69.6.3 Sequence unit registers

69.6.3.1 Input/output Inversion control state n (IOICn)

An input control register is provided for each event generated by the SLU. This register is programmed to specify how the input signals to each SLU are combined to generate the resulting event for that particular sequence. In total, there are 16 inputs for each state and only one (the first) of the inputs can be used with or without inversion. The input can be left unused if not required for that state by selecting 000000 (No input selected option) in the L2nSEL registers. The output of each AND gate has the optional inversion control as well. The output can be routed directly or with inversion from each AND gate to the input of OR gate. The following table shows the format of the IOICn register, where n, the state number, is equal to 0–7.

Offset 0x37 (State0) Access: User read/write
0x38 (State1)
0x39 (State2)
0x3A (State3)
0x3B (State4)
0x3C (State5)
0x3D (State6)

8	Output OR GATE Control.
OutOR	0 Output is used directly (without inversion) for this event
	1 Output is inverted for this event
9:31	Reserved. Read returns 0.

69.6.3.2 Sequence control (SCTRL)

This configuration register is provided to enable the sequence and to select the states that are part of a particular sequence. There can be at most four active sequences. Each sequence can have one state or a maximum of eight states. However, each state can only be used in one unique sequence. In other words, if one state has been selected for a sequence, then this state cannot be used for any other defined sequence. Each sequence has a start state and end state. The following table shows the format of the SCTRL register.

Offset 0x3F Access: User read/write

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

	110	State 6 is the Stop state for sequence 4
	111	State 7 is the Stop state for sequence 4
31	Reserved. Read returns 0.	

1. Multiple active sequences such as Sequence 2, Sequence 3 and Sequence 4 must be programmed with Div4 option only.
2. Ideally, the start state for a sequence should be the state immediately after the stop state for the previous sequence. For example, if sequence 1 starts at state 0 and ends at state3, sequence 2 should start at state4.

69.6.3.3 State n goto control (SnGC)

SLU states are linked to each other based on if-then-else conditions. There are two conditions: true and false. A SLU state can remain in the same state or jump to any other state. The state goto control register is programmed to specify the GoTo a particular state from current state.

The following table shows the format of the SnGC register, where n, the state number, is equal to 0–7.

Offset: 0x40 (State0) Access: User read/write

0x41 (State1)

0x42 (State2)

The SnGC register fields are described in the following table.

Table 69-13. SnGC register field descriptions

Field	Description	
0	GoTo Control of State Under True Condition. Defines the Goto control of a state under the true condition. If this bit is enabled, then the State moves to the next state based on bits[3:1]. If disabled, then this is the end of a sequence when the sequence comes to this state. Actions associated with states under true condition are executed. Disabling this bit ends the sequence under a true condition.	
TE	0	Disable Goto control
	1	Enable Goto control
3:1	Next State on True Condition. Defines the Goto next state in case of true condition from the present state. States may remain in the same state on a true condition if the same state is chosen as the next state.	
NT	000	Goto State 0
	001	Goto State 1
	010	Goto State 2
	011	Goto State 3
	100	Goto State 4
	101	Goto State 5
	110	Goto State 6
	111	Goto State 7
4	GOTO Control of State Under False Condition. Defines the Goto control of a state under the false condition. If this bit is enabled, then the state moves to the next state based on bits[7:5] . If disabled, then this is the is end of a sequence when the sequence comes to this state. Actions associated with states under false condition are executed. Disabling this bit end the sequence under a false condition.	
FE	0	Disable Goto control
	1	Enable Goto control
7:5	Next State on False Condition. Defines the Goto next state in case of false condition from the present state. States may remain in the same state on a false condition if the same state is chosen as the next state.	
NF	000	Goto State 0
	001	Goto State 1
	010	Goto State 2
	011	Goto State 3
	100	Goto State 4
	101	Goto State 5
	110	Goto State 6
	111	Goto State 7
31:8	Reserved. Read returns 0.	

69.6.4 SLU status (SS) register

The SLU status register indicates the states that have been hit/encountered in any of the active sequences. The following table shows the format of the SS register.

Offset 0x48 Access: User read/write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

	1	Match occurred
25	Reserved	
31:26	Reserved. Read returns 0	

69.6.5 SPU enable (SE) register

The SPU enable/disable register is used to enable and disable the SPU. If disabled, all inputs are masked. The following table shows the format of the SE register.

Offset: 0x49 Access: User read/write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	DIV	SED
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The SE register fields are described in the following table.

Table 69-15. SE register field descriptions

Field	Description
0	SPU Enable/Disable. This bit should be set after programming all of the SPU configuration registers.
SED	0 SPU is disabled
	1 SPU is enabled
1	Div Option. Select Div4 and Div1 programmable options based on number of active sequences.
DIV	0 Use Div4 option, when multiple up to four sequences are active or only one sequence is active which does not require the highest resolution.
	1 Use a Div1 option, when only one sequence (Sequence1) is active and highest resolution is required.
31:2	Reserved

NOTE

Div option mapping with active sequences must be correctly programmed by the user. No hardware checks are implemented.

69.6.6 Sample and hold mechanism

SPU supports Div4/Div1 sample and state processing frequency (both are effectively the same). For the Div1 option, the sample and state processing frequency is the SPU clock frequency. Likewise, for the Div4 option, the sample and state processing frequency is 1/4th the SPU clock frequency.

The Div1 or Div4 is related to hold circuitry (among other circuits as well), but the sample circuitry is always Div1. Therefore, if Div4 is selected for hold circuitry, then four samples are taken and then latched into a hold circuitry (for the next four Div1 clocks, synchronized for all inputs).

This sample and hold mechanism is applicable for external signals only, but counters logic process differently. These external signals may be considered as selected conditions for any sequence, and for any of the states of any sequence. There is no difference based on state or sequence, as all inputs are treated the same regardless.

69.6.6.1 Functional limitations

If there are multiple true conditions in a Div4 period, only one condition is registered. Never are there any missed true conditions, except for extra true conditions in a Div4 period. Therefore, the user should select the resolution of SPU based on number of active sequences.

- If the signal changes faster than the sample and state frequency, then the SPU would probably only detect one event per the sample period (for example: If there are multiple true conditions in a Div4 period, only one condition is registered).
- If the signal changes faster than the sample and state frequency, then the SPU would only be able to process one event per state processing frequency.

69.6.6.2 Assumption

When using Div1, SPU counter operations are not available for state evaluation in the immediately next clock cycle. Therefore, special handling must be done in state evaluation during this delayed effect to assure that it does not create undesirable results. Refer to counter workaround description in SPU actions.

When using Div4, however, there are no delayed effects when using SPU counter operations. This is because subsequent state evaluations are done four clocks apart, instead of every clock for Div1 selection. Therefore, counter workaround description in SPU actions, becomes redundant with Div4 option.

69.6.7 SLU action unit registers

The action unit of the SPU is responsible for generating the action triggers supported by various actions. List of the actions is given in SPU actions. The action triggers are mapped to the events by programming the action registers. Each event can be programmed to trigger interrupts, watchpoints, trace signals, counter stop/reset/increment and many other general actions. The following table shows the bit mapping for all the possible actions. All possible actions are divided in three groups: client based, counter based, system related.

Table 69-16. SPU action decoder

Group bit [11:10]		Client/counter bit [9:5]		Action bit [4:1]			Enable bit [0]
ID	Name	ID	Name	ID	Name	Comment	
00	Client group	00000	CPU0	0000	No action	—	0=Stop 1=Start
		00001	CPU1	0001	DTM	Valid for Cores, AHB, and trace group actions.	
		00010	Reserved	0010	OTM		
		00011–00111	Reserved	0011	PTM		
		01000	Reserved	0100	WTM

				1011–1111	Reserved	—	—
11	Reserved						

1. The valid actions for Trace group are OTM trace, PTM trace, DTM trace or WTM trace. No other actions can be selected with Trace group. The group can be defined using the Trace group configuration registers.

69.6.7.1 State n true action 0 (SnTA0)

The SPU can be programmed to enable up to four different actions against a True condition of every state. All the possible actions and their encoding are listed in Table 69-16. A total of 12 bits are needed to code every action. The first two actions for true condition are defined in SnTA0 and the next two actions are defined in SnTA1.

The following table shows the format of the SnTA0 register, where n, the state number, is equal to 0–7.

Offset: 0x01 (State0), 0x03 (State1), 0x05 (State2), 0x07 (State3), 0x09 (State4), 0x0B (State5), 0x0D (State6), 0x0F (State7) — Access: User read/write

28:31	Reserved

69.6.7.5 Trace group configuration registers (DTMGC, PTMGC, OTMGC and WTMGC)

There are four action trace groups and a configuration register for each trace group:

- DTM trace—clients are configured with the DTM trace group configuration (DTMGC) register

- PTM trace—clients are configured with the PTM trace group configuration (PTMGC) register
- OTM trace—clients are configured with the OTM trace group configuration (OTMGC) register
- WTM trace—clients are configured with the WTM trace group configuration (WTMGC) register

Each of these groups are specific to a trace. Any number of clients can be enabled for one trace using the action trace group.

The following table shows the format of the trace group configuration registers.

Offset 0x21 (DTMGC) 0x22 (PTMGC) 0x23 (OTMGC) 0x24 (WTMGC) Access: User read/write

The CCMPn register fields are described in the following table.

Table 69-24. CCMPn register field descriptions

Field	Description
31:0 COMPARE_VAL	Compare value. This value is compared with the corresponding counter/timer value to generate an event for the SPU.

69.6.10 Status registers

69.6.10.1 Counter compare status (CCOMS)

The counter compare status register shows the status of the comparisons for all the counters. The bits in this register can be cleared by writing a 1 to them. The following table shows the format of the CCOMS register. All of the CC fields in the CCOMS register have the same description as shown in Table 69-25. Counter compare values should not be changed dynamically. Thus, these fields should be cleared (by writing 1) only during these conditions:

- Counter is in disabled state (ENABLE bit of CCTRLn set to 0).
- Software reset bit (SW_RESET) is set.

Offset 0x46 Access: User read/write

	1	Counter captured

69.7 Functional description

This section discusses the functional description of the SPU.

69.7.1 Input Mux unit

The SPU receives numerous inputs in the form of complex triggers from various clients to create a predefined sequence. One state logic can accommodate 16 inputs at one point of time. Therefore, an input Muxing unit becomes essential for reducing the debug and

performance events to a manageable set of 16 inputs for each SLU. In addition to client input signals, there are certain performance events which are fed directly to the different counters inside the SPU.

The selection of 16 inputs for each state logic is done at two level of muxing both of which are shown in Figure 69-4.

- Level 1 Muxing—At this level, there are 167 inputs. Out of these possible inputs, 63 inputs are selected. This selection is done using an 8:1 Mux. Therefore, sixty-four 8×1 muxes are required. The set of 63 watchpoints are passed to the second level of muxing. The selection mechanism is shown in Figure 69-4.
- Level 2 Muxing—At this level, 16 inputs are selected out of the 63 possible inputs for each SLU. These 63 inputs consist of multiple set of 8 watchpoints from different clients, processor exception signals, interrupt from clients, and event IN/OUT signals. In addition, certain events from counters are used as feedback in the present state logic of each state.

  At level two there are 16 banks of 64:1 muxes for the selection of 16 inputs for one state logic. The inputs to these Muxes are expected to be somewhat unique. In general, care should be take to choose signal assignments that allow for key use cases to be achieved without encountering concurrency restrictions. Since there are eight such states, 16 × 8 banks of 64:1 mux are required. The selection mechanism is shown in the following figure.

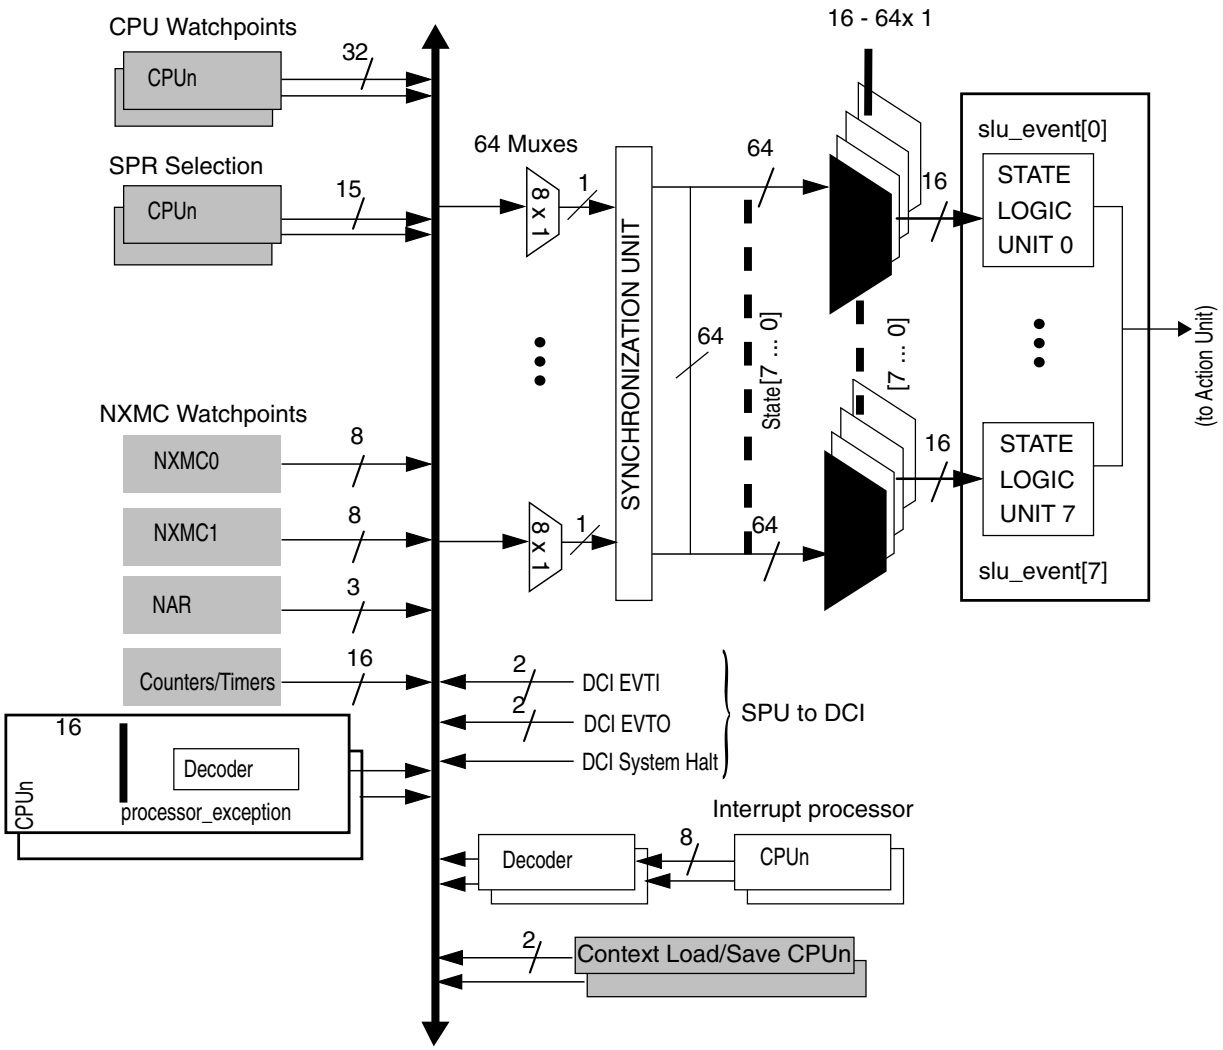

Figure 69-4. Input Mux unit block diagram

69.7.2 Processor exception vector encoding

Active-high input signals from the CPU indicate the particular exception being processed when the CPU exception enable signal is asserted. These signals can be used for debug triggering mechanisms. The SPU captures the CPU exception vector whenever the CPU exception enable signal is asserted and the SPU uses the exception vector as an input condition as shown in the following table. The CPU exception vector values from the CPUs must be byte swapped before they are programmed to the CPUn field of the CnPEVP registers as shown in the following table.

Table 69-28. Processor exception processing conditions

CPU exception vector	CnPEVP register CPUn field value	Exception condition
0x0000	0x0000	Critical Input—autovectored
0x0010	0x1000	Machine check
0x0020	0x2000	Data storage
0x0030	0x3000	Instruction storage

69.7.3 State logic unit (SLU)

Complex triggers and system performance monitor functions are implemented in the SLU. The SPU creates debug events based upon states in a sequence. A sequence can consist of a single state, or any number of states up to 8. Each state consists of combinational logic allowing AND/OR operations on inputs from the trigger source unit. Single or multiple (up to 8) actions can be triggered by a state machine.

A logic diagram of one SLU state is shown in the following figure.

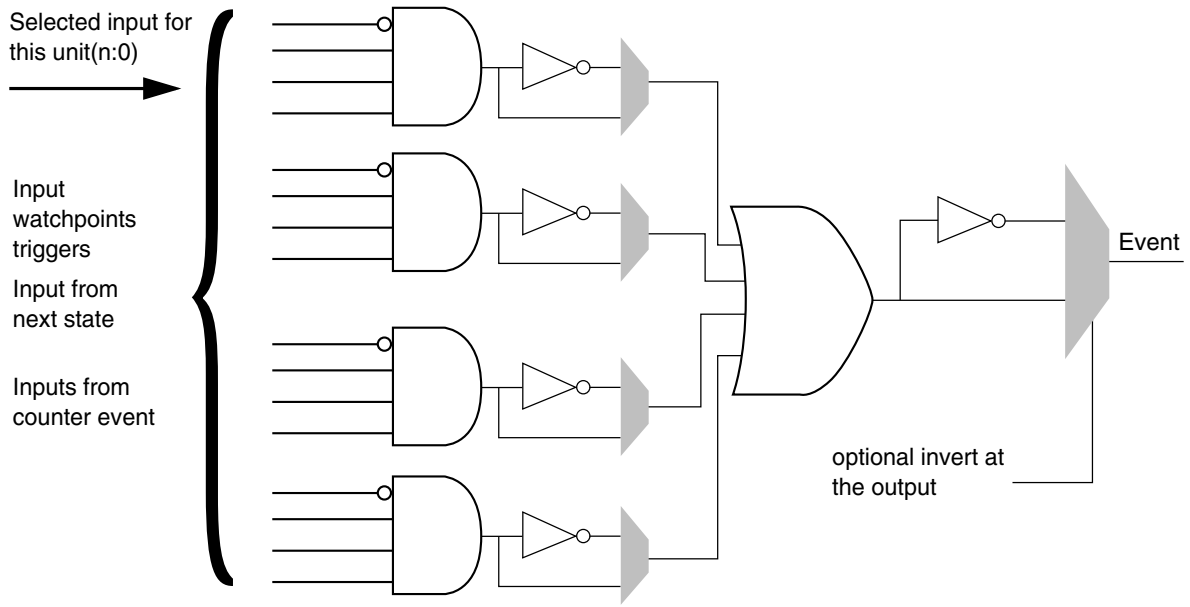

Figure 69-5. SLU block diagram

Each state consists of AND gates, the outputs of which are ORed together.

