, this applies to the DRDEN, DWDEN, and IDEN control bits.

The MPU0CSR0 bits are described in the following table.

Table 8-42. MPU0CSR0 field descriptions

Bits	Name	Description
0:15	—	Reserved
16	BYPSR	Bypass MPU protections for Supervisor Read accesses This bit controls whether supervisor-mode read accesses bypass the MPU protection mechanism. When bypass is enabled, supervisor-mode read accesses do not generate a DSI when no MPU match occurs. Supervisor-mode read accesses are still compared to MPU entries, and a hit will provide access attributes (CI, G). 0 No Bypass of MPU protections for Supervisor Read accesses 1 Bypass MPU protections for Supervisor Read accesses
17	BYPSW	Bypass MPU protections for Supervisor Write accesses This bit controls whether supervisor-mode write accesses bypass the MPU protection mechanism. When bypass is enabled, supervisor-mode write accesses do not generate a DSI when no MPU match occurs. Supervisor-mode write accesses are still compared to MPU entries, and a hit will provide access attributes (CI, G). 0 No Bypass of MPU protections for Supervisor Write accesses 1 Bypass MPU protections for Supervisor Write accesses

Table continues on the next page...

Table 8-42. MPU0CSR0 field descriptions (continued)

Bits	Name	Description
18	BYPSX	Bypass MPU protections for Supervisor Instruction accesses This bit controls whether supervisor-mode instruction accesses bypass the MPU protection mechanism. When bypass is enabled, supervisor-mode instruction accesses do not generate an ISI when no MPU match occurs. Supervisor-mode instruction accesses are still compared to MPU entries, and a hit will provide access attributes (CI). 0 No Bypass of MPU protections for Supervisor Instruction accesses 1 Bypass MPU protections for Supervisor Instruction accesses
19	BYPUR	Bypass MPU protections for User Read accesses This bit controls whether user-mode read accesses bypass the MPU protection mechanism. When bypass is enabled, user-mode read accesses do not generate a DSI when no MPU match occurs. User-mode read accesses are still compared to MPU entries, and a hit will provide access attributes (CI, G). 0 No Bypass of MPU protections for User Read accesses 1 Bypass MPU protections for User Read accesses
20	BYPUW	Bypass MPU protections for User Write accessesThis bit controls whether user-mode write accesses bypass the MPU protection mechanism. When bypass is enabled, user-mode write accesses do not generate a DSI when no MPU match occurs. User-mode write accesses are still compared to MPU entries, and a hit will provide access attributes (CI, G). 0 No Bypass of MPU protections for User Write accesses 1 Bypass MPU protections for User Write accesses
21	BYPUX	Bypass MPU protections for User Instruction accesses This bit controls whether user-mode instruction accesses bypass the MPU protection mechanism. When bypass is enabled, user-mode instruction accesses do not generate an ISI when no MPU match occurs. User-mode instruction accesses are still compared to MPU entries, and a hit will provide access attributes (CI). 0 No Bypass of MPU protections for User Instruction accesses 1 Bypass MPU protections for User Instruction accesses
22:23	—	Reserved
24	DRDEN	Data Read Debug Enable This bit controls whether data read accesses are enabled to generate MPU debug events. When disabled, no data read access will generate an MPU debug event, regardless of whether an access match occurs to a valid MPU region descriptor with DEBUG = 1. If such a match occurs, no MPU debug event is generated, and no access protection is performed. When enabled, data read accesses are not blocked from generating MPU debug events. 0 MPU debug events are disabled for data read accesses 1 MPU debug events are enabled for data read accesses

Table continues on the next page...

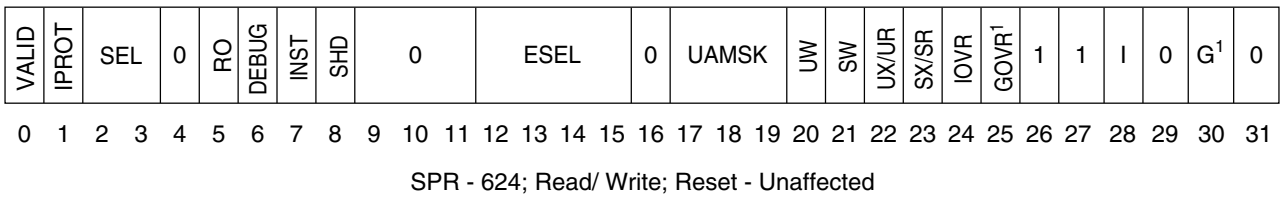

Table 8-42. MPU0CSR0 field descriptions (continued)

Bits	Name	Description
25	DWDEN	Data Write Debug Enable This bit controls whether data write accesses are enabled to generate MPU debug events. When disabled, no data write access will generate an MPU debug event, regardless of whether an access match occurs to a valid MPU region descriptor with DEBUG = 1. If such a match occurs, no MPU debug event is generated, and no access protection is performed. When enabled, data write accesses are not blocked from generating MPU debug events. 0 MPU debug events are disabled for data write accesses 1 MPU debug events are enabled for data write accesses
26	IDEN	Instruction Debug Enable This bit controls whether instruction accesses are enabled to generate MPU debug events. When disabled, no instruction access will generate an MPU debug event, regardless of whether an access match occurs to a valid MPU region descriptor with DEBUG = 1. When enabled, instruction accesses are not blocked from generating MPU debug events. 0 MPU debug events are disabled for instruction accesses 1 MPU debug events are enabled for instruction accesses
27	—	Reserved
28	TIDCTL	TID usage Control When TIDCTL is set to 1, the TID match is disabled (forced match) in Supervisor mode. 0 TID comparisons performed normally 1 No TID comparisons are performed for matching while in Supervisor mode
29	—	Reserved
30	MPUFI	MPU flash invalidate When written to a 1, a MPU invalidation operation is initiated by hardware. Once complete, this bit is reset to 0. Writing a 1 while an invalidation operation is in progress will result in an undefined operation. Writing a 0 to this bit while an invalidation operation is in progress will be ignored. MPU invalidation operations require 3 cycles to complete. 0 No flash invalidate 1 MPU1 invalidation operation **Note:** Entries that have the IPROT bit set will not be invalidated.
31	MPUEN	MPU Enable This bit enables operation of the MPU. When enabled, access addresses are compared to each entry in the MPU for a match condition. If no match condition occurs, and the access type is not enabled to bypass the MPU protections, then an ISI or DSI condition is signaled for the access. Note that this bit is ignored for matching entries with DEBUG = 1 if in EDM and hardware owns MPU Debug entries. 0 MPU is disabled 1 MPU is enabled

8.9.9 MPU Assist Registers (MAS)

The core uses four special-purpose registers (MAS0, MAS1, MAS2, and MAS3) to facilitate reading and writing MPU entries. The MAS registers can be read or written using the **mfspr** and **mtspr** instructions.

The MAS0 register is shown in Figure 8-19. Fields are defined in Table 8-43.

SPR - 624; Read/ Write; Reset - Unaffected

Figure 8-19. MPU Assist Register 0 (MAS0)

Note

[1] This bit is not implemented in dedicated instruction entries, and is ignored in shared entries with INST = 1

Table 8-43. MAS0—MPU Read/Write and Replacement Control

Bit	Name	Comments, or Function when Set
0	VALID	MPU Entry Valid 0 = This MPU entry is invalid 1 = This MPU entry is valid
1	IPROT	Invalidation Protect 0 = Entry is not protected from invalidation 1 = Entry is protected from invalidation
2:3	SEL	Selects MPU for access: 00 = Reserved, no access 01 = Reserved, no access 10 = Select MPU 11 = Reserved, no access
4	—	Reserved
5	RO	Read-Only When set to 1, the entry is no longer writable by software. Once set, this bit will remain set until a processor reset occurs. 0 = This MPU entry is writable 1 = This MPU entry is Read-only

Table continues on the next page...

Table 8-43. MAS0—MPU Read/Write and Replacement Control (continued)

Bit	Name	Comments, or Function when Set
6	DEBUG	Debug Control for Entry This bit is used to assign an entry for debug event use instead of normal access protection use. When used for debug purposes, an MPU debug event is generated when a hit to the entry occurs and the access permissions allow the access. 0 = This MPU entry is used for access protections and allows accesses when matched based on protection attributes 1 = This MPU entry is used for generating a debug event when a match occurs and the access protections would allow access
7	INST	Instruction Entry When SHD = 0, this bit is used to select the INST entry portion of the region descriptor table for **mpure** and **mpuwe** instruction operations. When SHD = 1, this bit is used to indicate whether the entry in the Shared portion of the region descriptor table is assigned as an entry for either instruction access or data access matching. Only one of these access types is monitored for matching by a given shared region descriptor entry. 0 = This MPU entry is used for matching data accesses only 1 = This MPU entry is used for matching instruction accesses only
8	SHD	Shared Entry Select This bit is used to control selection of the Shared portion of the region descriptor table. 0 = The shared portion of the region descriptor table is not accessed on a **mpure** or **mpuwe** operation. Either the instruction portion or the data portion is accessed based on the setting of INST. The entry within the selected portion is based on ESEL. 1 = The shared portion of the region descriptor table is accessed on a **mpure** or **mpuwe** operation. The instruction and data portions are not accessed. The INST bit is used to indicate whether the entry in the Shared portion of the region descriptor table is assigned as an entry for instruction access or data access matching. Only one of these access types is monitored for matching by a given shared region descriptor entry. ESEL defines which shared entry is selected.
9:11	—	Reserved
12:15	ESEL	Entry select for MPU. This field is used to select an entry for reading or writing in conjunction with the settings of SHD and INST. Only valid entry numbers should be used in this field, otherwise the result of an operation is boundedly undefined.
16	—	Reserved

Table continues on the next page...

Table 8-43. MAS0—MPU Read/Write and Replacement Control (continued)

Bit	Name	Comments, or Function when Set
17:19	UAMSK	Upper Address Mask Control This field is used to support masking of upper address bits before performing range comparisons. Masked bits will be forced to 0 for the purposes of the range compare. Range upper and lower bounds should be set accordingly. 000 = No upper address bits are masked, address matching uses all 32 address bits for accesses 001 = The most significant access address bit is forced to zero before matching 010 = The two most significant access address bits are forced to zero before matching 011 = The three most significant access address bits are forced to 0 before matching 100 = The four most significant access address bits are forced to 0 before matching 101 = The upper five access address bits are forced to zero before matching 11x = Reserved, do not use
20	UW	User Mode Write PermissionDetermines User mode Write (W) permission when INST = 0. Ignored when INST = 1. 0 = No User mode Write permission 1 = User mode has Write permission
21	SW	Supervisor Mode Write / Read Permission Determines Supervisor mode Write (W) permission when INST = 0. Ignored when INST = 1. 0 = No Supervisor mode Write permission 1 = Supervisor mode has Write permission
22	UX/UR	User Mode Execute / Read Permission Determines User mode Execute (X) permission when INST = 1, or User mode Read (R) permission when INST = 0. 0 = No User mode Execute/ Read permission 1 = User mode has Execute/ Read permission
23	SX/SR	Supervisor Mode Execute / Read Permission Determines Supervisor mode Execute (X) permission when INST = 1, or Supervisor mode Read (R) permission when INST = 0. 0 = No Supervisor mode Execute/ Read permission 1 = Supervisor mode has Execute/ Read permission
24	IOVR	Cache-Inhibit attribute OverrideDetermines whether this matching entry overrides the I bit settings of other matching entries and the cache-inhibited region configuration signals 0 = No override of I attribute by entry 1 = Entry I bit overrides I attribute

Table continues on the next page...

Table 8-43. MAS0—MPU Read/Write and Replacement Control (continued)

Bit	Name	Comments, or Function when Set
25	GOVR/—	G attribute Override Determines whether this entry overrides the G bit settings of other matching entries and the Guarded region configuration signals This bit is not implemented in dedicated instruction entries, and is ignored in shared entries with INST = 1. 0 = No override of G attribute by entry 1 = Entry G bit overrides G attribute
26	—	Reserved
27	—	Reserved
28	I	Cache Inhibited This attribute may be overridden by the cache-inhibited region configuration input settings. 0 = This region is considered cacheable 1 = This region is considered cache-inhibited
29	—	Reserved
30	G/—	Guarded This attribute may be overridden by the guarded region configuration input settings.This bit is not implemented in dedicated instruction entries, and is ignored in shared entries with INST = 1. 0 = Accesses to this region are not guarded, and can be performed before it is known if they are required by the sequential execution model 1 = All loads and stores to this region are performed without speculation (i.e. they are known to be required)
31	—	Reserved

The MAS1 register is shown in Figure 8-20. Fields are defined in Table 8-44.

0	TID	0	TIDMSK

8.9.10 MAS Registers Summary

The MAS registers are summarized in the following figure.

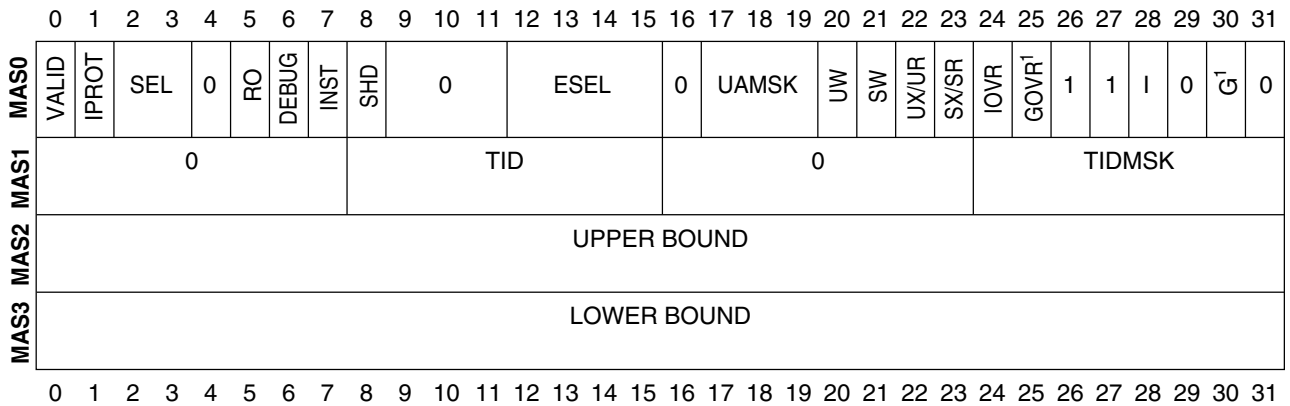

Figure 8-23. MPU Assist Registers Summary

Note

[1] This bit is not implemented in dedicated instruction entries, and is ignored in shared entries with INST = 1

8.10 Local memories

8.10.1 Local Instruction and Data Memory Overview

In order to provide for low latency memory access for critical instruction routines and data operands, local instruction (IMEM) and data (DMEM) memory capabilities have been added. This provides low latency access (zero wait-states) similar to an instruction or data cache, but does not suffer from the overhead of cache miss or cache writethrough operations. Instead, it provides a large-capacity, "tightly coupled" storage capability.

The IMEM and DMEM provide a dedicated port to the CPU's instruction fetch unit and load/store unit respectively. Access via this port is refered to as "frontdoor" access. Each local memory occupies a portion of the address space of the processor, and is conditionally accessed in parallel with the corresponding cache (if present) when a CPU request is made, based on an address decode comparison early in the access pipeline.

In addition to the CPU port, a shared slave port is provided to each local memory to allow external access. Access via this port is refered to as "backdoor" access. This slave port is implemented as an AHB 2.v6 slave interface. External masters use this port to access information from the IMEM and DMEM. The slave port accesses are arbitrated with the CPU port in a round-robin fashion, such that starvation is precluded from occurring on either port.

IMEM frontdoor accesses are always expected during instruction fetches from this local memory. However, when AHB Masters execute read/write accesses from/to IMEM, backdoor AHB slave accesses are expected.

NOTE

DMEM, by default, is always accessed through the frontdoor CPU interface, regardless of whether the program uses Decorated Access, Non-decorated Cache Bypass, Atomic Load and Reserve instructions, as well as regular load/store instructions (stw, lwz, for example). The only exception would be when the Core's DMEMCTL0 register is set to bypass the type of DMEM access used onto AHB backdoor slave interface. When regular load/store instructions are used, they will always access DMEM through the frontdoor CPU interface since no bypass control is available for these kinds of instructions.

8.10.2 Local memory control and configuration

DMEM and IMEM local memory configuration information is provided by a set of privileged read-only SPRs that are accessed using **mfspr** instructions. DMEM and IMEM local memory operation is controlled by a set of privileged device control registers

(DCRs) that are accessed using the **mfdcr** and **mtdcr** instructions. These registers and a description of the operation of various features are described in the following subsections.

8.10.2.1 DMEM Configuration Register 0 (DMEMCFG0)

The DMEM Configuration Register 0 (DMEMCFG0) is a 32-bit read-only register. DMEMCFG0 provides information about the configuration of the e200z425n3 local data memory design. The contents of the DMEMCFG0 register can be read using a **mfspr** instruction. The SPR number for DMEMCFG0 is 694 in decimal. The DMEMCFG0 register is shown in the following figure.

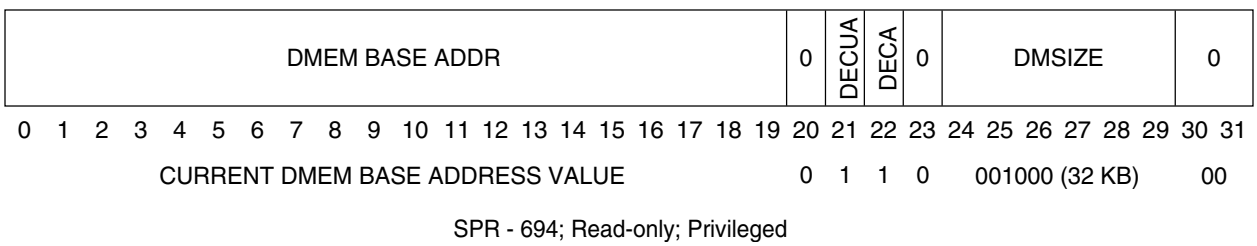

Figure 8-24. DMEM Configuration Register 0 (DMEMCFG0)

The DMEMCFG0 fields are described in the following table.

Table 8-47. DMEMCFG0 field descriptions

Bits	Name	Description
0:19	DMEM BASE ADDR	DMEM BASE ADDRESS (CPU Port) This field defines the current Base Address value being used for the CPU port to the DMEM. This field reflects the value of the external DMEM base address port inputs when the external base address port inputs are enabled via the DBAPD control bit, or the value of the BASE ADDRESS field of DMEMCTL0 when the external base address port inputs are disabled via the DBAPD control bit. **Note:** Low order bits of this field are driven to 0s when the DMEM size is > 4 KB
20	—	Reserved
21	DECUA	DMEM Error Correction Update Available DECUA indicates an error scrubbing function for the DMEM is available. 0 Error Correction Update is not available. 1 Error Correction Update is available for correction of a correctable single-bit error detected on a read access.
22	DECA	DMEM Error Correction Available DECA indicates an error correction function for the DMEM is available. 0 Error Correction is not available. 1 Error Correction is available.
23	—	Reserved

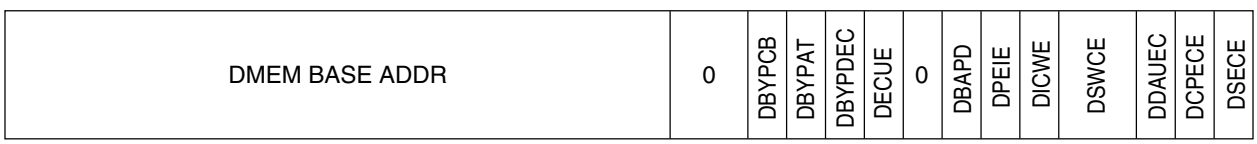

Table continues on the next page...

Table 8-47. DMEMCFG0 field descriptions (continued)

Bits	Name	Description
24:29	DMSIZE	DMEM Size 001000 The size of the DMEM is 32 KB.
30:31	—	Reserved

8.10.2.2 DMEM Control Register 0 (DMEMCTL0)

The DMEM Control Register 0 (DMEMCTL0) controls operation of certain functions of the DMEM logic.

DCR - 496; Read/Write; Reset - 19‘b0 || p_dmem_rstcfg[8,6:7,0] || 4‘b0 || p_dmem_rstcfg[1:5]; Privileged

Figure 8-25. DMEM Control Register 0 (DMEMCTL0)

Table 8-48. DMEMCTL0 field descriptions

Bits	Name	Description
0:16	DMEM BASEADDR	DMEM BASE ADDRESS Field (CPU Port) This field defines the Base Address used for the CPU port to the DMEM when the external base address port inputs are disabled via the DBAPD control bit.
17:18	—	Reserved
19	DBYPCB	DMEM Bypass Cache Bypass CPU accesses DBYPCB can be used to force Non-decorated Cache Bypass loads and Store with Writethrough (**lbcbx**, **lhcbx**, **lwcbx**, and **stwwtx**, **sthwtx**, **stbwtx**) accesses that target the DMEM address space to be presented to the external bus. Note that the protection settings in DMEMCTL1 are still applied to these accesses. 0 Non-decorated Cache Bypass loads and Store with Writethrough CPU accesses do not bypass the DMEM CPU port. 1 Non-decorated Cache Bypass loads and Store with Writethrough CPU accesses bypass the DMEM CPU port and are routed out through the BIU to the DAHB external interface.

Table continues on the next page...

Table 8-48. DMEMCTL0 field descriptions (continued)

Bits	Name	Description
20	DBYPAT	DMEM Bypass Atomic CPU accesses DBYPAT can be used to force atomic (load and reserve, store conditional) accesses to the DMEM address space to be presented to external reservation hardware in systems that support reservation and/or decoration functionality, since no internal reservation hardware is present in the CPU for the DMEM. In general, software must not rely on normal CPU write accesses to clear a reservation, since they are not monitored by reservation hardware; instead only store conditional accesses should be used for this purpose. Note that the protection settings in DMEMCTL1 are still applied to these accesses. 0 Atomic CPU accesses do not bypass the DMEM CPU port. 1 Atomic CPU accesses bypass the DMEM CPU port and are routed out through the BIU to the DAHB external interface.
21	DBYPDEC	DMEM Bypass Decorated CPU accesses DBYPDEC can be used to force decorated accesses (**lbdx, lhdx, lwdx, lbdcbx, lhdcbx, lwdcbx, stbdx, sthdx, stwdx, stbdcbx, sthdcbx, stwdcbx, dsn, dsncb**) to the DMEM address space to be presented to external decoration hardware for systems that support this functionality, since no internal decoration hardware is present in the CPU. Note that the protection settings in DMEMCTL1 are still applied to these accesses. 0 Decorated Load and Store CPU accesses do not bypass the DMEM CPU port. 1 Decorated Load and Store CPU accesses bypass the DMEM CPU port and are routed out through the BIU to the DAHB external interface.
22	DECUE	DMEM Error Correction Update Enable DECUE can be used in conjunction with DCPECE and DSECE to provide an error scrubbing function for the DMEM. 0 Error Correction Update is disabled. 1 Error Correction Update is enabled. A correctable single-bit error detected on a read access from either the CPU or the slave port will cause the DMEM to be rewritten with the corrected data if the corresponding error checking enable bit is set (DCPECE for CPU accesses, DSECE for slave port accesses). (Write accesses perform this correction automatically during partial-width writes when error checking is enabled.)
23	—	Reserved
24	DBAPD	DMEM Base Address Port Disable This bit controls usage of the external Base Address port to define the base address of the DMEM for CPU port accesses. It has no effect on DMEM slave port accesses. 0 The external DMEM base address port is used to define the base address of the DMEM for CPU accesses. 1 The external DMEM base address port is disabled for use, and instead the BASE ADDR field value is used to define the base address of the DMEM for CPU accesses.
25	DPEIE	DMEM Processor Error Injection Enable DPEIE will cause injection of errors regardless of the setting of DCPECE, although reporting of errors to the CPU will be masked while DCPECE = 0. 0 Error Injection is disabled. 1 A double-bit error will be injected on each CPU port write into the DMEM data array by inverting the two uppermost parity check bits.

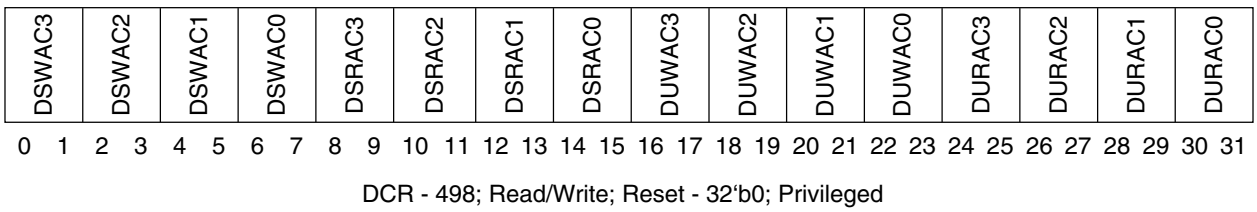

Table continues on the next page...

Table 8-48. DMEMCTL0 field descriptions (continued)

Bits	Name	Description
26	DICWE	DMEM Imprecise CPU Write Enable DICWE may allow for increased partial-width write performance when set. 0 Imprecise writes by the CPU are disabled. All partial-width write ECC errors are reported precisely (error report machine check). 1 Imprecise writes by the CPU are enabled. In certain cases, partial-width write errors may be reported imprecisely (async machine check only).
27:28	DSWCE	DMEM Slave port Write Check/Correct Enable 00 Slave write data is not checked or corrected for errors. 01 Slave write data is checked but not corrected for errors. Detected errors generate a slave port ERROR response and no Write is performed to the DMEM. 10 Slave write data is checked and corrected for errors on all writes. Single-bit correctable errors do not automatically generate an ERROR response, but are instead corrected. 11 Slave write data is checked and corrected for errors on partial-width (1, 2, 3, 5, 6, or 7 byte, or misaligned 4-byte writes) writes. Single-bit correctable errors on partial-width writes do not automatically generate an ERROR response, but are instead corrected. Aligned word or doubleword writes are not checked or corrected for errors.
29	DDAUEC	DMEM Disable Address Use in Error Check This bit controls usage of the address portion of the ECC H matrix. When use is disabled, the address portions are not used for checkbit/syndrome generation for DMEM CPU or slave port accesses. 0 Use of access address is enabled in checkbit and syndrome generation. 1 Use of access address is disabled in checkbit and syndrome generation.
30	DCPECE	DMEM CPU Port ECC Enable (CPU port) 0 End-to-End ECC is disabled for the CPU interface. No checking of read data is performed by the CPU. Writes will still generate the proper check bit values to be written. 1 End-to-End ECC is enabled for performing ECC on the CPU interface. Error checking of read data is performed with single-bit error correction. Detection of uncorrectable single- or multi-bit errors on a CPU port access cause a machine check to be generated.
31	DSECE	DMEM Slave port Error Checking Enable (Slave port) 0 End-to-End ECC checking logic is disabled for the Slave interface. No checking of read data is performed during read-modify-write operations for Slave port partial-width writes. Writes will still generate the proper check bit values to be written. 1 End-to-End ECC is enabled for performing ECC on the Slave Port interface. Error checking of read data is performed with single-bit error correction during read-modify-write operations for partial-width writes. Detection of uncorrectable single- or multi-bit errors on a Slave port partial-width write access causes a bus error ERROR response to be generated.

8.10.2.3 DMEM Control Register 1 (DMEMCTL1)

The DMEM Control Register 1 (DMEMCTL1) provides protection functions for the DMEM. Separate Supervisor-mode and User-mode read and write access controls allow accesses to be granted, denied, or conditionally granted independently for four equally sized blocks of DMEM. Conditional granting of access permissions causes the MPU memory protection functions to be employed. All other settings override MPU settings. The DMEMCTL1 settings are applied to all accesses that target DMEM address range, regardless of whether access may bypass the DMEM based on settings in DMEMCTL0$_{DBYPCB, DBYPATF, DBYPDEC}$.

A single control field is used for each access based on the upper two address bits used to index into the IMEM. IUXAC0 is used when these two bits = 2'b00

8.11 End-to-End ECC Support

This section describes end-to-end error detection and correction capability (e2eECC) enhancements to address additional diagnostic capabilities for the next generation of embedded designs.

8.11.1 End-to-End ECC control and configuration

e2eECC is controlled by a set of privileged device control registers (DCRs) accessed using the **mfdcr** and **mtdcr** instructions. These registers and the operation of various features are described in the following subsections.

8.11.1.1 End-to-End ECC Control Register 0 (E2ECTL0)

The End-to-End ECC Control Register 0 (E2ECTL0) controls operation of the e2eECC logic.

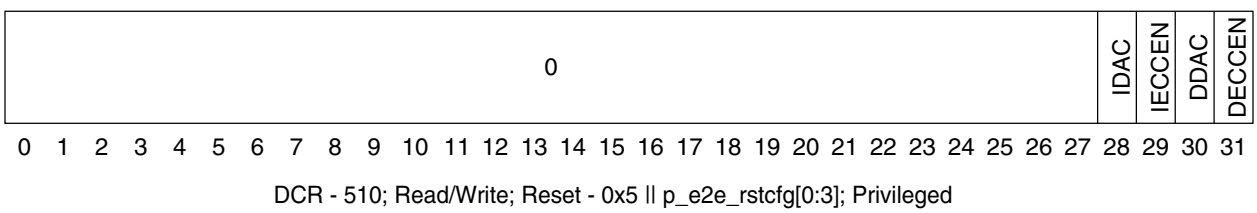

Figure 8-30. e2eECC Control Register 0 (E2ECTL0)

Table 8-53. E2ECTL0 field descriptions

Bits	Name	Description
0:27	—	Reserved
28	IDAC	Instruction Disable Address Checking This bit controls usage of the address portion of the ECC H matrix. When use is disabled, the address portion is not used for checkbit/syndrome generation for Instruction AHB accesses. 0 Use of access address is enabled in checkbit and syndrome generation. 1 Use of access address is disabled in checkbit and syndrome generation.

Table continues on the next page...

Table 8-53. E2ECTL0 field descriptions (continued)

Bits	Name	Description
29	IECCEN	Instruction ECC Enable Field 0 End-to-End ECC is disabled for the Instruction interface. No checking of instruction fetch data is performed. 1 End-to-End ECC is enabled for performing error detection and correction on the Instruction interface. Checking of instruction fetch data is performed with correction of single-bit data errors. Detection of any address errors or uncorrectable multi-bit data errors cause a machine check to be generated if the instruction fetch information is attempted to be used for instruction decoding and execution.
30	DDAC	Data Disable Address Checking This bit controls usage of the address portion of the ECC H matrix. When use is disabled, the address portion is not used for checkbit/syndrome generation for Data AHB accesses. 0 Use of access address is enabled in checkbit and syndrome generation. 1 Use of access address is disabled in checkbit and syndrome generation.
31	DECCEN	Data ECC Enable Field 0 End-to-End ECC is disabled for the Data interface. No checking of read data is performed. Writes will still generate the proper check bit values to be supplied to external storage devices. 1 End-to-End ECC is enabled for performing error detection and correction on the Data interface. Checking of read data is performed with correction of single-bit data errors. Detection of any address errors, or uncorrectable multi-bit data errors cause a machine check to be generated. Writes generate the proper check bit values to be supplied to external storage devices.

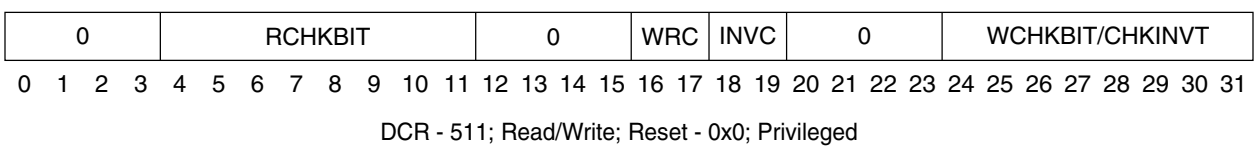
e2eECC is enabled by setting the [I,D]ECCEN bit of the E2ECTL0 DCR to a 1. On reset, e2eECC operation may be disabled from detecting or correcting errors based on reset configuration inputs, and no exceptions will be signaled for nonzero calculated syndrome values. This allows for the proper initialization of stored checkbits in any volatile storage by the CPU without causing error conditions due to uninitialized storage. Following the initialization, software may enable e2eECC operation by writing the appropriate values to the E2ECTL0[IECCEN] and E2ECTL0[DECCEN] control bits.

The $E2ECTL0_{[I,D]DAC}$ control bits can be used to remove the address checking component of the ECC logic for the Instruction AHB and Data AHB when address inclusion is not desired.

8.11.1.2 End-to-End ECC error generation by software

Error generation provides a way to test error recovery and portions of the error detection/ correction logic by intentionally injecting parity errors into the driven checkbit information on the external bus during write operations. No provision is made to generate

internal errors on read data due to timing issues; instead, software may intentionally generate errors in the checkbit values to emulate data, address, or checkbit error on external bus write cycles, and read back the written data to cause an error to be detected.



The End-to-End ECC Error Control/Status Register (E2EECSR0) controls operation of the e2eECC error injection logic. It allows for generation of a single error injection operation on the next CPU data write to the external bus only, or for a series of error injection write operations to the external bus, using the WRC and INVC control fields. The WRCHKBIT/CHKINVT field controls which of the outputs are affected.

Control is provided to allow for either inverting the value(s) of one or more of the checkbit outputs in hardware on one or more external write accesses, or for software to directly supply checkbit values to be used for the external write access(es).

The End-to-End ECC Error Control/Status Register (E2EECSR0) also supports access to raw checkbit values via the RCHKBIT status field. This field is updated with checkbit values received on each CPU data read operation to either the DMEM or to the external bus.

Note that Nexus 3 accesses do not cause error injection or the capture of read checkbits, regardless of the settings of the E2EECSR0 register.

The following figure shows the layout of E2EECSR0.

DCR - 511; Read/Write; Reset - 0x0; Privileged

Figure 8-31. e2eECC Error Control/Status Register 0 (E2EECSR0)

Table 8-54. E2EECSR0 field descriptions

Bits	Name	Description
0:3	—	Reserved
4:11	RCHKBIT	Read Checkbits This field provides the raw checkbits received on the last CPU data access to the DMEM or to external memory via the Data BIU. Software may use this information to determine the stored checkbits of external memories or the DMEM by performing CPU load operations and then accessing this field prior to the next load operation (assuming interrupts are masked).
12:15	—	Reserved

Table continues on the next page...

Table 8-54. E2EECSR0 field descriptions (continued)

Bits	Name	Description
16:17	WRC	Write Control 00 No write checkbit substitution is performed by this control bit 01 Checkbit substitution is performed for the next CPU external write access (only). Software must clear this field before rewriting to 01 in order to generate a subsequent checkbit substitution operation. 10 Checkbit substitution is performed for each CPU external write access while this field remains set to 10. This field must be cleared by software to discontinue further checkbit substitution. 11 Reserved Note: Checkbit substitution has priority over Error injection
18:19	INVC	Invert Control 00 No error injection is performed by this control bit 01 Error injection is performed for the next CPU external write access (only). Software must clear this field before rewriting to 01 in order to generate a subsequent error injection operation. 10 Error injection is performed for each CPU external write access while this field remains set to 10. This field must be cleared by software to discontinue further error generation. 11 Reserved Note: Checkbit substitution has priority over Error injection
20:23	—	Reserved
24:31	WCHKBIT/ CHKINVT	Write Checkbits / Checkbit Invert Mask This field provides the checkbit substitution values when performing checkbit substitution via the WRC control field, and controls which checkbits are inverted when performing error injection via the INVC control field. For Checkbit inversion operations via error injection: 0 Checkbit is driven normally 1 Checkbit is inverted before being driven out when error injection occurs.

Chapter 9
System Integration Unit Lite2 (SIUL2)

9.1 System Integration Unit Lite2 (SIUL2) chip-specific module information

9.1.1 SIUL2 interrupts

The SIUL2 supports 11 external interrupts on this device.

The 11 external interrupt sources are grouped into 2 sets, one with 8 sources and one with 3 sources. Each of the groups is assigned one interrupt vector and mapped to the INTC. Each external interrupt source can be masked, and its status can be read individually. Glitch filters are implemented for each external interrupt source.

9.1.2 Reset values of MIDRn

The reset value of MIDR1 is 0x5746_xxxx. The values represented by x vary by orderable part number. See the register's detailed description for the values corresponding to your part.

For the MPC5746R, the reset value of MIDR2 is 0x4000_5200. For devices in the family with different memory sizes, see the register's detailed description for the values corresponding to the device.

9.2 Introduction

9.2.1 Overview

The System Integration Unit Lite2 provides control over all the electrical pin controls and up to 32 ports with 16 bits of bidirectional, general-purpose input and output signals. One of the most important functions of the SIUL2 is that it enables the user to select the functions and electrical characteristics that appear on external device pins. It also controls the multiplexing of internal signals from one module to another and controls device I/O. It supports 11 external interrupts with trigger event configuration. The following figure is the block diagram of SIUL2 and its interfaces to other system components.

The module provides dedicated pad control to general-purpose pads that can be configured as either inputs or outputs. The SIUL2 module provides registers that enable user software to read values from GPIO pads configured as inputs, and write values to GPIO pads configured as outputs:

- When configured as output, you can write to an internal register to control the state driven on the associated output pad.
- When configured as input, you can detect the state of the associated pad by reading the value from an internal register.
- When configured as input and output, the pad value can be read back, which can be used as a method of checking if the written value appeared on the pad.

To assist software development, GPIO data registers can be accessed using various mechanisms. These differing mechanisms allow support for port access or for bit manipulation without the need to use read-modify-write operations or access with Power Architecture reservation.

- Access to two 16-bit ports in one access
- Read/write access to a single bit
- A 16-bit port write with a bit mask, using single 32-bit access.

The external interrupt sources can be configured at the MCU level to be used with any chip pad. The 11 interrupt sources can be configured to have a digital filter to reject short glitches on the inputs. The external interrupt/DMA requests map to the REQ pins in the device packages.

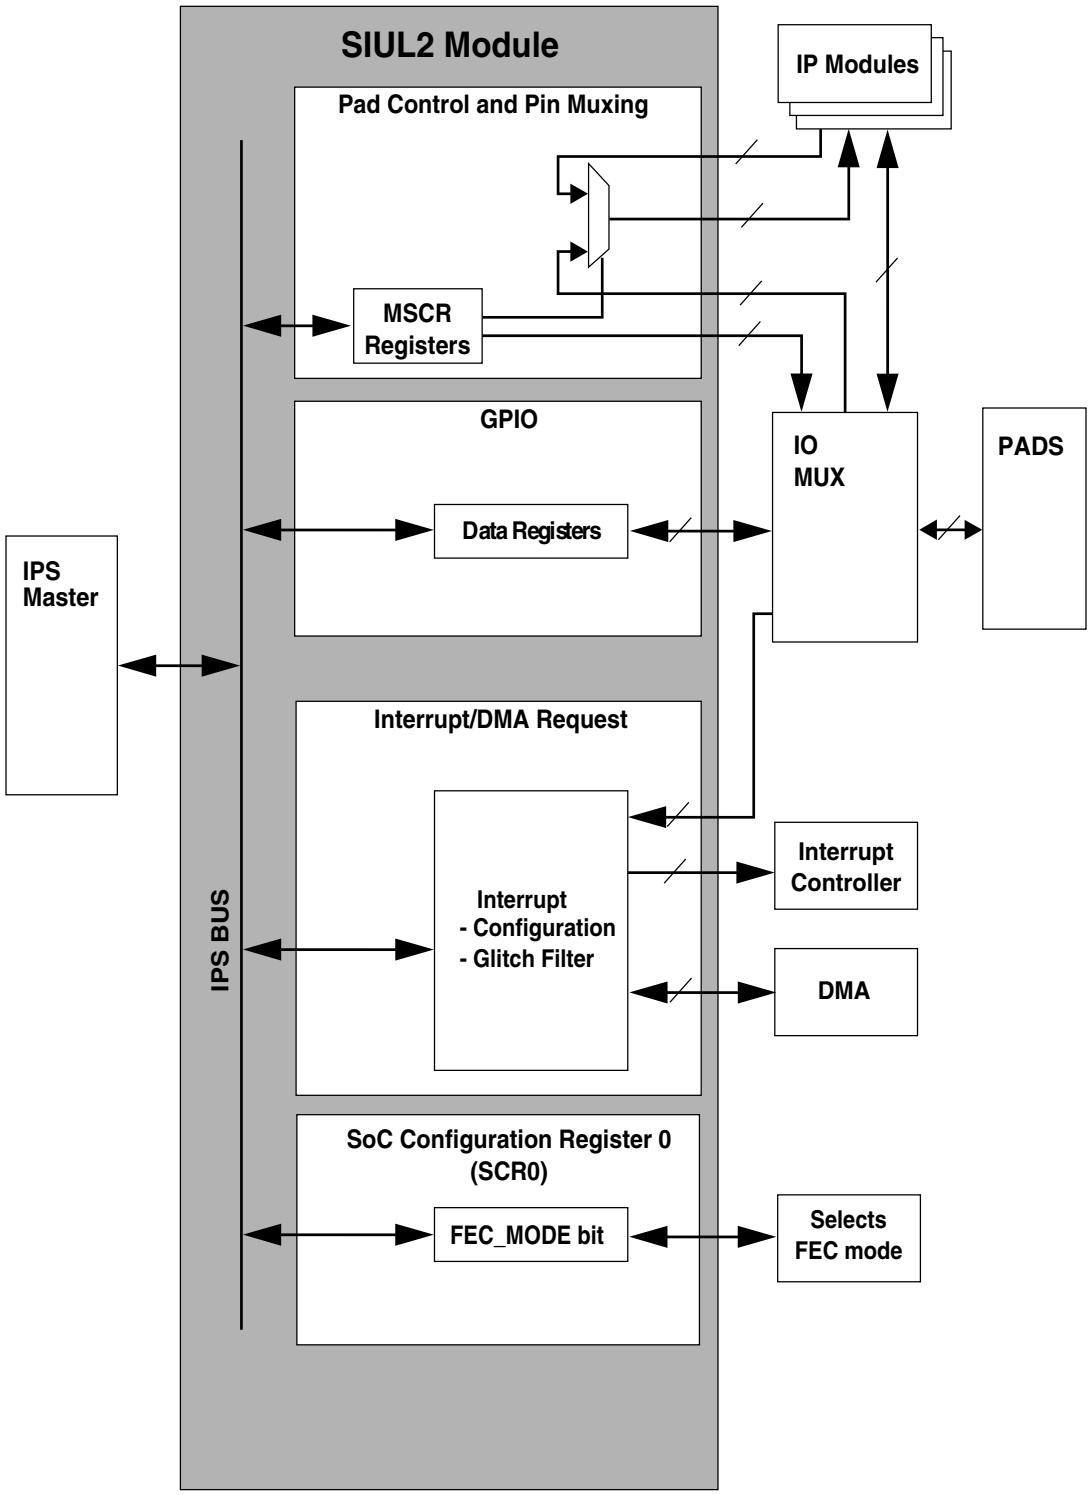


Figure 9-1. System Integration Unit Lite2 block diagram

9.2.2 Features

The SIUL2 supports the following features:

- 1 to 32 GPIO ports with data control
  - Drive data to as many as 16 independent I/O channels
  - Sample data from as many as 16 independent I/O channels

Two 16-bit registers can be read/written with one access for a 32-bit port, if needed.

External interrupt/DMA request support with:

- Two interrupt vectors for 11 interrupt sources with independent interrupt masks
- 11 programmable digital glitch filters, one for each REQ pin
- 8 DMA request channels for 8 REQ pins
- Edge detection

NOTE

SIUL2 supports 11 interrupt requests and 8 DMA requests. The 8 DMA request corresponds to REQ 0 - REQ 7 which are controlled by bits DIRSR0-DIRSR7 in register SIUL2 DMA/ Interrupt Request Select Register(SIUL2_DIRSR0).

Additionally the SIUL2 contains the Multiplexed Signal Configuration Registers that configure the electrical parameters and settings for 180 functional pads. The number of these registers that is actually implemented varies by device. These registers configure the following pad features:

- Drive strength
- Output impedance control
- Open drain/source output enable
- Slew rate control
- Hysteresis control
- Internal weak pull control and pull selection
- Pin function assignment
- Control of analog path switches
- Safe mode behavior configuration

9.2.3 Register protection

The System Integration Unit Lite2 uses the Register Protection Scheme to protect the individual registers from accidental writes. The following registers can be protected:

- SIUL2 DMA/Interrupt Request Enable Register 0 (SIUL2_DIRER0)
- SIUL2 DMA/Interrupt Request Select Register 0 (SIUL2_DIRSR0)
- SIUL2 Interrupt Rising-Edge Event Enable Register 0 (SIUL2_IREER0)
- SIUL2 Interrupt Falling-Edge Event Enable Register 0 (SIUL2_IFEER0)
- SIUL2 Interrupt Filter Enable Register 0 (SIUL2_IFER0)
- SIUL2 Interrupt Filter Maximum Counter Register (SIUL2_IFMCR0 to SIUL2_IFMCR31)
- SIUL2 Interrupt Filter Clock Prescaler Register (SIUL2_IFCPR)
- SIUL2 Multiplexed Single Configuration Register (SIUL2_MSCR0 to SIUL2_MSCR1023): Only the specific MSCRs that are actually implemented on a device are protected.

The Register Protection chapter provides a complete list of protected registers for this device.

9.3 Memory map and register description

This section provides a detailed description of all registers accessible in the SIUL2 module in address order. Each description includes a standard register diagram. Details of register bit and field function follow the register diagrams, in bit order.

The following table lists the implemented SIUL2 registers.

NOTE

Undocumented register spaces in the SIUL2 memory map, including addresses shown as "blank," are reserved. Reserved registers read as 0, and writes to these registers have no effect. Transfer errors are generated for attempts to access a completely reserved register space.

9.3.1 Memory map

Table 9-1. SIUL2 memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value
4	SIUL2 MCU ID Register #1 (SIUL2_MIDR1)	32	R	See section

17BC	SIUL2 Masked Parallel GPIO Pad Data Out Register (SIUL2_MPGPDO15)	32	W	0000_0000h

The following table lists the implemented SIUL2 registers.

NOTE

Undocumented register spaces in the SIUL2 memory map, including addresses shown as "blank," are reserved. Reserved registers read as 0, and writes to these registers have no effect. Transfer errors are generated for attempts to access a completely reserved register space.

9.3.2 SIUL2 MCU ID Register #1 (SIUL2_MIDR1)

This register holds identification information about the device.

NOTE

This register supports only 32-bit accesses. Byte and half-word write accesses are not supported.

NOTE

The reset value depends on the chip's package and mask version.

Address: 0h base + 4h offset = 4h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	PARTNUM															
W																
Reset	0	1	0	1	0	1	1	1	0	1	0	0	0	1	1	0

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	ED	PKG					0		MAJOR_MASK				MINOR_MASK			
W																
Reset	0	*	*	*	*	*	0	0	*	*	*	*	*	*	*	*

* Notes:
- MINOR_MASK field: Value is set at the factory and increments with each revision of the device.
- MAJOR_MASK field: Value is set at factory and increments with each revision of the device.
- PKG field: Values are set at factory and cannot be modified.

SIUL2_MIDR1 field descriptions

Field	Description
0–15 PARTNUM	MCU Part Number 0x5746 0x5745 0x5743 0x5742 For the full part number, this field must be combined with MIDR2.PARTNUM[23:16]
16 ED	Always reads 0 in the Production Device. This bit will be set when the Production Device is packaged with a Buddy Die in the Emulation Device.
17–21 PKG	Package Settings Can by read by software to determine the package type that is used for the particular device: 0b01000: 292-ball BGA 0b01101: 144-pin LQFP 0b01110: 252-pin BGA 0b10001: 176-pin LQFP All other bit combinations are reserved.
22–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

SIUL2_MIDR1 field descriptions (continued)

Field	Description
24–27 MAJOR_MASK	Major Mask Revision. 0x1 for Cut2.0B of this device.
28–31 MINOR_MASK	Minor Mask Revision. 0x1 for Cut2.0B of this device.

9.3.3 SIUL2 MCU ID Register #2 (SIUL2_MIDR2)

NOTE

This register supports only 32-bit accesses. Byte and half-word write accesses are not supported.

Address: 0h base + 8h offset = 8h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	SF	FLASH_SIZE_1				FLASH_SIZE_2				0						
W																
Reset	0	*	*	*	*	*	*	*	*	0	0	0	0	0	0	0

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	PARTNUM								0							
W																
Reset	*	*	*	*	*	*	*	*	0	0	0	0	0	0	0	0

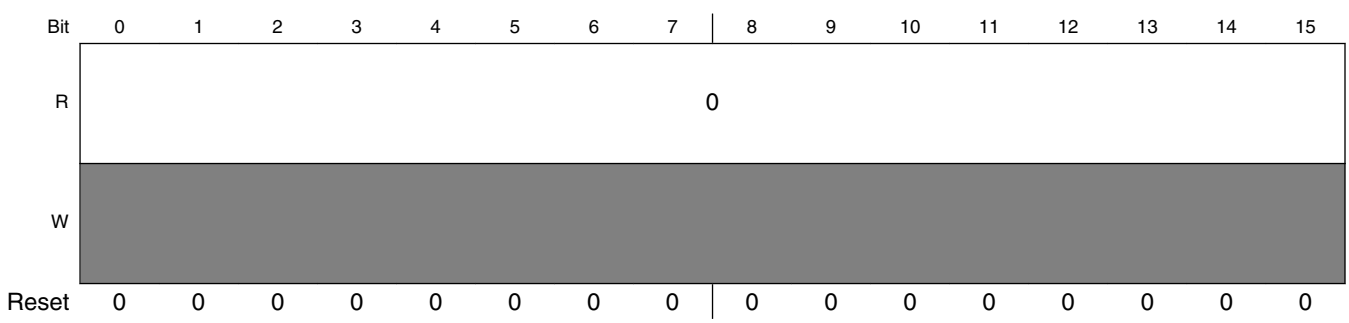
* Notes:
- PARTNUM field: Value is set at factory and cannot be changed.
- FLASH_SIZE_2 field: Value is set at factory and cannot be changed.
- FLASH_SIZE_1 field: Value is set at factory and cannot be changed.

SIUL2_MIDR2 field descriptions

Field	Description
0 SF	Manufacturer 0 Freescale Semiconductor, Inc. 1 Reserved
1–4 FLASH_SIZE_1	Coarse granularity for flash memory size Needs to be combined with FLASH_SIZE_2 to calculate the actual memory size of 4 MB. 0b0110: 1 MB 0b0111: 2 MB 0b1000: 4 MB All other values are reserved.

Table continues on the next page...

SIUL2_MIDR2 field descriptions (continued)



Field	Description
5–8 FLASH_SIZE_2	Fine granularity for flash memory size Needs to be combined with FLASH_SIZE_1 to calculate the actual memory size: 0b0000: 0 x (FLASH_SIZE_1 / 8) 0b0100: 4 x (FLASH_SIZE_1 / 8) All other values are reserved.
9–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–23 PARTNUM	ASCII character in MCU Part Number 0x52 R All other values are reserved.
24–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

9.3.4 SIUL2 DMA/Interrupt Status Flag Register0 (SIUL2_DISR0)

The DMA/Interrupt Status Register contains flag bits that record an event on the external IRQ pins. When an event as defined in IRQ Rising-Edge Event Enable Register (SIUL2_IREER0) and IRQ Falling-Edge Event Enable Register (SIUL2_IFEER0) occurs, the corresponding flag bit is set. The IRQ Flag bit is set regardless of the state of the corresponding DMA/Interrupt Request Enable bit in DMA/Interrupt Request Enable Register (SIUL2_DIRER0) - Standard. The IRQ Flag bit remains set until cleared by software or through the servicing of a DMA request. The IRQ Flag bits are cleared by writing a '1' to the bits. A write of '0' has no effect. The number of bits implemented is specified by the parameter that defines the number external IRQ pins.

This register supports 8-, 16-, and 32-bit accesses.

Address: 0h base + 10h offset = 10h

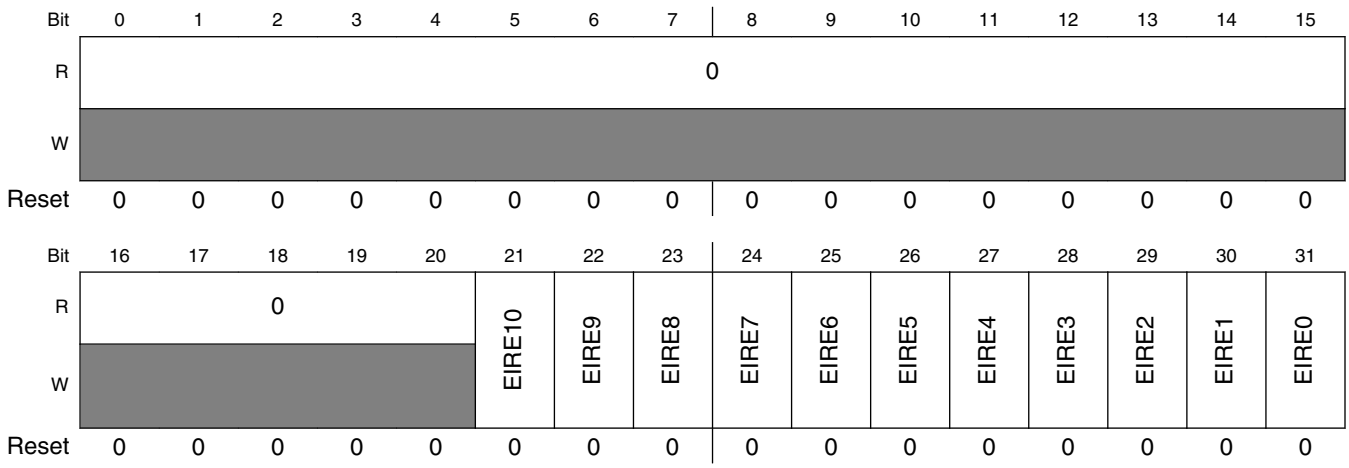
Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0					EIF10	EIF9	EIF8	EIF7	EIF6	EIF5	EIF4	EIF3	EIF2	EIF1	EIF0
W						w1c	w1c	w1c	w1c	w1c	w1c	w1c	w1c	w1c	w1c	w1c
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SIUL2_DISR0 field descriptions

Field	Description
0–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21 EIF10	External Interrupt Status Flag 10 This flag can be cleared only by writing 1. Writing 0 has no effect. If enabled (SIUL2_DIRER10), EIF10 causes an interrupt or DMA request. 0 No interrupt or DMA event has occurred on the pad 1 An interrupt or DMA event as defined by SIUL2_IREER10 and SIUL2_IFEER10 has occurred
22 EIF9	External Interrupt Status Flag 9 This flag can be cleared only by writing 1. Writing 0 has no effect. If enabled (SIUL2_DIRER9), EIF9 causes an interrupt or DMA request. 0 No interrupt or DMA event has occurred on the pad 1 An interrupt or DMA event as defined by SIUL2_IREER9 and SIUL2_IFEER9 has occurred
23 EIF8	External Interrupt Status Flag 8 This flag can be cleared only by writing 1. Writing 0 has no effect. If enabled (SIUL2_DIRER8), EIF8 causes an interrupt or DMA request. 0 No interrupt or DMA event has occurred on the pad 1 An interrupt or DMA event as defined by SIUL2_IREER8 and SIUL2_IFEER8 has occurred
24 EIF7	External Interrupt Status Flag 7 This flag can be cleared only by writing 1. Writing 0 has no effect. If enabled (SIUL2_DIRER7), EIF7 causes an interrupt or DMA request. 0 No interrupt or DMA event has occurred on the pad 1 An interrupt or DMA event as defined by SIUL2_IREER7 and SIUL2_IFEER7 has occurred
25 EIF6	External Interrupt Status Flag 6 This flag can be cleared only by writing 1. Writing 0 has no effect. If enabled (SIUL2_DIRER6), EIF6 causes an interrupt or DMA request. 0 No interrupt or DMA event has occurred on the pad 1 An interrupt or DMA event as defined by SIUL2_IREER6 and SIUL2_IFEER6 has occurred
26 EIF5	External Interrupt Status Flag 5 This flag can be cleared only by writing 1. Writing 0 has no effect. If enabled (SIUL2_DIRER5), EIF5 causes an interrupt or DMA request.

Table continues on the next page...

SIUL2_DISR0 field descriptions (continued)



Field	Description
	0 No interrupt or DMA event has occurred on the pad 1 An interrupt or DMA event as defined by SIUL2_IREER5 and SIUL2_IFEER5 has occurred
27 EIF4	External Interrupt Status Flag 4 This flag can be cleared only by writing 1. Writing 0 has no effect. If enabled (SIUL2_DIRER4), EIF4 causes an interrupt or DMA request. 0 No interrupt or DMA event has occurred on the pad 1 An interrupt or DMA event as defined by SIUL2_IREER4 and SIUL2_IFEER4 has occurred
28 EIF3	External Interrupt Status Flag 3 This flag can be cleared only by writing 1. Writing 0 has no effect. If enabled (SIUL2_DIRER3), EIF3 causes an interrupt or DMA request. 0 No interrupt or DMA event has occurred on the pad 1 An interrupt or DMA event as defined by SIUL2_IREER3 and SIUL2_IFEER3 has occurred
29 EIF2	External Interrupt Status Flag 2 This flag can be cleared only by writing 1. Writing 0 has no effect. If enabled (SIUL2_DIRER2), EIF2 causes an interrupt or DMA request. 0 No interrupt or DMA event has occurred on the pad 1 An interrupt or DMA event as defined by SIUL2_IREER2 and SIUL2_IFEER2 has occurred
30 EIF1	External Interrupt Status Flag 1 This flag can be cleared only by writing 1. Writing 0 has no effect. If enabled (SIUL2_DIRER1), EIF1 causes an interrupt or DMA request. 0 No interrupt or DMA event has occurred on the pad 1 An interrupt or DMA event as defined by SIUL2_IREER1 and SIUL2_IFEER1 has occurred
31 EIF0	External Interrupt Status Flag 0 This flag can be cleared only by writing 1. Writing 0 has no effect. If enabled (SIUL2_DIRER0), EIF0 causes an interrupt or DMA request. 0 No interrupt or DMA event has occurred on the pad 1 An interrupt or DMA event as defined by SIUL2_IREER0 and SIUL2_IFEER0 has occurred

9.3.5 SIUL2 DMA/Interrupt Request Enable Register0 (SIUL2_DIRER0)

The DMA/Interrupt Request Enable Register enables the assertion of DMA or interrupt request if the corresponding External IRQ Flag bit is set in SIUL2 DMA/Interrupt Status Flag Register0 (SIUL2_DISR0). The type of request enabled is determined by the corresponding DMA/Interrupt Request Select bit in SIUL2 DMA/Interrupt Request Select Register0 (SIUL2_DIRSR0). The number of bits implemented is specified by the parameter that defines the number of external IRQ pins. This register is used to enable the interrupt messaging to the interrupt controller.

This register supports 8-, 16-, and 32-bit accesses.

Address: 0h base + 18h offset = 18h

28 EIRE3	External Interrupt or DMA Request Enable 3

Table continues on the next page...

SIUL2_DIRER0 field descriptions (continued)

Field	Description
	0 Interrupt or DMA requests from the corresponding EIF[x] bit are disabled 1 Set EIF[x] bit causes either a DMA or an interrupt request depending on DIRSR register
29 EIRE2	External Interrupt or DMA Request Enable 2 0 Interrupt or DMA requests from the corresponding EIF[x] bit are disabled 1 Set EIF[x] bit causes either a DMA or an interrupt request depending on DIRSR register
30 EIRE1	External Interrupt or DMA Request Enable 1 0 Interrupt or DMA requests from the corresponding EIF[x] bit are disabled 1 Set EIF[x] bit causes either a DMA or an interrupt request depending on DIRSR register
31 EIRE0	External Interrupt or DMA Request Enable 0 0 Interrupt or DMA requests from the corresponding EIF[x] bit are disabled 1 Set EIF[x] bit causes either a DMA or an interrupt request depending on DIRSR register

9.3.6 SIUL2 DMA/Interrupt Request Select Register0 (SIUL2_DIRSR0)

The DIRSR selects between the DMA or interrupt request. If the corresponding bits are set in SIUL2 DMA/Interrupt Status Flag Register0 (SIUL2_DISR0) and SIUL2 DMA/Interrupt Request Select Register0 (SIUL2_DIRSR0), then the DMA/Interrupt Request Select bit determines whether DMA or a interrupt request is asserted. The number of bits implemented is specified by the parameter that defines the number of DMA request outputs.

This register supports 8-, 16-, and 32-bit accesses.

Address: 0h base + 20h offset = 20h

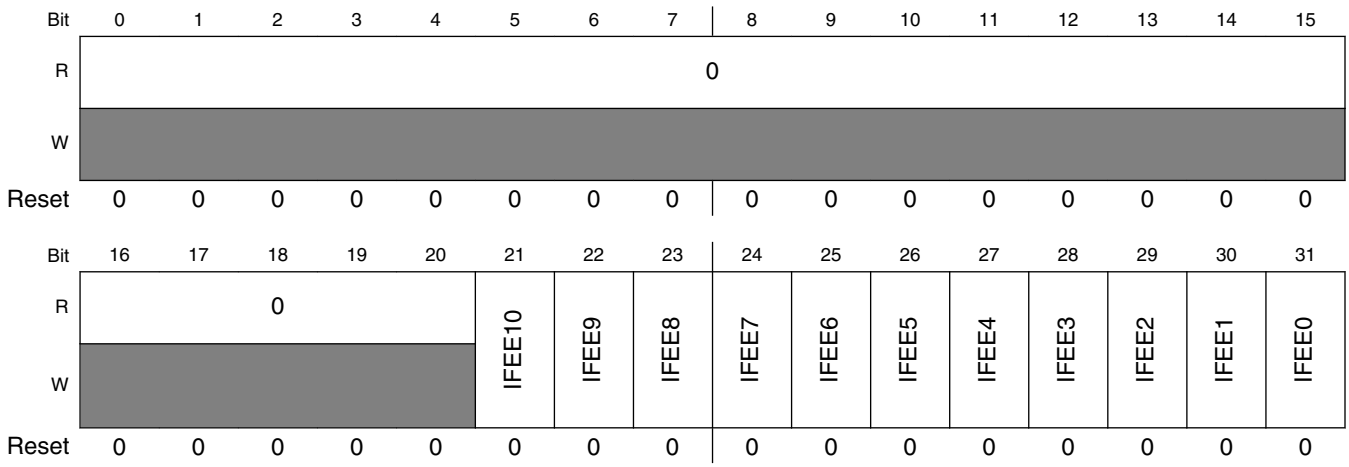
29 IREE2	Enable rising-edge events to cause the EIF2 bit to be set. 0 Rising-edge event is disabled 1 Rising-edge event is enabled
30 IREE1	Enable rising-edge events to cause the EIF1 bit to be set. 0 Rising-edge event is disabled 1 Rising-edge event is enabled
31 IREE0	Enable rising-edge events to cause the EIF0 bit to be set. 0 Rising-edge event is disabled 1 Rising-edge event is enabled

9.3.8 SIUL2 Interrupt Falling-Edge Event Enable Register 0 (SIUL2_IFEER0)



This register is used to enable falling-edge triggered events on the corresponding interrupt pads.

This register supports 8-, 16-, and 32-bit accesses.

NOTE

If both the IREE and the IFEE bits are cleared for the same interrupt source, the interrupt status flag for the corresponding external interrupt will never be set.

Address: 0h base + 30h offset = 30h

31 IFE0	Enable digital glitch filter on the interrupt pad input. 0 Filter is disabled 1 Filter is enabled

9.3.10 SIUL2 Interrupt Filter Maximum Counter Register (SIUL2_IFMCR*n*)

These registers are used to configure the filter counter associated with each digital glitch filter.

NOTE

This register supports only 32-bit accesses. Byte and half-word write accesses are not supported.

Address: 0h base + 40h offset + (4d × i), where i=0d to 31d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

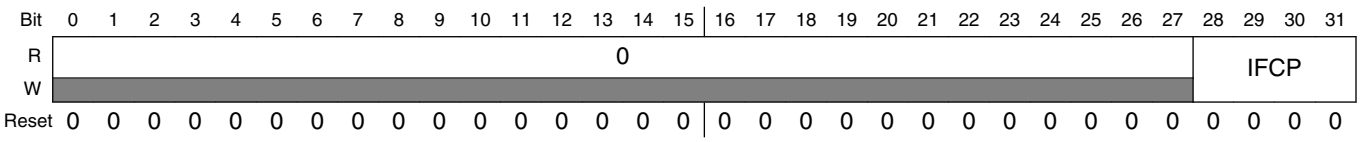
SIUL2_IFMCR*n* field descriptions

Field	Description
0–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28–31 MAXCNT	Maximum Interrupt Filter Counter setting MAXCNT can be 0d to 15d. • For a MAXCNT value of 0d, 1d, or 2d, the filter behaves as an ALL PASS filter. • For a MAXCNT value of 3d to 15d, the filter period is TCK*MAXCNT+n*TCK, where n is 0, 1, 2, 3, or 4. TCK is the prescaled filter clock period, which is the IRC clock prescaled to the IFCP value, which is specified in SIUL2_IFCPR. TIRC is the basic filter clock period: 62.5 ns (f = 16 MHz). **NOTE:** The filter delay is 2 TCK clock cycles more than the filter period. In general, TFILTER and TDELAY are not integer multiples of TCK because DIN is asynchronous whereas DOUT is synchronous with respect to the CK clock. The factor n accounts for this uncertainty in filter period calculation.



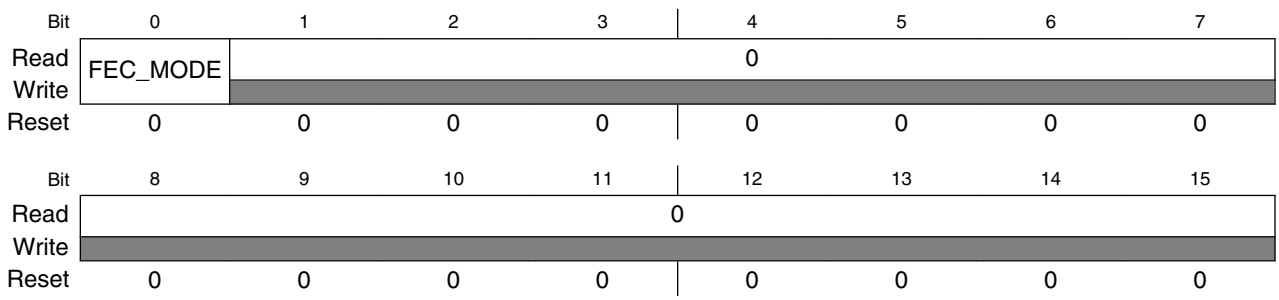
9.3.11 SIUL2 Interrupt Filter Clock Prescaler Register (SIUL2_IFCPR)

This register is used to configure a clock prescaler that selects the clock for all digital filters. A prescaler is applied to the input clock to the SIUL2, which is the system AIPS clock counter in the SIUL2.

NOTE

This register supports only 32-bit accesses. Byte and half-word write accesses are not supported.

Address: 0h base + C0h offset = C0h



SIUL2_IFCPR field descriptions

Field	Description
0–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28–31 IFCP	Interrupt Filter Clock Prescaler setting Prescaled Filter Clock Period = T(IRC) x (IFCP + 1) T(IRC) is the internal oscillator period. IFCP can be 0 to 15

9.3.12 SoC Configuration Register 0 (SIUL2_SCR0*n*)

This register allows selecting between the Media Independent Interface (MII) and the Reduced Media Independent Interface (RMII) mode for the Fast Ethernet Controller (FEC).

Address: 0h base + 100h offset + (1d × i), where i=0d to 0d

SIUL2_SCR0*n* field descriptions

Field	Description
0 FEC_MODE	FEC Mode Setting 0 RMII is selected 1 MII-Lite is selected
1–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

9.3.13 SIUL2 Multiplexed Signal Configuration Register (SIUL2_MSCR*n*)

The SIUL2_MSCR*n* register selects which source signal is connected to the register's associated destination, which is one of the following:

- A chip pin can be configured as an output
- An internal module port can be configured as an input

For the associated chip-pin destination, the register also specifies the pin's electrical properties.