- Each AND gate can have up to 4 inputs, selected from the trigger source unit by the user.
- The user has an option to invert one input signal into the AND gate.
- The OR gate has a user selectable option to invert the output.
- The output of the OR gate is used as the trigger to move to the next state in the sequence.

The SLUs are responsible for performing operations on the selected input events to produce derived events. Each SLU has a control register that manages how the various inputs are combined to produce a derived event.

An event is triggered from each state based on all the possible selected inputs for each state. This event is used to trigger an Action.

Note

With only one optional inversion at the input of each AND gate and optional inversion at the output of the OR gate, many combinations are not possible.

69.7.4 Sequence formation

Event sequencing can be accomplished with the if-then-else operations. The next event can be fed back as a necessary condition for the current event. For example, event5 can be designated as a necessary condition for event4 in case test condition fails in event5. Event5 can be in turn be designated as necessary for event6 in case test condition passes, and so on. In this way, events can be chained together to create a sequence.

To create complex triggers, a configurable state machine is implemented. This allows the user to join states together with if-then-else operations to create a sequence. The SPU supports up to four simultaneous sequences, however only eight states are supported regardless of the number of active sequences, and each state can only be used in one unique sequence.

For example, the following state configurations are possible:

- 1 active sequence, with 8 states
- 2 active sequences, each with 4 states
- 2 active sequences, the first with 3 states and the second with 5 states
- 4 active sequences, each with 2 states
- 4 active sequences, each with 1 state

Each sequence has the following options which are shown in the following figure:

- The ability to optionally trigger one or more actions based on a true condition from any state in the sequence.
- The ability to optionally trigger one or more actions based on a false condition from any state in the sequence.
- Each state in a sequence has the ability to route to another state on a true condition from the state logic, and the ability to route to a different state based on a false condition from the state logic

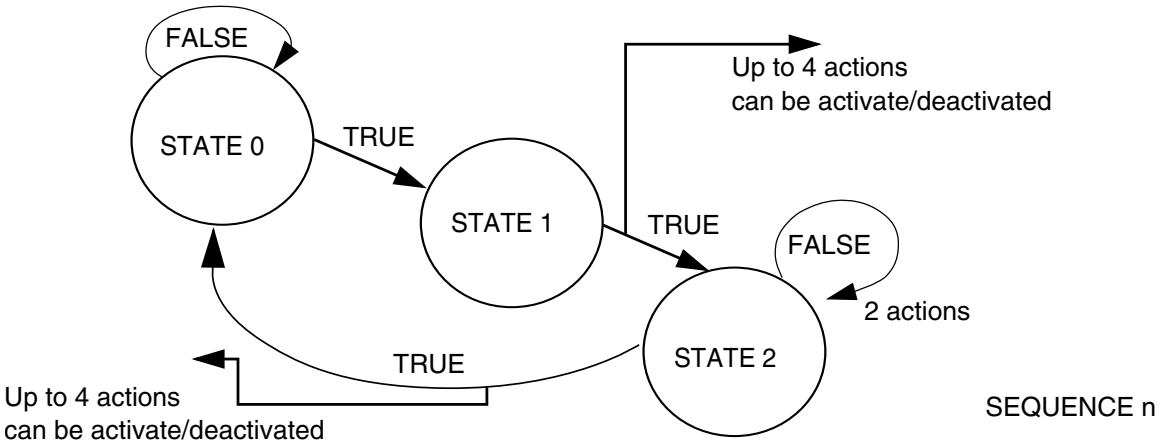

Figure 69-6. Example of a simple configurable if-then-else sequence

69.7.4.1 Complex sequence example

A user can create a complex sequence using five states as shown in the state transition diagram in the following figure.

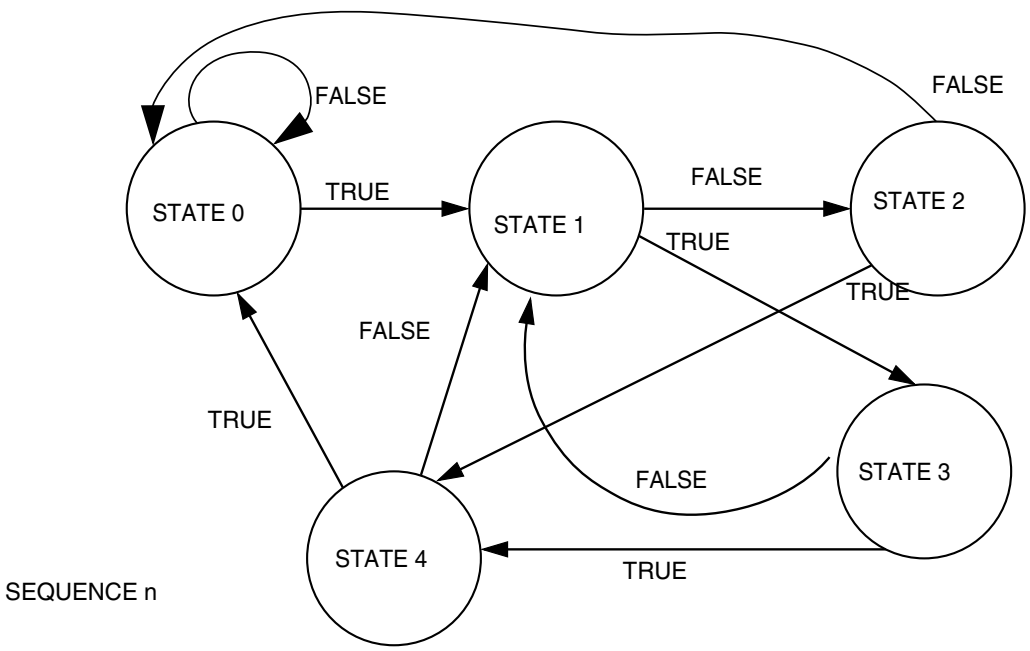

Figure 69-7. Complex sequence example

69.7.4.2 Typical sequence example

For this example, the user would like to create a timestamp in the trace stream each time a function is entered, and upon the 12th time of entering the function, stop the trace signal. This use case can be implemented as follows:

- State 0 takes an instruction address compare as its input. On a match of the instruction address to a specific function, called function_x, the sequence moves to State 1. Upon this action, State0 is configured to insert a timestamp into the trace stream and also increment an SPU counter, say counter[0].
- The sequence is now in State 1. State 1 takes an input from counter[0]. Counter[0] has been pre-configured to create a match event when the counter value is equal to 12.
  - If the value of counter[0] is less than 12, then the sequence moves back to State0.
  - If the value of couner[0] is equal to 12, then the sequence completes and an action from State1 disables the trace signal.

69.7.4.3 Sequence status register description

A status register providing feedback on each sequence is provided to allow debug tools to identify the source of a debug event from the SPU. The status register consists of two field types:

- States—each state has a sticky bit that is set upon a true match of the state logic. This sticky bit is cleared upon a write to this register.
- Sequence status—each sequence has a field indicating the active state of the state machine. This is a read only field.

69.7.5 Performance counters/timers unit

The SPU counters are 32-bit counters that may be used to delay events, count distances, count latencies or count events as shown in the following figure. Therefore, these counter are used as either counters or timers. The selection between counter or timer for each of the counters is done via configuration register. The basic counting operation is straightforward. Once enabled (default is disabled mode), whenever the selected input is driven to a logic 1, the counter increments using the platform clock.

Each of the counter/timer registers are accessible (via the JTAG interface) for the configuration of timer/counter, the compare registers and global SPU timer/counter status registers. These register are accessible via the JTAG interface even when the SPU is in disabled mode.

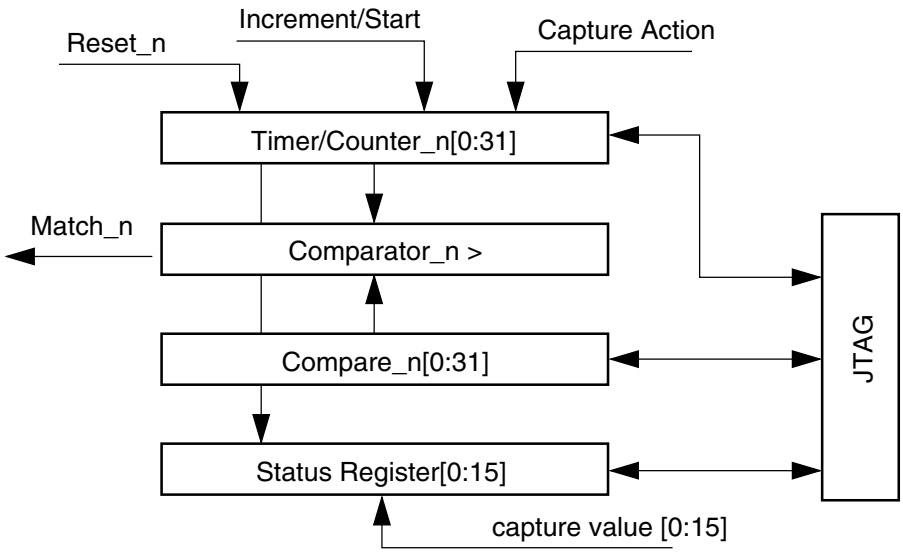

Figure 69-8. Counters/timers overview

69.7.5.1 Counter events and actions

Each counter is capable of detecting one event condition, such as compare value match. The compare value match is used for triggering actions in the SPU. Each counter can be reset in response to a reset action generated from the SPU. Capture registers are available for capturing the counter state in response to a SPU trigger condition. This capture information is updated in the status register which is accessible to users via JTAG interface. These status registers are if type write 1 to clear (W1C).

There are two classes of signals, actions and events:

- Actions—each timer/counter has an interface from the action unit to start/increment and reset as appropriate. The start/increment signal is a single signal, with the operation selected in the SPU configuration registers. The generation of the appropriate count/reset signal is generated in the SPU.

  On an action to insert the timer/counter value into the trace stream, the value stored in the timer/counter is buffered inside the SPU and routed to the appropriate SoC block to insert the value into the trace stream one by one.

- Events—on a match event, whereby the a timer/counter value matches the value of the respective compare register, a signal is sent to the trigger source unit to indicate this.

69.7.5.2 Counter input selection at SPU level

Counter increment inputs derive from the SPU action or direct from the CPU performance measurement counters (CPU_PMC), as shown in the following figure. These inputs include signals from the primary SPU muxes or SPU events of counters.

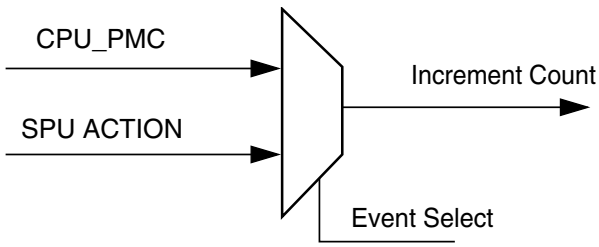

Figure 69-9. Input selection for count increment

69.7.5.3 Counters increment assignment

When configured as a counter, the counter has an increment signal. This can optionally be routed from the SPU action unit, or directly from a CPU performance counter signal. The assignment of which signal is used to increment a counter is handled in the SPU, and is configurable by user. The assignment of increment signals to counters is shown in the following figure.

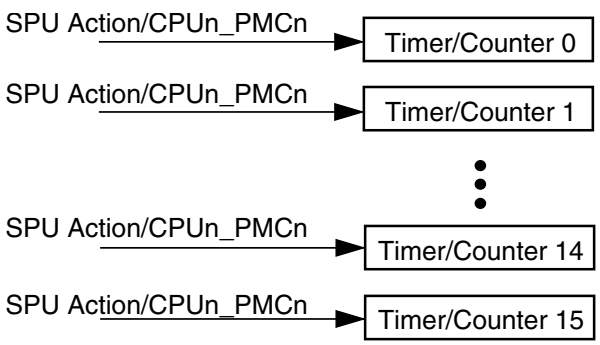

Figure 69-10. SPU counters increment assignment

69.7.5.4 CPU PMC mapping to counters

Each of the CPUs in the system has four performance measurement counters (PMC). The outputs (overflow signals) from these counters (of CPUn) are routed to the SPU debug unit. The counters inside the SPU can be configured to count the pulses from the PMCs. There is a one-to-one mapping between the PMC inputs and the counters that they trigger. Their mapping is shown in the following figure.

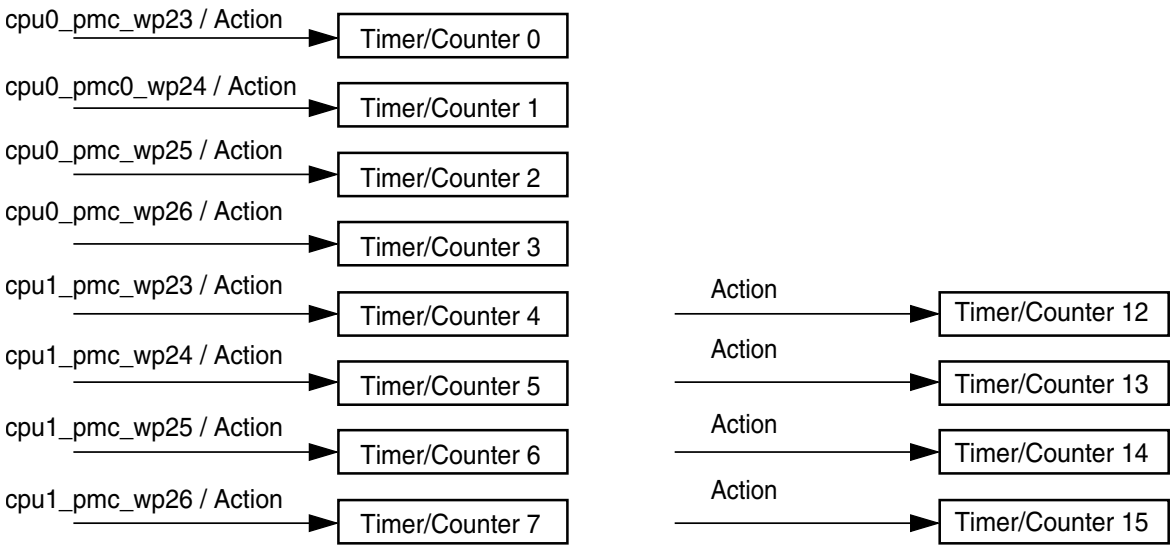

Figure 69-11. CPU PMC mapping inside the SPU unit

69.7.6 Action unit

The action unit block of the SPU is responsible for the generating the action triggers supported by various actions. A state has true and false (if-else-than) condition. Four simultaneous actions can be generated under true/false condition of a particular state. The list of the actions is given in the SPU actions. The actions triggers are mapped to the events by programming the set of SPU group action control for events registers. Each event can be programmed to trigger interrupts, timestamp watch points, trace signals, PMCs, start/reset/increment counters and many other general actions.

69.7.7 Optional trace group

User defined trace group can be defined through the configuration register. Configuration registers registers, defined in Table 69-21, are available where the user can group the different traces from same or different clients.

69.7.8 CKSRC and CKDATA format

The format of the CKSRC is defined for the SPU peripheral (as in-circuit trace client) as shown below:

ICT clients	CKSRC value
SPU counter trace client	b00_0000

Table continues on the next page...

ICT clients	CKSRC value
Reserved	b00_0001 — b11_1111

The format for the CKDATA field for the SPU counter trace client is as shown below:

CKDATA	
CKDATA[CTR_index]	CKDATA[CTR_value]
4 bits	32 bits

Chapter 70
JTAG Master (JTAGM)

70.1 Introduction

The JTAG Master (JTAGM) is a module that is able to act as JTAG master inside the device. The module has a parallel interface that can exchange data with another serial communication module or via customer software.

The data transferred to this module is transformed to produce TCK, TMS, TDI and TRST outputs and to accept TDO inputs. The JTAGM is connected in the device to allow these five signals to connect to the JTAGC as if the JTAG data is coming from an outside tool. The JTAGM generates all required JTAG scan chains to allow software and high speed serial communication access to all JTAG mapped resources.

70.1.1 Overview

The JTAGM is the master to drive JTAG signals from within the device. It has options to receive parallel data from software through the IPS interface . It then sends this data on TDI, TMS and TCK to the DCI. The JTAGM also receives serial data through TDO from the DCI. The JTAGM has the following registers:

- Configuration register
- Status register
- Four data output registers
- RxCRC receive register
- Two data input registers

All these registers are memory mapped and can be accessed by software.

The clocks for the JTAGM are derived from the system clock. The JTAGM also samples the ready signal from the Nexus, to provide a more efficient handshake to the external tool to read and write any memory mapped address location within the device.

This figure shows the block diagram of the JTAGM.