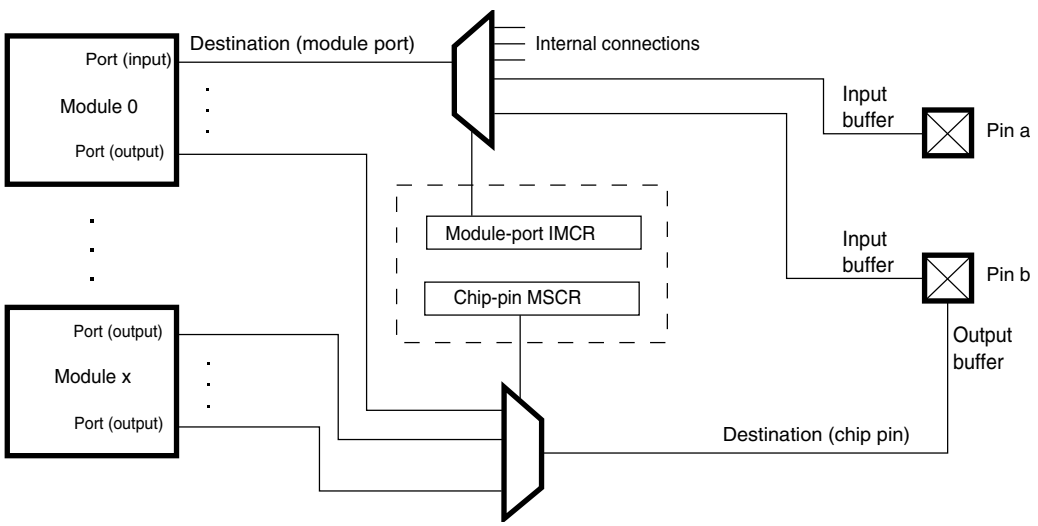


Figure 9-47. MSCR pin connection

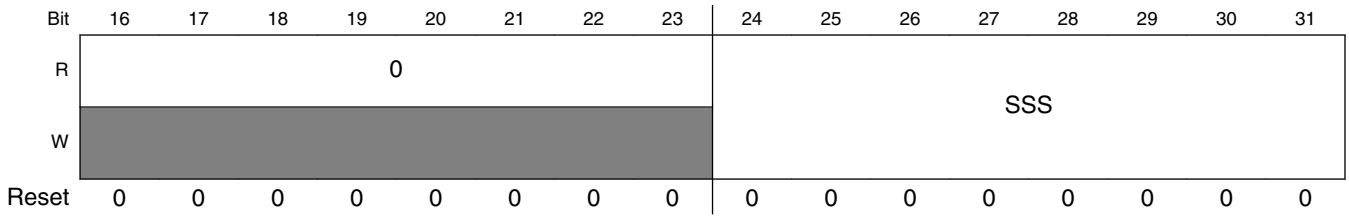

The fields in an MSCR vary depending on its associated destination (chip pin).

This register supports only 32-bit accesses. 8- and 16-bit accesses generate transfer errors.

For chip-pin MSCR assignments, pin types, APC support, and SSS values, see the pin-description table for your chip.

Address: 0h base + 240h offset + (4d × i), where i=0d to 255d

SIUL2_MSCR*n* field descriptions

Field	Description
0–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2–3 OERC	Output Edge Rate Control Specifies the drive strength and slew rate of the associated pin. Valid for pad_sr_hv pads only. 00 :Half drive strength with slew rate control 01 : Full drive strength with slew rate control 10 : Half drive strength without slew rate control 11 : Full drive strength without slew rate control Refer to table "GPIO pad output buffer electrical characteristics" in the Data Sheet for electrical characteristics corresponding to these OERC bits.
4–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6–7 ODC	Output Drive Control Used only when the associated destination is a chip pin. Specifies the type of output drive control for the associated pin. 00 Disabled (high impedance for turning off the pin or using it as an input) 01 Open-drain 10 Push-pull 11 Open-source
8 SMC	Safe Mode Control Used only when the associated destination is a chip pin. Specifies whether the chip disables the pin's output buffer when the chip enters Safe mode. 0 Disable (the output buffer returns to its previous state when the chip leaves Safe mode) 1 Don't disable
9 APC	Analog Pad Control Used only when the associated destination is a chip pin that supports analog I/O. Enables the pin's analog-input-path switch. 0 Disable (the switch is off) 1 Enable (another module can control the state of the switch)
10–11 ILS	Input Level Selection Used only when the associated destination is a chip pin. Specifies the logic family for the associated pin, which determines its logic switching levels.

Table continues on the next page...

SIUL2_MSCR*n* field descriptions (continued)

Field	Description
	NOTE: Supported input levels vary according to pad types. Pad type "pad_sr_hv" supports only the CMOS input level, while pad type "pad_isatww_st_hv" supports TTL and CMOS levels. Refer to the attached IO spreadsheet for the pad type of each pin. 00 Reserved 01 TTL 10 LVDS 11 CMOS
12 IBE	Input Buffer Enable Used only when the associated destination is a chip pin. Enables the associated pin's input buffer. 0 Disabled 1 Enabled
13 HYS	Input Hysteresis Used only when the associated destination is a chip pin. Enables input hysteresis for the associated pin. 0 Disabled 1 Enabled
14 WPDE	Weak Pulldown Enable Used only when the associated destination is a chip pin. Enables the associated pin's weak pulldown resistor. **NOTE:** If WPDE and WPUE are both set, the pull-up and pull-down are both disabled. 0 Disabled 1 Enabled
15 WPUE	Weak Pullup Enable Used only when the associated destination is a chip pin. Enables the associated pin's weak pullup resistor. For most of the pads, the WPUE reset value is 1. See the Signal Description IOMUX details for the reset values of the this bit. **NOTE:** If WPDE and WPUE are both set, the pull-up and pull-down are both disabled. 0 Disabled 1 Enabled
16–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–31 SSS	Source Signal Select Selects which source signal is connected to the associated destination (chip pin). This field has a variable width depending on the number of alternate functions available for that pin. For a chip pin, the source signals are outputs from module ports.

9.3.14 SIUL2 Input Multiplexed Signal Configuration Register (SIUL2_MSCR*n*)

This register selects which source signal is connected to the register's associated destination, which is an internal module port that can be configured as an input.

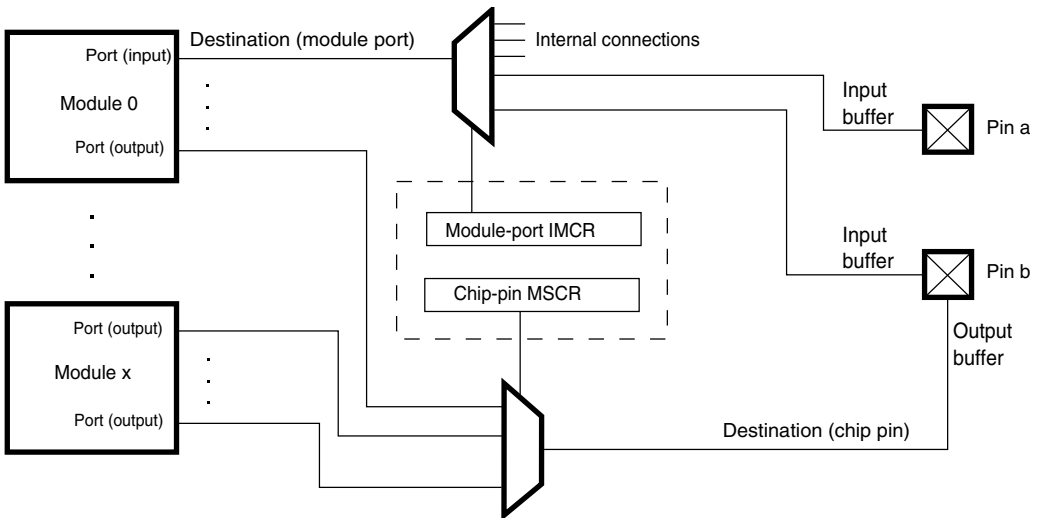

Figure 9-561. MSCR module-port connection

The fields in an MSCR vary depending on its associated destination (module port).

For MSCR assignments and SSS values, see the pin-description table.

Address: 0h base + A40h offset + (4d × i), where i=0d to 483d

7 PDI	Pad Data In This bit stores the value of the external GPIO pad associated with this register. 0 The value of the data in signal for the corresponding GPIO pad is logic low 1 The value of the data in signal for the corresponding GPIO pad is logic high

9.3.20 SIUL2 Parallel GPIO Pad Data Out Register (SIUL2_PGPDO*n*)

These registers are used to set or clear the respective pads of the device. Parallel port registers for input (PGPDI) and output (PGPDO) are provided to allow a complete port to be written or read in one operation, dependent on the individual pad configuration. The difference between PGPDO and GPDO is that PGPDO registers can be used to set the values of all output pins assigned to a device port with a single 16-bit register write vs. the GPDO registers, which are used to set the value on a specific pin with a byte write.

The SIUL2_PGPDO registers access the same physical resource as the SIUL2_PDO and SIUL2_MPGPDO address locations. Some examples of the mapping:

- PPDO[0][0] = PDO[0]
- PPDO[2][0] = PDO[32]
- PPDO[31][15] = PDO[511]

These registers support 8-, 16-, and 32-bit accesses.

Address: 0h base + 1700h offset + (2d × i), where i=0d to 15d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

SIUL2_PGPDO*n* field descriptions

Field	Description
0–15 PPDO	Parallel Pad Data Out Write or read the data register that stores the value to be driven on the pad in output mode. Access to this register location are coherent with access to the bit-wise GPIO Pad Data Output Registers (SIUL2_GPDO).The x and bit index define which PPDO register bit is equivalent to which PDO register bit according to the following equation: PPDO[x][y] = PDO[(x*16)+y]

9.3.21 SIUL2 Parallel GPIO Pad Data In Register (SIUL2_PGPDI*n*)

These registers hold the synchronized input value from the pads. Parallel port registers for input (PGPDI) and output (PGPDO) are provided to allow a complete port to be written or read in one operation, dependent on the individual pad configuration.The difference between PGPDI and GPDI registers is that PGPDI registers can be used to read the values of all input pins assigned to a device port with a single 16-bit register read vs. the GPDI registers, which are used to read the value on a specific pin with a byte read.

These registers support 8-, 16-, and 32-bit accesses.

Address: 0h base + 1740h offset + (2d × i), where i=0d to 15d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

SIUL2_PGPDI*n* field descriptions

Field	Description
0–15 PPDI	Parallel Pad Data In Reads the current pad value. Access to this register location are coherent with access to the bit-wise GPIO Pad Data Input Registers (SIUL2_GPDI). The x and bit index define which PPDI register bit is equivalent to which PDI register bit according to the following equation: PPDI[x][y] = PDI[(x*16)+y]

9.3.22 SIUL2 Masked Parallel GPIO Pad Data Out Register (SIUL2_MPGPDO*n*)

This register can be used to selectively modify the pad values associated to PPDO[x][0:15]. The MPGPDO[x] register may only be accessed with 32-bit writes. 8-bit or 16-bit writes will not modify any bits in the register and cause a transfer error response by the module. Read access will return 0.

NOTE

These registers support only 32-bit accesses. Byte and half-word write accesses are not supported.

Address: 0h base + 1780h offset + (4d × i), where i=0d to 15d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

9.4 Functional description

9.4.1 General

This section provides a complete functional description of the System Integration Unit Lite2.

9.4.2 Pad Control

The SIUL2 is capable of controlling the electrical characteristic of up to 512 pads. It provides a consistent interface for all pads, both on a by-port and a by-bit basis. The following describes the pad characteristics that can be supported by the SIUL2. Not all of these features will be supported on all devices or on all pads as this is dependent on the specific application needs an the pads implemented on the device.

The required controls are:

- Slew rate control
  - Offers improved EMC performance.
  - Support for a fast and a slow slew rate.
- Drive strength control
  - Offers improved EMC performance.
  - Up to 4 different drive strength levels can be supported.
- Pull capability

    - Offers flexibility in the device configuration and the elimination of external hardware in some cases.
    - The configuration of the pull on any pad should be independently controlled to be either pull-up, pull-down or no-pull enabled.
- Input and Output Buffer control
- Hysteresis
- Open drain
    - Needed to support different pads muxed (e.g. mux IIC, with non open drain pads)
- Pad Output Assignment
    - This setting defines which chip function has control over the output of the pad.

The setting of each pad out of reset is fixed per MCU, but can be configured individually. In this way it is possible to select special pull settings or peripheral pad ownership per design.

It is possible for the user software to configure each pad independently of all other pads on the device or other pads grouped within a single port. This allows different pad types to be grouped together in ports and allows the necessary flexibility needed for the pads individual operation. This is achieved by grouping all of the above functions into a single register for each pad on the device, and allows each pad to be configured with a single write to one register and allowing simplified duplication of software for each pad with indexed changes for each pad.

9.4.3 General Purpose Input and Output Pads (GPIO)

The SIUL2 allows each pad to be configured as either a General Purpose Input or Output pad (GPIO), and as one or more alternate functions (input or output), the function of which is determined by the peripheral that will use the pad.

GPIO pads can also optionally be implemented without any alternate function.

The SIUL2 is designed to manage as many as 512 GPIO pads organized as ports that can be recognized and addressed with read/write operations. The GPDI, GPDO, PGPDO, and PGPDI registers can be accessed with 8-, 16-, or 32-bit reads and writes. The MSCR registers can only be accessed with 32-bit reads and writes.

The SIUL2 has separate data input and data output registers for all pads, allowing the possibility of reading back an input or output value of a pad directly. This supports the ability to validate what is present on the pad rather than simply confirming the value that was written to the data register by accessing the data input registers.

The data output registers support both read and write operations to be performed.

The data input registers support read access only.

When the pad is configured to use one of its alternate functions, the data input value reflect the respective value of the pad. If a write operation is performed to the data output register for a pad configured as an alternate function (non GPIO), this write will not be reflected by the pad value until reconfigured to GPIO. All general purpose pads are implemented as bidirectional.

Note

In case the bidirectional operation impacts some performances (e.g. ADC accuracy), or is not required for a specific pad function it is acceptable to limit the functionality of some pads to "Input Only."

9.4.4 External Interrupts/DMA Requests (REQ Pins)

The SIUL2 supports 11 external interrupts, which can be allocated to the EIRQ pins.

For the assignments of the external interrupts, see the Signal Description details.

The SIUL2 supports 2 interrupt vectors, which are multiplexed to provide 3 and 8 external interrupt sources to the interrupt controller of the MCU. Each interrupt vector can support up to 8 external interrupt sources from the device pads.

All the external interrupt pads within a single group (maximum 8 pads) have equal priority. It is the responsibility of the user software to search through the group of sources in the most appropriate way for their application.

The priority of the vectors used by the external interrupt pads is fixed based on the platform and the interrupt controller and its priority levels, but the allocation of pads to each group of interrupts can be independently configured by the MCU.

The external interrupt lines can have digital glitch filters applied to them. The supported range is 1 to 32. The glitch filters need a running internal oscillator clock to work. If no such clock is available, external interrupts will be effectively disabled when the glitch filter is enabled on a interrupt line.

9.4.4.1 External interrupt initialization

When an external interrupt pin is first enabled, it is possible to get a false interrupt flag. To prevent a false interrupt request, during pin interrupt initialization, the user must do the following:

- Mask interrupts by clearing the EIREn bits in DIRER0.
- Select the pin polarity by setting the appropriate IREEn bits in IREER0 and the appropriate IFEEn bits in IFEER0 as desired.
- Configure the appropriate bits in the MSCR[0:511] register for the external interrupt pin(s) desired as follows:
  - Clear the ODC bits to disable output.
  - If using the internal weak pullup/pulldown, configure the appropriate WPUE and WPDE fields.

Note

MSCR[SSS] bits do not need to be changed for either MSCR[0:511] or IMCR[0:511] because the external interrupt pin input is directly connected to the SIUL for EIRQ pins.

External interrupt pins should never be configured as outputs (MSCR[ODC] bits are not zeros) when external interrupt inputs are desired because false interrupts could be detected (such as from a GPIO configuration).

- Select the request desired between DMA or Interrupt by writing the appropriate DIRSn bits in DIRSR0.
- Select the desired glitch filter setup for the pins by writing the following:
  - Write the Filter Counter setting to the desired value by writing the MAXCNT[3:0] bits in the IFMCn register for the respective external interrupt that is being used.
  - Set the Filter Clock Prescaler setting from 0 to 15 to the desired value by writing the IFCP[3:0] bits in the IFCPR register.
  - Enable the glitch filter for the desired external interrupt pins by setting the appropriate IFEn bits in IFER0.

- Write to EIFn bits in DISR0 to as desired to clear any flags.
- Enable the interrupt pins by setting the appropriate EIREn bits in DIREER0.

9.4.4.2 External interrupt management

The user can enable or disable each interrupt independently using a single rolled up register, SIUL2_DIRER0.

A pad defined as an external interrupt can be configured by the user to recognize interrupts with an active rising edge, an active falling edge, or both edges being active. A setting of having both edge events disabled is reserved and should not be configured. The user controls the active IRQ edge through the registers SIUL2_IREER and SIUL2_IFEER.

Each external interrupt supports an individual flag which is held in the Flag register (DISR0). This register is a clear-by-write-1 register type, preventing inadvertent overwriting of other flags in the same register.

Refer to the following figure for an overview of the external interrupt implementation.

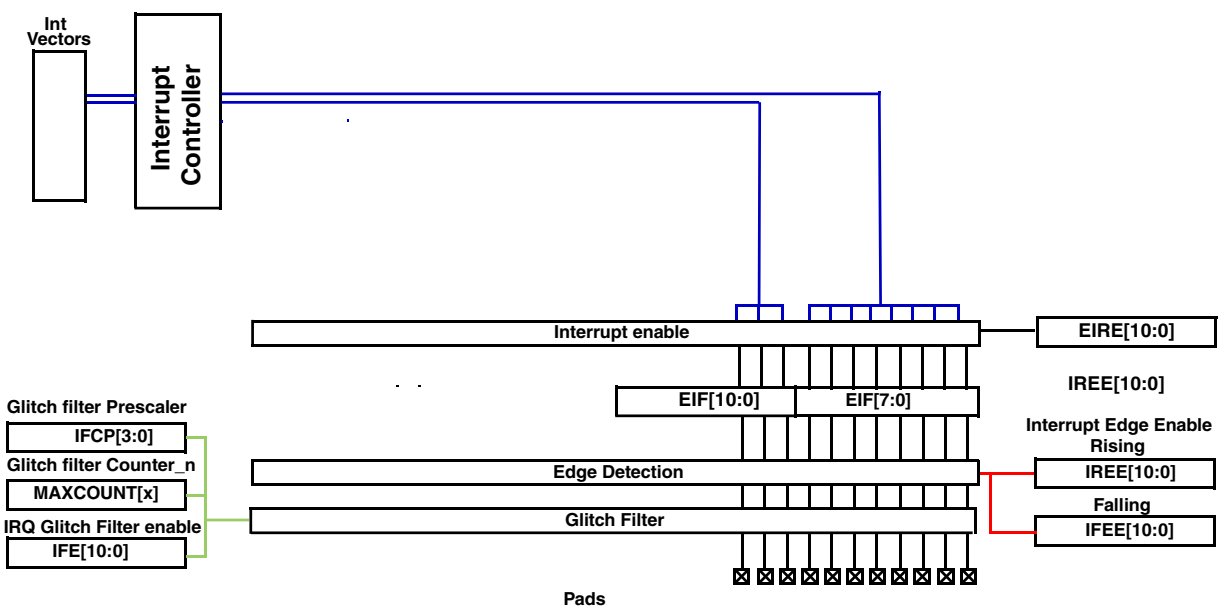

Figure 9-2098. External interrupt pad diagram

9.4.4.3 External Interrupt request

The REQ input pins on the device are sources for interrupt or DMA requests. The system has two interrupt vectors available for the REQ pins in the SIUL2. The mapping of 11 interrupt request sources to vectors and channels appears in the following table.

Table 9-1357. Interrupt source mapping to SIUL2 Interrupt request output for 11 interrupt sources

Vector/Channel #	Interrupt Vector Source
0	REQ[07] | REQ[06] | REQ[05] | REQ[04] | REQ[03] | REQ[02] | REQ[01] | REQ[00]
1	REQ[10] | REQ[09] | REQ[08]
2	Reserved
3	Reserved

9.4.4.4 DMA requests

The REQ pins on the device map to independent DMA request channels in the DMA controller. The eight DMA request pins are mapped to independent DMA request channels in the DMA controller. See the DMA request mapping table in the DMACHMUX chapter.

Chapter 10
Crossbar Switch (AXBS)

10.1 Crossbar switch configuration

This chip contains two crossbar switch modules:

- AXBS0
  - Computational shell crossbar switch
  - 64-bit data bus
- AXBS1
  - Peripheral shell crossbar switch
  - 32-bit data bus

The following sections describe how each is configured for this chip.

10.1.1 Computational shell crossbar switch configuration

This section summarizes how the module has been configured in the chip.

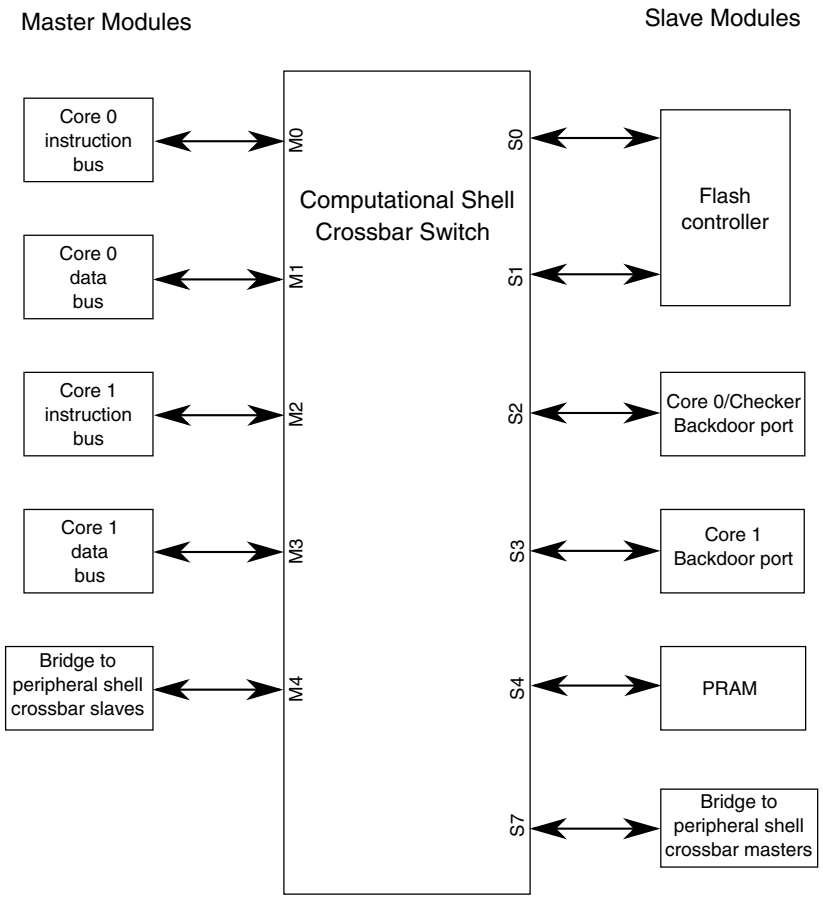

Figure 10-1. Computational shell crossbar switch integration

10.1.1.1 Computational Shell Crossbar Switch Master Assignments

This device contains five masters connected to the computational-shell crossbar switch.

The master assignment is as follows:

Master module	Master port number
Core 0 instruction bus	0
Core 0 data bus	1
Core 1 instruction bus	2
Core 1 data bus	3
Intelligent bridging bus gasket (peripheral-shell crossbar switch)	4

10.1.1.2 Computational Shell Crossbar Switch Slave Assignments

This device contains six slaves connected to the computational shell's crossbar switch.

The slave assignment is as follows:

Slave module	Slave port number
Flash memory controller port 0	0
Flash memory controller port 1	1
Core 0/Checker Core Unified Backdoor I/F	2
Core 1 Unified Backdoor I/F	3
PRAM controller	4
Intelligent Bridging Bus Gasket (peripheral-shell crossbar switch)	7

10.1.1.3 Crossbar Master and Slave Connections

The masters and slaves of the crossbar switches can be connected as follows:

Table 10-1. XBAR0 master and slave connections

	Slave	Flash memory controller port 0	Flash memory controller port 1	Core 0/ Checker Core Unified Backdoor I/F	Core 1 Unified Backdoor I/F	PRAM controller	XBAR0 to 1 interconnect

10.1.2 Peripheral Shell Crossbar Switch Configuration

This section summarizes how the peripheral-shell crossbar switch has been configured in the chip.

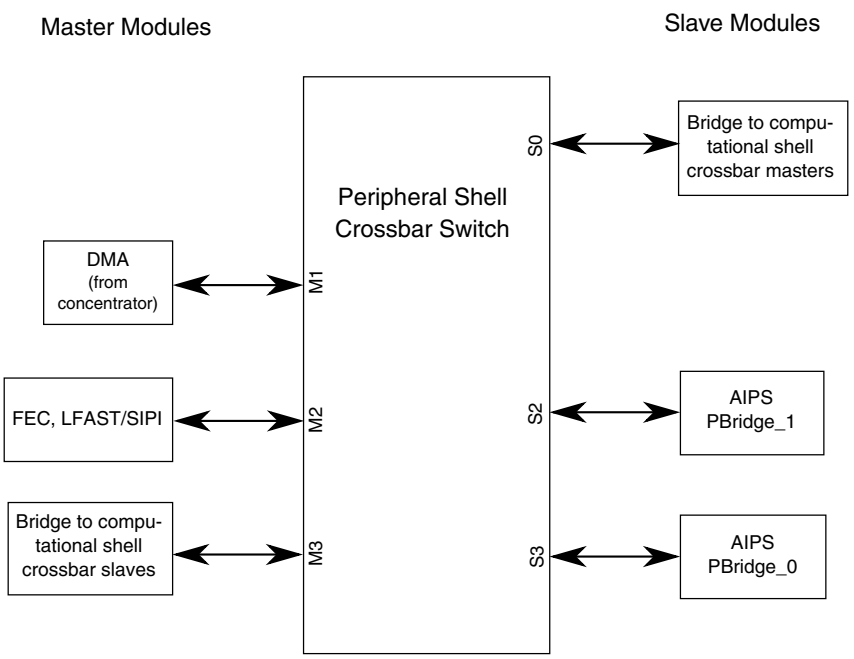

Figure 10-2. Peripheral shell crossbar switch integration

10.1.2.1 Peripheral Shell Crossbar Switch Master Assignments

This device contains three masters connected to the peripheral-shell crossbar switch.

The master assignment is as follows:

Master module	Master port number
DMA	1
FEC and LFAST/SIPI (Zipwire)	2
Intelligent Bridging Bus Gasket (computational-shell crossbar switch)	3

10.1.2.2 Peripheral Shell Crossbar Switch Slave Assignments

This device contains three slaves connected to the peripheral-shell crossbar switch.

The slave assignment is as follows:

Slave module	Slave port number
Intelligent Bridging Bus Gasket (computational-shell crossbar switch)	0
Peripheral bridge (AIPS) PBRIDGE_1	2
Peripheral bridge (AIPS) PBRIDGE_0	3

10.1.2.3 Peripheral shell (XBAR1) memory map

10.2 Introduction

The information found here provides information on the layout, configuration, and programming of the crossbar switch.

The crossbar switch connects bus masters and bus slaves using a crossbar switch structure. This structure allows all bus masters to access different bus slaves simultaneously, while providing arbitration among the bus masters when they access the same slave. A variety of bus arbitration methods and attributes may be programmed on a slave-by-slave basis.

10.2.1 Features

The crossbar switch includes these features:

- Symmetric crossbar bus switch implementation
  - Allows concurrent accesses from different masters to different slaves
  - Slave arbitration attributes configured on a slave-by-slave basis
- Up to single-clock 64-bit transfer
- Support for burst transfers of up to 16 beats of data
- Low-Power Park mode support

10.3 Memory Map / Register Definition

Each slave port of the crossbar switch contains configuration registers. Read- and write-transfers require two bus clock cycles. The registers can be read from and written to only in supervisor mode. Additionally, these registers can be read from or written to only by 32-bit accesses.

A bus error response is returned if an unimplemented location is accessed within the crossbar switch.

The CRS*n* and PRS*n* registers can be programmed to be read-only to prevent changes to their configuration. After being read-only protected, future writes to them will terminate with an error.

NOTE

This section shows the registers for all eight master and slave ports. If a master or slave is not used on this particular device, then unexpected results occur when writing to its registers. See the chip configuration details for the exact master/slave assignments for your device.

All references to the crossbar switch registers are based on the physical port connections.

10.3.1 Priority Registers Slave (XBAR_PRS*n*)

The priority registers (PRSn) set the priority of each master port on a per slave port basis and reside in each slave port. The priority register can be accessed only with 32-bit accesses. After the CRSn[RO] bit is set, the PRSn register can only be read; attempts to write to it have no effect on PRSn and result in a bus-error response to the master initiating the write.

Two available masters must not be programmed with the same priority level. Attempts to program two or more masters with the same priority level result in a bus-error response and the PRSn is not updated.

NOTE

Valid values for the M*n* priority fields depend on which masters are available on the chip. This information can be found in the chip-specific information for the crossbar.

- If the chip contains less than five masters, values 0 to 3 are valid. Writing other values will result in an error.
- If the chip contains five or more masters, valid values are 0 to n-1, where n is the number of masters attached to the Crossbar Switch. Other values will result in an error.

NOTE

See the chip-specific crossbar information for the reset value of this register.

10.4 Functional Description

10.4.1 General operation

When a master accesses the crossbar switch, the access is immediately taken. If the targeted slave port of the access is available, then the access is immediately presented on the slave port. Single-clock or zero-wait-state accesses are possible through the crossbar. If the targeted slave port of the access is busy or parked on a different master port, the requesting master simply sees wait states inserted until the targeted slave port can service the master's request. The latency in servicing the request depends on each master's priority level and the responding slave's access time.

Because the crossbar switch appears to be just another slave to the master device, the master device has no knowledge of whether it actually owns the slave port it is targeting. While the master does not have control of the slave port it is targeting, it simply waits.

A master is given control of the targeted slave port only after a previous access to a different slave port completes, regardless of its priority on the newly targeted slave port. This prevents deadlock from occurring when:

- A higher priority master has:
  - An outstanding request to one slave port that has a long response time and
  - A pending access to a different slave port, and
- A lower priority master is also making a request to the same slave port as the pending access of the higher priority master.

After the master has control of the slave port it is targeting, the master remains in control of the slave port until it relinquishes the slave port by running an IDLE cycle or by targeting a different slave port for its next access.

The master can also lose control of the slave port if another higher-priority master makes a request to the slave port. However, if the master is running a fixed- or undefined-length burst transfer it retains control of the slave port until that transfer completes. Based on

MGPCR[AULB], the master either retains control of the slave port when doing undefined-length, incrementing burst transfers or loses the bus to a higher-priority master.

The crossbar terminates all master IDLE transfers, as opposed to allowing the termination to come from one of the slave buses. Additionally, when no master is requesting access to a slave port, the crossbar drives IDLE transfers onto the slave bus, even though a default master may be granted access to the slave port.

When a slave bus is being idled by the crossbar, it can park the slave port on the master port indicated by CRS*n*[PARK] . This is done to save the initial clock of arbitration delay that otherwise would be seen if the same master had to arbitrate to gain control of the slave port. The slave port can also be put into Low Power Park mode to save power, by using CRS*n*[PCTL].

10.4.2 Register coherency

The operation of the crossbar is affected as soon as a register is written. The values of the registers do not track with slave-port-related master accesses, but instead track only with slave accesses.

The MGPCRx[AULB] bits are the exception to this rule. The update of these bits is only recognized when the master on that master port runs an IDLE cycle, even though the slave bus cycle to write them will have already terminated successfully. If the MGPCRx[AULB] bits are written between two burst accesses, the new AULB encodings do not take effect until an IDLE cycle is initiated by the master on that master port.

10.4.3 Arbitration

The crossbar switch supports two arbitration algorithms:

- Fixed priority
- Round-robin

The arbitration scheme is independently programmable for each slave port.

10.4.3.1 Arbitration during undefined length bursts

Arbitration points during an undefined length burst are defined by the current master's MGPCR[AULB] field setting. When a defined length is imposed on the burst via the AULB bits, the undefined length burst is treated as a single or series of single back-to-back fixed-length burst accesses.

The following figure illustrates an example:

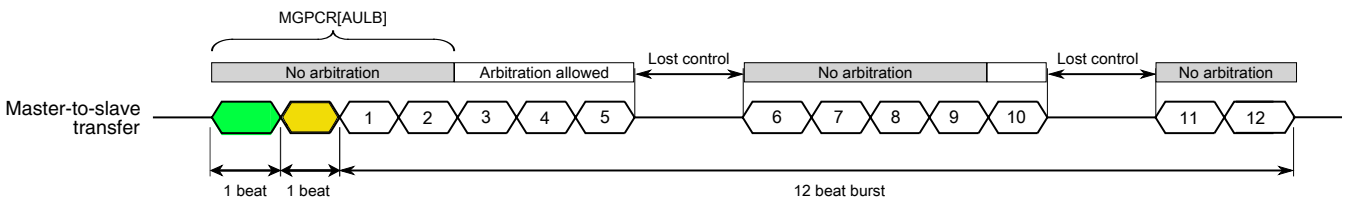

Figure 10-30. Undefined length burst example

In this example, a master runs an undefined length burst and the MGPCR[AULB] bits indicate arbitration occurs after the fourth beat of the burst. The master runs two sequential beats and then starts what will be a 12-beat undefined length burst access to a new address within the same slave port region as the previous access. The crossbar does not allow an arbitration point until the fourth overall access, or the second beat of the second burst. At that point, all remaining accesses are open for arbitration until the master loses control of the slave port.

Assume the master loses control of the slave port after the fifth beat of the second burst. After the master regains control of the slave port no arbitration point is available until after the master has run four more beats of its burst. After the fourth beat of the now continued burst, or the ninth beat of the second burst from the master's perspective, is taken, all beats of the burst are once again open for arbitration until the master loses control of the slave port.

Assume the master again loses control of the slave port on the fifth beat of the third now continued burst, or the 10th beat of the second burst from the master's perspective. After the master regains control of the slave port, it is allowed to complete its final two beats of its burst without facing arbitration.

Note

Fixed-length burst accesses are not affected by the AULB bits. All fixed-length burst accesses lock out arbitration until the last beat of the fixed-length burst.

10.4.3.2 Fixed-priority operation

When operating in fixed-priority mode, each master is assigned a unique priority level in the priority registers (PRS*n*). If two masters request access to the same slave port, the master with the highest priority in the selected priority register gains control over the slave port.

NOTE

In this arbitration mode, a higher-priority master can monopolize a slave port, preventing accesses from any lower-priority master to the port.

When a master makes a request to a slave port, the slave port checks whether the new requesting master's priority level is higher than that of the master that currently has control over the slave port, unless the slave port is in a parked state. The slave port performs an arbitration check at every clock edge to ensure that the proper master, if any, has control of the slave port.

The following table describes possible scenarios based on the requesting master port:

Table 10-35. How the Crossbar Switch grants control of a slave port to a master

When	Then the Crossbar Switch grants control to the requesting master
Both of the following are true: • The current master is not running a transfer. • The new requesting master's priority level is higher than that of the current master.	At the next clock edge
Both of the following are true: • The current master is running a fixed length burst transfer or a locked transfer. • The requesting master's priority level is higher than that of the current master.	At the end of the burst transfer or locked transfer
Both of the following are true: • The current master is running an undefined length burst transfer. • The requesting master's priority level is higher than that of the current master.	At the next arbitration point for the undefined length burst transfer **NOTE:** Arbitration points for an undefined length burst are defined in the MGPCR for each master.
The requesting master's priority level is lower than the current master.	At the conclusion of one of the following cycles: • An IDLE cycle • A non-IDLE cycle to a location other than the current slave port

10.4.3.3 Round-robin priority operation

When operating in round-robin mode, each master is assigned a relative priority based on the master port number. This relative priority is compared to the master port number (ID) of the last master to perform a transfer on the slave bus. The highest priority requesting master becomes owner of the slave bus at the next transfer boundary, accounting for locked and fixed-length burst transfers. Priority is based on how far ahead the ID of the requesting master is to the ID of the last master.

After granted access to a slave port, a master may perform as many transfers as desired to that port until another master makes a request to the same slave port. The next master in line is granted access to the slave port at the next transfer boundary, or possibly on the next clock cycle if the current master has no pending access request.

As an example of arbitration in round-robin mode, assume the crossbar is implemented with master ports 0, 1, 4, and 5. If the last master of the slave port was master 1, and master 0, 4, and 5 make simultaneous requests, they are serviced in the order: 4 then 5 then 0.

Parking may continue to be used in a round-robin mode, but does not affect the round-robin pointer unless the parked master actually performs a transfer. Handoff occurs to the next master in line after one cycle of arbitration. If the slave port is put into low-power park mode, the round-robin pointer is reset to point at master port 0, giving it the highest priority.

10.4.3.4 Priority assignment

Each master port must be assigned a unique 3-bit priority level. If an attempt is made to program multiple master ports with the same priority level within the priority registers (PRS*n*), the crossbar switch responds with a bus error and the registers are not updated.

10.5 Initialization/application information

No initialization is required for the crossbar switch.

Hardware reset ensures all the register bits used by the crossbar switch are properly initialized to a valid state. However, settings and priorities may be programmed to achieve maximum system performance.

Chapter 11
Crossbar Integrity Checker (XBIC)

11.1 Overview

The Crossbar Integrity Checker (XBIC) verifies the integrity of the crossbar transfers.

11.2 Features

The XBIC has the following features:

- Verification of attribute information for all crossbar transfers
  - EDC (72,64) code protects against single and double bit errors
- Verification of feedback information for each data phase during crossbar transfer
- Error injection for testing
  - Programmable master and slave port specifiers
  - Programmable 8-bit toggle vector to insert error in master EDC checkbit value
  - Address, EDC syndrome, master and slave port information captured on error
- Programmable integrity check enable on a per-slave-port basis
- Programmable integrity feedback check enable on a per-master-port basis

11.3 Block diagram

The crossbar transfer attribute information for all master and slave ports is routed to the XBIC, which calculates and checks the EDC parity over the attribute information as shown in the following diagram.

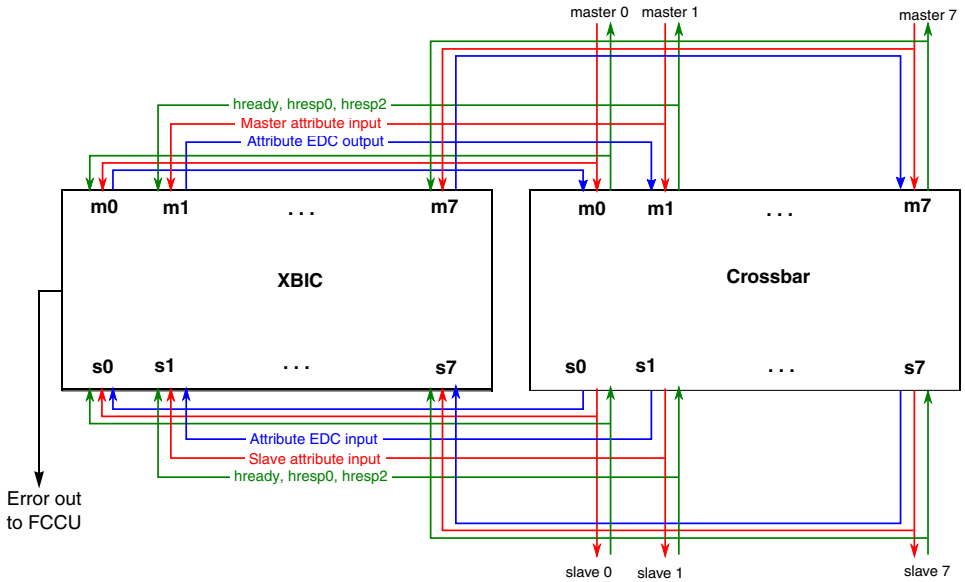

Figure 11-1. XBIC system block diagram

11.4 External signal description

The XBIC has no external interface signals.

11.5 Memory map and register definition

The XBIC programming model has four 32-bit registers. The programming model can only be accessed in supervisor mode using 32-bit (word) accesses. Attempted references with a different access size, to an undefined (reserved) address, with a non-supported access type (a write to a read-only register), or in user mode generate an error termination.

16–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

11.5.2 XBIC Error Injection Register (XBIC_EIR)

The XBIC_EIR contains fields for controlling the XBIC error injection function. When an error is injected, the EDC syndrome associated with the programmed master and slave ports is modified, causing the XBIC to assert the error indication to the FCCU and capturing the transfer information in the XBIC_ESR and XBIC_EAR registers. Otherwise, transfers are not affected by XBIC error injection.

Address: 0h base + 4h offset = 4h

XBIC_EIR field descriptions

Field	Description
0 EIE	Error Injection Enable. 0 Error injection disabled 1 Error injection enabled
1–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
17–19 SLV	Target Slave Port. Error injection is enabled for the designated slave port. Other slave ports are unaffected.
20–23 MST	Target Master ID. Error injection is enabled for the designated master ID. Transfers with other master IDs are not affected.
24–31 SYN	Syndrome. This value is exclusive-ored with the calculated syndrome (which should be zero) to generate an error with the specified syndrome. A value of zero does not generate an error.

11.5.3 XBIC Error Status Register (XBIC_ESR)

The Error Status Register (XBIC_ESR) contains two types of error information about the last transfer. If an attribute integrity check error was detected, the slave port, the master port, and the syndrome are captured in the SLV, MST, and SYN fields. If there is a mismatch among internal signals (hready, hresp0, and hresp2) during the data phase, the slave and master port are catured in the DPSE0-7 and DPME0-7 fields.

This register is cleared only on reset.

NOTE

When the XBIC detects back-to-back faults on a system bus path through the crossbar switch, the fault information captured in the XBIC_ESR does not correspond to the initial fault event but rather the subsequent fault event. While the fault event is properly detected, diagnostic status information in the XBIC_ESR register describing the initial fault event is lost. This can only occur in the event of a series of bus transactions targeting the same crossbar slave target where the series of bus transactions are not separated by idle or stall cycles.

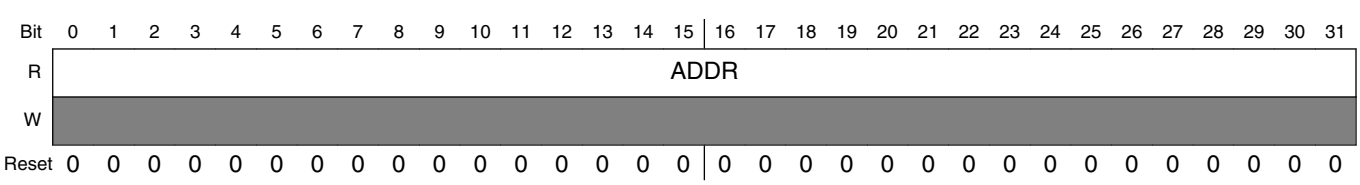
14 DPME5	Data phase master port error. 0 No error on master port 5 1 Data phase error on master port 5
15 DPME6	Data phase master port error. 0 No error on master port 6 1 Data phase error on master port 6
16 DPME7	Data phase master port error. 0 No error on master port 7 1 Data phase error on master port 7
17–19 SLV	Slave Port. The slave port targeted by the last transfer with an error.
20–23 MST	Master ID. The master ID value of the last transfer with an error.
24–31 SYN	Syndrome. The syndrome calculated for the last transfer with an error. For single bit errors the signal in error can be determined, see Table 11-6 .



11.5.4 XBIC Error Address Register (XBIC_EAR)

The Error Address Register (XBIC_EAR) contains the address of the first transfer in which an attribute integrity check error was detected on an enabled slave port. This register is only cleared on reset.

NOTE

When the XBIC detects back-to-back faults on a system bus path through the crossbar switch, the fault information captured in the XBIC_EAR does not correspond to the initial fault event but rather the subsequent fault event. While the fault event is properly detected, diagnostic status information in the XBIC_ESR register describing the initial fault event is lost. This can only occur in the event of a series of bus transactions targeting the same crossbar slave target where the series of bus transactions are not separated by idle or stall cycles.

Address: 0h base + Ch offset = Ch

XBIC_EAR field descriptions

Field	Description
0–31 ADDR	The address of the last transfer with an error.

11.6 Functional description

The Crossbar Integrity Checker (XBIC) verifies the integrity of the crossbar interface. The Module Control Register (XBIC_MCR) allows integrity checking to be enabled on a individual port basis. When an error is detected, it is captured in XBIC_ESR register and XBIC also sends out an error signal to the Fault Collection and Control Unit (FCCU). Detection of an error does not generate a bus error. The XBIC integrity checking is independent from the end-to-end ECC that covers the transfer address and data.

During the AHB address phase, the crossbar attribute information is checked using an 8-bit Error Detection Code (EDC), which detects any single- or double-bit errors. When an error is detected, due either to hardware fault or error injection, information related to the error is captured and reported in XBIC_ESR and XBIC_EAR. The cause of a single-bit error can be determined by the syndrome value reported in the XBIC_ESR as shown in Table 11-6. Any other syndrome indicates a multi-bit error.

During the AHB data phase, the responding signals from the slave to master are checked when passing through the crossbar. When an error is detected, the information is captured in XBIC_ESR DSME0-7 field.

The XBIC can also be programmed to intentionally inject EDC errors for testing. Error injection is targeted toward a single slave port and a single master ID at a time as determined by the settings in the Error Injection Register (XBIC_EIR). When an error is injected, the EDC syndrome is modified which causes the XBIC to assert the error indication to the FCCU. Otherwise transfers are unaffected by XBIC error injection. This approach allows the check logic to be verified without compromising the integrity of the data transfer. Once the error injection function is enabled by setting XBIC_EIR[EIE], errors are induced on all subsequent targeted transactions until XBIC_EIR[EIE] is cleared

Chapter 12
Peripheral Bridge (AIPS-Lite)

12.1 Peripheral Bridge chip-specific module information

This section summarizes how the AIPS-Lite modules have been configured in the chip.

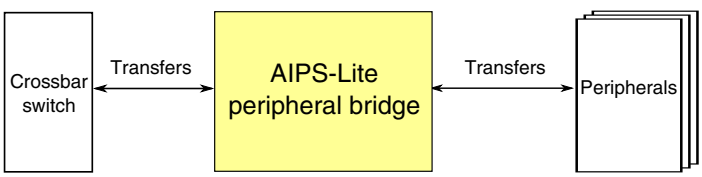

Figure 12-1. Peripheral bridge configuration

12.1.1 Number of peripheral bridges

This device contains two identical peripheral bridges, PBRIDGE_0 and PBRIDGE_1.

NOTE

Peripheral bridge instances PBRIDGE_0 and PBRIDGE_1 may also be referred to as AIPS0 and AIPS1, respectively, elsewhere in this document.

12.1.2 Memory maps

The peripheral bridges are used to access the registers of most of the modules on this chip. See the Peripheral memory map for the memory slot assignment for each module.

12.1.3 MPRA registers

The AIPS0_MPRA and AIPS1_MPRA registers contain the access-privilege fields for each master on this chip. The access-privilege field number corresponds to the logical master ID assigned to each master. Master 8 (Core 0 Debug) and master 9 (Core 1 Debug) share the same access privileges as master 0 (Core 0) and master 1 (Core 1), respectively. See System Memory Protection Unit (SMPU) chip-specific module information for the master port assignments for this chip.

The reset value for the AIPS0_MPRA and AIPS1_MPRA registers is 0x7777_7777.

12.1.4 PACR registers

Each peripheral on this chip is assigned to a 4-bit PACR field, PACR*n*, within the PACR*x* registers. See Peripheral memory map for the peripheral slot assignments for this chip. Unused PACR*n* fields are reserved.

The AIPS*n*_PACR*x* reset values depend on whether the peripheral is available on this chip. For each populated slot in Peripheral memory map, the corresponding peripheral's PACR field resets to 0x4.

12.2 Introduction

The peripheral bridge converts the crossbar switch interface to an interface that can access most of the slave peripherals on this chip.

The peripheral bridge occupies 64 MB of the address space, which is divided into peripheral slots of 16 KB. (It might be possible that all the peripheral slots are not used. See the memory map chapter for details on slot assignments.) The bridge includes separate clock enable inputs for each of the slots to accommodate slower peripherals.

12.2.1 Features

Key features of the peripheral bridge are:

- Supports peripheral slots with 8-, 16-, and 32-bit datapath width
- Programming model provides memory protection functionality

12.2.2 General operation

The slave devices connected to the peripheral bridge are modules which contain a programming model of control and status registers. The system masters read and write these registers through the peripheral bridge.

The register maps of the peripherals are located on 16 KB boundaries. Each peripheral is allocated one or more 16-KB block(s) of the memory map.

12.3 Memory map/register definition

The 32-bit peripheral bridge registers can be accessed only in supervisor mode by trusted bus masters. Additionally, these registers must be read from or written to only by a 32-bit aligned access. The peripheral bridge registers are mapped into the Peripheral Access Control Register A PACRA[PACR0] address space.

12.3.1 Master Privilege Register A (AIPS_MPRA)

This register specifies eight identical 4-bit fields defining the access-privilege level associated with a bus master in the device to various peripherals. The register provides one field per bus master. Each master is assigned a logical master number. See the device configuration information for details.

12.3.2 Peripheral Access Control Register (AIPS_PACR*n*)

Each of the on-platform peripherals has a 4-bit PACR *n* field, which defines the access levels supported by the given module. Eight PACR fields are grouped together to form a 32-bit PACR *x* register.

The peripheral assignments to each PACR are defined by the memory map slot that the peripherals are assigned. See the device's memory map details for the assignments for a particular device. If a peripheral is absent, the corresponding PACR field is not implemented. Reads to the location return zeroes and writes are ignored.

The following table shows the top-level structure of PACRs.

Offset	Register	[0:3]	[4:7]	[8:11]	[12:15]	[16:19]	[20:23]	[24:27]	[28:31]

When this field is set, the master privilege level must indicate the supervisor access attribute, and the MPR *x* [MPL *n*] control field for the master must be set. If not, access terminates with an error response and no peripheral access initiates. 0 This peripheral does not require supervisor privilege level for accesses. 1 This peripheral requires supervisor privilege level for accesses.
30 WP7	Write Protect Determines whether the peripheral allows write accessses. When this field is set and a write access is attempted, access terminates with an error response and no peripheral access initiates. 0 This peripheral allows write accesses. 1 This peripheral is write protected.
31 TP7	Trusted Protect Determines whether the peripheral allows accesses from an untrusted master. When this field is set and an access is attempted by an untrusted master, the access terminates with an error response and no peripheral access initiates. 0 Accesses from an untrusted master are allowed. 1 Accesses from an untrusted master are not allowed.

12.3.3 Off-Platform Peripheral Access Control Register (AIPS_OPACR*n*)

Each of the peripherals has a 4-bit OPACR *n* field, which defines the access levels supported by this module. Eight OPACR fields are grouped together to form a 32-bit OPACR *x* register.

The peripheral assignments to each OPACR are defined by the memory map slot that the peripherals are assigned. See the device's memory map details for the assignments for a particular device. If a peripheral is absent, the corresponding OPACR field is not implemented. Reads to the location return zeroes and writes are ignored.

The following table shows the top-level structure of OPACRs.

Offset	Register	[0:3]	[4:7]	[8:11]	[12:15]	[16:19]	[20:23]	[24:27]	[28:31]

Field	Description
	field for the master must be set. If not, access terminates with an error response and no peripheral access initiates. 0 This peripheral does not require supervisor privilege level for accesses. 1 This peripheral requires supervisor privilege level for accesses.
26 WP6	Write Protect Determines whether the peripheral allows write accessses. When this field is set and a write access is attempted, access terminates with an error response and no peripheral access initiates. 0 This peripheral allows write accesses. 1 This peripheral is write protected.
27 TP6	Trusted Protect Determines whether the peripheral allows accesses from an untrusted master. When this field is set and an access is attempted by an untrusted master, the access terminates with an error response and no peripheral access initiates. 0 Accesses from an untrusted master are allowed. 1 Accesses from an untrusted master are not allowed.
28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29 SP7	Supervisor Protect Determines whether the peripheral requires supervisor privilege level for accesses. When this field is set, the master privilege level must indicate the supervisor access attribute, and the MPR *x* [MPL *n*] control field for the master must be set. If not, access terminates with an error response and no peripheral access initiates. 0 This peripheral does not require supervisor privilege level for accesses. 1 This peripheral requires supervisor privilege level for accesses.
30 WP7	Write Protect Determines whether the peripheral allows write accessses. When this field is set and a write access is attempted, access terminates with an error response and no peripheral access initiates. 0 This peripheral allows write accesses. 1 This peripheral is write protected.
31 TP7	Trusted Protect Determines whether the peripheral allows accesses from an untrusted master. When this field is set and an access is attempted by an untrusted master, the access terminates with an error response and no peripheral access initiates. 0 Accesses from an untrusted master are allowed. 1 Accesses from an untrusted master are not allowed.

12.4 Functional description

The peripheral bridge functions as a bus protocol translator between the crossbar switch and the slave peripheral bus.

The peripheral bridge manages all transactions destined for the attached slave devices and generates select signals for modules on the peripheral bus by decoding accesses within the attached address space.

12.4.1 Access support

All combinations of access size and peripheral data port width are supported. An access that is larger than the target peripheral's data width will be decomposed to multiple, smaller accesses. Bus decomposition is terminated by a transfer error caused by an access to an empty register area.

Chapter 13
System Memory Protection Unit (SMPU)

13.1 System Memory Protection Unit (SMPU) chip-specific module information

This chip contains two instances of the System Memory Protection Unit (SMPU):

- SMPU0 for the data XBAR (XBAR_0)
- SMPU1 for the instruction XBAR (XBAR_1)

The following sections explain how each SMPU is configured on this chip.

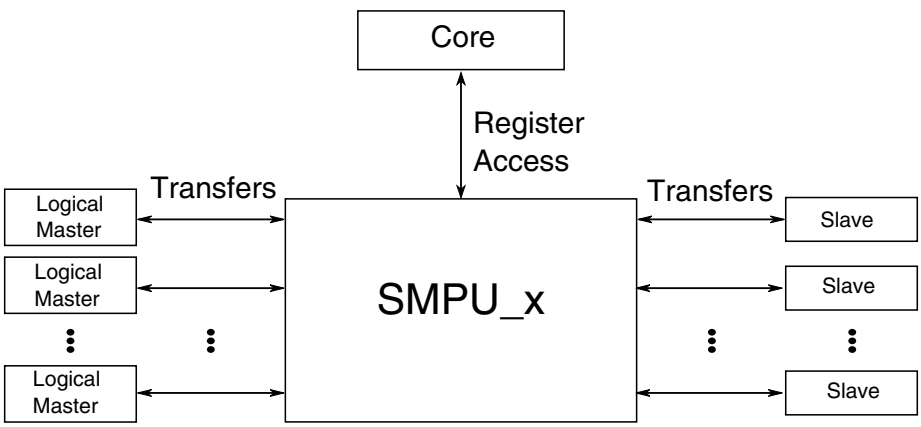

Figure 13-1. SMPUx configuration

13.1.1 SMPUx configuration

This section summarizes how the module instance has been configured in the chip.

13.1.1.1 SMPUx Logical bus Master Assignments

The logical bus master assignments for the SMPUx are shown in the following table.

Table 13-1. Master IDs

Master Name	Master ID
Core0	0
Core1	1

13.1.1.2 Number of region descriptors supported by SMPU0 and SMPU1

- SMPU0 supports a maximum of 12 region descriptors.
- SMPU1 supports a maximum of eight region descriptors.

13.2 Overview

The System Memory Protection Unit (SMPU) provides hardware access control for system bus memory references. The SMPU concurrently monitors system bus transactions and evaluates their appropriateness using preprogrammed region descriptors that define memory spaces and their access rights. Memory references that have sufficient access control rights are allowed to complete, while references that are not mapped to any region descriptor or have insufficient rights are terminated with an access error response.

13.2.1 Block diagram

A simplified block diagram of the SMPU module is shown in the following figure. The access signals coming from the crossbar switch slave ports are shown on the left. The access evaluation macros and region descriptors are in the middle, and the peripheral bus interface is on the right side.

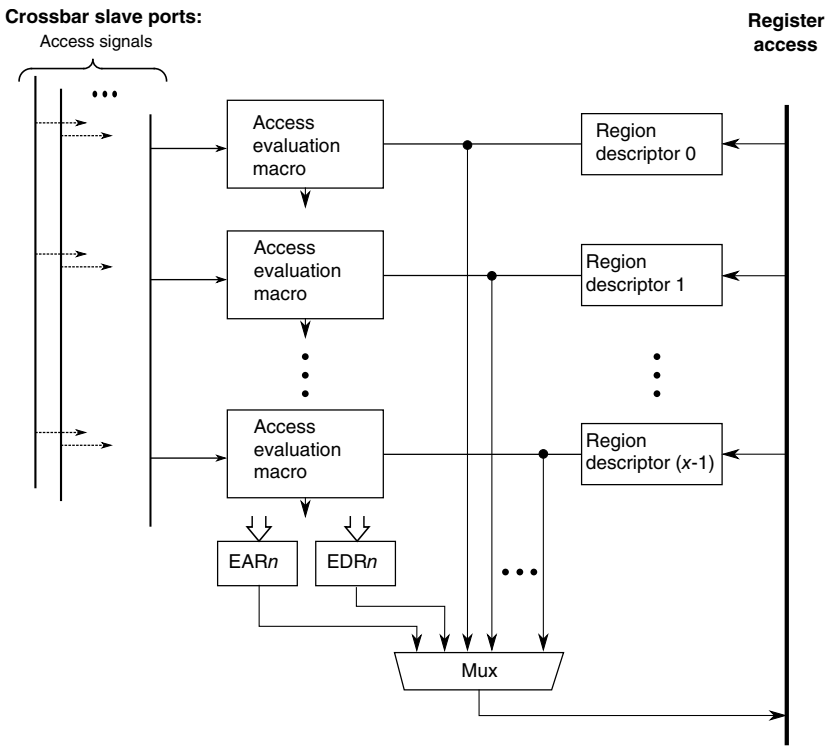

Figure 13-2. SMPU block diagram

The access evaluation macros determine hits to memory regions and detect violations to access protections. If a violation is detected, the macros update the appropriate master's error registers. For details of the access evaluation macro, see Access evaluation macro.

13.2.2 Features

The SMPU feature set includes:

- Arbitrarily sized protection regions alignable anywhere in memory.
  - Region sizes can vary from a minimum of 1 byte to a maximum of 4 GB.
- Read/write access control permissions are defined in the region descriptor.
- Global cache-inhibit attribute indicator.

- Hardware-assisted maintenance of the descriptor valid bit minimizes coherency issues.
- Priority given to granting permission over denying access for overlapping region descriptors.
- Detection of access errors if a memory reference does not hit in any memory region, or if the reference is illegal in all hit memory regions. If an access error occurs, the reference is terminated with an error response, and the SMPU inhibits the bus cycle being sent to the targeted slave device.
- Instruction storage (ISI) or data storage (DSI) interrupts generated by aborted core accesses. Buffered writes generate Machine check exception (refer to the documentation related to the core for details).
- Error registers (per bus master ID) capture the last faulting address, attributes, and other information.
- Global SMPU enable/disable control bit.

13.3 Memory map/register definition

The programming model is partitioned into three groups:

- Control registers
- Error capture registers
- Data structure containing the region descriptors

The programming model can be referenced only in supervisor mode using 32-bit accesses. Attempted references with a different access size, to an undefined (reserved) address, with a non-supported access type (a write to a read-only register, or a read of a write-only register), or in user mode generate an error termination.

NOTE

See the chip configuration details for any chip-specific register information for this module. For example, a specific instance of the module may support only eight or fewer region descriptors.

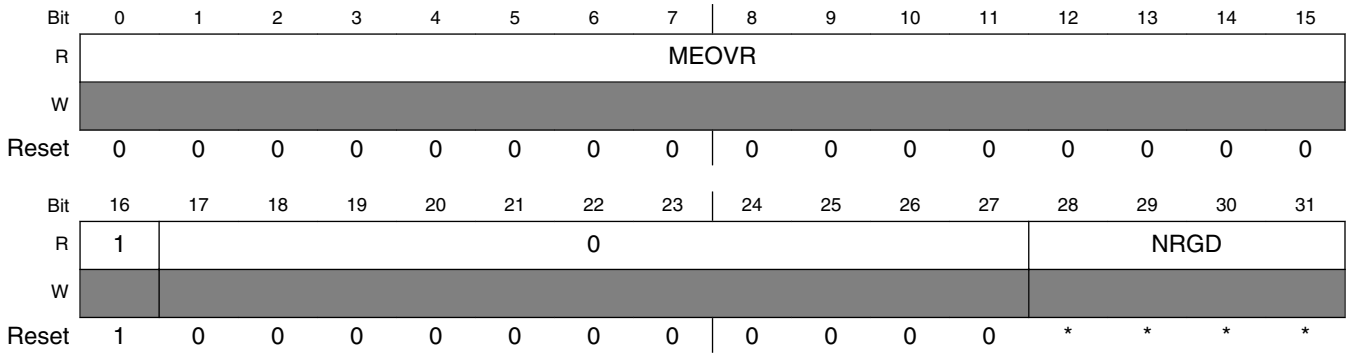
13.3.1 Control/Error Status Register 0 (SMPU_CESR0)

Address: 0h base + 0h offset = 0h



SMPU_CESR0 field descriptions

Field	Description
0–15 MERR	Master n error, where the bus master number matches the bit number Indicates a captured error in EARn and EDRn. A bit is set when the hardware detects an error and records the faulting address and attributes. It is cleared by writing one to it. If another error is captured at the exact same cycle as the write, the flag remains set. A find-first-one instruction (or equivalent) can detect the presence of a captured error. 0 No error has occurred for bus master n. 1 An error has occurred for bus master n.
16 Reserved	This field is reserved. This read-only field is reserved and always has the value 1.
17–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28–30 HRL	Hardware revision level Specifies the SMPU's hardware and definition revision level. It can be read by software to determine the functional definition of the module.
31 GVLD	Global Valid (global enable/disable for the SMPU) 0 SMPU is disabled. All accesses from all bus masters are allowed. 1 SMPU is enabled.

13.3.2 Control/Error Status Register 1 (SMPU_CESR1)

Address: 0h base + 4h offset = 4h

* Notes:
- NRGD field: See the chip-specific SMPU information for the reset value of this field.

SMPU_CESR1 field descriptions

Field	Description
0–15 MEOVR	Master n error overrun, where the bus master number matches the bit number Each bit in this field signals that another SMPU error for bus master n has occurred before the previous error was processed. The details of the first error are recorded in the EARn and EDRn registers and no information on subsequent errors is recorded until the associated CESR0[MERR] flag is cleared. 0 No error overrun condition has been detected for bus master n. 1 An error overrun condition has been detected for bus master n.
16 Reserved	This field is reserved. This read-only field is reserved and always has the value 1.
17–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28–31 NRGD	Number of region descriptors Indicates the number of region descriptors implemented in the SMPU. The number of region descriptors is (4 x NRGD). 0001 4 region descriptors 0010 8 region descriptors 0011 12 region descriptors 0100 16 region descriptors 0101 20 region descriptors 0110 24 region descriptors

13.3.3 Error Address Register, Bus Master n (SMPU_EAR*n*)

When the SMPU detects an access error on bus master n, the 32-bit reference address is captured in this read-only register and the corresponding bit in CESR0[MERR] set. Additional information about the faulting access is captured in the corresponding EDRn at the same time.[1]

Address: 0h base + 100h offset + (8d × i), where i=0d to 15d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

SMPU_EAR*n* field descriptions

Field	Description
0–31 EADDR	Error address Indicates the reference address from bus master n that generated the access error.

1. The corresponding EARn and EDRn registers contain information on the original access error; subsequent errors associated with the given master are recorded as overruns in the CESR1[MEOVR] field until the CESR0[MERR] flag associated with the original error is cleared (by writing a 1).

13.3.4 Error Detail Register, Bus Master n (SMPU_EDR*n*)

When the SMPU detects an access error associated with bus master n, 32 bits of error detail are captured in this read-only register and the corresponding bit in CESR0[MERR] is set. Information on the faulting address is captured in the corresponding EARn register at the same time. [1]

Address: 0h base + 104h offset + (8d × i), where i=0d to 15d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

W																
Reset	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0

SMPU_EDR*n* field descriptions

Field	Description
0–23 EACD	Error access control detail Indicates the region descriptor with the access error, where the region descriptor number matches the bit number. If EDRn contains a captured error and EACD is all zeroes, the access did not hit in any region descriptor. If only a single EACD bit is set, the access error was caused by a single non-overlapping region descriptor. If two or more EACD bits are set, the access error was caused by an overlapping set of region descriptors.
24 Reserved	This field is reserved. This read-only field is reserved and always has the value 1.
25–26 EATTR	Error attributes Indicates attribute information about the faulting reference. 00 User mode, instruction access 01 User mode, data access 10 Supervisor mode, instruction access 11 Supervisor mode, data access
27 ERW	Error read/write Indicates the access type of the faulting reference. 0 Read 1 Write
28–31 EMN	Error master number Indicates the logical bus master number of the faulting reference.

1. The corresponding EARn and EDRn registers contain information on the original access error; subsequent errors associated with the given master are recorded as overruns in the CESR1[MEOVR] field until the CESR0[MERR] flag associated with the original error is cleared (by writing a 1).

13.3.5 Region Descriptor n, Word 0 (SMPU_RGD*n*_WORD0)

The first word of the region descriptor defines the byte start address of the memory region. Writes to this register clear the region descriptor's valid bit (RGDn_WORD3[VLD]).

Address: 0h base + 400h offset + (16d × i), where i=0d to 11d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

SMPU_RGD*n*_WORD0 field descriptions

Field	Description
0–31 SRTADDR	Start address Defines the byte start address of the memory region.

13.3.6 Region Descriptor n, Word 1 (SMPU_RGD*n*_WORD1)

The second word of the region descriptor defines the end address of the memory region. (RGDn_WORD3[VLD]).

Address: 0h base + 404h offset + (16d × i), where i=0d to 11d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	ENDADDR																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SMPU_RGD*n*_WORD1 field descriptions

Field	Description
0–31 ENDADDR	End address Defines the byte end address of the memory region. **NOTE:** The SMPU does not verify that ENDADDR ≥ SRTADDR.

13.3.7 Region Descriptor n, Word 2 (SMPU_RGD*n*_WORD2)

RGD_WORD2 defines the access control rights of the memory region. The access control rights are defined by separate read and write permissions. For these fields, the bus master number refers to the *logical* bus master number.

For the access control rights, there are two flags:

- Read (r) permission refers to the ability to access the referenced memory address using an operand (data) fetch or an instruction fetch.
- Write (w) permission refers to the ability to update the referenced memory address using a store (data) operation.

Each field consists of the two flags, with (r) being in the more significant position. For example, M0P has (r) as bit 0 and (w) as bit 1.

The bit settings are as follows:

- If set, the corresponding flag allows the specific access type (r = memory read, w = memory write).
- If cleared, the specific access type is not allowed.

Writes to this word clear the region descriptor's valid bit.

Address: 0h base + 408h offset + (16d × i), where i=0d to 11d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R W	M0P		M1P		M2P		M3P		M4P		M5P		M6P		M7P

SMPU_RGD*n*_WORD2 field descriptions (continued)

Field	Description
30–31 M15P	Bus master 15 permissions

13.3.8 Region Descriptor n, Word 3 (SMPU_RGD*n*_WORD3)

The final word of the SMPU region descriptor contains the valid bit, plus other miscellaneous flags.

Address: 0h base + 40Ch offset + (16d × i), where i=0d to 11d

SMPU_RGD*n*_WORD3 field descriptions

Field	Description
0–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28 RO	Read-Only This bit is intended to prevent accidental writes of an SMPU region descriptor. **NOTE:** The valid bit of the RGD and the global valid bit have no effect on this bit functionality (once set, even if the RGD is not valid or SMPU is not global enabled, the RO functionality is present). 0 The region descriptor can be read or written. 1 Attempted writes to any location in the region descriptor are ignored with an error-free data transfer termination.
29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30 CI	Cache Inhibit Defines the cacheability attribute of the memory region. This bit is returned to the bus master that initiated the memory reference. **NOTE:** An address range specified in an SMPU region descriptor for a cacheable space (that is, CI = 0) must be defined with a starting address aligned on a 0-modulo-32 byte address and with a multiple of the 32 byte cache line size factoring into the end address.