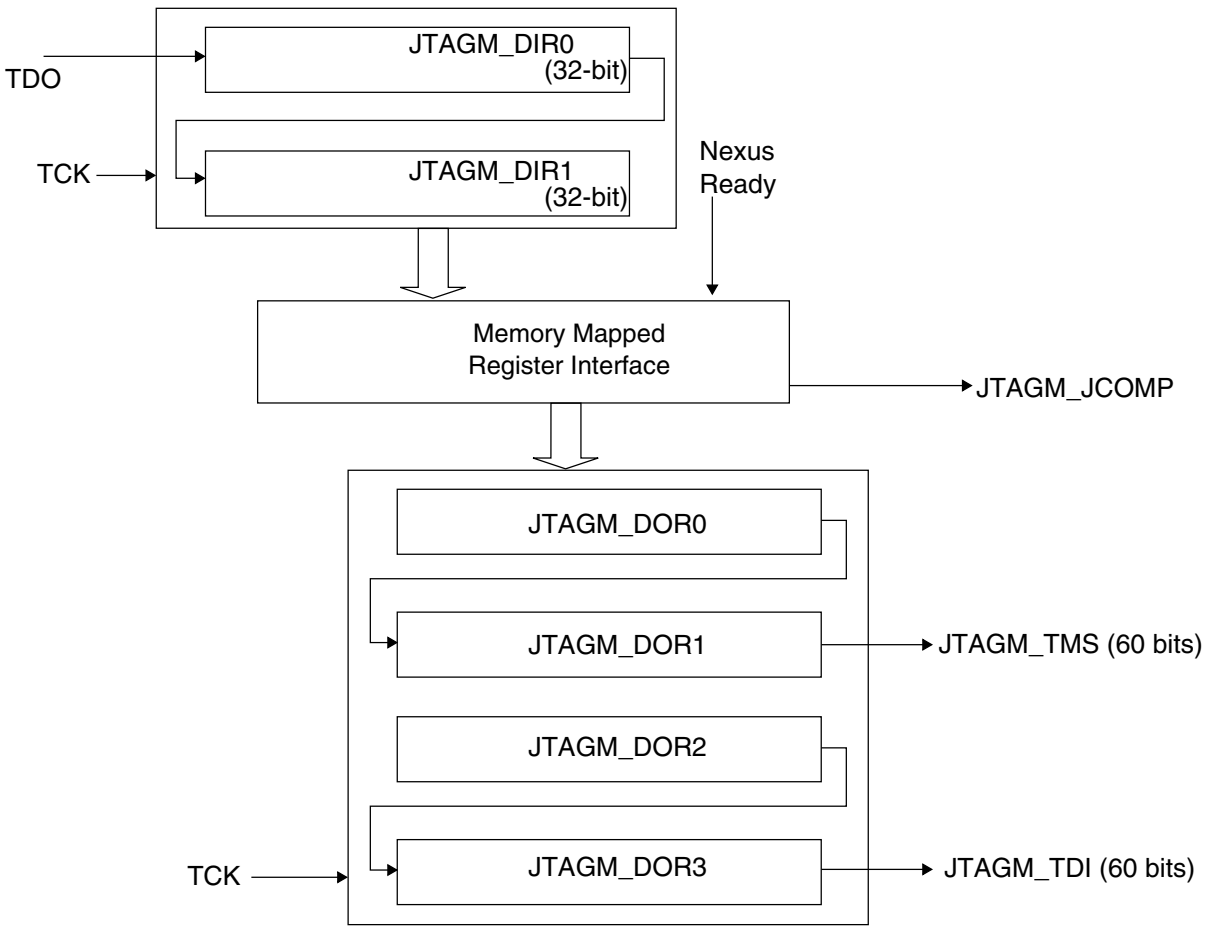

Figure 70-1. JTAGM block diagram

70.1.2 Feature description

The main features of the JTAGM are the following:

- Provides efficient handshake to the external tool to read any memory mapped address location within the device
- Provides software the option to write data for driving JTAG

70.2 Functional description

The JTAGM is simple in concept. TCK is generated from the device system clock. Data is pushed to the modules via a 32-bit wide parallel interface. The data is in the form of 60 bits of TMS data and 60 bits of TDI data. This data is the logical state to be driven onto the TMS and TDI output pins on each of the 60 TCK cycles. During these 60 TCK cycles, the TDO pin is sampled and the 60 bits of sampled data is transferred to the 32-bit wide module interface. This concept allows complete flexible generation on TMS and TDI data and capture of TDO data. The only limitation is that JTAG signals can only be generated in 60 TCK cycles packets. Extra cycles are wasted in idle cycles at the end of a scan chain.

70.2.1 JTAGM Ready signal

The Nexus Read/Write Access (RWA) module allows an external tool to read and write any memory mapped address location within the device via JTAG commands. Read accesses to memory take a finite amount of time and a JTAG read of the data register too soon results in erroneous data being read back. There is a bit in a JTAG register to show the read data is available.

70.2.1.1 Status register ready bit

A bit is provided in the JTAGM status register to indicate the status of the ready signal. To provide this ready signal functionality, the ready signal is monitored. If the ready signal has toggled between the start of the previous 60 TCK shift period and start of the current 60 TCK shift period, the ready bit in the JTAGM status register is set. Otherwise the ready bit in the status register is cleared.

The entire content of the 32-bit status register is appended to the 60 bits of JTAG TDO data captured along with 4 bits of 0-padding and sent as output on the parallel output port as a 96-bit payload on channel A. This provides back to the tool, an indication that the data read in the current transaction is valid.

70.2.1.2 Inter-JTAG frame gap timer

To operate in conjunction with the status register ready bit, a configurable timer is provided to force a programmable gap between the end of one 60-bit JTAG frame and the start of the next. This timer is configured via the JTAGM configuration register from 1 to 64 TCKs in 1 TCK intervals. Furthermore, if the ready signal asserts during this inter-frame gap period, the gap timer is aborted and the next JTAG frame starts immediately.

70.2.2 JTAGM to DCI serial interface

This figure shows the data transfer timings between JTAGM and DCI.

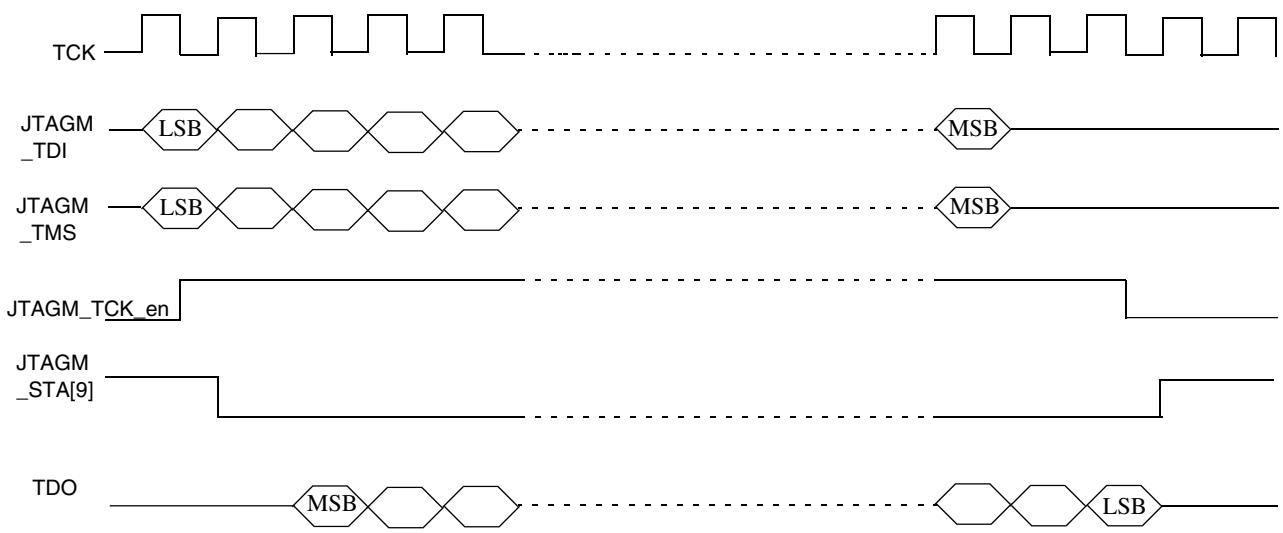

Figure 70-2. JTAGM to DCI serial interface diagram

70.2.3 Software interface

It is possible for software to write the 120 bits of JTAG data to be output and to read the 60 bits of data. The JTAGM module has an IPS interface.

70.3 Modes of operation

There are no special modes of operation. The JTAGM works normally in the debug mode.

70.4 Memory mapped registers

JTAGM supports only 32-bit write accesses to its registers. A byte write access will be converted into a 32-bit write; all other byte values in the register will become 0000_0000b.

JTAGM memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	Module Configuration Register (JTAGM_MCR)	32	R/W	0300_0002h	70.4.1/3027

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0

JTAGM_MCR field descriptions

Field	Description
0 SWRESET	Software Reset. Writing a 1 resets the state machine and counters inside JTAGM. It is a self clearing bit; after being written with a 1, this bit is auto-cleared within 3 TCK cycles. Writing a 0 has no effect.
1–17 Reserved	This field is reserved.
18–23 inter_jtag_frame_timer	TCK delay. 000000 0 TCK delay 000001 1 TCK delay ... ... 111111 63 TCK delay
24 Reserved	This field is reserved.
25 SIE	SPU Interrupt Enable. 0 JTAGM does not generate an interrupt to the CPU 1 JTAGM generates an interrupt to the CPU if the SPU interrupt request is asserted
26 IIE	Idle Interrupt Enable. 0 JTAGM does not generate an interrupt to the CPU upon completion of a 60-bit JTAG transfer 1 JTAGM generates an interrupt to the CPU upon completion of a 60-bit JTAG transfer
27–29 TCKSEL	TCK clock frequency selection. When the JTAGM is enabled, this bit should not be programmed with 000. 000 Reserved 001 TCK is system clock ÷ 2 010 TCK is system clock ÷ 3 011 TCK is system clock ÷ 4 100 TCK is system clock ÷ 5 101 TCK is system clock ÷ 6 110 TCK is system clock ÷ 7 111 TCK is system clock ÷ 8
30 jtagm_JCOMP	JTAG reset. 0 JCOMP low/asserted 1 JCOMP high/not asserted (default)
31 DTM	Data Transfer Mode. 0 Data transferred by software disabled. 1 Data for JTAG transferred by software.

70.4.2 Status Register (JTAGM_SR)

Address: 0h base + 4h offset = 4h

JTAGM_SR field descriptions

Field	Description
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

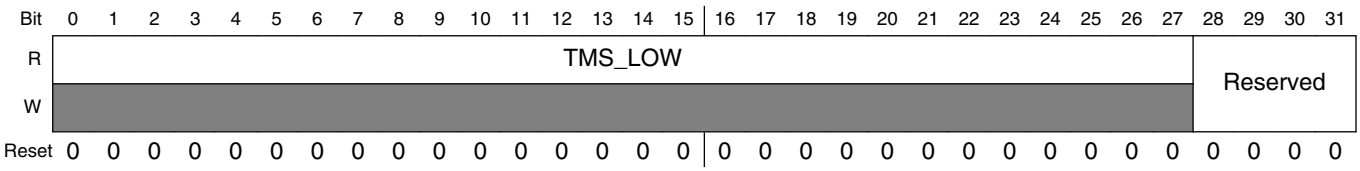
Table continues on the next page...

JTAGM_SR field descriptions (continued)

Field	Description
8 Reserved	This field is reserved. Reserved to 0
9 Reserved	This field is reserved. Reserved to 0
10 JTAGEN	DCI status: DCI JTAG port enable
11 Reserved	This field is reserved. Reserved to 0
12 JTAGSAFE	DCI status: DCI JTAG safe mode
13 Reserved	This field is reserved. Reserved to 0
14 Reserved	This field is reserved. Reserved to 0
15 TOOL	DCI status: DCI tool present, set when a debug tool is connected
16–17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
18 SPU_INT_CLR	Write 1 clears the SPU_INT. This is a self clearing bit. If SPU_INT is not set then SPU_INT_CLR remains set until SPU_INT is set, and both are cleared.
19 SPU_INT	This bit is set when the SPU interrupt request input rising edge is detected. Writing a 1 to SPU_INT_CLR resets this bit.
20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21 Nexus_err	Nexus error bit. It is set when there is an error, else it is 0.
22 Idle	Idle bit. Idle bit is cleared while a JTAG frame is in progress. This bit is set to 1 when a JTAG frame ends. Writing a 1 to the Idle bit clears the Idle_interrupt in SW Mode. A read always gives the JTAG frame status but does not give the write value.
23 NR	Status of Ready bit from Nexus RWA. This bit is automatically cleared when a new JTAG message is started. 0 RDY has not asserted indicating Nexus RWA is not ready 1 RDY has asserted indicating a Nexus RWA has completed bus access and is ready for the data register to be read
24–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

70.4.3 Data Out Register 0 (JTAGM_DOR0)

Address: 0h base + 8h offset = 8h



Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

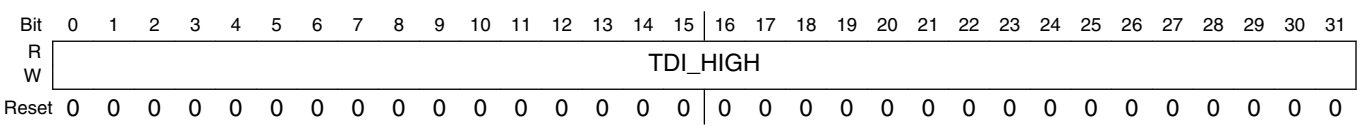
JTAGM_DOR0 field descriptions

Field	Description
0–31 TMS_HIGH	Higher word of data for TMS, bits 59-28. Writable by software only when DTM = 1

70.4.4 Data Out Register 1 (JTAGM_DOR1)

Address: 0h base + Ch offset = Ch

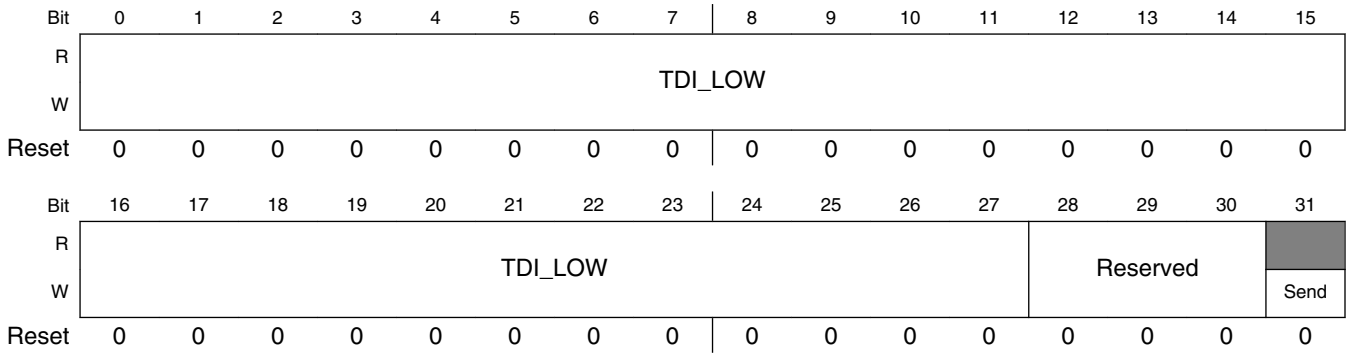


JTAGM_DOR1 field descriptions

Field	Description
0–27 TMS_LOW	Lower word of data for TMS, bits 27-0. Writable by software only when DTM = 1. TMS_LOW[0] is shifted out first
28–31 Reserved	This field is reserved.

70.4.5 Data Out Register 2 (JTAGM_DOR2)

Address: 0h base + 10h offset = 10h

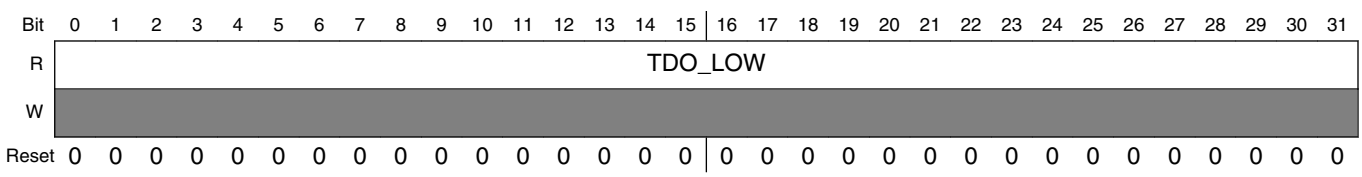


JTAGM_DOR2 field descriptions

Field	Description
0–31 TDI_HIGH	Higher word of data for TDI, bits 59-28. Writable by software only when DTM = 1

70.4.6 Data Out Register 3 (JTAGM_DOR3)

Address: 0h base + 14h offset = 14h

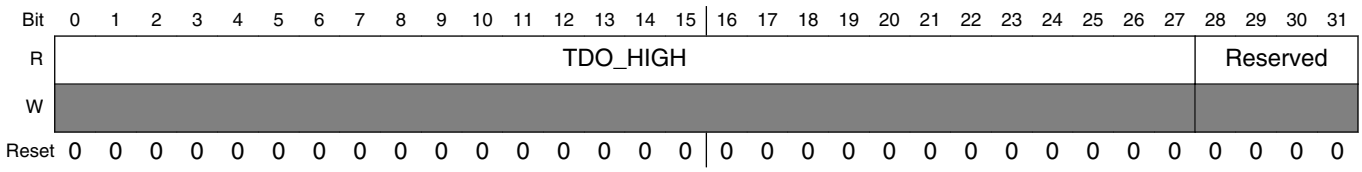


JTAGM_DOR3 field descriptions

Field	Description
0–27 TDI_LOW	Lower word of data for TDI, bits 27-0. Writable by software only when DTM = 1. TDI_LOW[0] is shifted out first
28–30 Reserved	This field is reserved.
31 Send	Send bit. When this bit is set, data is sent to the DCI. It is a self-clearing bit and is always read as 0. Writable by software only when DTM = 1

70.4.7 Data Input Register 0 (JTAGM_DIR0)

Address: 0h base + 1Ch offset = 1Ch



JTAGM_DIR0 field descriptions

Field	Description
0–31 TDO_LOW	Lower word of data received on TDO, bits 0-31

70.4.8 Data Input Register 1 (JTAGM_DIR1)

Address: 0h base + 20h offset = 20h

JTAGM_DIR1 field descriptions

Field	Description
0–27 TDO_HIGH	Higher word of data received on TDO, bits 32-59
28–31 Reserved	This field is reserved.