Table continues on the next page...

SMPU_RGD*n*_WORD3 field descriptions (continued)

Field	Description
	0 References to this region can be cached. 1 References to this region cannot be cached.
31 VLD	Valid Signals the region descriptor is valid. Any write to RGDn_WORD0–2 clears this bit. 0 Region descriptor is invalid. 1 Region descriptor is valid.

13.4 Functional description

In this section, the functional operation of the SMPU is detailed, including the operation of the access evaluation macro and the handling of error-terminated bus cycles.

13.4.1 Access evaluation macro

The basic operation of the SMPU is performed in the access evaluation macro, a hardware structure replicated in the connection matrix. The following block diagram represents an individual macro.

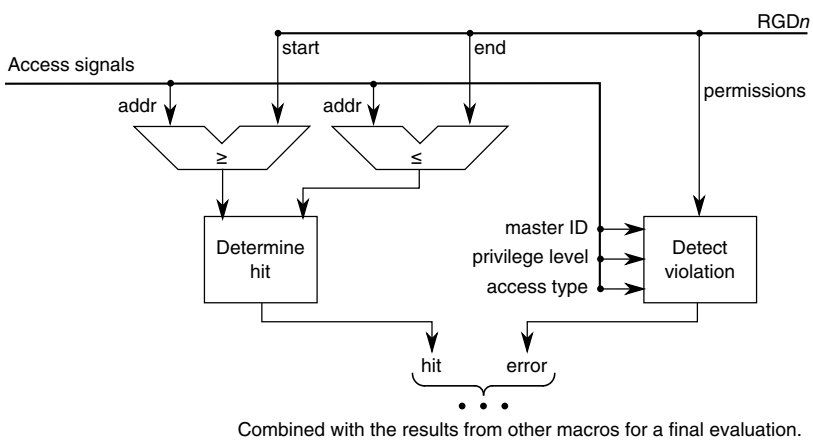

Figure 13-91. SMPU access evaluation macro

Each macro uses the information contained in the access signals (the address, the access type, and the master's ID and privilege level) and the contents of its corresponding region descriptor (RGD*n*) to perform two major functions: Hit determination and Violation determination. The individual hit and error results from each macro are then combined for a final evaluation; see Final evaluation and error terminations.

13.4.1.1 Hit determination

To determine if the current reference hits in the given region, two magnitude comparators are used with the region's start and end addresses. When RGD*n*_Word3[VLD] is 1, a region hit occurs when the requested address is between the start address (RGD*n*_Word0[SRTADDR]) and the end address (RGD*n*_Word1[ENDADDR]), inclusive.

NOTE

If ENDADDR < SRTADDR, no hit occurs.

NOTE

Region hit determination is based only on an address comparison of the first byte being accessed; that is, the SMPU does not check the size of the access to make sure it fits within an allowed region.

13.4.1.2 Violation determination

While the access evaluation macro is determining region hit, the logic is also evaluating if the current access is allowed by the permissions defined in the region descriptor. Using the master ID, a set of effective permissions is generated from the appropriate fields in the region descriptor. The protection violation logic then evaluates the access against the effective permissions using the specification shown below.

Table 13-91. Protection violation definition

Access type	Access permissions		Protection violation?
	r	w	
Instruction fetch read	0	—	Yes, no execute permission
	1	—	No, access is allowed
Data read	0	—	Yes, no read permission
	1	—	No, access is allowed
Data write	—	0	Yes, no write permission
	—	1	No, access is allowed

13.4.2 Final evaluation and error terminations

For each slave port monitored, the SMPU performs a reduction-AND of all the individual terms from each access evaluation macro. This expression then terminates the bus cycle with an error and reports an access error for three conditions:

1. The access does not hit in any region descriptor.
2. The access hits in a single region descriptor and that region has a protection violation.
3. The access hits in multiple (overlapping) regions and all regions have protection violations.

As shown in the third condition, granting permission is a higher priority than denying access for overlapping regions. This approach is more flexible to system software in region descriptor assignments. For an example of the use of overlapping region descriptors, see Application information.

NOTE

Similarly, the cache inhibit function gives a higher priority to the less restrictive result of overlapping regions. If two regions are hit and one has cache inhibit set, and the other does not, the result will not include a cache inhibit. It should also be noted that only the hit logic is taken into account for cache inhibit. For example, two region hits, one has protection violation and no cache inhibit, one has no violation and cache inhibit set. The result will be a granted access with no cache inhibit.

13.5 Initialization information

At system startup, load the appropriate number of region descriptors, including setting RGD*n*_Word3[VLD]. Setting CESR0[GVLD] enables the module.

If the system requires that all the loaded region descriptors be enabled simultaneously, first ensure that the entire SMPU is disabled (CESR0[GVLD]=0). Next, load the appropriate region descriptors (RGDn), including the setting of the RGDn_Word3[VLD] bits. Finally, set CESR0[GVLD] to enable the entire module.

Note

A region descriptor must be set to allow access to the SMPU registers if further changes are needed.

13.6 Application information

In an operational system, interfacing with the SMPU is generally classified into the following activities:

- Creating a new memory region

  Load the appropriate region descriptor into an available RGD*n*, using four sequential 32-bit writes. The hardware assists in the maintenance of the valid bit, so if this approach is followed, there are no coherency issues with the multi-cycle descriptor writes.

- Modifying a region descriptor

  Load the updates into the region descriptor using sequential 32-bit writes. Writing to Word 3 re-enables the region descriptor valid bit. The hardware assists in the maintenance of the valid bit, so if this approach is followed, there are no coherency issues with the multi-cycle descriptor writes.

- Removing a region descriptor

  Clearing RGD*n*_Word3[VLD] deletes an existing region descriptor.

- Accessing the SMPU

  Allocate a region descriptor to restrict SMPU access to supervisor mode from specific masters as appropriate.

- Detecting an access error

  The current bus cycle is terminated with an error response and EAR*n* and EDR*n* capture information on the faulting reference. The error-terminated bus cycle typically initiates an error response in the originating bus master. For example, a processor core may respond with a bus error exception, while a data movement bus master may respond with an error interrupt. The processor can retrieve the captured error address and detail information simply by reading E{A,D}R*n*. CESR0[MERR] signals which error registers contain captured fault data. Once the error information is retrieved, write a 1 to the appropriate CESR0[MERR] bit to clear it, thereby rearming the error capture logic associated with the EAR*n* and EDR*n* registers.

- Overlapping region descriptors

Applying overlapping regions often reduces the number of descriptors required for a given set of access controls. In the overlapping memory space, the protection rights of the corresponding region descriptors are logically summed together (the boolean OR operator).

Chapter 14
Intelligent AHB Gasket (IAHBG)

14.1 IAHBG chip-specific module information

14.1.1 IAHBG implemented operation modes

Table 14-1 shows the operating modes implemented in the IAHBG on this chip.

Table 14-1. IAHBG implemented operating modes

Operating mode (Master:Slave)	Comments
1:1	Master and slave at same operating frequency; gasket performance optimizations on by default
2:1	Master at twice frequency of slave; gasket performance optimizations on by default
1:2	Slave at twice frequency of master; gasket performance optimizations on by default

14.1.2 IAHBG clock selection ratios

The IAHBG is used as a bus gasket to connect busses running at different bus clock speeds. Internal signals generated by the MC_CGM module are connected to the IAHBG module that determine the clock ratio selection. User software is not used to determine the clock ratio setting for the IAHBG.

14.1.3 IAHBG features enabled by Platform Configuration Module (PCM)

The Platform Configuration Module (PCM) is used to enable/disable features of the IAHBG module. In general, the default setting in the PCM enables IAHBG features for the highest performance case. Unless otherwise noted, you generally do not have to change the PCM default settings that control IAHBG features.

14.2 Introduction

This section details the intelligent bridging gasket between the fast and slow clock domains. The intelligent operation of the gasket initiates pending reads early and optimizes bursts to recover some of the performance that is lost on a registered interface between different clock domains. Pending reads begin even if there is not an hready to the master. Non-bursted writes only begin when the slave is IDLE, pending writes wait until IDLE.

The IAHBG complies with the AHBV6lite protocol, including an extension to support masters that do address retraction during the error termination sequence or abort a burst read due to an error termination or another non-error termination like cache inhibit termination.

Table 14-2 lists the available operation modes.

Table 14-2. Operation modes available

Operating mode (Master:Slave)	Comments
0:0	Flowthru (no register wall)
1:1	Master and slave at same operating frequency; gasket performance optimizations on by default
2:1	Master at twice frequency of slave; gasket performance optimizations on by default
1:2	Slave at twice frequency of master; gasket performance optimizations on by default
4:1	Master at four times frequency of slave; gasket performance optimizations disabled at this time
1:4	Slave at four times frequency of master; gasket performance optimizations disabled at this time

14.3 Timing modes

14.3.1 1:1

In the 1:1 timing mode the master is running at the same clock frequency as the slave. The pending read can either be a single or burst transaction.

14.3.2 2:1

In the 2:1 timing mode the master is running at twice the clock frequency of the slave. The 4:1 mode is not shown because it is very similar to the 2:1 mode. The pending read can either be a single or burst transaction.

14.3.3 1:2

In the 1:2 timing mode, the slave is running at twice the clock frequency of the master. The 1:4 mode is not shown because it is very similar to the 1:2 mode. The pending read can either be a single or burst transaction.

Because the slave is operating at a faster clock frequency than the master, the transactions from the master must be stored into a queue of data and response attribute registers. At a certain point during the master burst transactions, the queue is either emptied into the master for a burst read or it is emptied into the slave for a burst write..

Chapter 15
Platform Configuration Module (PCM)

15.1 PCM memory map

The Platform Configuration Module contains three miscellaneous configuration registers for the device. Currently, the configuration registers are related to the operation of the FEC and intelligent bus bridging gasket. The module is mapped to PBRIDGE on-platform slot 10 with a base address of 0xFC02_8000.

PCM memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	FEC Burst Optimization Master Control Register (PCM_FBOMCR)	32	R/W	0000_0000h	15.1.1/382
4	Bus Bridge Configuration Register 1 (PCM_IAHB_BE1)	32	R/W	0007_0707h	15.1.2/383
8	Bus Bridge Configuration Register 2 (PCM_IAHB_BE2)	32	R/W	0007_0707h	15.1.3/385
C	IPS Clock Gating Module Enable 0 Register (PCM_IPS_CGM_EN0)	32	R/W	0111_1111h	15.1.4/386

15.1.1 FEC Burst Optimization Master Control Register (PCM_FBOMCR)

The FEC burst optimization master control register (FBOMCR) controls FEC burst optimization behavior on the system bus.

Address: 0h base + 0h offset = 0h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R	0					ACCERR	WBEN	RBEN	FXSBE							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PCM_FBOMCR field descriptions

Field	Description
0–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21 ACCERR	Accumulate error This bit determines whether an error response for the first half of the write burst is accumulated to the second half of the write burst or discarded. In order to complete the burst, the FEC interface to the system bus responds by indicating that the first half of the burst completed without error before it actually writes the data so that it can fetch the second half of the write data from the FIFO. When actually written onto the system bus, the first half of the write burst can have an error. Because this half initially responded without an error to the FIFO, the error is discarded or accumulated with the error response for the second half of the burst. 0 Any error to the first half of the write burst is discarded. 1 Any actual error response to the first half of the write burst is accumulated in the second half's response. In other words, an error response to the first half will be seen in the response to the second half, even if the second half does not contain an error.
22 WBEN	Global write burst enable to XBAR slave port designated by FXSBE*n* 0 Write bursting to all XBAR slave ports is disabled. 1 Write bursting is enabled to any XBAR slave port whose FXSBE*n* bit is asserted.
23 RBEN	Global read burst enable from XBAR slave port designated by FXSBE*n* 0 Read bursting from all XBAR slave ports is disabled. 1 Read bursting is enabled from any XBAR slave port whose FXSBE*n* bit is asserted.

Table continues on the next page...

PCM_FBOMCR field descriptions (continued)

Field	Description
24–31 FXSBE	FEC XBAR slave burst enable. FXSBEn enables bursting by the FEC interface to the XBAR slave port controlled by that respective FXSBEn bit. If FXSBEn is asserted, then that XBAR slave port enabled by the bit can accept the bursts allowed by RBEN and WBEN. Otherwise, the FEC interface will not burst to the XBAR slave port controlled by that respective FXSBEn bit. Read bursts from that XBAR slave port are enabled by RBEN. Write bursts to that XBAR slave port are enabled by WBEN. FXSBEn assignments to XBAR slave ports: FXSBE0 = Flash FXSBE1 = reserved FXSBE2 = RAM, TCMA, TCMB FXSBE3 = reserved FXSBE4 = reserved FXSBE5 = reserved FXSBE6 = reserved FXSBE7 = PBRIDGE_0 and PBRIDGE_1

15.1.2 Bus Bridge Configuration Register 1 (PCM_IAHB_BE1)

NOTE

This register can only be accessed in supervisor mode.

Address: 0h base + 4h offset = 4h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0													1

31 BWE_FEC	Burst write enable (BWE) FEC. This bit controls the bus gasket's handling of burst write transactions. 0 Burst writes are converted into a series of single transactions on the slave side of the gasket. 1 Burst writes are optimized for best system performance. Note this setting treats writes as "imprecise" such that an error response on any beat of the burst is reported on the last beat..

15.1.4 IPS Clock Gating Module Enable 0 Register (PCM_IPS_CGM_EN0)

Address: 0h base + Ch offset = Ch

PCM_IPS_CGM_EN0 field descriptions

Field	Description
0–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 IPS_CGM_MPU1	IPS clock gating enable for MPU1 0 Disable clock gating. 1 Enable clock gating, one IPS clock delay is introduced between master and slave.
8–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11 IPS_CGM_ AXBS1	IPS clock gating enable for AXBS1 0 Disable clock gating. 1 Enable clock gating, one IPS clock delay is introduced between master and slave.
12–14 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15 IPS_CGM_INTC	IPS clock gating enable for INTC 0 Disable clock gating. 1 Enable clock gating, one IPS clock delay is introduced between master and slave.
16–18 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
19 IPS_CGM_MPU0	IPS clock gating enable for MPU0 0 Disable clock gating. 1 Enable clock gating, one IPS clock delay is introduced between master and slave.
20–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23 IPS_CGM_ AXBS0	IPS clock gating enable for AXBS0 0 Disable clock gating. 1 Enable clock gating, one IPS clock delay is introduced between master and slave.
24–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 IPS_CGM_ PRAM	IPS clock gating enable for PRAM Controller 0 Disable clock gating. 1 Enable clock gating, one IPS clock delay is introduced between master and slave.
28–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 IPS_CGM_ PFLASH	IPS clock gating enable for Flash Controller 0 Disable clock gating. 1 Enable clock gating, one IPS clock delay is introduced between master and slave.

Chapter 16
Semaphores2 (SEMA42)

16.1 Introduction

The SEMA42 is a memory-mapped module that provides robust hardware support needed in multi-core systems for implementing semaphores and provides a simple mechanism to achieve "lock and unlock" operations via a single write access. The hardware semaphore module provides hardware-enforced gates as well as other useful system functions related to the gating mechanisms.

16.1.1 Features

- Supports 16 hardware-enforced gates in a multi-processor configuration
  - Gates appear as an 16-entry byte-size array with read and write accesses.
    - Processors lock gates by writing "processor_number+1" to the appropriate gate and must read back the gate value to verify the lock operation was successful.
    - Once locked, the gate is unlocked by a write of zeroes from the locking processor.
    - The number of implemented gates is specified by a hardware configuration define.
  - Each hardware gate appears as a 16-state, 4-bit state machine.
    - 16-state implementation

      if gate = 0x0, then state = unlocked
      if gate = 0x1, then state = locked by processor (master) 0
      if gate = 0x2, then state = locked by processor (master) 1
      …
      if gate = 0xF, then state = locked by processor (master) 14

- Uses the logical bus master number as a reference attribute plus the specified data patterns to validate all write operations.
- Once locked, the gate can (and must) be unlocked by a write of zeroes from the locking processor.

- Secure reset mechanisms are supported to clear the contents of individual gates, as well as a clear_all capability.

A simplified block diagram of the Semaphores module is shown in the following figure. In the diagram, the register blocks named gate0, gate1,…, gate (n-2), gate (n-1) include the finite state machines implementing the semaphore gates.

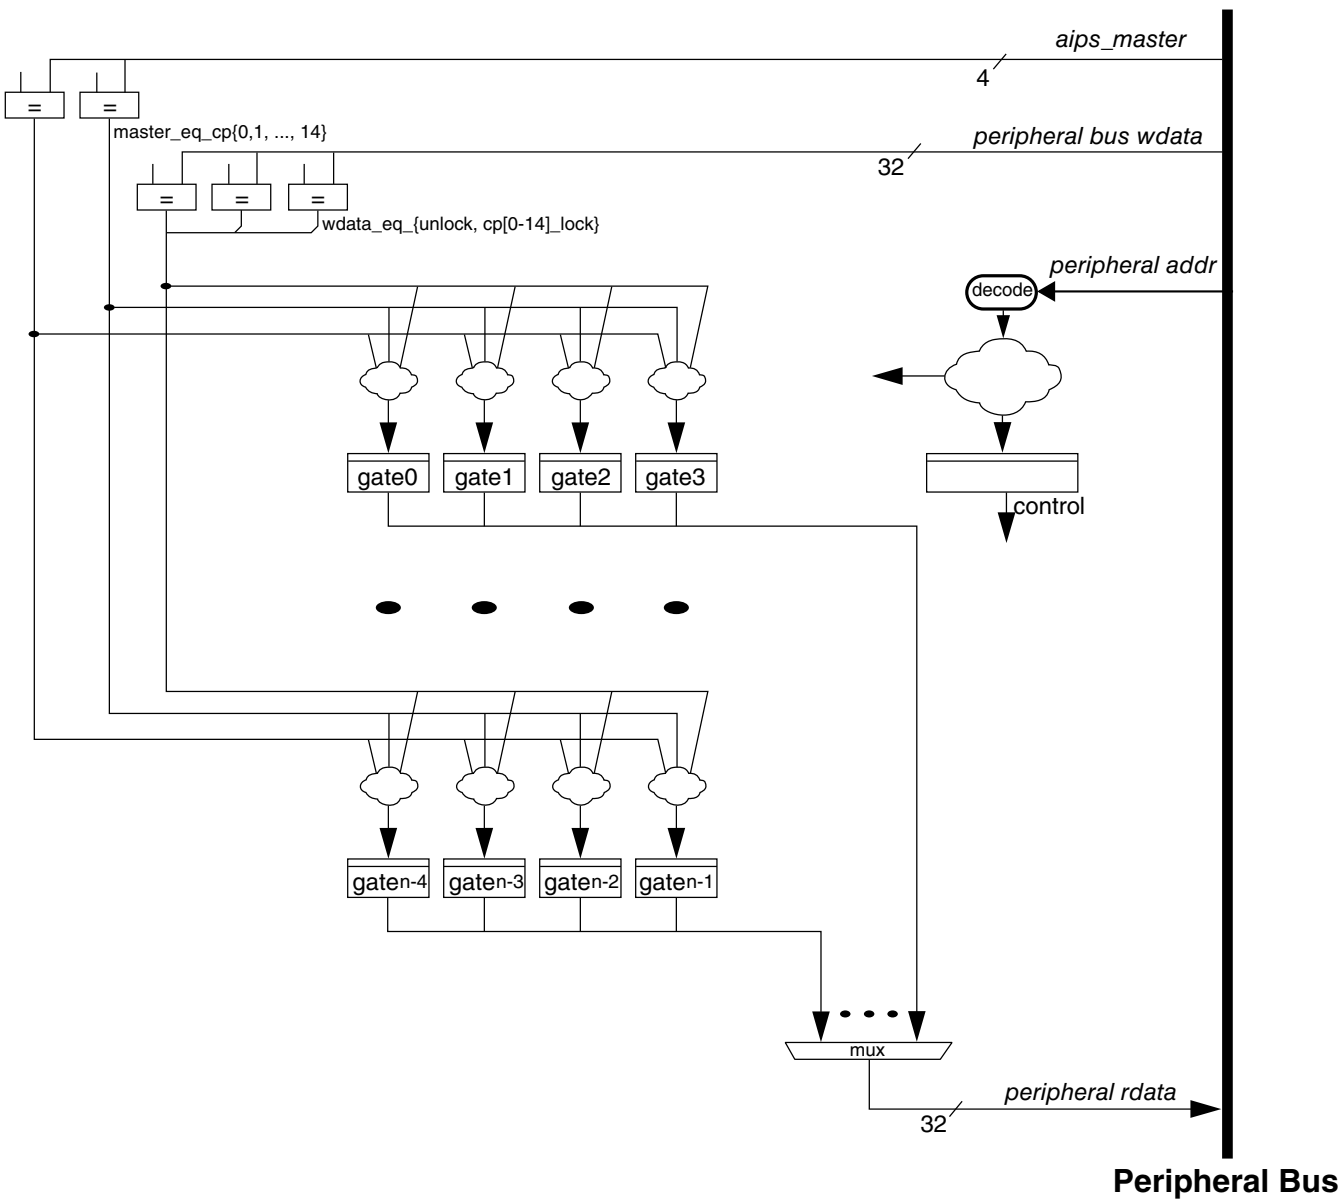

Figure 16-1. Semaphores2 block diagram

16.2 Memory map/register definition

Only Supervisor Mode accesses are allowed on these registers. User accesses will be terminated with an error.

SEMA42 memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	Gate Register (SEMA42_GATE0)	8	R/W	00h	16.2.1/391

16.2.1 Gate Register (SEMA42_GATE*n*)

Each semaphore gate is implemented in a 4-bit finite state machine, right-justified in a byte data structure. The hardware uses the logical bus master number in conjunction with the data patterns to validate all attempted write operations. Only processor bus masters can modify the gate registers. Once locked, a gate can (and must) be opened (unlocked) by the locking processor core.

Multiple gate values can be read in a single access, but only a single gate can be updated via a write operation at a time. Attempted writes with a data value that is neither the unlock value (0x00) nor the appropriate lock value (processor_number + 1) are simply

treated as "no operation" and do not affect any gate state. Attempts to write multiple gates in a single aligned access with a size larger than an 8-bit (byte) reference generate an error termination and do not allow any gate state changes.

Address: 0h base + 0h offset + (1d × i), where i=0d to 15d

Read	0				GTFSM			
Write								
Reset	0	0	0	0	0	0	0	0

SEMA42_GATE*n* field descriptions

Field	Description
0–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4–7 GTFSM	Gate Finite State Machine. The state of the gate reflects the last processor that locked it, which can be useful during system debug. The hardware gate is maintained in a 16-state implementation, defined as: 0000 The gate is unlocked (free). 0001 The gate has been locked by processor 0. 0010 The gate has been locked by processor 1. 0011 The gate has been locked by processor 2. 0100 The gate has been locked by processor 3. 0101 The gate has been locked by processor 4. 0110 The gate has been locked by processor 5. 0111 The gate has been locked by processor 6. 1000 The gate has been locked by processor 7. 1001 The gate has been locked by processor 8. 1010 The gate has been locked by processor 9. 1011 The gate has been locked by processor 10. 1100 The gate has been locked by processor 11. 1101 The gate has been locked by processor 12. 1110 The gate has been locked by processor 13. 1111 The gate has been locked by processor 14.

16.2.2 Reset Gate Write (SEMA42_RSTGT_W)

NOTE

This section and the following section, Reset Gate Read (SEMA42_RSTGT_R), describe the same register. This section describes the general operation of the register and also shows how the register fields appear when the register is written. Reset Gate Read (SEMA42_RSTGT_R) shows how the register fields appear when the register is read.

Although the intent of the hardware gate implementation specifies a protocol where the locking domain must unlock the gate, it is recognized that system operation may require a reset function to re-initialize the state of any gate(s) without requiring a system-level reset.

To support this special gate reset requirement, the Semaphores module implements a "secure" reset mechanism that allows a hardware gate (or all the gates) to be initialized by following a specific dual-write access pattern. Using a technique similar to that required for the servicing of a software watchdog timer, the secure gate reset requires two consecutive writes with predefined data patterns from the same domain to force the clearing of the specified gate(s). The required access pattern is:

1. A domain performs a 16-bit write to the SEMA42_RSTGT memory location. The most significant byte (SEMA42_RSTGT[RSTGDP]) must be E2h; the least significant byte is a "don't_care" for this reference.
2. The same domain then performs a second 16-bit write to the SEMA42_RSTGT location. For this write, the upper byte (SEMA42_RSTGT[RSTGDP]) is the logical complement of the first data pattern (1Dh) and the lower byte (SEMA42_RSTGT[RSTGTN]) specifies the gate(s) to be reset. This gate field can specify a single gate be cleared, or that all gates are to be cleared. If the same domain writes incorrect data on the second access or another domain performs the second write access, the special gate reset sequence is aborted and no error signal is asserted.
3. Reads of the SEMA42_RSTGT location return information on the 2-bit state machine (SEMA42_RSTGT[RSTGSM]) that implements this function, the domain performing the reset (SEMA42_RSTGT[RSTGMS]), and the gate number(s) last cleared (SEMA42_RSTGT[RSTGTN]). Reads of the SEMA42_RSTGT register do not affect the secure reset finite state machine in any manner.

Address: 0h base + 40h offset = 40h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read																
Write	RSTGDP								RSTGTN							
Reset	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*

* Notes:
- Reset value is not applicable for writes.

SEMA42_RSTGT_W field descriptions

Field	Description
0–7 RSTGDP	Reset Gate Data Pattern. This write-only field is accessed with the specified data patterns on the two consecutive writes to enable the gate reset mechanism. For the first write, RSTGDP = E2h while the second write requires RSTGDP = 1Dh.

Table continues on the next page...

SEMA42_RSTGT_W field descriptions (continued)

Field	Description
8–15 RSTGTN	Reset Gate Number. This 8-bit field specifies the specific hardware gate to be reset. This field is updated by the second write. If RSTGTN < 64, then reset the single gate defined by RSTGTN, else reset all the gates.

16.2.3 Reset Gate Read (SEMA42_RSTGT_R)

This section describes how the Reset Gate register fields appear when the register is read. See Reset Gate Write (SEMA42_RSTGT_W) for the description of the register's overall operation and how the register fields appear when the register is written.

Address: 0h base + 40h offset = 40h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	ROZ		RSTGSM		RSTGMS				RSTGTN							
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SEMA42_RSTGT_R field descriptions

Field	Description
0–1 ROZ	This field always returns the value 0 when read.
2–3 RSTGSM	Reset Gate Finite State Machine. Reads of the SEMA42_RSTGT register return the encoded state machine value. Note the RSTGSM = 10 state is valid for only a single machine cycle, so it is impossible for a read to return this value. The reset state machine is maintained in a 2-bit, 3-state implementation, defined as: 00 Idle, waiting for the first data pattern write. 01 Waiting for the second data pattern write. 10 The 2-write sequence has completed. Generate the specified gate reset(s). After the reset is performed, this machine returns to the idle (waiting for first data pattern write) state. The "01" state persists for only one clock cycle. Software cannot observe this state. 11 This state encoding is never used and therefore reserved.
4–7 RSTGMS	Reset Gate Bus Master. This 4-bit read-only field records the logical number of the bus master performing the gate reset function. The reset function requires that the two consecutive writes to this register must be initiated by the same bus master to succeed. This field is updated each time a write to this register occurs. The association between system bus master port numbers, the associated bus master device, and the logical processor number is SoC-specific. Consult the device reference manual for this information.
8–15 RSTGTN	Reset Gate Number. This 8-bit field specifies the specific hardware gate to be reset. This field is updated by the second write. If RSTGTN < 64, then reset the single gate defined by RSTGTN, else reset all the gates.

16.3 Functional description

Functional operation of the Semaphores module and specific details of the state machines of the SEMA42_GATEn registers are provided as follows.

As described previously, each of the SEMA42_GATEn registers implements a 4-bit, 16-state machine. A *simplified* diagram of the state transitions for each gate is shown in Figure 16-21.

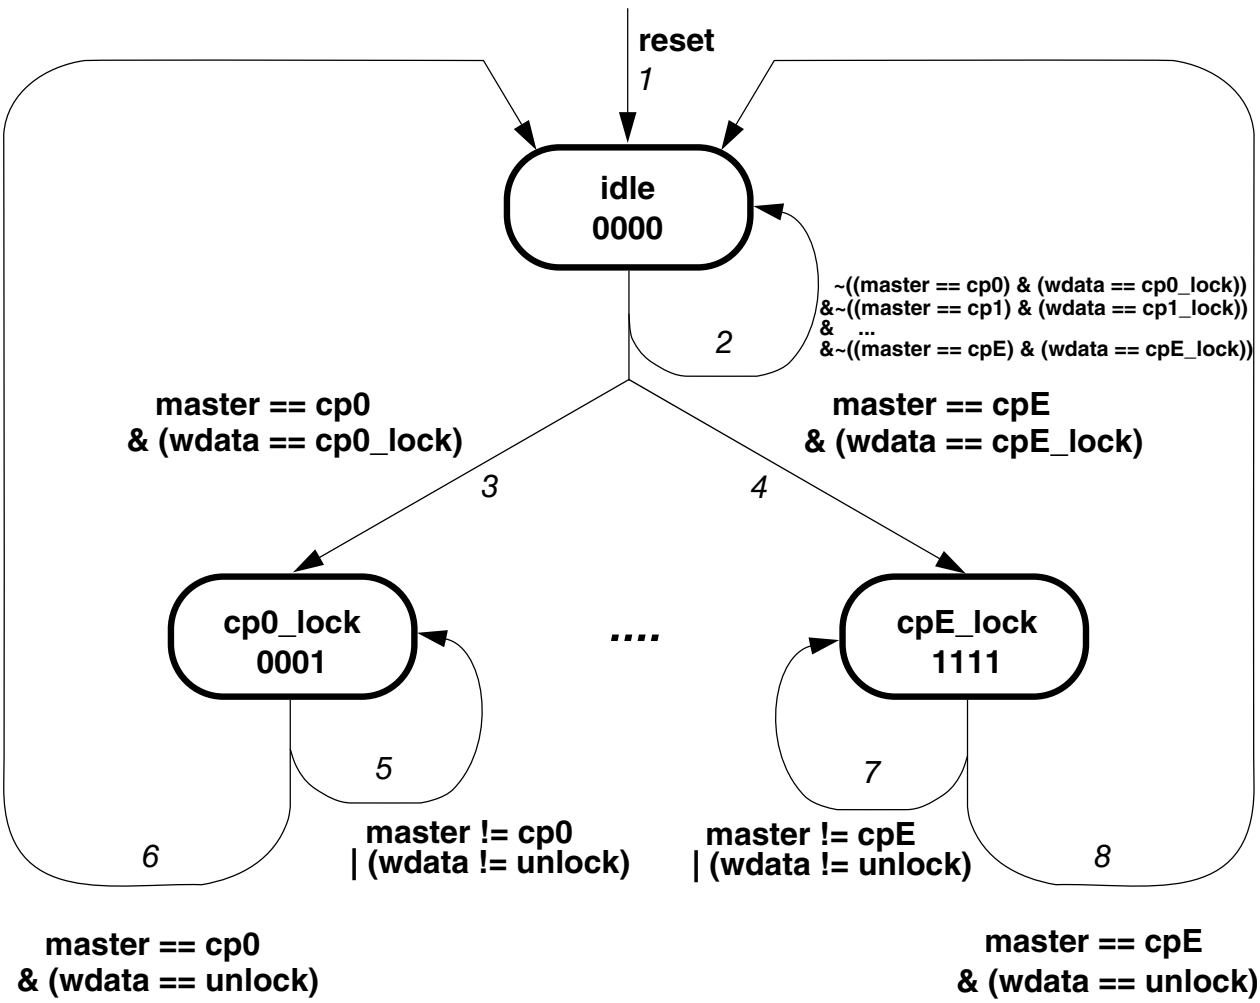

Figure 16-21. SEMA42_GATEn state machine

The bus master number is used to identify core processor *X* (cp*X*) where the notation cpE is used to represent core processor 14 (= 0xE). The platform passes the AHB bus master number through the peripheral bridge controller and drives a signal to the Semaphores module.

The state transitions for SEMA42_GATEn are defined in Table 16-21.

Table 16-21. SEMA42_GATEn state transitions

Current State	Next State	Transition	Description
–	idle	1	Any reset, whether a system reset or a software-initiated gate reset, unconditionally forces the gate into the idle state.
idle	idle	2	Unless a write of the appropriate lock value from the corresponding processor occurs, the gate remains in the idle state.
idle	cp0_lock	3	When a write of the "cp0_lock" data value is initiated by processor 0, the gate transitions into the cp0_lock state.
idle	cpE_lock	4	When a write of the "cpE_lock" value is initiated by processor 0xE, the gate transitions into the cpE_lock state.
cp0_lock	cp0_lock	5	Once in this state, the gate remains here if any attempted write is not from cp0 with the unlock data value.
cp0_lock	idle	6	The gate returns to the idle (unlocked) state once a write from cp0 with the unlock data value occurs.
cpE_lock	cpE_lock	7	Once in this state, the gate remains here if any attempted write is not from cpE with the unlock data value.
cpE_lock	idle	8	The gate returns to the idle (unlocked) state once a write from cpE with the unlock data value occurs.

The following gate data values are used:

- The lock data value is (processor number + 1) where the processor number and the platform bus master number are the same.
- The unlock data value is 0x00.

Chapter 17
Interrupt Controller (INTC)

17.1 Interrupt Controller (INTC) chip-specific module information

17.1.1 INTC configurable parameters

The INTC on this chip supports 2 processors.

17.1.2 Interrupt sources

The following table defines the interrupt sources for the INTC on this chip. All IRQ numbers not specifically listed are not used.

Table 17-1. Interrupt sources

IRQ #	Offset	Source description	Source name
0	1000	Software settable flag 0	INTC_SSCIR0[CLR0]

17.2 Introduction

The INTC:

- Provides priority-based preemptive scheduling of interrupt requests
- Schedules interrupt requests (IRQs) from software and internal peripherals to one or more processors (PRCs)
- Provides interrupt prioritization and preemption, interrupt masking, interrupt priority elevation, and protocol support

This scheduling scheme is suitable for statically scheduled hard real-time systems.

The INTC is targeted to work with a Power Architecture processor and is capable of processing high-demand interrupt sources where the Interrupt Service Routines (ISRs) nest to multiple levels, but it also can be used with other processors and applications.