Chapter 71
Development Trigger Semaphore (DTS)

71.1 Introduction

The Development Trigger Semaphore (DTS) module enables software to signal an external tool by driving a persistent (affected only by reset or an external tool) signal on an external device pin. There are a variety of ways this module can be used, including as a component of an external real-time data acquisition system.

Note

When used as a component of a triggered data acquisition system, Nexus read/write access is different than the data acquisition protocol defined in the IEEE-ISTO 5001-2003 or IEEE-ISTO 5001-2012 Nexus standards, which use the Nexus Auxiliary port.

71.2 Overview

The Development Trigger Semaphore (DTS) module consists of registers and a small amount of combinational logic to generate an output signal—DTS Trigger Output (DTO). The registers are as follows:

- DTS_SEMAPHORE register—Any bit in this 32-bit register, when set to a value of logic '1', causes the DTS module output signal to be asserted if the corresponding DTS_EN bit is set in the DTS_ENABLE register. This enables an external tool to detect up to 32 signals from the application software. In an application, each bit is generally associated with a specific data set. Only the processor core and DMA module can set bits in this register. The bits can only be cleared by a tool access via Nexus Read/Write Access.

- DTS_SEMAPHORE_B register—Any bit in this 32-bit register, when set to a value of logic '1', causes the DTS module output signal to be asserted if the corresponding DTS_EN_B bit is set in the DTS_ENABLE register. This enables an external tool to detect an additional 32 signals from the application software. In an application, each bit is generally associated with a specific data set. Only the processor core and DMA module can set bits in this register. The bits can only be cleared by a tool access via Nexus Read/Write Access.
- DTS_STARTUP register—This register provides a mechanism for the external tool to notify software running on the CPU that the tool is connected and can provide information about either the type of tool or options that can be used by the software.
- DTS_ENABLE register—This register provides an enable/disable capability for the DTS feature.

The architecture is shown in the following figure.

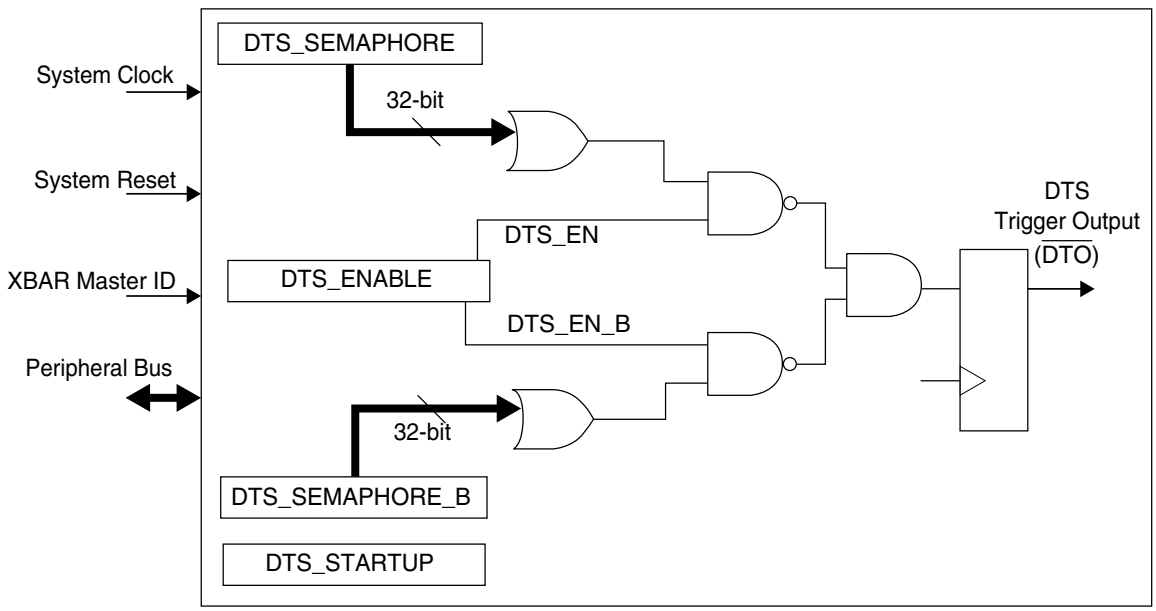


Figure 71-1. DTS block diagram

The DTS Trigger Output (DTO) signal is connected to one of the EVTO inputs of the Debug and Calibration Interface (DCI). The other EVTO inputs are connected to the other Nexus modules in the device. DTO is asserted when any bit in a semaphore register is set and the DTS function of that register is enabled.

Note

When the DTS module is enabled (DTS_ENABLE[DTS_EN] = 0b1 or DTS_ENABLE[DTS_EN_B] = 0b1), all other Nexus EVTO functions associated should be disabled by the tool and

EVTO becomes the DTO. Unlike the EVTO function that only asserts for one clock, the DTO function remains asserted until the tool reads the semaphore register that is the source of the assertion, clearing the register's contents.

The following figure shows an example of the chain of events that begins with setting of a bit in the DTS_SEMPAHORE register and the clearing of the register caused by a Nexus read.

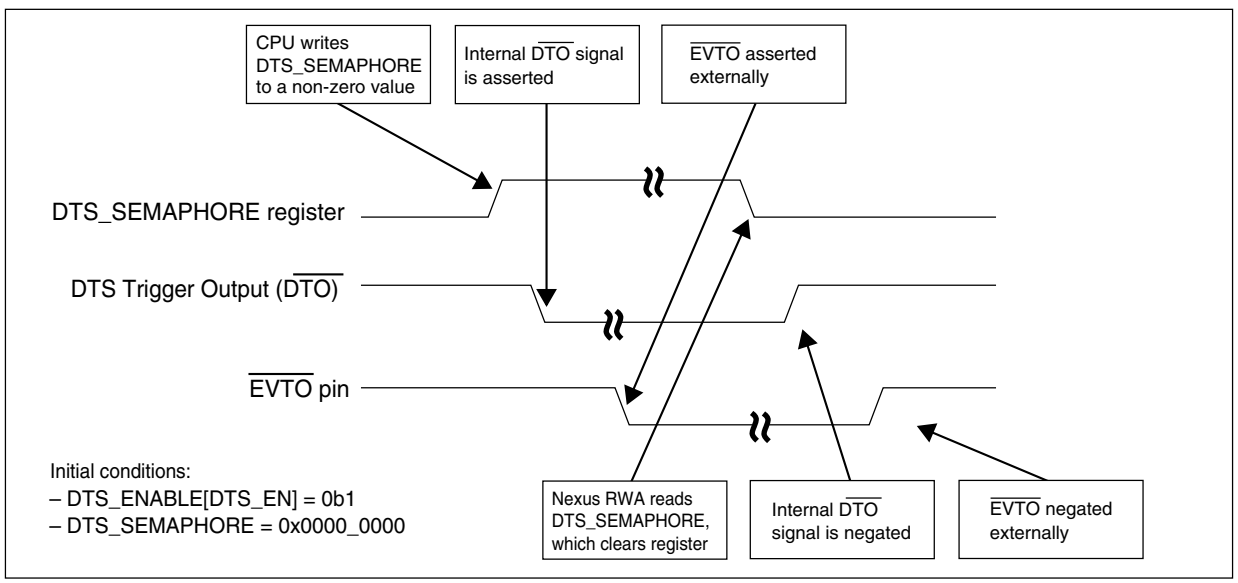

Figure 71-2. DTO event sequence example

71.3 DTS device connections

The following figure shows the DTS device connections. The DTS module connects to the Peripheral Bridge (PBRIDGE) for access to the registers. The PBRIDGE is connected to the device modules through a slave port of the Crossbar bus interface (XBAR).

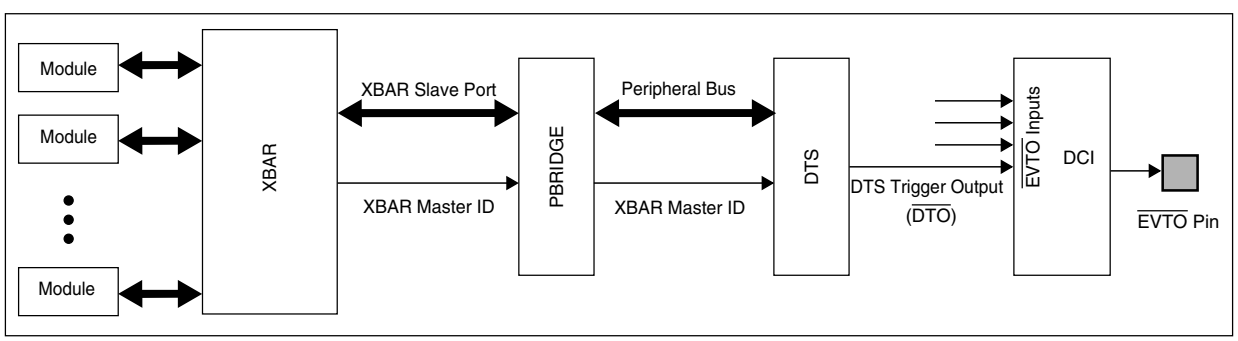

Figure 71-3. DTS device connections

The registers have limited access as described in DTS register access. Access is based on the XBAR Master ID of the accessing module. Writing to the semaphore registers is limited to the cores and the eDMA module and is restricted to only setting bits. Only an access via a Nexus Read/Write Access from an external tool can clear bits in the semaphore registers (semaphore register bits are cleared automatically when read). Similarly, the DTS_ENABLE and DTS_STARTUP registers can only be written via a Nexus Read/Write Access.

Note

Nexus Read/Write Accesses use the core load/store bus to perform accesses, but Nexus accesses have a different Master ID than normal core load/stores.

71.3.1 DTS register access

A summary of accesses to all DTS registers by bus masters is provided in the following table. Only proper 32-bit accesses are valid. The effects of write accesses that are not 32 bits are not defined.

Table 71-1. DTS register access effects

Register	32-bit read				32-bit write			
	RWA[1, 1]	Core	eDMA	Other crossbar masters	RWA [1]	Core	eDMA	Other crossbar masters
DTS_ENABLE	Data	Data	Data	Data	Data	No effect	No effect	No effect
DTS_STARTUP	Data	Data	Data	Data	Data	No effect	No effect	No effect
DTS_SEMAPHORE	Data and Clear[2, 2]	Data	Data	Data	No effect	Bit OR	Bit OR	No effect
DTS_SEMAPHORE_B	Data and Clear[2]	Data	Data	Data	No effect	Bit OR	Bit OR	No effect

1. Nexus Read/Write access via an external tool
2. A read of the semaphore registers by Nexus Read/Write Access module is destructive and clears all bits in the register

Access to DTS module registers is controlled based on the XBAR Master ID of the accessing module.

Note

The XBAR Master ID should not be confused with the Master Port number of the XBAR. See the Crossbar Switch (XBAR) chapter for details.

Tools must access the DTS registers through the Nexus Read/Write Access mechanism of a core. External tool accesses through either core appear as if the access is via the core and therefore do not have the same level of access as a Nexus Read/Write Access.

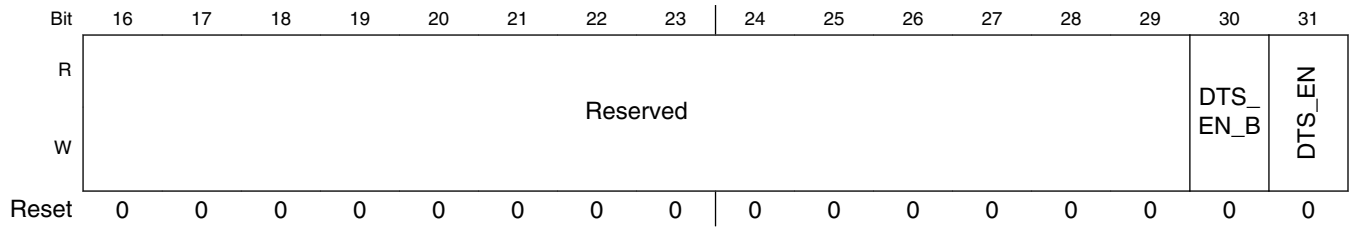
71.4 Memory mapped registers

Only certain types of accesses are allowed to the DTS registers. See the description for each register to determine the accesses that are allowed.

DTS memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	Output Enable Register (DTS_ENABLE)	32	R/W	0000_0000h	71.4.1/3039
4	Startup Register (DTS_STARTUP)	32	R/W	0000_0000h	71.4.2/3040
8	Semaphore Register (DTS_SEMAPHORE)	32	R/W	FFFF_FFFFh	71.4.3/3041
C	Semaphore Extension (DTS_SEMAPHORE_B)	32	R/W	FFFF_FFFFh	71.4.4/3042

71.4.1 Output Enable Register (DTS_ENABLE)



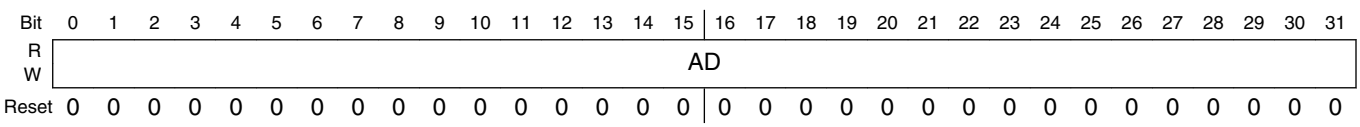
The DTS_ENABLE register controls the DTS Trigger Output ($\overline{\text{DTO}}$) and whether $\overline{\text{DTO}}$ is active on the $\overline{\text{EVTO}}$ output pin of the device. The DTS_ENABLE register can be read by the core, but can only be written by a Nexus Read Write Access (RWA).

NOTE

Access to the DTS_SEMAPHORE, DTS_SEMAPHORE_B, and DTS_STARTUP registers are unaffected by the state of this register.

Address: 0h base + 0h offset = 0h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	Reserved															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0



DTS_ENABLE field descriptions

Field	Description
0–29 Reserved	This field is reserved.
30 DTS_EN_B	DTS Enable B. Controls whether the $\overline{\text{DTO}}$ signal is routed to the $\overline{\text{EVTO}}$ pin. The DTS Enable bit is cleared by a device reset (either the assertion of the external $\overline{\text{RESET}}$ or by an internally generated reset). A Nexus reset does not change the state of this register. 0 DTS output disabled. Any bit set in the DTS_SEMAPHORE_B register does not assert the DTS trigger output signal. 1 DTS output enabled. Any bit set in the DTS_SEMAPHORE_B register asserts the DTS trigger output signal ($\overline{\text{DTO}}$).
31 DTS_EN	DTS Enable. Controls whether the $\overline{\text{DTO}}$ signal is routed to the $\overline{\text{EVTO}}$ pin. The DTS Enable bit is cleared by a device reset (either the assertion of the external $\overline{\text{RESET}}$ or by an internally generated reset). A Nexus reset does not change the state of this register. 0 DTS output disabled. Any bit set in the DTS_SEMAPHORE register does not assert the DTS trigger output signal. 1 DTS output enabled. Any bit set in the DTS_SEMAPHORE register asserts the DTS trigger output signal ($\overline{\text{DTO}}$).

71.4.2 Startup Register (DTS_STARTUP)

The DTS_STARTUP register is used for tool detection and startup information exchange between external data acquisition tool and the embedded controller. DTS_STARTUP register can be read by the core, the eDMA module and Nexus but can only be updated by a Nexus Read Write Access (RWA).

Address: 0h base + 4h offset = 4h

DTS_STARTUP field descriptions

Field	Description
0–31 AD	Application Dependent register bits. The bits have no defined meaning to the microcontroller. They are used to by an external tool to pass information (for example, application options and status) to application

DTS_STARTUP field descriptions (continued)

Field	Description
	software running on target microcontroller at startup time. Use a Nexus RWA 32-bit write access to update the contents of this register. A device reset (either from the $\overline{\text{RESET}}$ pin or an internally generated reset) clears all bits in the register. A Nexus reset does not change the contents of the register.

71.4.3 Semaphore Register (DTS_SEMAPHORE)

The DTS_SEMAPHORE register is used by software to assert the $\overline{\text{DTO}}$ signal on the device $\overline{\text{EVTO}}$ pin. A one in any bit of this register causes the $\overline{\text{DTO}}$ signal on the $\overline{\text{EVTO}}$ pin to be driven low. The intended use of this register is for the $\overline{\text{DTO}}$ signal to notify tools that data is available. Individual bits are used to identify the specific data.

Address: 0h base + 8h offset = 8h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	ST

DTS_SEMAPHORE field descriptions

Field	Description
0–31 ST	Semaphore Trigger. When a core or eDMA writes a logical '1' to a bit, the bit is set. A write of '0' by the core or DMA does not change the state of the bit. • All register bits are set to '1' by a device reset. • A Nexus reset does not change the state of this register. • The register can be accessed, with restrictions, by any core, DMA or any Nexus RWA. • For the core or DMA, only 32-bit write or read accesses are valid. • A core or DMA valid read access returns the current value of the register and leaves the register unchanged. 0 No flag 1 Flag is set

71.4.4 Semaphore Extension (DTS_SEMAPHORE_B)

The DTS_SEMAPHORE_B register is used by software to assert the $\overline{\text{DTO}}$ signal on the device $\overline{\text{EVTO}}$ pin. A one in any bit of this register causes the $\overline{\text{DTO}}$ signal on the $\overline{\text{EVTO}}$ pin to be driven low. The intended use of this register is for the $\overline{\text{DTO}}$ signal to notify tools that data is available. Individual bits are used to identify the specific data.

Address: 0h base + Ch offset = Ch

DTS_SEMAPHORE_B field descriptions

Field	Description
0–31 ST_B	Semaphore Trigger Extension. When a core or eDMA writes a logical '1' to a bit, the bit is set. A write of '0' by the core or DMA does not change the state of the bit. • All register bits are set to '1' by a device reset. • A Nexus reset does not change the state of this register. • The register can be accessed, with restrictions, by any core, DMA or any Nexus RWA. • For the core or DMA, only 32-bit write or read accesses are valid. • A core or DMA valid read access returns the current value of the register and leaves the register unchanged. 0 No flag 1 Flag is set

71.5 Example application

The calibration process of a new engine requires real-time access to calibration tables and the ability to update the tables in real-time The DTS module enables this capability by enabling software to assert a signal to an external device pin to notify an external tool that data is available. The tool can then retrieve the data.

In this type of application the DTS_SEMAPHORE register and DTS Trigger Output (DTO) signal provide a mechanism to notify the calibration tool that the calibration variable or variables (or sets of measurements), up to 32, have been updated with new values and are available for the tool to access.

Note

It is the user's responsibility to ensure that the tool has time to retrieve the data prior to that particular trigger being set a second time. It is also permissible to have multiple triggers active at the same time or for a second trigger to be set before a previous trigger has been serviced, as long as it is not the same trigger (unless it is acceptable to the tool to not receive every data set).

The following table shows an example DTS startup sequence for an external real-time data acquisition system. The startup and synchronization sequence can be as simple or as complicated as the need requires. However, a typical startup sequence is as follows:

1. The DTS_STARTUP register is cleared by a power on reset or any CPU reset.
2. The tool writes a non-zero value to the DTS_STARTUP register.
3. The CPU (user application software) then reads the value of the DTS_STARTUP register. Based on this value, different initialization options can be selected. The bits can be used for any application specific definitions.
4. Since the DTS_SEMAPHORE register is cleared when the tool reads the current value. The tool should perform all necessary initialization before reading this register. The application software can then check that the DTS_SEMAPHORE register was cleared by the tool, to determine that it is safe to start using it for its intended raster trigger semaphore function.
5. An optional hand shake from the CPU can be used to inform the tool that the user software has detected that the tool is attached and the CPU has performed the proper initialization for the tool by writing a predefined value to the DTS_SEMAPHORE register (the example shown in the figure above uses 0xAAAA_AAAA—all A's was used since it is unrealistic that 16 channels could be enabled very quickly after start up after a reset).

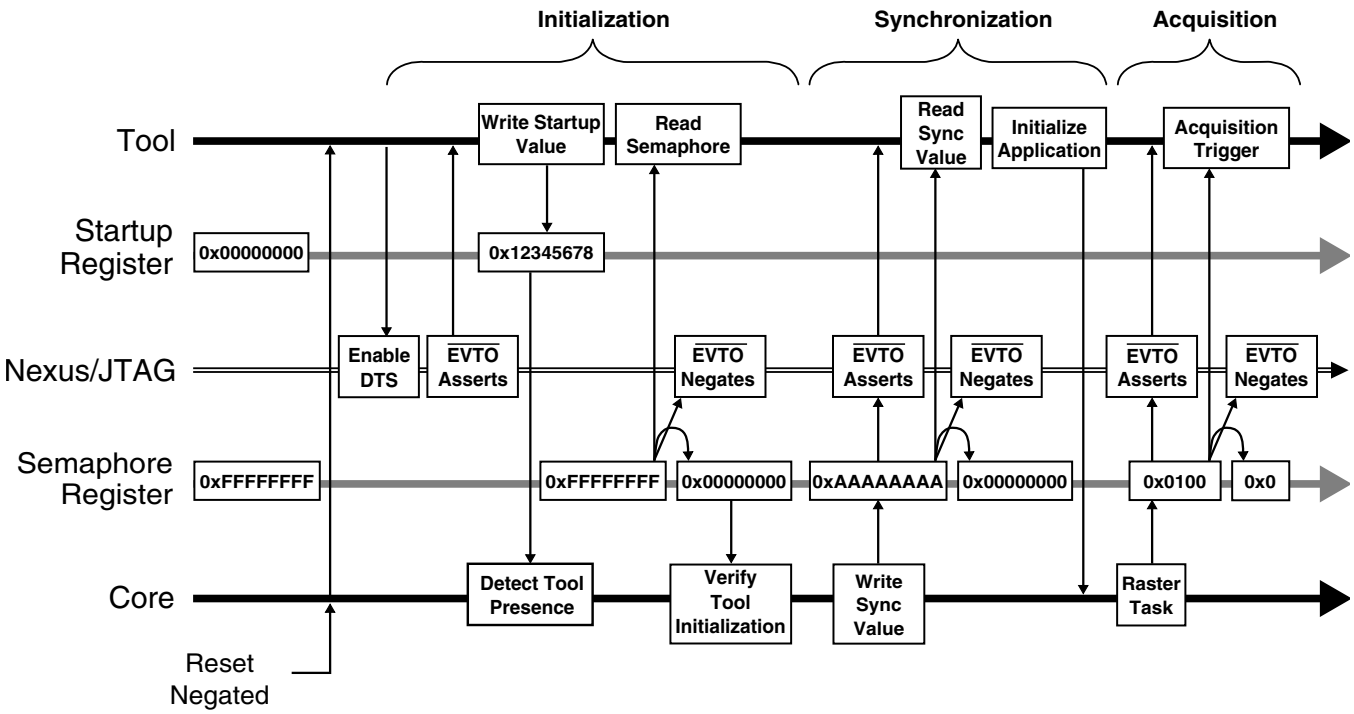

Figure 71-8. DTS startup sequence example

Chapter 72
Nexus Aurora Router (NAR)

72.1 Nexus Aurora Router (NAR) chip-specific information

72.1.1 NAR DID value

The NAR Device ID (DID) value for Cut 2.0B is 0x1834_601D.

72.2 Introduction

On the device, there are multiple blocks that require development interface support. The blocks that are Nexus-compliant (based on the IEEE-ISTO 5001 standard) are expected to interface with the development tool through a dedicated high-bandwidth debug port. The Nexus Aurora Router (NAR) controls the usage of the output port in a manner that allows all the individual development interface blocks to share the port, and appear to the development tool to be a single block.

Top-level architecture is shown in the following figure. Multiple clients send messages by sharing the high-bandwidth port through the NAR. For a list of the specific clients that are connected to the NAR, see the Calibration and Debug configuration chapter which describes how the modules are configured.

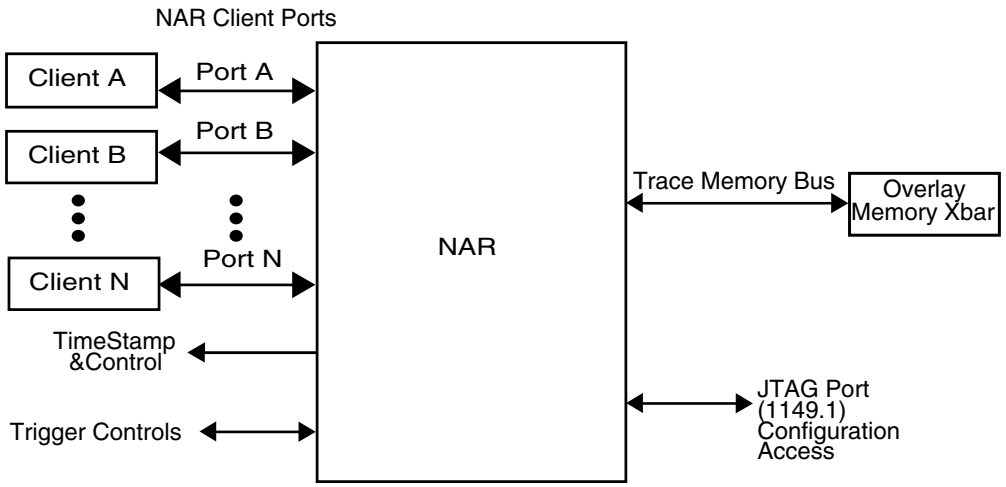

Figure 72-1. NAR top level block diagram

The trace memory bus port provides added flexibility to the channel trace data to memory on the Nexus Aurora crossbar. Setup and configuration of the NAR is performed by accessing the configuration registers via a JTAG (1149.1) port.

Each Nexus client has a dedicated receive queue to allow seamless switching between sources at Nexus message boundaries. Incoming Nexus data is parsed into the receive queues so that end-of-message can be determined. Messages are then transferred into the main queue. An arbitration block determines the order in which clients are serviced, using an optional client request level bus to prioritize the data (lacking request level data, a simple round-robin algorithm is used). The NAR has two output ports: the high bandwidth debug port (Aurora out) and the trace memory bus. If both output ports are enabled at the same time, the main queue is logically partitioned inside NAR. The Production Device (PD) does not support partitioning of the main queue; therefore, only one of the ports can be active at a time. Data going through the Aurora out port or the Trace port goes through an additional translation block to put the data in the correct format. The actual Aurora formatting is done in the NAL. Additional blocks for message generation and timestamp generation are described in more detail in the following sections.

The NAR supports the following client interfaces:

- Legacy interface to support existing client interface protocol through a conversion gasket logic with clock domain transfer
- New client interface with clock domain transfer

72.3 Overview

The NAR serves as an arbiter for the high-bandwidth debug port (HBDP). The NAR pulls Nexus messages from multiple clients, queues the data, and forwards it (based on the user-controlled configuration) to the high-speed Aurora Out port and/or the Trace port. The trace memory bus controller allows the NAR to transmit data via the normal system interface. NAR control and configuration registers are accessed via JTAG (IEEE 1149.1) port.

72.4 Features

The NAR supports the following features:

- Connects 7 client(s) with dedicated receive queue(s). Clients can transmit data as long as there is space in its associated receive queue, but only the active port receive queue empties into the main queue.
- Legacy client interface for backward compatibility
- Aurora output data format for dedicated high-bandwidth serial transmission
- Aurora output format support at client interface
- Trace Memory port (64-bit address and data) can be used to write Nexus messages directly to external overlay memory. Block transfer mode provides highest-bandwidth option.
- Configurable Start Address and Range Selection for Trace Memory port write operation provides flexibility to choose Overlay memory Section and range to store Trace data.
- Time-stamping provides a central synchronization resource for message ordering. Gray coded timer output for clients working in different clock domians.
- Re-allocatable receive queues allow queue-space of an inactive client to be reassigned to an active client
- Stall detection and handling allows NAR to continue when a client stops sending data in the middle of a message

- Event generation on External Trace Memory (overlay) programmable full
- Suppress mode can be used to shut down message delivery and relieve back-pressure to clients without turning off Nexus messaging in the clients.

72.5 Register definition

The NAR configuration registers provide configuration and control for all NAR operations. They are accessible through the JTAG (IEEE 1149.1) port. Addressing (within the local NAR address space) for the NAR registers is shown in the following table. If the NAR clock is turned off, the NAR registers cannot be accessed.

Table 72-1. NAR registers

Register name	Read/Write	JTAG index (NAR relative)
NAR_CR—NAR Control Register	R/W	0
NAR_ST—NAR Status Register	R	1
NAR_SFR—Source Filter Register	R/W	2
NAR_TFR—Type Filter Register	R/W	3
NAR_TBALO—Trace memory port base address, low	R/W	4
NAR_TBAHI—Trace memory port base address, high	R/W	5
NAR_TCR—Trace Memory bus control register	R/W	6
NAR_STCR—Suppress Trigger Control Registers 1–4	R/W	7 (Trigger 1) 8 (Trigger 2) 9 (Trigger 3) A (Trigger 4)
NAR_CSSR–Client Suppress Status Register	R	B
NAR_CDR—Client Disable Register	R/W	C
NAR_AHFPAR—Trace memory fill level and partition configuration	R/W	E

72.5.1 NAR control register (NAR_CR)

The NAR control register provides all the main control and enable bits for the NAR and its output ports. The following table shows the format of the NAR_CR.

Register index: 0

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	NEN	NCD	TEN	TRS	TSG		SED	SRD	TBW	AQP		0	0	0	0	0

Table continues on the next page...

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	WPE			0	0	0	0	0	ALT		0	AFA	0	0	PUS	NSR
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The NAR_CR is described in the following table.

Table 72-2. NAR_CR field descriptions

Field	Description
31 NEN	NAR Enable. 0 NAR is disabled unless HBDP is independently enabled. See Disabled for more information. 1 NAR is enabled.
30 NCD	NAR Communication Disable. 0 NAR monitors clients for activity 1 NAR communication with clients is disabled
29 TEN	Timestamp Enable. 0 Timestamp packet is not included in messages 1 Timestamp packet is included in messages from all client including NAR generated messages
28 TRS	Timestamp Reset. 0 to 1 transition: reset timestamp counter in NAR
27–26 TSG	Timestamp Granularity (Mode). **Note:** Some clients may only support timestamps on every message. 00 Add timestamp to every message 01 Add timestamp to every 4th message 10 Add timestamp to every 16th message 11 Add timestamp to every 32nd message
25 SED	Stall Error Disable. 0 NAR injects dummy complete message when active client stalls 1 NAR does not inject dummy complete message
24 SRD	Stall Recovery Disable. 0 Stalled receive queue resumes operation when its client comes back on line 1 Stall error recovery is disabled
23 TBW	Tracebuffer Wrap. 0 NAR does not capture new data when main queue is full 1 NAR begins overwriting main queue from the beginning upon queue overflow

Table continues on the next page...

Table 72-2. NAR_CR field descriptions (continued)

Field	Description	
22–21 AQP	Alternate Queue Partition.	
	00	Queue partitioning is disabled
	01	Reserved
	10	Reserved
	11	Reserved
20	Reserved and must be written with 0	
19–16	Reserved and must be written with 0s	
15–13 WPE	Watchpoint Enable	
	000	NAR watchpoint messaging is disabled
	xx1	NAR generates a watchpoint message upon a sync event
	x1x	NAR generates a watchpoint message upon a trace memory bus or tracebuffer block full/wrap event
	1xx	NAR generates a watchpoint message upon a suppress-mode event
12	Reserved	
11	Reserved. This bit must be written with 0.	
10–9	Reserved and must be written with 0s.	
8	Reserved	
7–6 ALT	Alternate Port. Defines which port is the target for non-filtered messages; main port in single-port applications.	
	00	No alternate port. Running in trace-buffer mode.
	01	Aurora out is the ALT
	10	Trace memory bus is the ALT
	11	Reserved
5	Reserved	
4 AFA	Automatic Flush Accumulators.	
	0	Output queue accumulators do not flush stranded beats
	1	Accumulators automatically flush stranded beats
3	Reserved. This bit must be written with 0.	
2	Reserved and must be written with 0.	
1 PUS	Power-Up Suppressed.	
	0	NAR powers up active
	1	NAR powers up in global suppressed mode
0 NSR	NAR Soft Reset.	
	1	Resets all configuration registers and sets queue address pointers to the top of their respective queues. Also resets itself after a single-cycle delay. (This does not affect other blocks)

72.5.2 NAR status register (NAR_ST)

The NAR_ST register provides information on NAR activity and queue status, as well as HBDP status and errors. It is a read-only register. The following table shows the format of the NAR_ST.

Register index: 1

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	NEN	NUM			NCE				0	0	0	0	0	0	0	0
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	HPR	HPE	MPE	MOV	0	TOV	QWA									
W		w1c	w1c	w1c		w1c										
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

The NAR_ST register is described in the following table.

Table 72-3. NAR_ST field descriptions

Field	Description	
31 NEN	NAR Enabled.	
	0	NAR is disabled and inactive
	1	NAR is enabled with clocks on
30–28 NUM	NAR Mode.	
	000	NAR is in disabled mode
	001	NAR is in global suppressed mode
	010	NAR is in communication-disabled mode
	011	NAR is in tracebuffer mode
	100	NAR is in active transmit mode
	101	Reserved
	110	Reserved
	111	NAR is in run-control mode
27–24 NCE	NAR Config Error. See Table 72-17 for coding	
23–16	Reserved	
15 HPR	HBDP Ready.	
	0	HBDP (Aurora Out port) is not ready
	1	HBDP is ready and accepts data for transmission
14 HPE	HBDP Error.	
	0	No HBDP error
	1	Error condition exists on HBDP

Table continues on the next page...

Table 72-3. NAR_ST field descriptions (continued)

Field	Description	
13 MPE	Trace memory bus Error.	
	0	No Trace memory bus error
	1	Error condition detected on trace transaction
12 MOV	Trace memory bus block overflow.	
	0	No Trace memory bus overflow
	1	Targeted external memory block is full. Trace memory bus writes are halted (or wrapped).
11	Reserved	
10 TOV	Tracebuffer Overflow.	
	0	No tracebuffer overflow
	1	The tracebuffer has overflowed/wrapped at least once
9–0 QWA	Queue Write Address. Current value of the output queue write pointer (last valid write + 1)	

72.5.3 Message filtering registers

The two output ports (HBDP and trace memory bus) are independently controllable. In the BD NAR, two ports can be active simultaneously. When multiple ports are active, user-programmable filters are determine which port receives a message, based on the message source or type. Filters apply to the designated Message Select Port (MSP), and are used to select messages for that port. All other messages go to the other (alternate) port. If multiple ports are used, an MSP must be designated; otherwise a configuration error results.

72.5.3.1 Source filter register (NAR_SFR)

The MSP can be configured to accept or exclude messages from up to four sources. The sources which are to be filtered are programmed in the source filter register (NAR_SFR) as shown in the following table. This register should only be set in the BD NAR because partitioning is not supported in the PD NAR.

Register index: 2

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	SFI	FE0	SF0				0	0	0	FE1	SF1				0	0
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Table continues on the next page...

The NAR_SFR is described in the following table. The source trace IDs, that are compared to the source filter fields (SFn), are device specific. For a list of the clients that are connected to the NAR and their corresponding Nexus source trace IDs, see the Calibration and Debug configuration chapter which describes how the modules are configured.