For high-priority interrupt requests in these target applications, it is necessary to minimize the interval between the assertion of the interrupt request from the peripheral and the point at which the processor is performing useful work to service the interrupt request. The INTC supports this goal by providing a unique vector for each interrupt

request source. It also provides 64 priorities so that lower priority ISRs do not delay the execution of higher priority ISRs. Since each individual application will have different priorities for each source of interrupt request, the priority of each interrupt request is configurable.

When multiple tasks share a resource, coherent accesses to that resource need to be supported. The INTC supports the Priority Ceiling Protocol for coherent accesses. By providing a modifiable priority mask, the priority can be raised temporarily so that all tasks which share the resource are unable to preempt each other.

Multiple processors can assert interrupt requests to each other through software-settable interrupt requests. These same software-settable interrupt requests can also be used to separate the work involved in servicing an interrupt request into two parts, a high-priority portion and a low-priority portion. The high-priority portion is initiated by a peripheral interrupt request, but then the ISR can assert a software-settable interrupt request to finish the servicing in a lower priority ISR. Therefore these software-settable interrupt requests can be used instead of having the peripheral ISR schedule a task through the RTOS.

17.3 Block diagram

The following figure shows the block diagram of an INTC with four processors (PRC0...PRC3). The actual number of processors is described in the chip-specific INTC information. The structure of the INTC remains the same for each implemented processor.

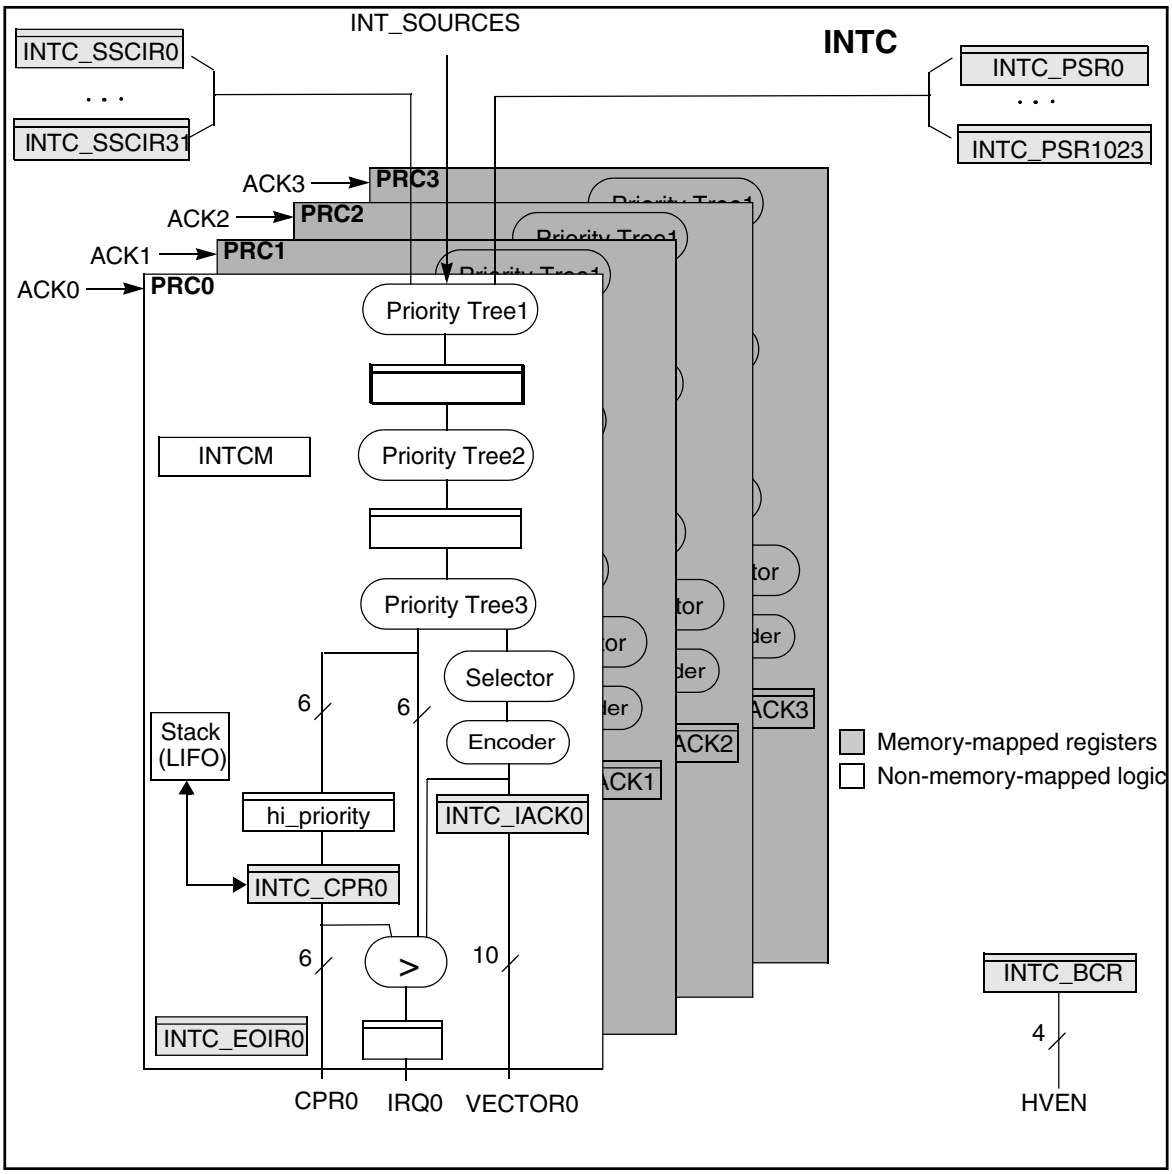

Figure 17-1. Block diagram for an INTC with four processors

17.4 Features

- Each peripheral interrupt source is software-steerable to any combination of interrupt request outputs to the following:
  - Processor 0
  - Processor 1
- 32 software-settable interrupt request sources
- 10-bit vector

    - Unique vector for each interrupt request source
    - Hardware connection to processor or read from register
- Each interrupt source can be programmed to one of 64 priorities
- Each interrupt source can be triggered by software
- Preemption
    - Preemptive prioritized interrupt requests to processor
    - ISR with higher priority preempts ISRs or tasks with lower priorities
    - Automatic pushing or popping of preempted priority to or from a LIFO
    - Ability to modify the ISR or task priority; modifying the priority can be used to implement the Priority Ceiling Protocol for accessing shared resources
    - 3 INTC clock cycles from interrupt request into interrupt request to CPU
- Low latency
    - 3 INTC clock cycles from receipt of interrupt request from peripheral to interrupt request to processor; four clock cycles from receipt of software request
- Monitor
    - The Interrupt Controller Monitor (INTCM) provides a way to set a maximum timer count for the interrupt latency from interrupt request (IRQ) to interrupt acknowledge (IACK) or from IRQ to return from interrupt (RFI). The purpose of this function is to provide a mechanism to monitor the latency of interrupt sources for a corresponding Processor to ensure that these critical interrupts execute within the expected window of time, increasing the reliability of the device. The hardware for this function is isolated in its own hierarchy to decrease the risk of fault interference.

17.5 Modes of operation

The interrupt controller has two handshaking modes with the processor: software vector mode and hardware vector mode. The state of the hardware vector enable bit, INTC_BCR[HVEN], determines which mode is used. In Power Architecture devices, software vector mode uses the autovector mode of the Processor for a single entry point for the ISR (16 bytes of vector space available), whereas the hardware vector mode uses the non-autovector mode where the vector offset from the INTC is provided to the Processor (4 bytes for each IRQ).

In debug mode the interrupt controller operation is identical to its normal operation of software vector mode or hardware vector mode.

17.5.1 Software vector mode

In software vector mode, software (that is, the interrupt exception handler) must read a register in the INTC to obtain the vector associated with the interrupt request to the processor. The INTC will use software vector mode for a given processor when its associated HVEN_PRCn bit in the INTC_BCR is negated. The hardware vector enable signal to any processor is driven as negated when its associated HVEN_PRC*n* bit is negated. The vector is read from the INTC_IACKRn registers. Reading the INTC_IACKR*n* negates the interrupt request to the associated processor. Even if a higher priority interrupt request has arrived while waiting for this interrupt acknowledge, the interrupt request to the processor will negate for at least one clock. The reading also pushes the PRI value in the INTC_CPRn onto the associated LIFO, and updates PRI in the associated INTC_CPR_PRC*n* with the new priority.

17.5.2 Hardware vector mode

In hardware vector mode, the hardware causes the first instruction that will be executed (when handling the interrupt request to the processor) to be an instruction that is specific to that vector. Therefore the interrupt exception handler is specific to a peripheral or software-settable interrupt request, rather than being common to all of them. The INTC will use hardware vector mode for a given processor when its associated HVENn bit in the INTC_BCR is asserted. The hardware vector enable signal to the associated processor is driven as asserted.

When the interrupt request to the associated processor asserts, the interrupt vector signal is updated. The value of that interrupt vector is the unique vector associated with the preempting peripheral or software-settable interrupt request. The vector value matches the value of the INTVEC field in the INTC_IACKRn, depending on which processor was assigned to handle a given interrupt source.

The assertion of the interrupt acknowledge signal for a given processor pushes the associated PRI value in the associated INTC_CPR*n* register onto the associated LIFO and updates the associated PRI in the associated INTC_CPR*n* register with the new priority. This pushing of the PRI value onto the associated LIFO and updating PRI in the associated INTC_CPR*n* does not occur when the associated interrupt acknowledge signal asserts and the INTC_SSCIRs is written at a time such that the PRI value in the associated INTC_CPR*n* register would need to be pushed and the previously last pushed

PRI value would need to be popped simultaneously. In this case, PRI in the associated INTC_CPR*n* is updated with the new priority, and the associated LIFO is neither pushed or popped.

17.6 Memory map and register definition

A transfer error will be asserted if an access is attempted outside of the memory map or for any unimplemented registers. For example, if the design has only 512 interrupt sources and a source > 512 is accessed, a transfer error is asserted.

With the exception of the INTC_SSCIR *n* and INTC_PSR *n* registers, all of the registers are 32-bit. Any combination of accessing the four bytes of a register with a single access is supported, provided that the access does not cross a register boundary. These supported accesses include types and sizes of 8 bits, aligned 16 bits, misaligned 16 bits to the middle two bytes, and aligned 32 bits.

Although INTC_SSCIR*n* are 8 bits wide and INTC_PSR*n* are 16 bits wide, they can be accessed with a single 16-bit or 32-bit access, provided that the access does not cross a 32-bit boundary.

Some registers have specific exceptions to these rules, as outlined in their definitions.

When writing to INTC_PSRs or INTC_SSCIRs, the following restrictions (illustrated in Figure 17-2) apply:

- For PSRs, write accesses must not span 16-bit boundaries where one register is implemented and one is unimplemented (unimplemented interrupt source).
- For SSCIRs, write accesses must not span 8-bit boundaries where one register is implemented and one is unimplemented (unimplemented interrupt source).

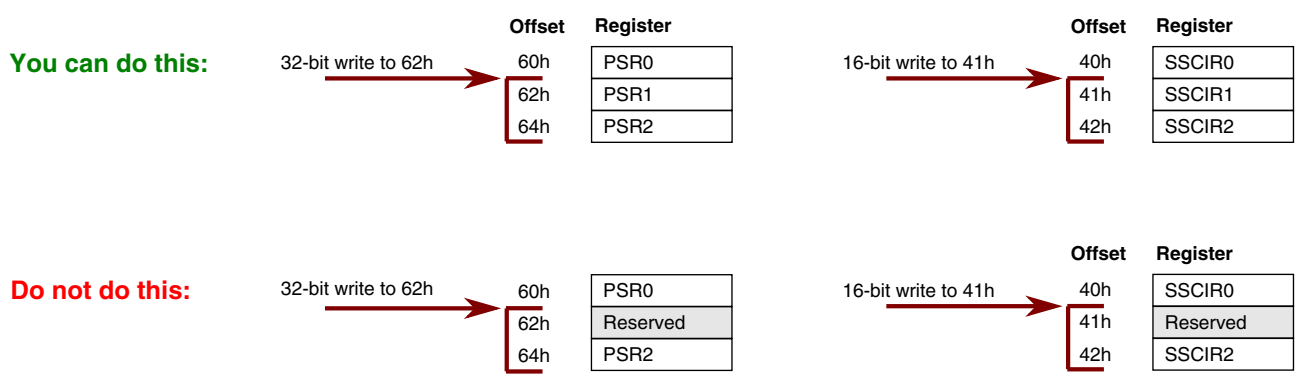

Figure 17-2. INTC_PSR*n* and INTC_SSCIR*n* write restrictions

In software vector mode, the effects of a read of the INTC Interrupt Acknowledge register (INTC_IACKR *n*) are the same regardless of the size of the read. In either software or hardware vector mode, the size of a write to the INTC end-of-interrupt register (INTC_EOIR *n*) does not affect the operation of the write.

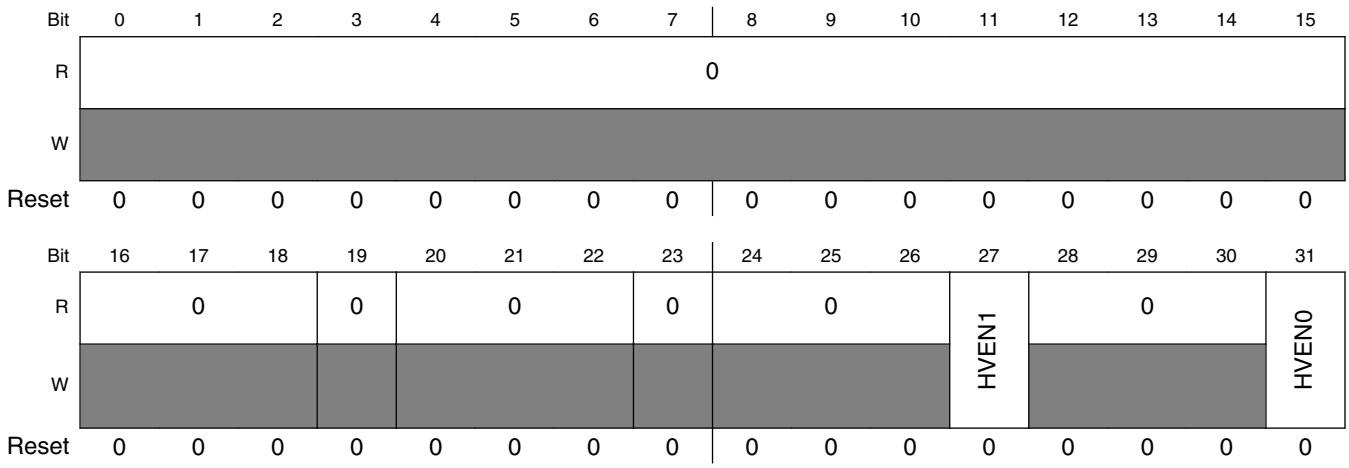
17.6.1 INTC Block Configuration Register (INTC_BCR)



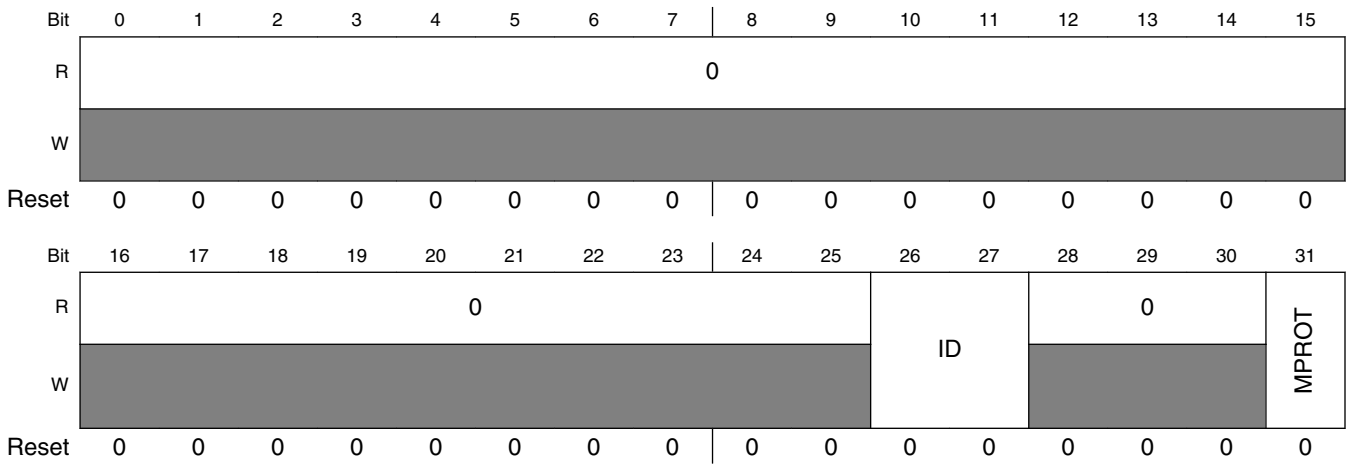
The Block Configuration Register is used to configure options of the INTC.

The master ID is used to determine if this register can be written by a given processor. Only the processor with master ID zero will be allowed write access, otherwise, a termination error is asserted.

If INTC_MPROT[MPROT]=0 (disabled), all processors have write access to this register.

If INTC_MPROT[MPROT]=1 (enabled), the processor with master ID (0-3) = INTC_MPROT[ID] has write access, otherwise, a termination error is asserted.

Address: 0h base + 0h offset = 0h



INTC_BCR field descriptions

Field	Description
0–18 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 HVEN1	Hardware vector enable for processor 1. Controls whether the INTC is in hardware vector mode or software vector mode. See Modes of operation for the details of the handshaking with the processor in each mode. 0 Software vector mode 1 Hardware vector mode
28–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 HVEN0	Hardware vector enable for processor 0. Controls whether the INTC is in hardware vector mode or software vector mode. See Modes of operation for the details of the handshaking with the processor in each mode. 0 Software vector mode 1 Hardware vector mode

17.6.2 INTC Master Protection Register (INTC_MPROT)

The Master Protection Register is used to protect cores from writing to other cores INTC registers.

Address: 0h base + 4h offset = 4h

INTC_MPROT field descriptions

Field	Description
0–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26–27 ID	ID This register can only be updated if MPROT=0 or if processor master ID=ID. When MPROT is set, the ID should also be updated to indicate which master can write to any register in the INTC memory map. Only the field values related to core bus masters can be selected. Non-core bus masters cannot be selected and would result in a bus access error. 00 master0 (reset default) 01 master1 10 master2 11 master3
28–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 MPROT	Master Protection Controls what programming space a given master can write to. If MPROT is disabled, then all masters can write to any valid entry of the INTC memory map. If MPROT is enabled, INTC_MPROT[ID] can write to any valid entry of the INTC memory map but other masters can only write to their assigned resources. Once MPROT is enabled by a master, only that master may modify INTC_MPROT. 0 Master programming space protection disabled 1 Master programming space protection enabled

17.6.3 INTC Current Priority Register for Processor 0 (INTC_CPR0)

The INTC_CPRn masks any peripheral or software-settable interrupt request that is set at the same or lower priority as the current value of the INTC_CPR*n*[PRI] field from generating an interrupt request to the processor. When the INTC Interrupt Acknowledge register (INTC_IACKR*n*) is read in software vector mode or the interrupt acknowledge signal from the processor is asserted in hardware vector mode, the value of PRI is pushed onto the LIFO, and PRI is updated with the priority of the preempting interrupt request. When the INTC end-of-interrupt register (INTC_EOIR*n*) is written, the LIFO is popped into the INTC_CPR*n* PRI field. An exception case in hardware vector mode to this behavior is described in Hardware vector mode.

The masking priority can be raised or lowered by writing to the PRI field, supporting the priority ceiling protocol. See Priority ceiling protocol.

The master ID is used to determine if this register can be written by a given processor. The processor with master ID zero will be allowed write access. Only the corresponding processor will have write access, otherwise, a termination error is asserted.

If INTC_MPROT[MPROT]=0 (disabled), all processors have write access to this register.

If INTC_MPROT[MPROT]=1 (enabled), the processor with master ID (0-3) = INTC_MPROT[ID] or the corresponding processor has write access, otherwise, a termination error is asserted.

NOTE

A store to modify the PRI field that closely precedes or follows an access to a shared resource may result in a non-coherent access to that resource. See Ensuring coherency for example code to ensure coherency.

Address: 0h base + 10h offset = 10h

INTC_CPR0 field descriptions

Field	Description
0–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26–31 PRI	Priority of the currently executing ISR, according to the field values 63 (highest priority) down to 0 (lowest priority).

17.6.4 INTC Current Priority Register for Processor 1 (INTC_CPR1)

The INTC_CPRn masks any peripheral or software-settable interrupt request that is set at the same or lower priority as the current value of the INTC_CPR*n*[PRI] field from generating an interrupt request to the processor. When the INTC Interrupt Acknowledge register (INTC_IACKR*n*) is read in software vector mode or the interrupt acknowledge signal from the processor is asserted in hardware vector mode, the value of PRI is pushed onto the LIFO, and PRI is updated with the priority of the preempting interrupt request. When the INTC end-of-interrupt register (INTC_EOIR*n*) is written, the LIFO is popped into the INTC_CPR*n* PRI field. An exception case in hardware vector mode to this behavior is described in Hardware vector mode.

The masking priority can be raised or lowered by writing to the PRI field, supporting the priority ceiling protocol. See Priority ceiling protocol.

The master ID is used to determine if this register can be written by a given processor. The processor with master ID zero will be allowed write access. Only the corresponding processor will have write access, otherwise, a termination error is asserted.

If INTC_MPROT[MPROT]=0 (disabled), all processors have write access to this register.

If INTC_MPROT[MPROT]=1 (enabled), the processor with master ID (0-3) = INTC_MPROT[ID] or the corresponding processor has write access, otherwise, a termination error is asserted.

NOTE

A store to modify the PRI field that closely precedes or follows an access to a shared resource may result in a non-coherent access to that resource. See Ensuring coherency for example code to ensure coherency.

Address: 0h base + 14h offset = 14h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

INTC_CPR1 field descriptions

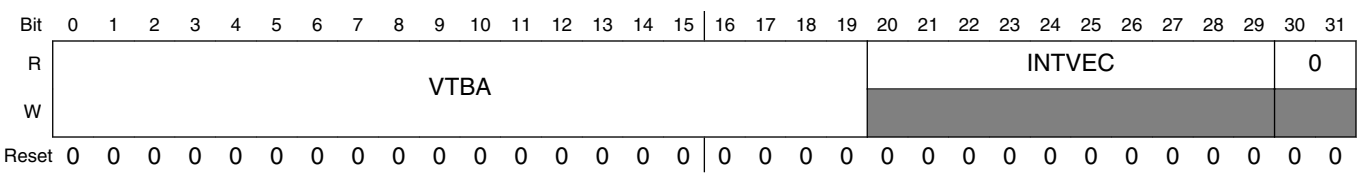
Field	Description
0–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26–31 PRI	Priority of the currently executing ISR, according to the field values 63 (highest priority) down to 0 (lowest priority).

17.6.5 INTC Interrupt Acknowledge Register for Processor 0 (INTC_IACKR0)

The Interrupt Acknowledge Register for Processor *n* provides a value which can be used to load the address of an ISR from a vector table. The vector table can be composed of addresses of the ISRs specific to their respective interrupt vectors.

Also, in software vector mode, the INTC_IACKR*n* has side effects from reads unless INTC_MPROT[MPROT]=1 and processor with master ID (0-3) != INTC_MPROT[ID]. Therefore, it must not be read speculatively while in this mode. The side effects are the same regardless of the size of the read. Reading the INTC_IACKRn does not have side effects in hardware vector mode.

The master ID is used to determine if this register can be written by a given processor. The processor with master ID zero will be allowed write access. Only the corresponding processor will have write access, otherwise, a termination error is asserted.



If INTC_MPROT[MPROT]=0 (disabled), all processors have read and write access to this register.

If INTC_MPROT[MPROT]=1 (enabled), the processor with master ID (0-3) = INTC_MPROT[ID] or the corresponding processor has read and write access, otherwise, a termination error is asserted.

NOTE

When the corresponding INTC_BCR[HVENn] = 1, a read of the INTC_IACKR has no side effects.

Address: 0h base + 20h offset = 20h

INTC_IACKR0 field descriptions

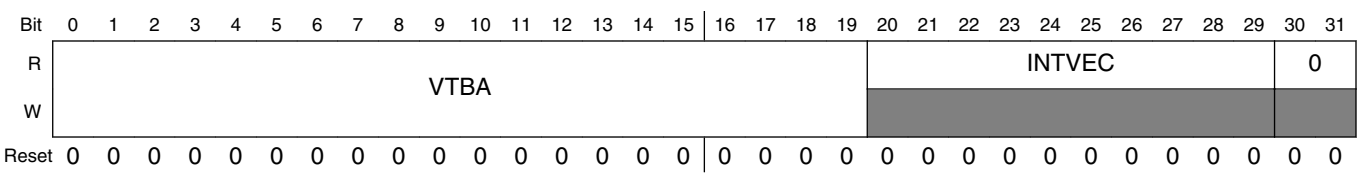
Field	Description
0–19 VTBA	Vector table base address. Can be the base address of a vector table of addresses of ISRs.
20–29 INTVEC	Interrupt vector. Vector of the peripheral or software-settable interrupt request that caused the interrupt request to the processor. When the interrupt request to the processor asserts, the INTVEC is updated, whether the INTC is in software or hardware vector mode.
30–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

17.6.6 INTC Interrupt Acknowledge Register for Processor 1 (INTC_IACKR1)

The Interrupt Acknowledge Register for Processor *n* provides a value which can be used to load the address of an ISR from a vector table. The vector table can be composed of addresses of the ISRs specific to their respective interrupt vectors.

Also, in software vector mode, the INTC_IACKR*n* has side effects from reads unless INTC_MPROT[MPROT]=1 and processor with master ID (0-3) != INTC_MPROT[ID]. Therefore, it must not be read speculatively while in this mode. The side effects are the same regardless of the size of the read. Reading the INTC_IACKRn does not have side effects in hardware vector mode.

The master ID is used to determine if this register can be written by a given processor. The processor with master ID zero will be allowed write access. Only the corresponding processor will have write access, otherwise, a termination error is asserted.



If INTC_MPROT[MPROT]=0 (disabled), all processors have read and write access to this register.

If INTC_MPROT[MPROT]=1 (enabled), the processor with master ID (0-3) = INTC_MPROT[ID] or the corresponding processor has read and write access, otherwise, a termination error is asserted.

NOTE

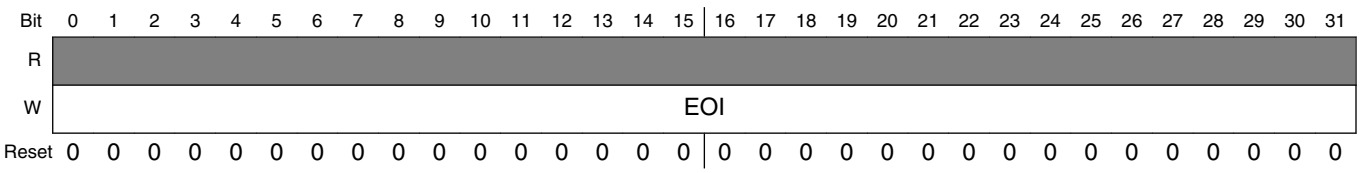
When the corresponding INTC_BCR[HVENn] = 1, a read of the INTC_IACKR has no side effects.

Address: 0h base + 24h offset = 24h

INTC_IACKR1 field descriptions

Field	Description
0–19 VTBA	Vector table base address. Can be the base address of a vector table of addresses of ISRs.
20–29 INTVEC	Interrupt vector. Vector of the peripheral or software-settable interrupt request that caused the interrupt request to the processor. When the interrupt request to the processor asserts, the INTVEC is updated, whether the INTC is in software or hardware vector mode.
30–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

17.6.7 INTC End Of Interrupt Register for Processor 0 (INTC_EOIR0)



Writing to the INTC_EOIR*n* signals the end of the servicing of the interrupt request. When the INTC_EOIR*n* is written, the priority last pushed on the LIFO is popped into INTC_CPR*n*. The values and size of data written to the INTC_EOIR*n* are ignored. Those values and sizes written to this register neither update the INTC_EOIR*n* contents nor affect whether the LIFO pops. Typically, when you write to this register, write four all-zero bytes.

The master ID is used to determine if this register can be written by a given processor. The processor with master ID zero will be allowed write access. Only the corresponding processor will have write access, otherwise, a termination error is asserted.

If INTC_MPROT[MPROT]=0 (disabled), all processors have write access to this register.

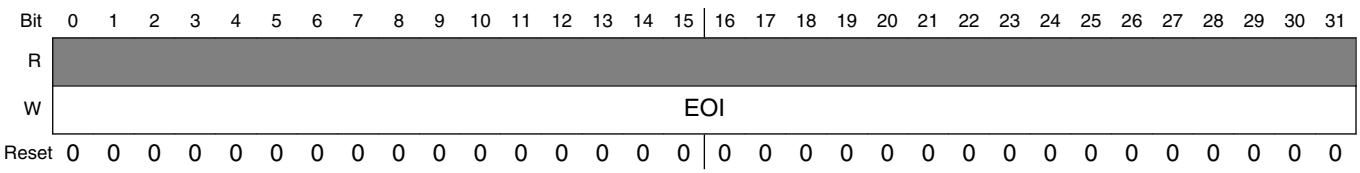
If INTC_MPROT[MPROT]=1 (enabled), the processor with master ID (0-3) = INTC_MPROT[ID] or the corresponding processor has write access, otherwise, a termination error is asserted.

Address: 0h base + 30h offset = 30h

INTC_EOIR0 field descriptions

Field	Description
0–31 EOI	End of Interrupt. Write four all-zero bytes to this field to signal the end of the servicing of an interrupt request.

17.6.8 INTC End Of Interrupt Register for Processor 1 (INTC_EOIR1)



Writing to the INTC_EOIR*n* signals the end of the servicing of the interrupt request. When the INTC_EOIR*n* is written, the priority last pushed on the LIFO is popped into INTC_CPR*n*. The values and size of data written to the INTC_EOIR*n* are ignored. Those values and sizes written to this register neither update the INTC_EOIR*n* contents nor affect whether the LIFO pops. Typically, when you write to this register, write four all-zero bytes.

The master ID is used to determine if this register can be written by a given processor. The processor with master ID zero will be allowed write access. Only the corresponding processor will have write access, otherwise, a termination error is asserted.

If INTC_MPROT[MPROT]=0 (disabled), all processors have write access to this register.

If INTC_MPROT[MPROT]=1 (enabled), the processor with master ID (0-3) = INTC_MPROT[ID] or the corresponding processor has write access, otherwise, a termination error is asserted.

Address: 0h base + 34h offset = 34h

INTC_EOIR1 field descriptions

Field	Description
0–31 EOI	End of Interrupt. Write four all-zero bytes to this field to signal the end of the servicing of an interrupt request.

17.6.9 INTC Software Set/Clear Interrupt Register (INTC_SSCIR*n*)

The INTC_SSCIR registers support the setting or clearing of software-settable interrupt requests. These registers contain independent sets of bits to set and clear a corresponding flag bit by software. Unlike the SWT bit in the PSRs, the INTC_SSCIR registers do not require a read-modify-write. With the exception of being set by software, this flag bit behaves the same as a flag bit set within a peripheral. This flag bit generates an interrupt request within the INTC just like a peripheral interrupt request. Writing a 1 to SET will leave SET unchanged at 0 but will set CLR. Writing a 0 to SET will have no effect. CLR is the flag bit. Writing a 1 to CLR will clear it. Writing a 0 to CLR will have no effect. If a 1 is written to a pair of SET and CLR bits at the same time, CLR is asserted, regardless of whether CLR was asserted before the write.

Any processor will be allowed to write to any of the SET bits in the INTC_SSCIRn registers. The CLR bit will only be writable by the processor which has been assigned to handle that interrupt request, as determined by the setting of the INTC_PSRn[PRC_SEL]. An attempt by any other processor to write the CLR bit and not the SET bit will result in a termination error.

See Figure 17-2 for limitations on writing to this register.

NOTE

Since the four software setable interrupts in a word can be assigned to different processors, the cores with non-zero master IDs must only write the INTC_SSCIRn registers using a byte operation. A write of any other size will result in a termination error.

Any processor will be allowed to write to any of the SET bits in the INTC_SSCIRn registers.

If INTC_MPROT[MPROT]=0 (disabled), all processors can write to the CLR bit.

If INTC_MPROT[MPROT]=1 (enabled), the processor with master ID (0-3) = INTC_MPROT[ID] or the corresponding processor can write to the CLR bit, otherwise, a termination error is asserted.

NOTE

If INTC_MPROT[MPROT] is enabled, processors with master ID != INTC_MPROT[ID] must only write the INTC_SSCIRn registers using a byte operation. A write of any other size will result in a termination error.

Address: 0h base + 40h offset + (1d × i), where i=0d to 31d

Bit	0	1	2	3	4	5	6	7
Read	0						0	CLR
Write							SET	w1c
Reset	0	0	0	0	0	0	0	0

INTC_SSCIR*n* field descriptions

Field	Description
0–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6 SET	Set flag bits. Writing a 1 will set the corresponding CLR bit. Writing a 0 will have no effect. Each SET is read as a 0.
7 CLR	Clear flag bits. CLR is the flag bit. Writing a 1 to CLR will clear it provided that a 1 is not written simultaneously to its corresponding SET bit. Writing a 0 to CLR will have no effect. 0 Interrupt request not pending within INTC. 1 Interrupt request pending within INTC.

17.6.10 INTC Priority Select Register (INTC_PSR*n*)

The Priority Select Registers support the selection of an individual priority for each source of interrupt request, and the routing of the request to one or more processors. The unique vector of each peripheral or software-settable interrupt request determines which INTC_PSRn is assigned to that interrupt request. The software-settable interrupt requests are assigned the lowest numbered vectors, and their priorities are configured in the lowest numbered INTC_PSR registers. The peripheral interrupt requests are assigned to vectors immediately following the software-settable interrupt requests, and their priorities are configured in the immediately following INTC_PSR registers. The peripheral interrupt requests are assigned vectors 32-1023, and their priorities are configured in INTC_PSR32-1023, respectively.