Table 72-4. NAR_SFR field descriptions

Field	Description	
31 SFI	Source Filter Invert.	
	0	Match if message source equals any of the enabled filters
	1	Match if message source equals none of the enabled filters
30 FE0	Enable Filter 0.	
	0	Filter 0 disabled. SF0 ignored
	1	Filter 0 enabled and contained in SF0
29–26 SF0	Source Filter 0. The message source trace ID is compared with this field.	
25–23	Reserved.	
22 FE1	Enable Filter 1.	
	0	Filter 1 disabled. SF1 ignored
	1	Filter 1 enabled and contained in SF1
21–18 SF1	Source Filter 1. The message source trace ID is compared with this field.	
17–15	Reserved	
14 FE2	Enable Filter 2.	
	0	Filter 2 disabled. SF2 ignored
	1	Filter 2 enabled and contained in SF2
13–10 SF2	Source Filter 2. The message source trace ID is compared with this field.	
9–7	Reserved	
6 FE3	Enable Filter 3.	
	0	Filter 3 disabled. SF3 ignored
	1	Filter 3 enabled and contained in SF3
5–2 SF3	Source Filter 3. The message source trace ID is compared with this field.	
1	Reserved	
0 ACC	OR source and type filters.	
	0	Match if source AND type filters match
	1	Match if source OR type filters match

72.5.3.2 Message type filter register (NAR_TFR)

The MSP can be configured to accept or exclude messages of up to four types, as encoded in the message TCODE field. The TCODEs which are to be filtered are programmed in the message type filter register (NAR_TFR) as shown in the following table. This register should only be set in the BD NAR because partitioning is not supported in the PD NAR.

Register index: 3

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	TFI	FE0	TF0						0	FE1	TF1

R	0	FE2	TF2						0	FE3	TF3					
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The NAR_TFR is described in the following table.

Table 72-5. NAR_TFR field descriptions

Field	Description
31 TFI	Type Filter Invert. 0 Match if message TCODE equals any of the enabled filters 1 Match if message TCODE equals none of the enabled filters
30 FE0	Enable Filter 0. 0 Filter 0 disabled. TF0 ignored 1 Filter 0 enabled and contained in TF0
29–24 TF0	Type Filter 0. The message TCODE is compared with this field.
23	Reserved
22 FE1	Enable Filter 1. 0 Filter 1 disabled. TF1 ignored 1 Filter 1 enabled and contained in TF1
21–16 TF1	Type Filter 1. The message TCODE is compared with this field.
15	Reserved

Table continues on the next page...

Table 72-5. NAR_TFR field descriptions (continued)

Field	Description	
16 FE2	Enable Filter 2.	
	0	Filter 2 disabled. TF2 ignored
	1	Filter 2 enabled and contained in TF2
13–8 TF2	Type Filter 2. The message TCODE is compared with this field.	
7	Reserved	
6 FE3	Enable Filter 3.	
	0	Filter 3 disabled. TF3 ignored
	1	Filter 3 enabled and contained in TF3
5–0 SF3	Type Filter 3. The message TCODE is compared with this field.	

72.5.4 Trace memory bus configuration registers

The trace memory bus can be used to transfer debug messages out to a dedicated block of external memory space. The trace memory bus configuration registers are used to specify the location and size of the external debug space.

72.5.4.1 Trace memory bus base address registers (NAR_TBALO and NAR_TBAHI)

The trace memory bus base address registers determine where Nexus data sent out through the trace memory bus goes. The NAR sends out blocks of data on the trace memory bus, writing to an address block defined by the specified base address. Data can transmitted either on an as-available, word-wide basis, or in larger blocks. In block transfer mode, the size of the data block is determined by the BTM field of the Control Register; the default is 64 bytes. Even if block transfer mode is not used, the 5, 6, 7, or 8 (depending on the BTS field in NAR_TCR register) LSBs of the base address are not accessible. This forces the debug memory space to be aligned to a block boundary.

When read, the address registers return the current address, allowing the user to monitor the progress of a trace memory transfer. The following tables show the format of the trace memory base address registers (NAR_TBALO and NAR_TBAHI). For a description of the allowed address for these registers, see the Calibration and Debug configuration chapter which describes how the modules are configured.

Register index: 5

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

The NAR_TBALO and NAR_TBAHI registers are described in the following tables.

Table 72-6. NAR_TBAHI field descriptions

Field	Description
31–0 TBAHI	Trace Debug Memory Base Address on AHB-EW port, upper part. For 32-bit address applications this field is all zeros.

Table 72-7. NAR_TBALO field descriptions

Field	Description
31–10 TBALO	Trace Debug Memory Base Address on AHB-EW port, lower part
9 ADRLO[9]	Base Address LSB for BTS = 11 (384-byte block)
8 ADRLO[8]	Base Address LSB for BTS = 10 (256-byte block)
7 ADRLO[7]	Base Address LSB for BTS = 01 (128-byte block)
6 ADRLO[6]	Base Address LSB for BTS = 00 (64-byte block)
5–0	Reserved

72.5.4.2 Trace memory bus control register (NAR_TCR)

The trace memory bus control register is used to control the attributes of the trace memory bus port, such as block transfer size and message priority. Since the trace memory bus transfers are expected to go to a static block of external memory, a maximum transfer size must be specified to prevent the NAR from overwriting memory it is not authorized to access. This is done via the MXFR max transfer size register field. The memory allocation is specified in units of the trace memory bus block transfer size (64, 128, 256, or 384 bytes), so the actual size of the reserved memory block depends on the BTS setting. The following table shows the format of the NAR_TCR.

Register index: 6

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	BTM	BTS		BTH		0	0	0	TBW	MXFR						
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	MXFR															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The NAR_TCR is described in the following table.

Table 72-8. NAR_TCR field description

Field	Description	
31 BTM	Block Transfer Mode.	
	0	Data for the Trace Memory bus port is transmitted one word at a time, upon first availability
	1	Data to the Trace Memory bus port is bundled into blocks before transmitting
30–29 BTS	Block Transfer Size.	
	00	Block transfer size = 64 bytes
	01	Block transfer size = 128 bytes
	10	Block transfer size = 256 bytes
	11	Block transfer size = 384 bytes
28–27 BTH	Block Transfer Threshold.	
	00	Full threshold. Number of entries in partition must equal block transfer size before block transfer starts
	01	Begin transfer when block is 25% full
	10	Begin transfer when block is 50% full
	11	Begin transfer when block is 75% full
26–24	Reserved. These bits must be written with 0.	

Table continues on the next page...

Table 72-8. NAR_TCR field description (continued)

Field	Description	
23 TBW	Trace Memory Bus Block Wrap.	
	0	NAR stops writing to the Trace Memory bus debug memory space once Max Size has been reached
	1	NAR overwrites Trace Memory bus debug memory from the beginning upon Trace Memory bus block overflow.
22–0 MXFR	Trace Memory Bus Max Transfer Size. Total size of the dedicated debug memory space, in Trace Memory bus data transfer blocks.	

72.5.5 Suppress mode triggers registers (NAR_STCR)

Four suppress mode triggers are provided for precise control of the NAR suppress mode feature described in Suppress mode. Each trigger can be programmed to suppress or wake clients individually or the entire NAR. All receive queues can be suppressed on the occurrence of a selected trigger, or the full NAR can be brought out of suppress mode upon the occurrence of the appropriate trigger. A trigger can also be programmed to toggle one or more clients between the suppressed and active states. Each Suppress Trigger Control Register, shown in the following table, is associated with one of the triggers, and are used to determine the action taken, if any, upon the assertion of that trigger. The suppress triggers are connected to the Sequence Processing Unit (SPU) action unit.

Register index: 7-A

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	GST	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	LST															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The NAR_STCR are described in the following table. The set of clients connected to the NAR is device specific. For a list of the clients that are connected to the NAR and their corresponding NAR client index for the local suppress trigger, see the Calibration and Debug configuration chapter which describes how the modules are configured.

Table 72-9. NAR_STCR field descriptions

Field	Description	
31 GST	Global Suppress Trigger.	
	0	The associated trigger cannot cause NAR to enter global suppress mode
	1	The associated trigger is enabled for global suppress mode

Table continues on the next page...

Table 72-9. NAR_STCR field descriptions (continued)

Field	Description	
29–16	Reserved	
15–0	Local Suppress Trigger.	
LST	0000000000000000	The associated trigger is disabled for local suppress mode for all clients
	xxxxxxxxxxxxxxx1	Trigger is enabled for Client 1 local suppress
	xxxxxxxxxxxxxx1x	Trigger is enabled for Client 2 local suppress
	xxxxxxxxxxxxx1xx	Trigger is enabled for Client 3 local suppress
	xxxxxxxxxxxx1xxx	Trigger is enabled for Client 4 local suppress

	xxxxxxx1xxxxxxxx	Trigger is enabled for Client 9 local suppress
	xxxxxx1xxxxxxxxx	Trigger is enabled for Client 10 local suppress
	xxxxx1xxxxxxxxxx	Trigger is enabled for Client 11 local suppress
	xxxx1xxxxxxxxxxx	Trigger is enabled for Client 12 local suppress
	xxx1xxxxxxxxxxxx	Trigger is enabled for Client 13 local suppress
	xx1xxxxxxxxxxxxx	Trigger is enabled for Client 14 local suppress
	x1xxxxxxxxxxxxxx	Trigger is enabled for Client 15 local suppress
	1xxxxxxxxxxxxxxx	Trigger is enabled for Client 16 local suppress
	All other options	Reserved

72.5.6 Client suppress status register (NAR_CSSR)

Clients can be individually suppressed, leaving the rest of the NAR unaffected. When enabled for local suppress, assertion of one of the suppress triggers causes one or more client receive queues to stop queueing messages. A subsequent pulse of the same trigger causes the client(s) to awaken. Local suppress mode is enabled by setting the appropriate bit in one of the NAR_STCRs. An additional status register, Client Suppress Status (NAR_CSSR), shown in the following table, can then be read to determine which clients are suppressed, and which are active.

Register index: B

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	LSS																0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	xxx1xxxxxxxxxxxx	Client 13 is suppressed
	xx1xxxxxxxxxxxxx	Client 14 is suppressed
	x1xxxxxxxxxxxxxx	Client 15 is suppressed
	1xxxxxxxxxxxxxxx	Client 16 is suppressed
	All other options	Reserved
15–0	Reserved	

72.5.7 Receive queue client disable register (NAR_CDR)

Disabling a client reallocates its receive queue to the next active client, allowing that memory space to be put to use. The Client Disable Register, shown in the following table, allows the user to individually disable or enable clients as needed. The status bits also inform the user when the client has new data available.

Register index: C

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	CAS																RQD

	1xxxxxxxxxxxxxxx	Disable receive queue for Client 16
	All other options	Reserved

72.5.8 Trace Memory fill level and partition configuration register (NAR_AHFPAR)

This register provides the configuration to set the fill level marker for debug trace memory, connected at the trace memory bus, to generate the partial full event indication and the partition related configuration for main queue (internal central queue). The following table shows the format of the NAR_AHFPAR.

Register index: E

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
W																
Reset	0	0	0	0	0	0	0	0	0	0	0			0		

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0	0	0	0	0	AHB01kEN	0	0	0	0	0	0	AHB_01K_Marker			
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The NAR_AHFPAR is described in the following table.

Table 72-12. NAR_AHFPAR field description

FIELD	Description
31-11	Reserved and must be written with 0s
10 AHB01kEN	Enable 1K Marker Event
9-4	Reserved and must be written with 0s
3–0 AHB_01K_Marker	Value at this field is used to compare a 4-bit slice of internal Trace Memory address bus which works at boundary of 1K. A match with this value generates an event to SPU to indicate the fill status of External Overlay Trace memory. See Overlay and internal trace memory full status generation **Note:** memory ranges from 1K to 15K

72.6 Functional description

High-level descriptions of the operation of the NAR and its main functional blocks are given in the following sections.

72.6.1 Reset/Startup

Assertion of global reset causes the NAR operation to immediately cease. All queues and configuration registers are reset. Upon exiting reset, the Nexus Port Controller (NPC) block inside the NAR is disabled. Holding TMS high for five consecutive rising edges of TCK puts TAP controller into the Test-Logic-Reset state regardless of the current state. This applies reset to only TAP controller and JTAG related logic. Applying soft reset through the NAR_CR resets the entire NAR including the TAP controller and configuration registers.

The typical startup procedure for running a trace through the NPC is as follows:

1. Reset the block
2. Upon exiting reset, the Aurora Phy configuration is determined by sampling the configuration pin values from the Nexus Aurora Phy (NAP). If the NAP is enabled, then the NAR is enabled. The Aurora communication is started only when the NAP is ready to accept data. (If any debug lanes are enabled, the Aurora Link begins training at this time.)

3. Debugger/external user sets the NAR enable (NEN) bit in the NAR_CR and configures the NAR. The configuration includes setting up message selection/ filtering when two output ports are enabled, enabling timestamp and so on.
4. User programs additional device level debug facilities, such as event-processing, performance-monitoring, and so on.
5. User sets up trace filtering.
6. Enable Nexus transmission in clients.

To enable NAR operation, either the Aurora Link must be enabled at reset, or the user must set the NEN bit in the NAR control register.

Note

The HBDP may already be active by the time the NAR comes up. The NAR only tries to initialize the HBDP if it is currently inactive.

The NAR can be enabled to begin immediate operation, or to start in suppress mode, see Suppress mode. Once the NAR and desired ports are enabled, the user should wait until the NAR-ready and HBDP port-ready status bits are set in the NAR status register before beginning Nexus messaging in the clients.

72.6.2 Operation modes

The NAR operating mode is determined by the state of the main control signals: reset and Phy enable. In its enabled state, operation is controlled by its configuration registers. A truth table for all the NAR states is given in the following table.

Table 72-13. NAR operational modes truth table

Reset	NAR enable	NAR comm disable	Global suppress	HBDP enable	ALT partition	MSP partition	Mode
0	x	x	x	x	x	x	RESET
1	0	x	x	0	x	x	Disabled
1	1	1	x	0	x	x	Trace-Disable
1	x	1	x	1	x	x	Trace-Disable
1	0	x	x	1	x	x	Trace-Disable
1	1	0	1	x	x	x	Suppressed
1	1	0	0	x	Trace Memory bus	x	NAR Transmit
1	1	0	0	1	AUR	x	NAR Transmit

Table continues on the next page...

Table 72-13. NAR operational modes truth table (continued)

Reset	NAR enable	NAR comm disable	Global suppress	HBDP enable	ALT partition	MSP partition	Mode
1	1	0	0	1	Trace Memory bus	AUR	NAR Transmit
1	1	0	0	1	AUR	Trace Memory bus	NAR Transmit

There can be overlap between modes as modes are not mutually exclusive.

72.6.2.1 Reset

During reset all internal resources and queues are reset and all output ports are disabled. All inputs are ignored. Upon exiting reset mode, the NAR is in a fully disabled state.

72.6.2.2 Disabled

In the disabled state, all message traffic is ignored, and all output ports are disabled. The NAR is disabled if and only if the NAR enable bit of the NAR control register is not set and the Aurora Link is inactive.

72.6.2.3 Suppressed

The suppressed state differs from the disabled state in that the NAR is on. The NAR pulls out any messages that come up at the clients, keeping the Message Start-End Out (MSEO) bits (so that it can keep track of message boundaries) and discarding the rest.

In the suppressed state, the NAR is waiting for a trigger to begin normal operation. Once that trigger is received, the NAR begins queueing messages that started after the trigger arrived. Incomplete messages that were in transit to the NAR when the trigger arrived are discarded. The NAR can be put into suppressed mode by enabling one of the global suppress states.

72.6.2.4 Trace disable

In trace disable mode, the NAR is powered up but all client-trace is disabled, and no messages are pulled. This mode is also useful for port initialization (to prevent any activity from occurring before the outputs are ready) or for debug/trace-buffer mode, to ensure that, during data retrieval, the NARs queues are stable.

The NAR goes into trace disable (communication-disable) mode when the NAR-enable and NAR communication-disable bits are set or when the HBDP channel is active while the NAR-enable bit is not set.

72.6.2.5 NAR transmit

This is the standard operational mode of the NAR when it is transferring Nexus messages from multiple clients to one or two enabled output port(s). The NAR performs four main operations as described in the following table on the incoming messages before transmitting to one of the output ports.

Table 72-14. NAR transmit operations

Operation	Description
Data reception	NAR accepts data from each client based on the status of the client receive queue status. The maximum data rate is 8 × 32-bit data words (where 8 is the number of Nexus message beats in a full entry and 32 is the number of bits in the Nexus word) per cycle per client. MSEO bits of incoming data are monitored to identify end-of-message boundaries.
Input Arbitration	Active receive queue unloads into main queue(s), 8 × 32 bits per cycle (where 8 is the number of Nexus message beats in a full entry and 32 is the number of bits in the Nexus word). If end-of-message detected, new active receive queue is determined based on client request level or round-robin algorithm.
Output Arbitration	If multiple output ports are enabled, route messages from top of queue to appropriate output port based on message type or source. If split queue is used, outputs can run simultaneously, with each sub-queue communicating directly with a port.
Translation	Data going out the Aurora or trace memory bus ports must be translated into the correct format prior to transmission.

Enabling the NAR and one or more output ports without setting the communication-disable bit puts the NAR into transmit mode.

72.6.3 Data reception and arbitration

The NAR supports 7 clients. Each client has a dedicated input port on the NAR and communicates with its associated input port via a dedicated data bus. A data transmission must consist of an integer number of 32-bit Nexus words (32-bit word is called a beat).

The number of beats varies from client to client. The number of beats (Bn) for each client are described in the Calibration and Debug configuration chapter which describes how the modules are configured.

There are two types of clients supported at NAR client interface. The client types have their own protocols to send Nexus messages. The only common parameter is the Nexus word size (beat). One Nexus word consists of 30 Message Data Out (MDO) bits plus two Message Start/End Out (MSEO) control bits. Internally, the NAR converts all client interfaces to a common interface. To achieve this, the NAR instantiates interface level gaskets that handle the protocol conversion and clock domain transfer.

When new data is available in the core, it is transferred over to the asynchronous gasket in the internal NAR clock domain. The gasket then asserts enough data valids to fill internal receive queue, using a receive queue available signal to track available space in the associated queue, under the assumption that the receive queue available signal is initialized with the size of the queue. If the internal arbiter consumes any of its queued entries, it responds with a data accept signal, which increments the receive queue available signal and allows the gasket to send the next piece of data. Under certain circumstances, like receive queue reallocation, it is possible for the internal arbiter to send out surplus data accept signals such that the receive queue available signal can become larger than the size of the queue. If the receive queues are sized correctly, when NAR is actively servicing a particular client, then asserted data accept signals allow the client to continually stream data until the NAR switches to a new client. The data tracking at the gasket assures that it never sends more data than the receive queue can accept and inactive queues are always full and ready for when they are switched to.

The client gaskets must always be in sync with the internal logic of NAR in terms of the number of available entries in each receive queue. For this reason, the internal NPC and its client gaskets need to be reset by the same signal. Any soft-reset of the NAR (via the SRESET configuration bit) is communicated to all gaskets and used to reset every thing inside it.

Each input port has a dedicated receive queue with a minimum of two entries, where an entry is wide enough to store an entire Bn × 32 data word (where 32 is the number of bits in the Nexus word or the beat). The receive queue can be made larger to allow the NAR to continue transmitting during switches from one client to another in a pipelined environment. Every cycle, if there is space in a particular receive queue, it latches in one full AUX word from its client. Because the client may be running at a much higher frequency than the NAR, several cycles worth of Nexus messages are contained in a single transaction, as shown in the following figure for a 3-beat per word transaction.

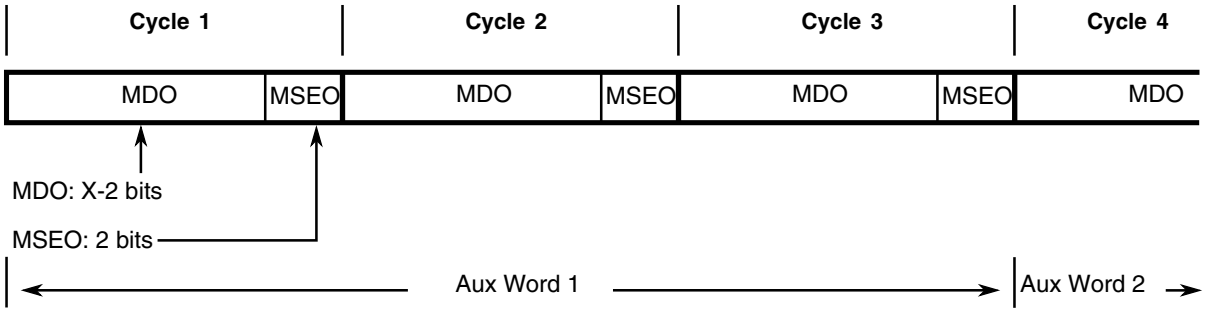

Figure 72-2. AUX bus parsing

Each AUX word consists of Bn cycles of Nexus data, along with an optional request-level sideband signal consisting of a priority field (bit 0) and a weight field (bits 1 and 2). Request level priority indicates to the NAR the clients queue status, allowing it to give preferential treatment to clients that are closer to queue overflow. Clients with a set priority bit are always chosen ahead of clients without the bit. For this reason, priority should be used sparingly, only when a client is in danger of overflowing. Request-level weighting also gives a client preferential treatment, but without entirely shutting out the other clients. Normally, the NAR attempts to switch to a new client every time it sees an end-of-message boundary.

As the AUX word is pulled into the receive queue, the MSEO bits are monitored to determine the current Nexus state of the data flow; since Nexus is a variable-length protocol, messages can end in any cycle. If the start message or end message state is detected on any data beat, the beat is marked as containing an end-of-message boundary.

Any received beat which is in the idle state, indicating null data content, is discarded (see the IEEE-ISTO 5001-2003 standard for details of the Nexus protocol). At the same time, if two outputs are enabled, then the source and TCODE fields are extracted from each new message and compared with the user-programmed filters. Messages that generate a match are tagged with an MSP bit, which allows the NAR to route it to the correct port.

Every cycle, the NAR transfers 8 beats of data from the receive queues into the main output queue. Only one port (the active port) is allowed to empty into the main queue at a time: the active port unloads its receive queue into the main queue until the end of the current Nexus message is detected. At that point, a new active port is selected based on the latest request level received at each port. In the case where multiple ports have the same request level (or when request level is not used), then the active port is rotated amongst those ports. If the end of message occurs in the middle of an AUX word, then all the beats up to the end of message are transferred from the old active port, while the rest of the beats come from the new active port. For example, if the message ended at beat two of a three-beat AUX word, then the first two beats into the main queue would come from the original active port, while the last beat would come from the new active port.

72.6.4 Suppress mode

The suppress mode feature enables the user to quickly turn Nexus messaging through the NAR on or off, based on the four dedicated suppress-mode triggers. A suppress can either be global, meaning messaging is turned off for all clients, or local, which only applies to selected clients. In suppress mode, the NAR pulls messages from the suppressed client(s), but does not queue or deliver them. After extracting the MSEO bits to keep track of message boundaries, the rest of the message is discarded. This allows the NAR to better keep up with fast-running Nexus clients without having to turn off messaging in the client.

Typically, a client would be suppressed during less interesting periods, and would be awakened when some preset condition is detected. This is communicated to the NAR via the one of the suppress triggers, which can be sourced by a client or an external Event Processing block. When an enter suppress trigger is received, the NAR output queue finishes servicing the current active ports until the end of the message. If the end of the message occurs in a middle beat of a Nexus word, then the remainder of the word is padded with null messages. Once the last message has been loaded into the output queue, the receive queues are all emptied. New messages are pulled from clients as they appear, go through their respective receive queues and then are discarded. In this way, the NAR can naturally monitor the MSEO bits and keep track of each client's Nexus state. In suppress mode, the output ports remain active until the output queue is emptied, meaning there is a delay between the assertion of the suppress trigger and the end of messaging.

When the NAR is in suppress mode and receives a wake-up trigger, it continues discarding any partial messages still in the receive queues. Any message that begins after the trigger is queued normally, insuring that only complete messages are sent to the output queue.

Global suppress mode applies to all clients. Any of the suppress triggers can be programmed to cause the NAR to toggle between suppressed and awake by setting the GST bit of the associated Suppress Trigger Control Register (NAR_STCR). Additionally, the NAR starts up in global suppress mode if the PUS bit of the Control Register is set when the NAR is enabled. All clients are then suppressed until a wake-up trigger is received. If the PUS bit is set without enabling any of the triggers for global suppress, a configuration error results and the NAR powers up in active mode.

Clients can go also into local suppress mode without putting the entire NAR to sleep. Each NAR_STCR has a 16-bit LST field. Setting one or more of these bits causes the trigger assigned to that NAR_STCR to toggle the associated clients between suppressed and awake. All other clients are unaffected. Thus, suppress trigger one can be assigned to one set of clients, while suppress trigger two can be assigned to another set of clients, and

different parts of the device can be ignored at different times, all based on different, programmable events. Global suppress always has higher priority than local suppress. That is, if the NAR is in global-suppressed mode, any local suppress wake-up triggers are ignored. Also, if some clients are in local suppress when a global suppress trigger hits, then all go into suppress mode; however, upon the subsequent global wake-up, the clients that were previously in local suppress remain so.

72.6.5 Stall detection

Since the NAR can only switch between clients on an end-of-message boundary, every message that goes into the NAR must complete. If a client happens to die or stall in the middle of transmitting a message, this uncompleted message could cause the NAR to stall, at a time when other clients might still be able to deliver useful information. To prevent this from occurring, the NAR monitors each client for a stall condition, which is defined as occurring when data is not valid in the middle of a Nexus message for a set number of cycles.

When a stall condition is detected, the NAR can do one thing. If the client stalls, then the NAR must complete the current stalled message to continue operating. This scenario is termed a stall error. On a stall error, the NAR injects a dummy message beat into the message stream after the last valid beat of data received from the stalled client. The dummy message is a single beat injected at the output of the receive queue into the main queue. The MSEO bits of the data payload are set to 2b11 regardless of the previous Nexus state. This forces the dummy message into the End Message state. When the NAR injects a dummy message, it also generates an error message to notify the user what has happened.

Injecting a dummy message is an intrusive act, which alters the data stream from the client. If a stalled client is thought likely to recover cleanly, it might be advisable to suppress stall errors to prevent the data stream from being corrupted. This can be done by setting the SED bit of the configuration register, which carries the risk of a truly dead client causing the NAR to hang. Otherwise, the default operation is for the NAR to inject the dummy message and then monitor the client for signs of recovery. If the client does come back online, the NAR attempts to wait until it sees an end-of-message boundary before capturing new data. At best, if the client recovers smoothly, only the interrupted message is lost; if the client does not recover smoothly, it might not be possible for the client and NAR to get back in sync in terms of their Nexus states, which would lead to nothing but garbled data coming out. For this reason, it is also possible to prevent the NAR from trying to recover from a stall error, by setting the SRD bit of the NAR_CR. If the SRD bit is set, a stalled client is not allowed to recover until the SRD bit is unset or the NAR is reset.

72.6.6 Message translation and formatting

The NAR performs the formatting on Nexus messages before sending them to an output port. The exact translation performed depends on the destination port.

72.6.6.1 Trace memory bus format

The trace memory bus works on AHB-EW protocol. Data destined for the trace memory bus port is split back out into 32-bit beats (Nexus word). Depending on the relative sizes of the beat and the width of the trace memory bus port, one or more Nexus words are packed into a trace memory bus data word, with any remaining bits padded to 0.

For example, if the size of the beat = 32 and the width of the trace memory bus = 64, then each trace memory bus data packet contains two beats of Nexus data. Since the data is stored in a regular format (MSEO bits in same place at every location), this makes data interpretation straightforward, regardless of where the trace memory bus port is sending the data. The trace memory bus translation block performs the necessary accumulation and resizing in the likely case where the trace memory bus width does not equal the queue entry size.

72.6.7 Trace memory bus output port usage

The NAR can communicate directly to external memory by sending Nexus data out onto the trace memory bus port, using the AHB-EW (Early Write) protocol. This provides a convenient, secondary area for data in applications or in situations where the HBDP is not available. The trace memory bus access are generated internally by trace memory bus controller.

Because in many systems it is desirable to have the trace memory bus interface run at a divided clock rate relative to the main platform clock, the trace memory bus port operates off of a separate AHB clock. This clock is assumed to be free-running (i.e. unaffected by NAR-enable and the status of the Aurora Link), synchronous to the platform clock used by the rest of the NAR, and either running at the same rate as the platform clock or an integer divide of that rate.

The trace memory bus interface protocol is a slightly modified version of AMBA AHB specification. The write data comes in the address phase instead of data phase and it is termed as Early Write (EW). When NAR uses the trace memory bus port as a destination for Nexus data, it performs a series of writes to a predefined block of memory space.

This memory space is specified through the trace memory bus base address and trace memory bus max transfer configuration registers. The size of the block is set by the max transaction count (MXFR field in NAR_TCR) times the size of a transaction (trace memory bus-width, 64-byte, 128-byte, 256-byte, or 384-byte, depending on block transfer mode and block transfer size). For example, if:

- Base address = 0x0D00_0000 (i.e. TBAHI = 0x0, TBALO = 0x0D00_0000)
- NAR_TCR[BTM] = 1 (Block-transfer mode enabled)
- NAR_TCR[BTS] = 00 (Block-transfer size = 64-byte)
- NAR_TCR[MXFR] = 0x100 (max transaction count)

then the total block size would be 0x100 × 0x40 = 0x4000 bytes. The dedicated debug address range would then be 0x0D00_0000 – 0x0D00_3FFF.

The NAR can either write to the debug space one (trace memory bus-width) word at a time, or for improved performance, it can use a block transfer. If the BTM bit of the trace memory bus Control Register (NAR_TCR) is set, then the NAR uses block transactions to send data through the trace memory bus port, where the size of the block is determined by the setting of the BTS field of the NAR_TCR.

In block transfer mode, the NAR waits until the main queue partition dedicated to the trace memory bus port reaches a specified threshold point, determined by the BTH field of the NAR_TCR, before initiating a block transfer. The default threshold is the size of the block transfer. That is, a block transfer does not start until there is enough data in the associated partition to fill the block. But it might be desirable, for bandwidth reasons or because the associated partition is smaller than the block transfer size, to begin the transfer sooner. Hence, based on BTH, a transfer can begin when the partition is at 25%, 50%, or 75% of the block transfer size. This capability should be used with caution. If the Nexus client does not generate enough new data during the transfer to fill the block, then a block transfer error results.

The NAR generates Nexus trace write transactions for the trace memory bus port using the address from the base address register for the first transaction and then incrementing through the memory space. Once the programmed max number of transactions have been sent, the NAR sets the trace memory bus overflow status bit and, if desired, asserts the NAR event-out. At this point, the NAR can either shut down the trace memory bus port for trace, or, if the TBW bit of the NAR_TCR is set, reset the address to the beginning of the debug space and continue sending trace data. This allows the debugger to view the most recent data, in cases where the buffer overflows.

When TBW bit of NAR_TCR is not set then NAR shuts down the trace memory bus port. To restart the trace memory write again from trace memory base address, the user should write either the NPC trace memory bus base address (TBALO/TBAHI) or the transaction count (MXFR). The user does not have to actually change the value, but can write the same target base address again. The NAR sees any write to one of these registers as a reconfiguration of the trace memory bus port, and resets its internal address pointer to the base address along with clearing the target-space-full flag.

72.6.8 Internal message generation

Generally, the NAR simply conveys Nexus messages from client to port, and does not generate messages of its own. There are, however, certain situations when the NAR needs to communicate directly with the debugger. Internally generated messages are added to the queue the same as external messages. If the queue is partitioned, then internal messages are always channeled to whichever partition is dedicated to the HBDP.

The NAR generates the following message types:

- Device_ID—The first message transmitted when the NAR comes up. It consists of a 6-bit TCODE (TCODE = 1) and the 32-bit device ID. The first beat of the message is always an IDLE (MSEO = 2b11, MDO = all 0s) to allow the debugger Nexus state machine to correctly initialize (by moving to end message or idle state). Device_ID is also generated if the queue is repartitioned (by changing either the ALT or MSP setting in the NAR_CR) while it is not empty. This serves the dual purpose of insuring that the user always gets at least one device_ID message and providing a message boundary in the case where there might have been corruption due to the lost data.
- Watchpoint—The NAR generates its own watchpoint match message under the circumstances shown in Table 72-18.
- NAR_Error (TCODE = 8)—If an error condition is detected inside the NAR, it generates its own error message. An NAR_Error message consists of the 6-bit TCODE, the 6-bit NAR source ID, and a 32-bit data field which corresponds to the NAR status register. An NAR error can be triggered by:
  - HBDP error
  - Illegal configuration
  - Stall Error
  - Trace memory bus read/write access error

This table describes the NAR message formats.

Table 72-15. NAR message formats

Message name	Min packet size (bits)	Max packet size (bits)	Packet type	Packet name	Packet description
Device ID	6	6	fixed	TCODE	TCODE value = 1
	32	32	fixed	DID	DID register value
	0	24	variable	TSTAMP	Optional, globally synchronized timestamp
Error Message[1]	6	6	fixed	TCODE	TCODE value = 8
	6	6	fixed	SRC [2, 2]	NAR source ID
	4	4	fixed	ETYPE	See Table 72-16
	12	12	fixed	ECODE	See Table 72-17
	0	24	variable	TSTAMP	Optional, globally synchronized timestamp
Watchpoint Hit Message[3]	6	6	fixed	TCODE	TCODE value = 15
	6	6	fixed	SRC [2]	NAR source ID
	6	6	fixed	WPHIT	See Table 72-18
	0	24	variable	TSTAMP	Optional, globally synchronized timestamp

1. The Error message conforms to the IEEE-ISTO 5001-2012 standard.
2. Tools should treat the NAR SRC field as a 4-bit SRC field and a 2-bit unused field. The extra 2-bit field (the two most significant bits of the 6-bit TCODE) is always 0b00. This operation is not compliant to the IEEE-ISTO 5001 Nexus standard.
3. The Watchpoint Hit message does not conform to the IEEE-ISTO 5001-2012 standard, it conforms to the IEEE-ISTO 5001-2003 standard. The WPHIT should be a variable length packet, but is implemented as a fixed length packet. In most cases, tools will not see a difference, however, a difference will be seen if a timestamp field is appended to the message.

72.6.8.1 Error conditions

NAR errors can occur upon events such as illegal memory accesses, block-transfer overloads, communication errors, or when the NAR is configured incorrectly. If the configuration registers are programmed incorrectly, it is possible to put the NAR into an illegal state. The NARs response varies depending on the error. For a minor error, the NAR reverts to a default mode and continues operation, while major errors result in complete shutdown.

In either case, a Nexus error message is sent to the Aurora out port, if its enabled, otherwise to the trace memory bus port. The Nexus error message contains both ETYPE and ECODE fields:

- ETYPE is used to denote the basic type of error that has occurred
- ECODE carries specific additional information about the error

All NAR error types are defined in the following table.