Only the processor with master ID zero will be allowed to write the INTC_PSRn[PRC_SEL,SWT]. When writing the INTC_PSR[PRI], only the processor with master ID 0 and the processor who's master ID matches the setting of the INTC_PSRn[PRC_SEL] will be allowed to write the INTC_PSRn[PRI]. An attempt by any other processor to write the PSRn[PRIn] will result in a termination error.

If INTC_MPROT[MPROT]=0 (disabled), all processors have write access.

If INTC_MPROT[MPROT]=1 (enabled), the processor with master ID (0-3) = INTC_MPROT[ID] or the corresponding processor has write access to INTC_PSRn[PRC_SEL,SWT], otherwise, a termination error is asserted. When writing the INTC_PSRn[PRI], only the processor with master ID (0-3) = INTC_MPROT[ID] and the processor whose master ID (0-3) matches the setting of the INTC_PSRn[PRC_SEL] will be allowed to write the INTC_PSRn[PRI]. An attempt by any other processor to write the INTC_PSRn[PRI] will result in a termination error.

See Figure 17-2 for limitations on writing to this register.

NOTE

Unlike the peripheral interrupt request PSRs, there is no SWT bit in the PSRs corresponding to the software-settable interrupt requests.

NOTE

Interrupts are not detected while the PSRs are being written.

NOTE

If INTC_MPROT[MPROT] is enabled, the core with master ID (0-3) = INTC_MPROT[ID] will be able to write the INTC_PSRn with either byte, half-word or word operations. All

other master IDs are restricted to byte operations to the INTC_PSRn[PRI] bits (i.e the odd addresses). Any other sized write operation, or a byte operation to the INTC_PSRn[PRC_SEL] (i.e. the even byte) will result in a termination error.

NOTE

The core with master ID 0 will be able to write the INTC_PSRn with either byte, half-word or word operations. All other master IDs are restricted to byte operations to the PSRn[PRIn] bits (i.e the odd addresses). Any other sized write operation, or a byte operation to the INTC_PSRn[PRC_SEL] (i.e. the even byte) will result in a termination error.

Address: 0h base + 60h offset + (2d × i), where i=0d to 1023d

8–31 TIMER	Timer is used to count the number of INTC clock cycles up to 24 bits of resolution.

17.7 Functional description

The functional description involves the areas of interrupt request sources, priority management, and handshaking with the processor. In addition, spaces in the memory map have been reserved for other possible implementations of the INTC.

17.7.1 Interrupt request sources

The INTC has two types of interrupt requests, peripheral and software-settable. These interrupt requests can assert on any clock cycle.

The INTC has no spurious vector support. Therefore, if an asserted peripheral or software-settable interrupt request, whose PRI*n* value in INTC_PSR*n* is higher than the PRI value in INTC_CPR*n*, negates before the interrupt request to the processor for that peripheral or software-settable interrupt request is acknowledged, then the interrupt request to the processor still can assert (or will remain asserted) for that peripheral or software-settable interrupt request. In this case, the interrupt vector will correspond to that peripheral or software-settable interrupt request. Also, the PRI value in the associated INTC_CPR*n* is updated with the corresponding PRI*n* value in INTC_PSR*n*.

Furthermore, clearing the peripheral interrupt request's enable bit in the peripheral, or (alternatively) setting its mask bit, has the same consequences as clearing its flag bit. Setting its enable bit or clearing its mask bit while its flag bit is asserted has the same effect on the INTC as an interrupt event setting the flag bit.

17.7.1.1 Peripheral interrupt requests

An interrupt event in a peripheral's hardware sets a flag bit which resides in that peripheral. The interrupt request from the peripheral is driven by that flag bit.

The time from when the peripheral starts to drive its peripheral interrupt request to the INTC, to the time that the INTC starts to drive the interrupt request to the processor, is three clocks.

17.7.1.2 Software-settable interrupt requests

The software set/clear interrupt registers (INTC_SSCIR*n*) support the setting or clearing of software-settable interrupt requests. These registers contain independent sets of bits to set and clear a corresponding flag bit by software. An interrupt request is triggered by software by writing a 1 to a SET bit in INTC_SSCIR*n*. This write sets the corresponding CLR bit, which is a flag bit, resulting in the interrupt request. The interrupt request is cleared by writing a 1 to the CLR bit. Specific behavior includes the following:

- Writing a 1 to SET leaves SET unchanged at 0 but sets the flag bit (which is the CLR bit).
- Writing a 0 to SET has no effect.
- Writing a 1 to CLR clears the flag (CLR) bit.
- Writing a 0 to CLR has no effect.
- If a 1 is written to a pair of SET and CLR bits at the same time, the flag (CLR) is set, regardless of whether CLR was asserted before the write.

The time from the write to the SET bit, to the time that the INTC starts to drive the interrupt request to the processor, is four clocks.

Any Processor n will be allowed to write to any of the SET bits in the Software Set/Clear Interrupt registers. The CLR bit will only be writable by the Processor n which has been assigned to handle that interrupt request, as determined by the setting of the INTC_PSRn[PRC_SELn] bits.

17.7.1.3 Unique vector for each interrupt request source

Each peripheral and software-settable interrupt request is assigned a hardwired unique 10-bit vector. Software-settable interrupts 0–31 are assigned vectors 0–31, respectively. The peripheral interrupt requests are assigned vectors from 32 to a number as high as needed to cover all peripheral interrupt requests.

17.7.2 Priority management

The asserted interrupt requests are compared to each other based on their PRI*n* and PRC_SEL*n* values set in INTC_PSR*n*. The result of that comparison also is compared to PRI in the associated INTC_CPR*n*. The results of those comparisons are used to manage the priority of the ISR being executed by the associated processor. The associated LIFO also assists in managing that priority.

17.7.2.1 Current priority and preemption

The priority arbitrator, selector, encoder, and comparator logic shown in Figure 17-1 are used to compare the priority of the asserted interrupt requests to the current priority. If the priority of any asserted peripheral or software-settable interrupt request is higher than the current priority for a given processor, then the interrupt request to the processor is asserted. Also, a unique vector for the preempting peripheral or software-settable interrupt request is generated for the associated INTC_IACKR*n*, and if in hardware vector mode, for the interrupt vector provided to the processor.

17.7.2.1.1 Priority tree

The priority tree for each processor compares all the priorities of all of the asserted interrupt requests assigned to that processor, both peripheral and software-settable. The output of the priority tree is the highest of those priorities assigned to a given processor. Also, any interrupt requests which have this highest priority are output as asserted interrupt requests to the associated selector logic.

17.7.2.1.2 Selector

If only one interrupt request from the associated priority tree is asserted, then it is passed as asserted to the associated encoder logic. If multiple interrupt requests from the associated priority tree are asserted, then only the one with the lowest vector is passed as asserted to the associated encoder logic. The lower vector is chosen regardless of the time order of the assertions of the peripheral or software-settable interrupt requests.

17.7.2.1.3 Encoder

The encoder logic generates the unique 10-bit vector for the asserted interrupt request from the request selector subblock for the associated processor.

17.7.2.1.4 Comparator

The comparator logic compares the highest priority output from the associated priority arbitrator subblock with PRI in the associated INTC_CPR*n*. If the comparator detects that this highest priority is higher than the current priority, then it asserts the interrupt request to the associated processor. This interrupt request to the processor asserts whether this highest priority is raised above the value of PRI in the associated INTC_CPR*n*, or the PRI value in the associated INTC_CPR*n* is lowered below this highest priority. This highest priority then becomes the new priority which is written to PRI in the associated INTC_CPR*n* when the interrupt request to the processor is acknowledged. Interrupt requests whose PRI*n* in INTC_PSR*n* are zero will not cause a preemption because their PRI*n* will not be higher than PRI in the associated INTC_CPR*n*.

Another function of the comparator is to signal an update of the INTC_IACKR*n* with the vector number of the first interrupt that arrives that has a priority higher than the current priority. Once the vector number and priority are captured, they cannot be superseded by a higher priority interrupt until an update of the INTC_CPR*n* occurs. In software vector mode, higher priority interrupts can supersede the previously captured interrupt vector number and priority until the time a hardware or software interrupt acknowledge is processed.

17.7.2.2 Stack (LIFO)

The LIFO stores the preempted PRI values from the associated INTC_CPR*n*. Therefore, because these priorities are stacked within the INTC, if interrupts need to be enabled during the ISR, at the beginning of the interrupt exception handler the PRI value in the associated INTC_CPR*n* does not need to be loaded from the associated INTC_CPR*n* and stored onto the context stack. Likewise at the end of the interrupt exception handler, the priority does not need to be loaded from the context stack and stored into the associated INTC_CPR*n*.

The PRI value in the associated INTC_CPR*n* is pushed onto the LIFO when the associated INTC_IACKR*n* is read in software vector mode or the interrupt acknowledge signal from the associated processor is asserted in hardware vector mode. The priority is popped into PRI in the associated INTC_CPR*n* whenever the associated INTC_EOIR*n* is written. An exception case in hardware vector mode to this behavior is described in Hardware vector mode.

Although the INTC supports up to 64 priorities, an ISR executing with PRI in the INTC_CPR*n* equal to 63 will not be preempted. Therefore, the LIFO supports the stacking of 63 priorities. However, the LIFO is only 62 entries deep. An entry for a priority of 0 is not needed because of the ways that pushing onto a full LIFO and popping an empty LIFO are treated. If the LIFO is pushed 63 or more times than it is popped, the priorities first pushed are overwritten. A priority of 0 would be an overwritten priority. However, the LIFO will pop zeroes if it is popped more times than it is pushed. Therefore, although a priority of 0 was overwritten, it is regenerated with the popping of an empty LIFO.

17.7.3 Handshaking with processor

This section describes handshaking with the processor.

17.7.3.1 Software vector mode handshaking

This section describes the software vector mode handshaking.

17.7.3.1.1 Acknowledging interrupt request to processor

The software vector mode handshaking can be used with processors that only support an interrupt request to them, or processors that support both an interrupt request by itself as well as an interrupt request with an interrupt vector. The software vector mode handshaking even supports processors that always expect an interrupt vector with the interrupt request to them. Refer to Figure 17-1101.

A timing diagram of the interrupt request and acknowledge handshaking in software vector mode, along with the handshaking near the end of the interrupt exception handler, is shown in Figure 17-1101. The INTC examines the peripheral and software-settable interrupt requests. When it finds an asserted peripheral or software-settable interrupt request with a higher priority than PRI in the associated INTC_CPR*n*, it asserts the interrupt request to the associated processor. The INTVEC field in the associated INTC_IACKR*n* is updated with the preempting interrupt request's vector when the interrupt request to the processor is asserted. The INTVEC field retains that value until the next time the interrupt request to the processor is asserted. The rest of the handshaking is described in Software vector mode.

17.7.3.1.2 End of interrupt exception handler

Before the interrupt exception handling completes, INTC_EOIR*n* must be written. When it is written, the associated LIFO is popped so that the preempted priority is restored into PRI of the associated INTC_CPR*n*. Before it is written, the peripheral or software-settable flag bit must be cleared so that the peripheral or software-settable interrupt request is negated.

When returning from the preemption, the INTC does not search for the peripheral or software-settable interrupt request whose ISR was preempted. Depending on how much the ISR has progressed, that interrupt request may no longer even be asserted. When PRI in the associated INTC_CPR*n* is lowered to the priority of the preempted ISR, the interrupt request for the preempted ISR or any other asserted peripheral or software-settable interrupt request at or below that priority will not cause a preemption. Instead, after the restoration of the preempted context, the processor will return to the instruction address that it had been going to execute next, before it was preempted. This next instruction is part of the preempted ISR or the interrupt exception handler's prolog or epilog.

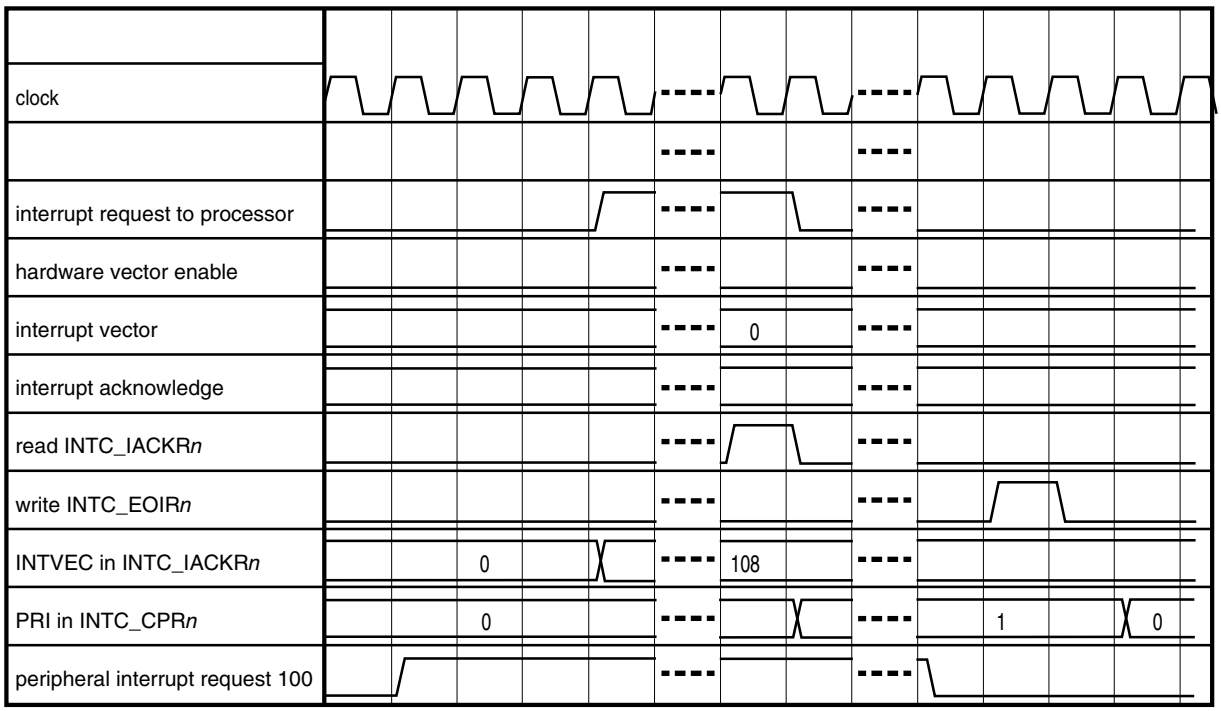

Figure 17-1101. Timing diagram of software vector mode handshaking

17.7.3.2 Hardware vector mode handshaking

A timing diagram of the interrupt request and acknowledge handshaking in hardware vector mode, along with the handshaking near the end of the interrupt exception handler, is shown in Figure 17-1102. As in software vector mode, the INTC examines the peripheral and software-settable interrupt requests, and when it finds an asserted interrupt request with a higher priority than PRI in the associated INTC_CPR*n*, it asserts the interrupt request to the associated processor. The INTVEC field in the associated INTC_IACKR*n* is updated with the preempting peripheral or software-settable interrupt request's vector when the interrupt request to the processor is asserted. The INTVEC field retains that value until the next time the interrupt request to the associated processor is asserted. In addition, the value of the interrupt vector to the associated processor matches the value of the INTVEC field in the associated INTC_IACKR*n*. The rest of the handshaking is described in Hardware vector mode.

The handshaking near the end of the interrupt exception handler, that is the writing to the associated INTC_EOIR*n*, is the same as in software vector mode. See End of interrupt exception handler.

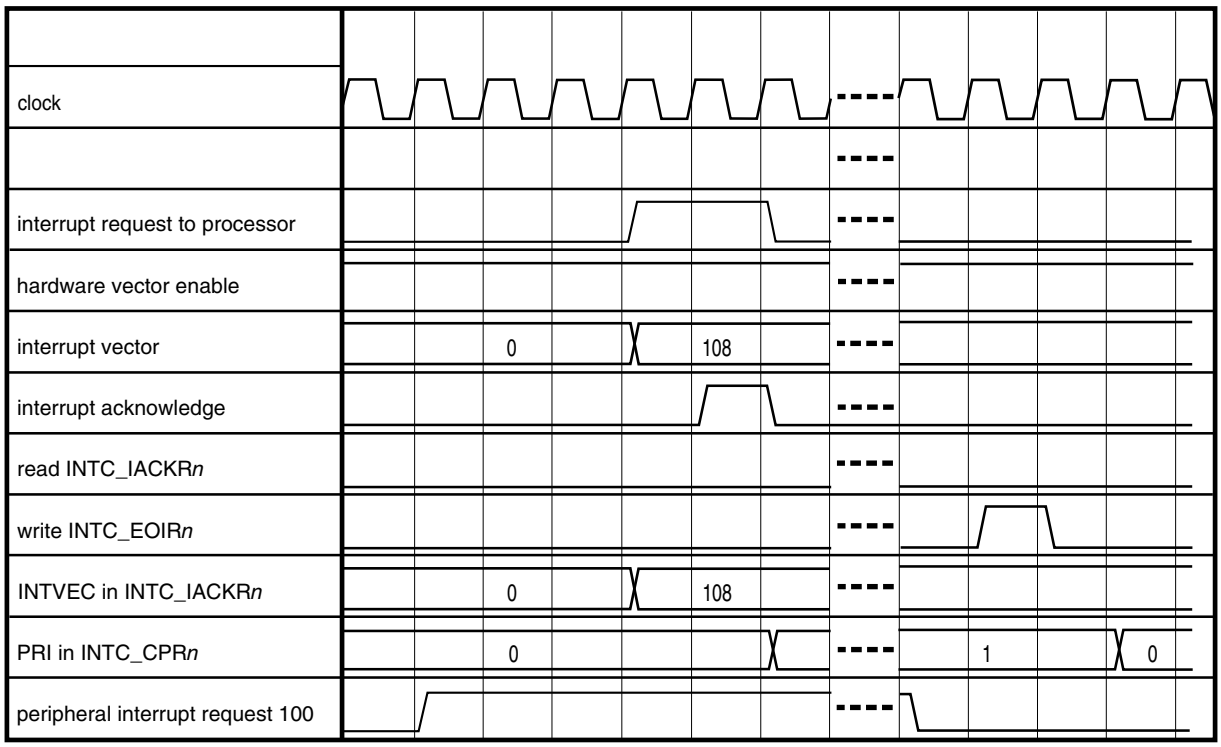

Figure 17-1102. Timing diagram for hardware vector mode handshaking

17.7.4 Interrupt Controller Monitor (INTCM)

Isolated in its own hierarchy, the interrupt latency monitor logic is used to monitor or check interrupt latency for reliability, safety, and interrupt software requirements.

17.7.4.1 Operation

The following section lists the operation of the INTCM.

17.7.4.1.1 TIMERn

A clear of TIMERn will clear the corresponding error.

The TIMERn will not run if there is a corresponding error.

If the INTC_MMRn[MM] is enabled and an error is signaled, disable TIMERn.

If the INTC_MMRn[MM] is enabled, for a transition from 0 to 1 of SOURCE input that is being monitored by INTC_HIPRIn registers, clear and enable TIMERn. Once the timer reaches the maximum count, it will stop and not roll over. Software can read the TIMERn value at any time.

If the INTC_MMRn[MM] is enabled and if the TIMERn is enabled, then it should increment each cycle.

If the INTC_MMRn[MM] is enabled and if INTC_LATn is non-zero, an error will be signaled if the timer exceeds INTC_LATn or if the TIMERn reaches the maximum count.

If the INTC_MMRn[MM] is IACK and an interrupt acknowledge asserts for the monitored source, INTC_HIPRIn[IRQ], then the enabled TIMERn should stop. As an extra check, the IRQ is used to ensure that the acknowledged interrupt matches the monitored interrupt INTC_HIPRIn[IRQ].

If the INTC_MMRn[MM] is SW and an interrupt acknowledge occurs where a monitored interrupt is preempted, the enabled TIMERn should stop.

If the INTC_MMRn[MM] is EOI or SW for a monitored interrupt which has an INTC_EOIRn, the enabled TIMERn should stop.

If the INTC_MMRn[MM] is SW and if INTC_EOIRn, and if the previous one is monitored, it will be re-enabled.

17.8 Initialization/application information

This section contains initialization/application information.

17.8.1 Initialization flow

After exiting reset, all of the PRI*n* and PRC_SEL*n* fields in INTC_PSR*n* are zero, and PRI in the INTC_CPRn registers is 63. These reset values will prevent the INTC from asserting the interrupt request to the processors. The enable or mask bits in the peripherals are reset such that the peripheral interrupt requests are negated. An initialization sequence for allowing the peripheral and software-settable interrupt requests to cause an interrupt request to the processor is:

- interrupt_request_initialization:
  - Configure HVENn in INTC_BCR.
  - Configure VTBAn in INTC_IACKRn.
  - Raise the PRIn fields and set the PRC_SELn fields to the desired processor in INTC_PSRn.
  - Set the enable bits or clear the mask bits for the peripheral interrupt requests.
  - Lower PRI in INTC_CPRn to zero.
  - Enable processor(s) recognition of interrupts.

17.8.2 Interrupt exception handler

These example interrupt exception handlers excerpts use Power Architecture assembly code.

17.8.2.1 Software vector mode

In software vector mode for Power Architecture, there are 16 bytes of vector space available at the single ISR entry point.

```

17.8.3 ISR, RTOS, and task hierarchy

The RTOS and all of the tasks under its control typically execute with PRI in INTC_CPR*n* having a value of 0. The RTOS will execute the tasks according to whatever priority scheme it may have, but that priority scheme is independent and has a lower priority of execution than the priority scheme of the INTC. In other words, the ISRs execute above INTC_CPR*n* priority 0 and outside the control of the RTOS, the RTOS executes at INTC_CPR*n* priority 0, and while the tasks execute at different priorities under the control of the RTOS, they also execute at INTC_CPRn priority 0.

If a task shares a resource with an ISR and the Priority Ceiling Protocol (PCP) is being used to manage that shared resource, then the task's priority can be elevated in the INTC_CPR*n* while the shared resource is being accessed.

An ISR whose PRI*n* in INTC_PSR*n* has a value of 0 will not cause an interrupt request to the selected processor, even if its peripheral or software-settable interrupt request is asserted. For a peripheral interrupt request, not setting its enable bit or disabling the mask bit will cause it to remain negated, which consequently also will not cause an interrupt request to the processor. Since the ISRs are outside the control of the RTOS, this ISR will not run unless called by another ISR or the interrupt exception handler, perhaps after executing another ISR.

17.8.4 Order of execution

An ISR with a higher priority can preempt an ISR with a lower priority, regardless of the unique vectors associated with each of their peripheral or software-settable interrupt requests. However, if multiple peripheral or software-settable interrupt requests are asserted, more than one of these interrupt requests has the highest priority and that priority is high enough to cause preemption, the INTC selects the one with the lowest unique vector regardless of the order in time that they asserted. However, the ability to meet deadlines with this scheduling scheme is no less than if the ISRs execute in the time order that their peripheral or software-settable interrupt requests asserted.

The example in the following table shows the order of execution of both cases, ISRs with different priorities and ISRs with the same priority.

Table 17-1101. Order of ISR execution example

Step #	Step Description	Code executing at end of step						PRI in INTC_CPR at end of step
		RTOS	ISR108 [1]	ISR208	ISR308	ISR408	interrupt exception handler	
1	RTOS at priority 0 is executing.	X						0
2	Peripheral interrupt request 100 at priority 1 asserts. Interrupt taken.		X					1
3	Peripheral interrupt request 400 at priority 4 asserts. Interrupt taken.					X		4
4	Peripheral interrupt request 300 at priority 3 asserts.					X		4
5	Peripheral interrupt request 200 at priority 3 asserts.					X		4
6	ISR408 completes. Interrupt exception handler writes to INTC_EOIR*n*.						X	1
7	Interrupt taken. ISR208 starts to execute, even though peripheral interrupt request 300 asserted first.			X				3
8	ISR208 completes. Interrupt exception handler writes to INTC_EOIR*n*.						X	1
9	Interrupt taken. ISR308 starts to execute.				X			3

Table continues on the next page...

Table 17-1101. Order of ISR execution example (continued)

Step #	Step Description	Code executing at end of step						PRI in INTC_CPR at end of step
		RTOS	ISR108 [1]	ISR208	ISR308	ISR408	interrupt exception handler	
10	ISR308 completes. Interrupt exception handler writes to INTC_EOIR*n*.						X	1
11	ISR108 completes. Interrupt exception handler writes to INTC_EOIR*n*.						X	0
12	RTOS continues execution.	X						0

1. ISR108 executes for peripheral interrupt request 100 because the first eight ISRs are for software-settable interrupt requests.

17.8.5 Priority ceiling protocol

This section describes the priority ceiling protocol.

17.8.5.1 Elevating priority

The PRI field in INTC current priority register (INTC_CPR*n*) is elevated in the OSEK PCP to the ceiling of all of the priorities of the ISRs that share a resource. This protocol therefore allows coherent accesses of the ISRs to that shared resource.

For example, ISR1 has a priority of 1, ISR2 has a priority of 2, and ISR3 has a priority of 3. They all share the same resource. Before ISR1 or ISR2 can access that resource, they must raise the PRI value in INTC_CPR*n* to 3, the ceiling of all of the ISR priorities. After they release the resource, they must lower the PRI value in INTC_CPR*n* to prevent further priority inversion. If they do not raise their priority, then ISR2 can preempt ISR1, and ISR3 can preempt ISR1 or ISR2, possibly corrupting the shared resource. Another possible failure mechanism is deadlock if the higher priority ISR needs the lower priority ISR to release the resource before it can continue, but the lower priority ISR cannot release the resource until the higher priority ISR completes and execution returns to the lower priority ISR.

Using the PCP instead of disabling processor recognition of all interrupts eliminates the time when accessing a shared resource that all higher priority interrupts are blocked. For example, while ISR3 cannot preempt ISR1 while it is accessing the shared resource, all of the ISRs with a priority higher than 3 can preempt ISR1.

17.8.5.2 Ensuring coherency

This section discusses how to ensure coherency.

17.8.5.2.1 Interrupt with blocked priority

A scenario can exist that can cause non-coherent accesses to the shared resource. As an example, ISR1 and ISR2 both share a resource. ISR1 has a lower priority than ISR2. ISR1 is executing, and it writes to the INTC_CPR*n*. The instruction following this store is a store to a value in a shared coherent data block. Either just before or at the same time as the first store, the INTC asserts the interrupt request to the processor because the peripheral interrupt request for ISR2 has asserted. As the processor is responding to the interrupt request from the INTC, and as it is aborting transactions and flushing its pipeline, it is possible (in some implementations) that both of these stores are executed. ISR2 thereby assumes that it can access the data block coherently, but the data block has been corrupted.

OSEK uses the GetResource and ReleaseResource system services to manage access to a shared resource. To prevent this corruption of a coherent data block, modifications to PRI in INTC_CPR*n* can be made by those system services with the code sequence:

```
GetResource:
        wrteei 0                # disable external interrupts to the Processor
        raise PRI                # Write to CPR, cache inhibit, guarded
        mbar                    # flush out writes from store buffer
        wrteei 1                # enable external interrupts to the Processor
        isync                    # re-fetch Processor pipeline

ReleaseResource:
        mbar                    # flush out writes from store buffer
        wrteei 0                # disable external interrupts to the Processor
        lower PRI                # Write to CPR, cache inhibit, guarded
        wrteei 1                # enable external interrupts to the Processor
```

17.8.5.2.1.1 Interrupt request to processor

Referencing Figure 17-1, the interrupt request logic to the processor is shown in the following figure.

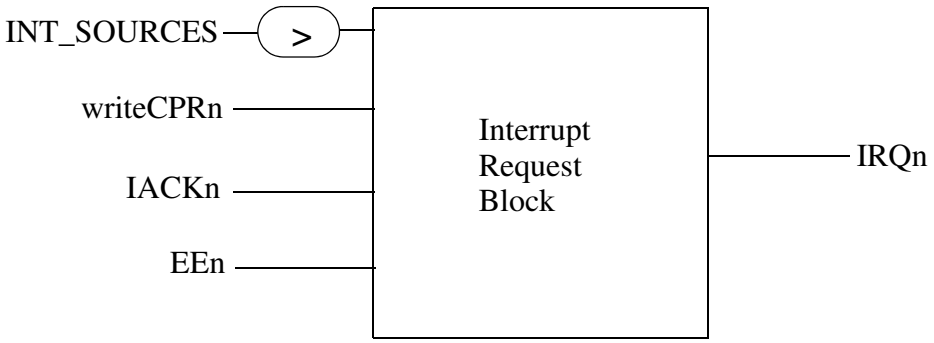

Figure 17-1103. Interrupt Request Block Diagram

Assuming that there are no IRQn deasserted (no pending interrupt requests to processor n), if one of the external interrupt sources (INT_SOURCES) has a priority higher than the INTC_CPRn, then interrupt request to the processor (IRQn) is asserted. It will stay asserted until one of the following conditions is true:

- Interrupt acknowledge (IACK) is asserted
- If the EEn bit has been cleared by the wrteei instruction (see the code sequence in Interrupt with blocked priority), IRQn will be re-evaluated when processor n writes to the INTC_CPRn while processor n ignores IRQn

This provides a safe way to guarantee that no interrupts will be recognized by processor n while updating the INTC_CPRn.

17.8.5.2.2 Raised priority preserved

Before the instruction after the GetResource system service executes, all pending transactions have completed. These pending transactions can include an ISR for a peripheral or software-settable interrupt request whose priority was equal to or lower than the raised priority. The shared coherent data block now can be accessed coherently. The following figure shows the timing diagram for this scenario, and the following table explains the events. The example is for software vector mode. Except for the method of retrieving the vector and acknowledging the interrupt request to the processor, hardware vector mode is identical.

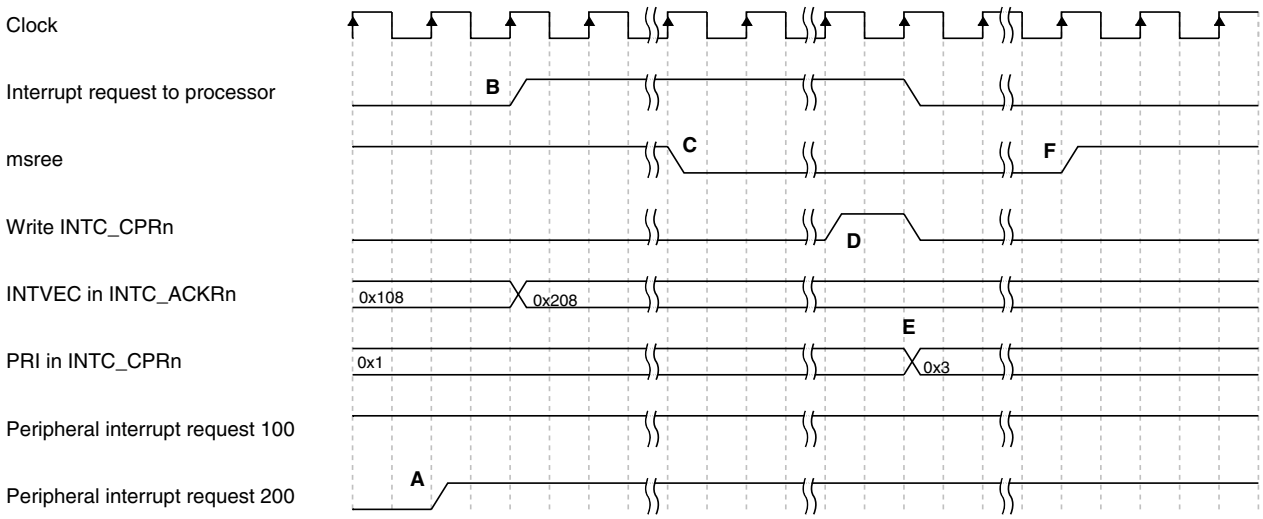

Figure 17-1104. Timing diagram of raised priority preserved

Table 17-1102. Raised priority preserved events

Event	Description
A	Peripheral interrupt request 200 of priority 2 asserts during execution of ISR108 running at priority 1.
B	Interrupt request to processor asserts. INTVEC in INTC_IACKRn updates with vector for that peripheral interrupt request.
C	Write to msree bit to disable external interrupts
D	ISR108 writes to INTC_CPRn to raise priority to 3 before accessing shared coherent data block.
E	PRI in INTC_CPRn now at 3, reflecting the write. This write, just before accessing data block, is the last instruction the processor executes before being interrupted.
F	Write to msree bit to enable external interrupts

17.8.6 Selecting priorities according to request rates and deadlines

The selection of the priorities for the ISRs can be made using Rate Monotonic Scheduling (RMS) or a superset of it, Deadline Monotonic Scheduling (DMS). In RMS, the ISRs which have higher request rates have higher priorities. In DMS, if the deadline is before the next time the ISR is requested, then the ISR is assigned a priority according to the time from the request for the ISR to the deadline, not from the time of the request for the ISR to the next request for it.

For example, ISR1 executes every 100 µs, ISR2 executes every 200 µs, and ISR3 executes every 300 µs. ISR1 has a higher priority than ISR2 which has a higher priority than ISR3. However, if ISR3 has a deadline of 150 µs, then it has a higher priority than ISR2.

The INTC supports 64 priorities, which may be many fewer than the number of ISRs. In this case, the ISRs should be grouped with other ISRs that have similar deadlines. For example, a priority could be allocated for every time the request rate doubles. ISRs with request rates around 1 ms would share a priority, ISRs with request rates around 500 µs would share a priority, ISRs with request rates around 250 µs would share a priority, and so on. With this approach, a range of ISR request rates of 2^{16} could be covered, regardless of the number of ISRs.

Reducing the number of priorities does cause some priority inversion, which reduces the processor's ability to meet its deadlines. However, reducing the number of priorities can reduce the size and latency through the interrupt controller. It also allows easier management of ISRs with similar deadlines that share a resource. They can be placed at the same priority without any further priority inversion, and they do not need to use the PCP to access the shared resource.

17.8.7 Software-settable interrupt requests

The software-settable interrupt requests can be used in two ways. They can be used to schedule a lower priority portion of an ISR and for processors to interrupt other processors in a multiple processor system.

17.8.7.1 Scheduling a lower priority portion of an ISR

A portion of an ISR needs to be executed at the PRIn value in INTC_PSR*n*, which becomes the PRI value in INTC_CPR*n* with the interrupt acknowledge. The ISR, however, can have a portion of it which does not need to be executed at this higher priority. Therefore, executing this later portion which does not need to be executed at this higher priority can prevent the execution of ISRs which do not have a higher priority than the earlier portion of the ISR but do have a higher priority than the later portion of the ISR needs. This preemptive scheduling inefficiency reduces the processor's ability to meet its deadlines.

One option is for the ISR to complete the earlier higher priority portion, but then schedule through the RTOS a task to execute the later lower priority portion. However, some RTOSs can require a large amount of time for an ISR to schedule a task. Therefore, a second option is for the ISR, after completing the higher priority portion, to set a SET bit

in INTC_SSCIR*n*. Writing a '1' to SET causes a software-settable interrupt request. This software-settable interrupt request, which usually will have a lower PRI*n* value in the INTC_PSR*n*, therefore will not cause preemptive scheduling inefficiencies.

17.8.7.2 Scheduling an ISR on another processor

Since the SET bits in the INTC_SSCIR*n* are memory mapped, processors in multiple processor systems can schedule ISRs on the other processors. One possible application is if one processor simply wants to command another processor to perform a piece of work, and the initiating processor does not need to use the results of that work. If the initiating processor needs to know if the processor executing the software-settable ISR has not completed the work before asking it to again execute that ISR, it can check if the corresponding CLR bit in INTC_SSCIR*n* is asserted before again writing a 1 to the SET bit.

Another application is the sharing of a block of data. For example, a first processor has completed accessing a block of data and wants a second processor to then access it. Furthermore, after the second processor has completed accessing the block of data, the first processor again wants to access it. The accesses to the block of data must be done coherently. The procedure is that the first processor writes a 1 to a SET bit on the second processor. The second processor, after accessing the block of data, clears the corresponding CLR bit and then writes 1 to a SET bit on the first processor, informing it that it now can access the block of data.

17.8.8 Lowering priority within an ISR

In implementations without the software-settable interrupt requests in INTC_SSCIR*n*, one way (besides scheduling a task through an RTOS) to prevent preemptive scheduling inefficiencies with an ISR whose work spans multiple priorities (as described in Scheduling a lower priority portion of an ISR) is to lower the current priority. However, the INTC has a LIFO whose depth is determined by the number of priorities.

Note

Lowering the PRI value in INTC_CPR*n* within an ISR to below the ISR's corresponding PRI value in INTC_PSR*n* allows more preemptions than the depth of the LIFO can support.

Therefore, through its use of the LIFO the INTC does not support lowering the current priority within an ISR as a way to avoid preemptive scheduling inefficiencies.

17.8.9 Negating an interrupt request outside of its ISR

This section discusses the negation of an interrupt service request outside of its ISR.

17.8.9.1 Negating an interrupt request as a side effect of an ISR

Some peripherals have flag bits which can be cleared as a side effect of servicing a peripheral interrupt request. For example, reading a specific register can clear the flag bits, and consequently their corresponding interrupt requests too. This clearing as a side effect of servicing a peripheral interrupt request can cause the negation of other peripheral interrupt requests besides the peripheral interrupt request whose ISR presently is executing. This negating of a peripheral interrupt request outside of its ISR can be a desired effect.

17.8.9.2 Negating multiple interrupt requests in one ISR

An ISR can clear other flag bits besides its own flag bit. One reason that an ISR clears multiple flag bits is because it serviced those other flag bits, and therefore the ISRs for these other flag bits do not need to be executed.

17.8.9.3 Proper setting of interrupt request priority

Whether an interrupt request negates outside of its own ISR due to the side effect of an ISR execution or the intentional clearing of a flag bit, the priorities of the peripheral or software-settable interrupt requests for these other flag bits must be selected properly. Their PRI*n* values in INTC_PSR*n* must be selected to be at or lower than the priority of the ISR that cleared their flag bits. Otherwise, those flag bits still can cause the interrupt request to the processor to assert. Furthermore, the clearing of these other flag bits also has the same timing relationship to the writing to INTC_SSCIR*n* as the clearing of the flag bit that caused the present ISR to be executed. Refer to End of interrupt exception handler for more information.

A flag bit whose enable bit or mask bit is negating its peripheral interrupt request can be cleared at any time, regardless of the peripheral interrupt request's PRI*n* value in INTC_PSR*n*.

17.8.10 Examining LIFO contents

There are multiple methods for tracking interrupts in a system, one of which is described here using existing hardware (LIFO) within the INTC. Although the LIFO contents are not memory-mapped, the user can read the contents by popping the LIFO and reading the PRI field in the INTC current priority register (INTC_CPR*n*). To avoid a lower-level interrupt being serviced because the popping of the LIFO updates the INTC_CPR*n*, the processor recognition of interrupts should be disabled when examining LIFO contents. The pseudo-code is as follows:

```
      wrteei 0                # disable processor recognition of external interrupts
      oldCPRn = INTC_CPRn;    # save INTC_CPRn
      (branch to the pop_lifo)

pop_lifo:
      store INTC_EIORn        # pop INTC_CPR from LIFO, examine PRI, etc...
      examine INTC_CPRn[PRI], and store onto stack
      if PRI is not zero or value when interrupts were enabled, branch to pop_lifo
      branch to push_lifo
```

When the examination is complete, the LIFO can be restored using this code sequence:

```
push_lifo:
      load stacked PRI value and store to INTC_CPRn
      load INTC_IACKn         # IACK; push INTC_CPRn into LIFO
      if stacked PRI values are not depleted, branch to push_lifo

      INTC_CPRn    = oldCPRn; # restore original INTC_CPRn and re-evaluate pending external
interrupts
      wrteei 1                # enable processor recognition of interrupts
```

NOTE

Disabling the processor recognition of interrupts during LIFO examination will introduce latency, but none of the interrupt requests will be missed.

17.9 Interrupt sources

The list of interrupt sources is chip-specific. For this list, see the chip-specific INTC information.

Chapter 18
Enhanced Direct Memory Access (eDMA)

18.1 Introduction

The enhanced direct memory access (eDMA) controller is a second-generation module capable of performing complex data transfers with minimal intervention from a host processor. The hardware microarchitecture includes:

- A DMA engine that performs:
  - Source- and destination-address calculations
  - Data-movement operations
- Local memory containing transfer control descriptors for each of the 64 channels

The following figure is a block diagram of the eDMA module.

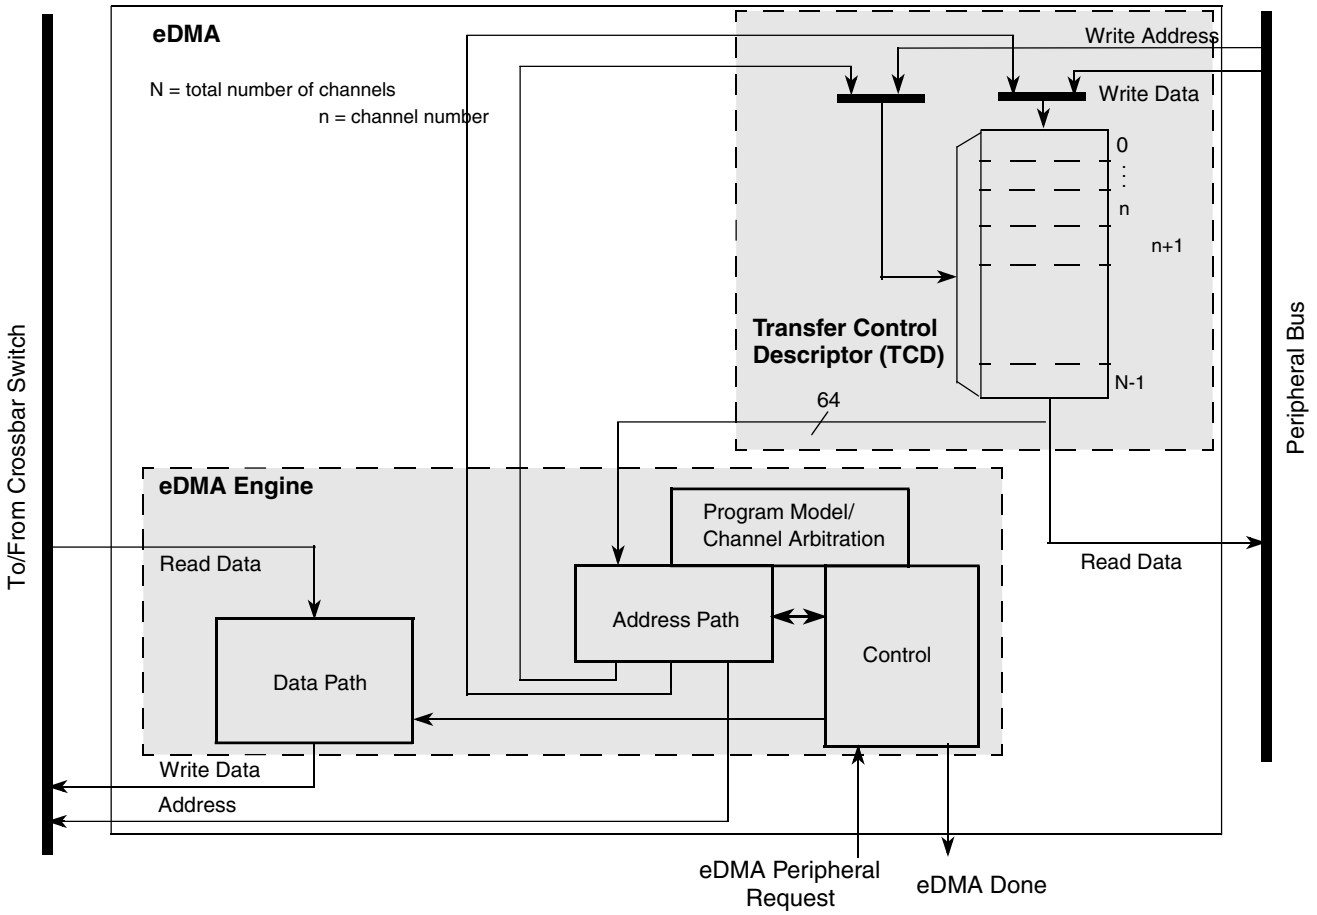

Figure 18-1. eDMA Block Diagram

18.2 Overview

The eDMA is a highly-programmable data-transfer engine optimized to minimize the required intervention from the host processor. It is intended for use in applications where the data size to be transferred is statically known and not defined within the data packet itself.

Throughout this chapter, n is used to reference the channel number. Additionally, data sizes are defined as byte (8-bit), halfword (16-bit), word (32-bit) and doubleword (64-bit).

18.3 Features

The eDMA module has these features:

- All data movement via dual-address transfers: read from source, write to destination

- Programmable source, destination addresses, transfer size, plus support for enhanced addressing modes
- 64-channel implementation that performs complex data transfers with minimal intervention from a host processor
  - Internal data buffer, used as temporary storage to support 16-byte burst transfers
  - Connections to the crossbar switch for bus mastering the data movement
- Transfer control descriptor organized to support two-deep, nested transfer operations
  - An inner data transfer loop defined by a “minor” byte transfer count
  - An outer data transfer loop defined by a “major” iteration count
- Channel service request via one of the three following methods. For all three methods, one service request per execution of the minor loop is required.
  a. Explicit software initiation
  b. Initiation via a channel-to-channel linking mechanism for continuous transfers with independent channel linking at end of minor loop and/or major loop
  c. Peripheral-paced hardware requests (one per channel)
- Support for fixed-priority and round-robin channel arbitration
- Channel completion reported via optional interrupt requests (chip dependent)
  - One interrupt per channel, optionally asserted at completion of major iteration count
  - Error terminations are optionally enabled per channel, and logically summed together to form a small number of error interrupt outputs
- Support for scatter/gather DMA processing
- Support for complex data structures
- Support to cancel transfers via software or hardware

The structure of the transfer control descriptor is fundamental to the operation of the eDMA module. It is defined below in a ‘C’ pseudo-code specification, where int refers to a 32-bit variable (unless noted otherwise) and short is a 16-bit variable.

NOTE

To compile these structures, change any periods '.' in the variable name to underscores '_'.

```
typedef union {
    struct { /* citer.e_link = 1 */
        unsigned short citer.linkch:6; /* link channel number, */
        unsigned short citer:9; /* current (“major”) iteration count */
    } minor_link_enabled;/* channel link at end of the minor loop */
    struct {/* citer.e_link = 0 */
        unsigned short citer:15; /* current (“major”) iteration count */
    } minor_link_disabled;/* no linking at end of the minor loop */
} t_minor_link_citer;

typedef union {
    struct { /* biter.e_link = 1 */
        unsigned short biter.linkch:6; /* link channel number, */
        unsigned short biter:9; /* beginning (“major”) iteration count */
    } init_minor_link_enabled;/* channel link at end of the minor loop */
    struct {/* biter.e_link = 0 */
```

```
        unsigned short biter:15; /* beginning ("major") iteration count */
    } init_minor_link_disabled;/* no linking at end of the minor loop */
} t_minor_link_biter;

typedef struct {
unsigned intsaddr;/* source address */
unsigned intsmod:5;/* source address modulo */
unsigned intssize:3;/* source transfer size */
unsigned intdmod:5;/* destination address modulo */
unsigned intdsize:3;/* destination transfer size */
shortsoff;/* signed source address offset */
unsigned intnbytes;/* inner ("minor") byte count */
intslast;/* last source address adjustment */
unsigned intdaddr;/* destination address */
unsigned shortciter.e_link:1;/* enable channel linking on minor loop */
t_minor_link_citerminor_link_citer;/* conditional current iteration count */
shortdoff;/* signed destination address offset */
intdlast_sga;/* last destination address adjustment, or
         scatter/gather address (if e_sg = 1) */
unsigned shortbiter.e_link:1;/* beginning channel link enable */
t_minor_link_biterminor_link_biter;/* beginning ("major") iteration count */
unsigned intbwc:2;/* bandwidth control */
unsigned intmajor.linkch:6;/* link channel number */
unsigned intdone:1;/* channel done */
unsigned intactive:1;/* channel executing */
unsigned intmajor.e_link:1;/* enable channel linking on major loop*/
unsigned inte_sg:1;/* enable scatter/gather descriptor */
unsigned intd_req:1;/* disable ipd_req when done */
unsigned intint_half:1;/* interrupt on citer = (biter >> 1) */
unsigned intint_maj:1;/* interrupt on major loop completion */
unsigned intstart:1;/* explicit channel start */
} tcd/* transfer_control_descriptor */
```

The basic operation of a channel is defined as:

1. The channel is initialized by software loading the transfer control descriptor into the eDMA's programming model, memory-mapped through the slave bus space, and implemented as local memory.
2. The channel requests service; either explicitly by software, a peripheral request or a linkage from another channel.

NOTE

The major loop executes one iteration per service request.

3. The contents of the transfer control descriptor for the activated channel is read from the local memory and loaded into the eDMA engine's internal register file.
4. The eDMA engine executes the data transfer defined by the transfer control descriptor, reading from the source and writing to the destination. The number of iterations in the minor loop is automatically calculated by the eDMA engine. The number of iterations within the minor loop is a function of the number of bytes to transfer (nbytes), the source size (ssize), and the destination size (dsize). The completion of the minor loop is equal to one iteration of the major loop.
5. At the conclusion of the minor loop's execution, certain fields of the transfer control descriptor are written back to the local TCD memory.

The process (steps 2-5) is repeated until the outer major loop's iteration count is exhausted. At that time, additional processing steps are completed, e.g., the optional assertion of an interrupt request signaling the transfer's completion, final adjustments to the source and destination addresses, etc. A more detailed description of the channel processing is listed in the pseudo-code below. This simplified example is intended to represent basic data transfers. Detailed processing associated with the error handling is omitted.

```
/* the given eDMA channel is requesting service by the software assertion of the
   tcd[channel].start bit, the assertion of an enabled ipd_req from a device, or
   the implicit assertion of a channel-to-channel link */

/* begin by reading the transfer control descriptor from the local RAM
   into the local dma_engine registers */
dma_engine        = read_from_local_memory [channel];
dma_engine.active = 1;                /* set active flag */
dma_engine.done   = 0;                /* clear done flag */

/* check the transfer control descriptor for consistency */
if (dma_engine.config_error == 0) {

    / * begin execution of the inner "minor" loop transfers */
    {

        /* convert the source transfer size into a byte count */
        switch (dma_engine.ssize) {
        case 0:                       /* 8-bit transfer */
            src_xfr_size = 1;
            break;
        case 1:                       /* 16-bit transfer */

}
```

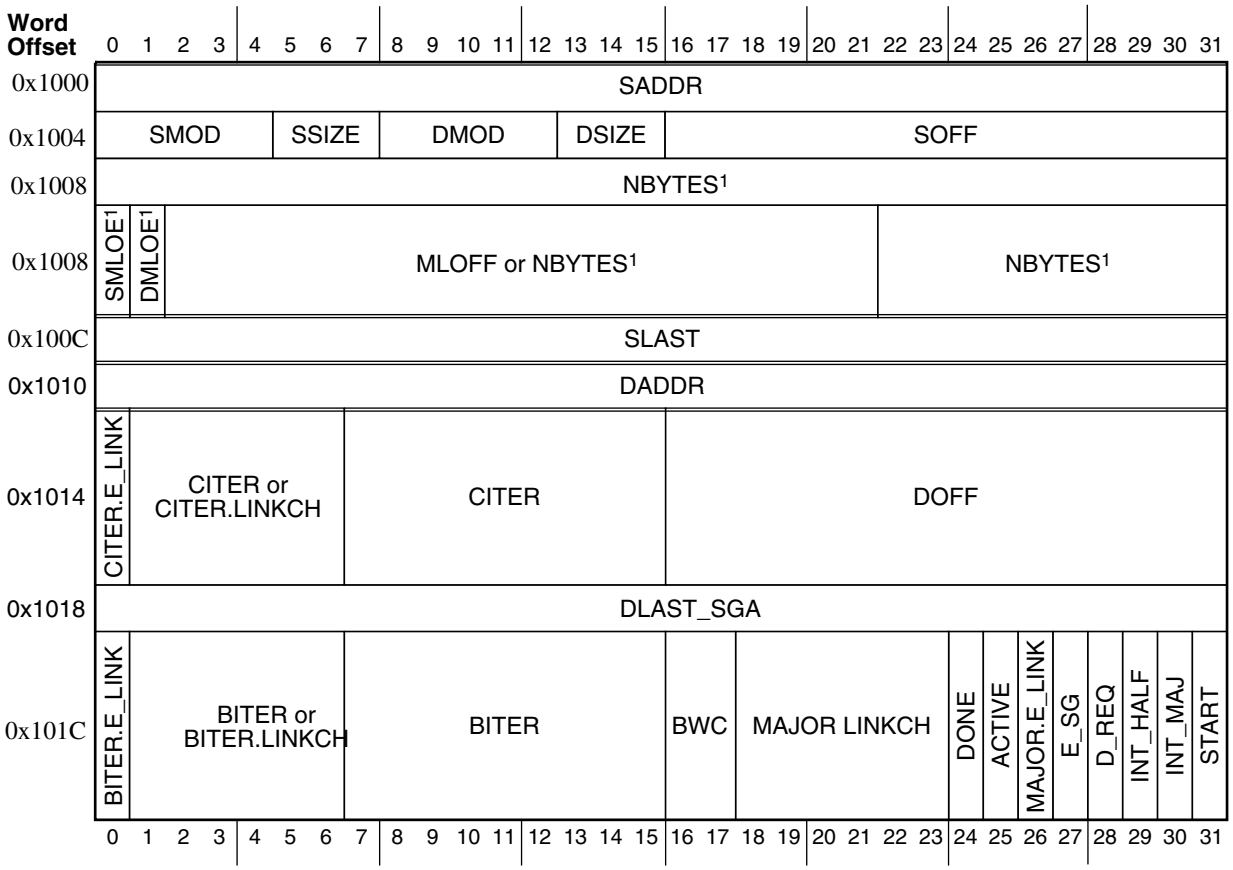
18.4 Memory map/register definition

The eDMA's programming model is partitioned into two sections, both mapped into the slave bus space: the first region defines a number of registers providing control functions, while the second region corresponds to the local transfer control descriptor memory.



Reading an unimplemented register bit or memory location will return the value of zero. Write the value of zero to unimplemented register bits. Any access to a reserved memory location will result in a bus error. Reserved memory locations are indicated in the memory map. For a 64-channel implementation, reserved memory also includes the high order "H" registers containing channels 63-32 data (for example, the ERQH, EEIH, and INTH registers).

Registers associated with a 64-channel design are implemented as two 32-bit registers, and include an "H" and "L" suffixes, signaling the "high" and "low" portions of the control function. The descriptions in this section define the 64-channel implementation.

The initialization of the TCD memory is performed by the eDMA controller after reset. The initialization runs for 256 eDMA clock cycles. All fields in the TCD memory are initialized to 0. All application read or write accesses to the TCD are delayed until the initialization is finished. Prior to activating a channel, you must initialize its TCD with the appropriate transfer profile.

The TCD structure is shown in the following figure.

- One DMA engine has a number of channels to react to DMA requests
- Each channel has its own TCD

[1] The fields implemented in Word 2 (0x1008) depend on whether EDMA_CR[EMLM] bit is set to 0 or 1.

Figure 18-2. TCD Structure

The following table shows a 32-bit view of the eDMA's memory map.

Table 18-1. eDMA 32-bit memory map

eDMA Offset	Register

18.5.1 Control Register (DMA_CR)

This register defines the basic operating configuration of the eDMA.

The eDMA arbitrates channel service requests in groups of 16 channels. The 64- and 32-channel configurations have four groups (3,2,1,0) and two groups (1,0), respectively; the 16 channel configuration has only one group (0). Group 3 contains channels 63-48, group 2 contains channels 47-32, group 1 contains channels 31-16, and group 0 contains channels 15-0.

Arbitration within a group can be configured to use either a fixed-priority or a round-robin selection. In fixed-priority arbitration, the highest priority channel requesting service is selected to execute. The priorities are assigned by the channel priority registers (see Channel n Priority Register (DMA_DCHPRI*n*). In round-robin arbitration mode, the channel priorities are ignored and the channels within each group are cycled through without regard to priority.

The group priorities operate in a similar fashion. In group fixed-priority arbitration mode, channel service requests in the highest priority group are executed first where priority level 3 is the highest and priority level 0 is the lowest. The group priorities are assigned in the GRPnPri registers. All group priorities must have unique values prior to any channel service requests occur, otherwise a configuration error will be reported. Unused group priority registers, per configuration, are unimplemented in the CR. In group round-robin mode, the group priorities are ignored and the groups are cycled through without regard to priority.

Minor loop offsets are address offset values added to the final source address (SADDR) or destination address (DADDR) upon minor loop completion. When minor loop offsets are enabled, the minor loop offset (MLOFF) is added to the final source address (SADDR), or the final destination address (DADDR), or both prior to the addresses being written back into the TCD. If the major loop is complete, the minor loop offset is ignored and the major loop address offsets (SLAST and DLAST_SGA) are used to compute the next SADDR and DADDR values.

When minor loop mapping is enabled (CR[EMLM] = 1), TCDn_WORD_2 is redefined. A portion of TCDn_WORD_2 is used to specify multiple fields: a source enable bit (smloe) to specify the minor loop offset should be applied to the source address (saddr) upon minor loop completion, a destination enable bit (DMLOE) to specify the minor loop offset should be applied to the destination address (DADDR) upon minor loop completion, and the sign extended minor loop offset value (MLOFF). The same offset value (MLOFF) is used for both source and destination minor loop offsets. When either minor loop offset is enabled (SMLOE set or DMLOE set), the NBYTES field is reduced to 10 bits. When both minor loop offsets are disabled (SMLOE cleared and DMLOE cleared), the NBYTES field is a 30-bit vector.

When minor loop mapping is disabled (CR[EMLM] = 0), all 32 bits of TCDn_WORD_2 are assigned to the NBYTES field.

DMA_CR field descriptions

Field	Description
0–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14 CX	Cancel Transfer

Table continues on the next page...

DMA_CR field descriptions (continued)

Field	Description
	0 Normal operation 1 Cancel the remaining data transfer. Stop the executing channel and force the minor loop to be finished. The cancel takes effect after the last write of the current read/write sequence. The CX bit clears itself after the cancel has been honored. This cancel retires the channel normally as if the minor loop was completed.
15 ECX	Error Cancel Transfer 0 Normal operation 1 Cancel the remaining data transfer in the same fashion as the CX bit. Stop the executing channel and force the minor loop to finish. The cancel takes effect after the last write of the current read/write sequence. The ECX bit clears itself after the cancel is honored. In addition to canceling the transfer, ECX treats the cancel as an error condition, thus updating the Error Status register (ES) and generating an optional error interrupt.
16–17 GRP3PRI	Channel Group 3 Priority Group 3 priority level when fixed priority group arbitration is enabled.
18–19 GRP2PRI	Channel Group 2 Priority Group 2 priority level when fixed priority group arbitration is enabled.
20–21 GRP1PRI	Channel Group 1 Priority Group 1 priority level when fixed priority group arbitration is enabled.
22–23 GRP0PRI	Channel Group 0 Priority Group 0 priority level when fixed priority group arbitration is enabled.
24 EMLM	Enable Minor Loop Mapping. 0 Minor loop mapping disabled. TCDn_WORD_2 is defined as a 32-bit nbytes field. 1 Minor loop mapping enabled. When set, TCDn_WORD_2 is redefined to include individual enable fields, an offset field and the nbytes field. The individual enable fields allow the minor loop offset to be applied to the source address, the destination address, or both. The nbytes field is reduced when either offset is enabled.
25 CLM	Continuous Link Mode 0 A minor loop channel link made to itself will go through channel arbitration before being activated again. 1 A minor loop channel link made to itself will not go through channel arbitration before being activated again. Upon minor loop completion, the channel will be active again if that channel has a minor loop channel link enabled and the link channel is itself. This effectively applies the minor loop offsets and restarts the next minor loop.
26 HALT	Halt DMA Operations 0 Normal operation 1 Stall the start of any new channels. Executing channels are allowed to complete. Channel execution resumes when this bit is cleared.
27 HOE	Halt On Error 0 Normal operation 1 Any error causes the HALT bit to set. Subsequently, all service requests are ignored until the HALT bit is cleared.

Table continues on the next page...

DMA_CR field descriptions (continued)

Field	Description
28 ERGA	Enable Round Robin Group Arbitration 0 Fixed priority arbitration is used for selection among the groups. 1 Round robin arbitration is used for selection among the groups.
29 ERCA	Enable Round Robin Channel Arbitration 0 Fixed priority arbitration is used for channel selection within each group. 1 Round robin arbitration is used for channel selection within each group.
30 EDBG	Enable Debug 0 The assertion of the ipg_debug input is ignored. 1 The assertion of the ipg_debug input causes the eDMA to stall the start of a new channel. Executing channels are allowed to complete. Channel execution will resume when either the ipg_debug input is negated or the EDBG bit is cleared.
31 EBW	Enable Buffered Writes 0 The bufferable write signal (hprot[2]) is not asserted during AMBA AHB writes. 1 The bufferable write signal (hprot[2]) is asserted on all AMBA AHB writes except for the last write sequence.

18.5.2 Error Status Register (DMA_ES)

This register provides information concerning the last recorded channel error. Channel errors can be caused by a configuration error (an illegal setting in the transfer control descriptor or an illegal priority register setting in fixed arbitration mode) or an error termination to a bus master read or write cycle.

A configuration error is caused when the starting source or destination address, source or destination offsets, minor loop byte count, and the transfer size represent an inconsistent state. The addresses and offsets must be aligned on 0-modulo-transfer_size boundaries, and the minor loop byte count must be a multiple of the source and destination transfer sizes. All source reads and destination writes must be configured to the natural boundary of the programmed transfer size respectively. In fixed arbitration mode, a configuration error is caused by any two channel priorities being equal within a group, or any group priority levels being equal among the groups. All channel priority levels within a group must be unique and all group priority levels among the groups must be unique when fixed arbitration mode is enabled. If a scatter/gather operation is enabled upon channel completion, a configuration error is reported if the scatter/gather address (DLAST_SGA) is not aligned on a 32-byte boundary. If minor loop channel linking is enabled upon channel completion, a configuration error is reported when the link is attempted if the TCDn_WORD_5[CITER_E_LINK] bit does not equal the TCDn_WORD_7[BITER_E_LINK] bit. All configuration error conditions except scatter/gather and minor loop link error are reported as the channel is activated and assert an

error interrupt request, if enabled. A scatter/gather configuration error is reported when the scatter/gather operation begins at major loop completion when properly enabled. A minor loop channel link configuration error is reported when the link operation is serviced at minor loop completion.

If a system bus read or write is terminated with an error, the data transfer is stopped and the appropriate bus error flag set. In this case, the state of the channel's transfer control descriptor is updated by the eDMA engine with the current source address, destination address and current iteration count at the point of the fault. When a system bus error occurs, the channel is terminated after the read or write transaction, which is already pipelined after errant access, has completed. If a bus error occurs on the last read prior to beginning the write sequence, the write will execute using the data captured during the bus error. If a bus error occurs on the last write prior to switching to the next read sequence, the read sequence will execute before the channel is terminated due to the destination bus error.

A transfer may be canceled by software via the CR[CX] bit. When a cancel transfer request is recognized, the eDMA engine stops processing the channel. The current read-write sequence is allowed to finish. If the cancel occurs on the last read-write sequence of a major or minor loop, the cancel request is discarded and the channel retires normally.

The error cancel transfer is the same as a cancel transfer except the ES register is updated with the canceled channel number and error cancel bit is set. The TCD of a canceled channel has the source address and destination address of the last transfer saved in the TCD. The user should initialize the TCD again if the channel needs to be restarted because the aforementioned fields have been modified by the eDMA engine and no longer represent the original parameters. When a transfer is canceled via the error cancel transfer mechanism (setting the CR[ECX] or asserting the dma_err_cancel_xfer input), the channel number is loaded into the ERRCHN field and the ECX and VLD bits are set in the ES register. In addition, an error interrupt may be generated if enabled. See the Enable Error Interrupt Register High (DMA_ERRH) and Enable Error Interrupt RegisterLow (DMA_ERRL) registers for error interrupt details.

The occurrence of any type of error causes the eDMA engine to immediately stop, and the appropriate channel bit in the eDMA Error register to be asserted. At the same time, the details of the error condition are loaded into the ES register. The major loop complete indicators, setting the transfer control descriptor done flag and the possible assertion of an interrupt request, are not affected when an error is detected.

DMA_ES field descriptions

Field	Description
0 VLD	Logical OR of all ERRH and ERRL status bits. 0 No ERR bits are set 1 At least one ERR bit is set indicating a valid error exists that has not been cleared
1–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14 UCE	Uncorrectable ECC error during channel execution. The UCE bit is set when an uncorrectable ECC error occurs on an access generated by the DMA only. If a CPU access to the TCD causes an uncorrectable ECC error, that access will receive a bus error response.” 0 No uncorrectable ECC error 1 The last recorded error was an uncorrectable TCD RAM error
15 ECX	Transfer Canceled. 0 No canceled transfers 1 The last recorded entry was a canceled transfer by the error cancel transfer input
16 GPE	Group Priority Error. 0 No group priority error 1 The last recorded error was a configuration error among the group priorities. All group priorities are not unique.
17 CPE	Channel Priority Error. 0 No channel priority error 1 The last recorded error was a configuration error in the channel priorities within a group. All channel priorities within a group are not unique.
18–23 ERRCHN	Error/Cancelled Channel Number. The channel number of the last recorded error (excluding GPE and CPE errors) or last recorded transfer that was canceled with error exit.
24 SAE	Source Address Error. 0 No source address configuration error. 1 The last recorded error was a configuration error detected in the TCDn_WORD_0[SADDR] field. TCDn_WORD_0[SADDR] is inconsistent with TCn_TCDn_WORD_1[SSIZE].
25 SOE	Source Offset Error 0 No source offset configuration error 1 The last recorded error was a configuration error detected in the TCD_TCDn_WORD_1[SOFF] field. TCDTCDn_WORD_1[SOFF] is inconsistent with TCDTCDn_WORD_1[SSIZE].
26 DAE	Destination Address Error.

Table continues on the next page...

DMA_ES field descriptions (continued)

Field	Description
	0 No destination address configuration error 1 The last recorded error was a configuration error detected in the TCDTCDn_WORD_4[DADDR] field. TCDTCDn_WORD_4[DADDR] is inconsistent with TCDTCDn_WORD_1[DSIZE].
27 DOE	Destination Offset Error. 0 No destination offset configuration error 1 The last recorded error was a configuration error detected in the TCDTCDn_WORD_5[DOFF] field. TCDTCDn_WORD_5[DOFF] is inconsistent with TCDTCDn_WORD_1[DSIZE].
28 NCE	NBYTES/CITER Configuration Error. 0 No NBYTES/CITER configuration error 1 The last recorded error was a configuration error detected in the TCDTCDn_WORD_2[NBYTES] or TCDTCDn_WORD_5[CITER] fields. TCDTCDn_WORD_2[NBYTES] is not a multiple of TCDTCDn_WORD_1[SSIZE] and TCDTCDn_WORD_1[DSIZE], or TCDTCDn_WORD_5[CITER] is equal to zero, or TCD[CITER_E_LINK] is not equal to TCDTCDn_WORD_7[BITER_E_LINK].
29 SGE	Scatter/Gather Configuration Error. 0 No scatter/gather configuration error 1 The last recorded error was a configuration error detected in the TCDTCDn_WORD_6[DLAST_SGA] field. This field is checked at the beginning of a scatter/gather operation after major loop completion if TCDn_WORD_7[ESG] is enabled. TCDn_WORD_6[DLAST_SGA] is not on a 32 byte boundary.
30 SBE	Source Bus Error. 0 No source bus error 1 The last recorded error was a bus error on a source read
31 DBE	Destination Bus Error. 0 No destination bus error 1 The last recorded error was a bus error on a destination write

18.5.3 Enable Request Register High (DMA_ERQH)

The ERQ{H,L} registers provide a bit map to enable the request signal for each of the 64 channels. ERQH supports channels 63-32, while ERQL covers channels 31-00. The state of any given channel enable is directly affected by writes to this register; it is also affected by writes to the SERQ and CERQ registers. The SERQ and CERQ registers are provided so that the request enable for a single channel can easily be modified without the need to perform a read-modify-write sequence to the ERQ{H,L} registers.

Both the eDMA request input signal and enable request flag must be asserted before a channel's hardware service request is accepted. The state of the eDMA enable request flag does not affect a channel service request made explicitly through software or a linked channel request.