Table 72-16. NAR error types

ETYPE	Description	Classification	NAR action	Comment
0000 (h'0)	Receive queue overrun	Minor	Dropped message	If a client sends a data word that the NAR cannot accept (due to a full receive queue), the new data word is dropped.
0001 (h'1)	Internal message contention	Minor	Dropped message	Internal errors/watchpoints occurred faster than NAR could generate messages for them, causing lower-priority message(s) to be dropped. The type of message dropped is conveyed in the ECODE field, see Table 72-17.
0011 (h'3)	Trace memory bus port read/ write access error	Minor	Access fails	Unable to send an Aurora-to-trace memory bus request. Typical causes would be writes larger than the data buffer or sending in a new request before the previous one completes.[1]
0101 (h'5)	Invalid NRR	Minor	Access fails	Tried to access an un-implemented NRR.
1001 (h'9)	Config error	Major	See Table 72-17	The specific configuration error is conveyed in bits 0–3 of the ECODE field (Table 72-17), as well as the NCE field of Status Register.
1100 (h'C)	HBDP error	Minor	N/A	A hard error is automatically reset the Aurora Link and causes it to re-initialize. Although the Link is down, the error message is queued and released as soon as the Link comes back up.
1101 (h'D)	Receive Queue Overrun	Minor	Drop message	If a client sends a data word that the NPC cannot accept (due to a full receive queue), the new data word will be dropped2.
1110 (h'E)	Block transfer error	Minor	Dummy fill	If the Trace memory bus port becomes data-starved during a block transfer, it fills the rest of the block with IDLE messages.
1111 (h'F)	Stall error	Minor	—	—

1. In the case where a request was successfully translated to a Trace memory bus transaction which itself returned an error, that is conveyed in the STATUS field of the Nexus Target Response message subsequently returned to the debugger.

Typically, the ECODE field is used to communicate which type of message was dropped in queue overflow or message contention situation, but for the NAR it is also used to denote the type of configuration error that occurred. If a configuration error is detected, the NAR generates a Config Error Nexus message and transmits it, with the actual type of error encoded in the four MSBs of ECODE, as well as the NCE field of the Status Register. The ECODE field encodings are listed in the following table.

Table 72-17. Configuration error codes

ECODE	ETYPE	Description	NAR action	Comment
0000xxxxxxx1	0001	Watchpoint message dropped	N/A	Occurs with internal message overflow error.
0000xxxxxx1x	0001	Data trace message dropped	N/A	Occurs with internal message overflow error; MMA response message was dropped.

Table continues on the next page...

Table 72-17. Configuration error codes (continued)

ECODE	ETYPE	Description	NAR action	Comment
00001xxxxxxx	0001	Response message dropped	N/A	Occurs with internal message overflow error; target response (memory access or NRR) message was dropped.
0000xxx1xxxx	0001	Status message dropped	N/A	Occurs with internal message overflow error.
000100000000	1001	Config error: multiply defined port	Communication disable mode	Both MSP and ALT were assigned to the same port. NPC waits until the configuration is fixed before proceeding.
001000000000	1001	Config error: no ALT defined	Tracebuffer	An MSP was defined without defining the ALT. The NPC reverts to tracebuffer mode.
001100000000	1001	Config error: cannot enable port	Communication disable mode	User has attempted to enable a port that does not exist in this implementation of the NPC.
010000000000	1001	Config error: cannot support message filtering	Message filtering and/or queue partitioning disabled	User has attempted to enable message filtering or queue partitioning with only one output enabled. Filtering/partitioning is turned off.
100100000000	1001	Config error: no wakeup trigger	Power up in active mode	Occurs if none of the defined clients in the system can cause a wakeup (PUS is set in NAR_CR, but no NAR_STCRs have WUT set).

72.6.8.2 Watchpoint messages

The NAR generates its own watchpoint match message under the circumstances shown in the following table. The value of the Watchpoint Hit field of the Watchpoint Message is also shown in this table.

Table 72-18. Watchpoint hit values

WPHIT	Description	Comment
b010000	Entering Suppress Mode	If (local or global) suppress mode is enabled and the appropriate trigger is received, the NAR generates a watchpoint message. The type of event (in this case, a suppress event) is encoded in the WPHIT field of the watchpoint message (see the Nexus standard, sec. 5.3.21).
b100000	Client Sync	If sync messaging is enabled, the NAR generates a sync watchpoint message whenever a client sync event occurs.
b000100	Trace Memory bus Block Overflow (TBO)	If the trace memory bus block is filled, causing it to either disable trace memory bus data trace or wrap back to the beginning of the dedicated debug memory block and if trace memory bus overflow messaging is enabled, then an TBO message is generated.
b001000	Tracebuffer Wrap	If the NAR is being used in tracebuffer mode with the wrap-around feature, then a watchpoint message is generated every time the tracebuffer wraps back to address 0. This would be useful in informing the user that the buffer had wrapped and that older data had been overwritten.

72.6.9 Timestamp function

The NAR and its clients may transmit timestamps to allow precise ordering of events. Synchronous or asynchronous clients use the NAR timer value broadcasted over a bus to ensure that all timestamps are in sync as shown in the following figure. The NAR uses enable signal to centrally control the enabling of time stamping, which informs the clients to start adding the timestamp field to their message traffic.

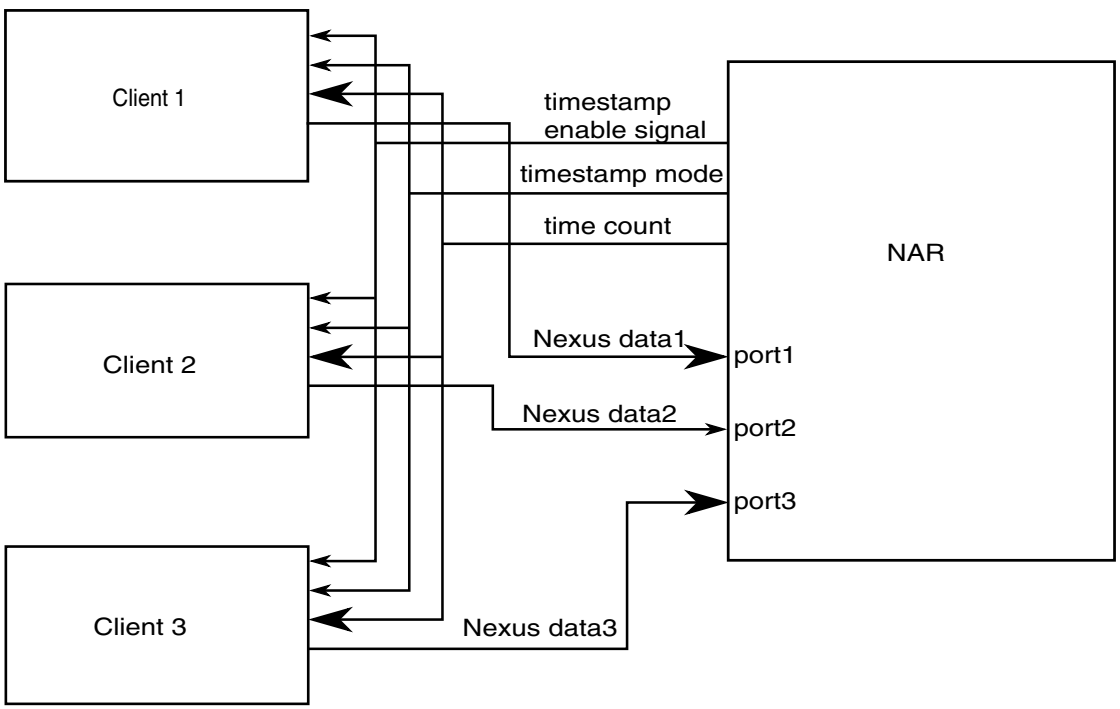

Figure 72-3. Timestamp architecture

Timestamping is enabled by setting the TEN bit of the NAR_CR. This causes the NAR to assert the time stamp enable signal to clients. Typically, the user would also set the TRS bit at this time to reset the NAR Time stamp counter. Internally the NAR has a 30-bit counter external to the NPC block. This 30-bit counter is broadcast to all clients after encoding its value in Gray code. This minimizes the error in synchronization by the clients. The NPC uses an additional internal 24-bit counter to send the timestamp inside its messages. The client converts the gray coded timestamp to binary to append to the Nexus messages.

The timestamp mode, a 2-bit field, is broadcasted to all client which tells the granularity of sending time stamps into message. This is controlled by the TSG bits of the NAR_CR.

Asynchronous clients, those on a separate clock domain from the NAR, synchronize the enable, mode, and timestamp value in their domain. The error introduced by this is assumed to be within tolerable range by application.

A timestamp counter reset can be forced by causing a 0 to 1 transition in the TRS bits of the NAR_CR. The NAR deasserts the enable signal to clients while the reset occurs, and then the counter is restarted (assuming the TEN bit is set). Data throughput can be increased (at the loss of timestamp granularity) by controlling the TSG bits of the NAR_CR. Rather than adding a timestamp to every message, clients can be told to only stamp every 4th, 16th, or 32nd message, easing the bandwidth requirements on the output ports.

The timestamp block maintains the timestamp counter for NAR. It is the central time source for all synchronous/asynchronous clients.

72.6.10 Overlay and internal trace memory full status generation

In certain events, such as main memory (internal trace memory) full or external overlay trace memory full, it is required to control the clients to stop sending data, to avoid any loss of messages from the clients.

The NAR provides three outputs (triggers) to indicate three different situations as described below:

- Internal trace memory (the main queue) is full
- External debug memory on trace memory bus is full
- External debug memory on trace memory bus is full up to a programmable watermark set by the configuration register

The last two triggers are used by SPU to generate stall and suppress triggers. Typically the stall request should be generated whenever space in the external memory connected to trace memory bus has been exhausted. The NAR starts writing from the first location (wrap) as specified in trace memory bus address register in this condition if overwrite trace memory bus debug memory (TBW bit) is set in the NAR_TCR.

The user should configure the partial full watermark register such that it can give around 90% full indication of external debug memory on the trace memory bus. The emulator tool memory full indication is typically generated from the DCI block which actually communicates with the tool.

For example, the following steps can be used to generate event at around 90% fill level for trace memory connected in AHB-EW and to set the watermark in the configuration register.

- From the configuration, the programmer knows the following:

  - AHB start (base) address—Base address = 0x0D00_0000 (i.e.TBAHI = 0x0, TBALO = 0x0D00_0000
  - Block transfer size—NAR_TCR[BTM] = 1 (Block-transfer mode enabled)
  - Max transfer count—NAR_TCR[MXFR] = 0xC0 (maximum transaction count)
- Thus, the total block size is (0xC0 × 0x40) = 0x3000 bytes. The dedicated debug address range is then 0x0D00_0000 – 0x0D00_2FFF.
- To generate an event at nearly 90% fill level of the trace memory at 1 KB boundary, the value to be programmed in the register NAR_AHFPAR[3:0] is calculated as:
  - Number of 1K blocks in 0x3000 bytes = (3000 right shift by 10 bits) = C = 12
  - So the value to be programmed should be 11 as 90% of 12 is almost 11.
- NAR_AHFPAR[3:0] = (NAR_TBALO[13:10] + 0xB) = (0x7+0xB) 0x2 (upper bits truncated due to width) and enable this with NAR_AHFPAR[10] = 1.

This assumes that NAR starts writing from base address and stops at maximum address and no reading is done in overlay memory trace data area during this operation. Whenever the address bus bits [13:10] match with this value, the partial event is generated (toggled).

72.6.11 Configuration/debug interface JTAG

The configuration and status registers of the NAR are accessed through the standard IEEE 1149.1 JTAG interface. The JTAG frequency (TCK) must be 1/2 of the NAR operating clock. The access mechanism through JTAG is described in this section.

The NAR block uses the IEEE 1149.1-2001 TAP for accessing registers. TAP signals include TCK, TDI, TMS, and TDO. The NAR implements a TAP controller state machine that transitions based on the state of the IEEE 1149.1-2001 16-state state machine. It also implements Nexus controller state machine as defined by the IEEE-ISTO 5001-2001 standard.

The instructions implemented by the NAR TAP controller are listed in Table 72-19. Each unimplemented instruction acts like the BYPASS instruction. The size of the NAR instruction register is 4 bits.

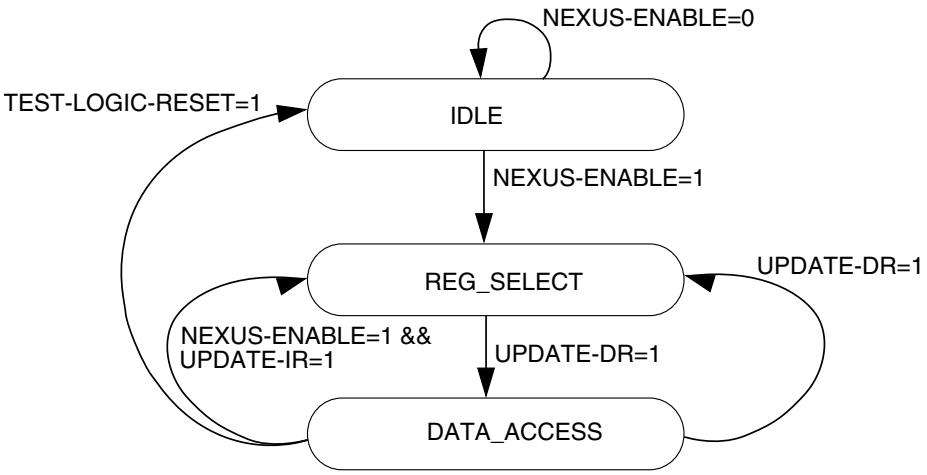

Figure 72-4. Nexus controller state machine

Table 72-19. Implemented instructions

Instruction Name	Private/ Public	Opcode	Description
NEXUS_ENABLE	Public	0x0	Activate Nexus controller state machine to read and write NAR registers.
BYPASS	Private	0x0F	NAR BYPASS instruction. Also the value loaded into the NAR IR upon exit of reset.

Data is shifted between TDI and TDO starting with the least significant bit as illustrated in the following figure. This applies for the instruction register and all Nexus tool-mapped registers.

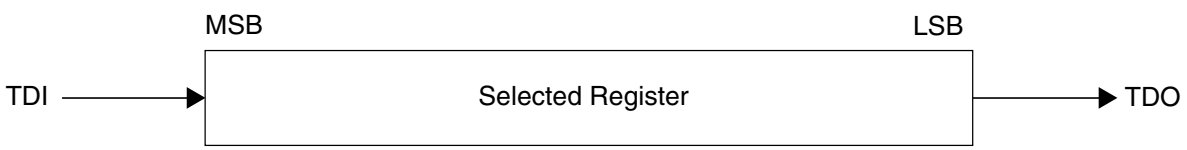

Figure 72-5. Shifting data into register

72.6.11.1 Enabling the NAR TAP controller

Assertion of the power-on reset signal resets the NAR TAP controller. When not in power-on reset the NAR TAP controller is enabled by driving JCOMP with the NAR enable value and exiting the Test-Logic-Reset state. Loading the NEXUS-ENABLE instruction then grants access to Nexus debug.

72.6.11.2 Loading NEXUS-ENABLE instruction

Access to the NAR registers is enabled when the TAP controller instruction register is loaded with the NEXUS-ENABLE instruction. This instruction is shifted in via the SELECT-IR-SCAN path and loaded in the UPDATE-IR state. At this point, the Nexus controller state machine, shown in Figure 72-4, transitions to the REG_SELECT state. The Nexus controller has three states: idle, register select, and data access. The following table illustrates the IEEE 1149.1 sequence to load the NEXUS-ENABLE instruction.

Table 72-20. Loading NEXUS-ENABLE instruction

Clock	TMS	IEEE 1149.1 state	Nexus state	Description
0	0	RUN-TEST/IDLE	IDLE	IEEE 1149.1-2001 TAP controller in idle state
1	1	SELECT-DR-SCAN	IDLE	Transitional state
2	1	SELECT-IR-SCAN	IDLE	Transitional state
3	0	CAPTURE-IR	IDLE	Internal shifter loaded with current instruction
4	0	SHIFT-IR	IDLE	TDO becomes active, and the IEEE 1149.1-2001 shifter is ready. Shift in all but the last bit of the NEXUS-ENABLE instruction.
5 TCKS				
12	1	EXIT1-IR	IDLE	Last bit of instruction shifted in
13	1	UPDATE-IR	IDLE	NEXUS-ENABLE loaded into instruction register
14	0	RUN-TEST/IDLE	REG_SELECT	Ready to be read/write Nexus registers

72.6.11.3 Selecting a JTAG register to create a bus (memory or peripheral) access

When the NEXUS-ENABLE instruction is decoded by the TAP controller, the input port allows the development tool access to all NAR registers. Each register has a 7-bit address index.

All register access is performed via the SELECT-DR-SCAN path. The Nexus controller defaults to the REG_SELECT state when enabled. Accessing a register requires two passes through the SELECT-DR-SCAN path: one pass to select the register and the second pass to read/write the register.

The first pass through the SELECT-DR-SCAN path is used to enter an 8-bit Nexus command consisting of a read/write control bit in the LSB followed by a 7-bit register address index, as illustrated in the following figure. The read/write control bit is set to 1 for writes and 0 for reads. The index for registers are shown in Table 72-1.

Table 72-21. Nexus command format for register selection

MSB	LSB
7-bit register index	R/W

The second pass through the SELECT-DR-SCAN path is used to read or write the register data by shifting in the data (LSB first) during the SHIFT-DR state.When reading a register, the register value is loaded into the IEEE 1149.1-2001 shifter during the CAPTURE-DR state.When writing a register, the value is loaded from the IEEE 1149.1-2001 shifter to the register during the UPDATE-DR state. When reading a register, there is no requirement to shift out the entire register contents. Shifting may be terminated once the required number of bits have been acquired.

The following table illustrates a sequence which writes a 32-bit value to a register.

Table 72-22. Writing a 32-bit value to a register

Clock	TMS	IEEE 1149.1 State	Nexus State	Description
0	0	RUN-TEST/IDLE	REG_SELECT	IEEE 1149.1-2001 TAP controller in idle state
1	1	SELECT-DR-SCAN	REG_SELECT	First pass through SELECT-DR-SCAN path
2	0	CAPTURE-DR	REG_SELECT	Internal shifter loaded with current value of controller command input.
3	0	SHIFT-DR	REG_SELECT	TDO becomes active, and write bit and 4 bits of register index shifted in.
7 TCKs				
11	1	EXIT1-DR	REG_SELECT	Last bit of register index shifted into TDI
12	1	UPDATE-DR	REG_SELECT	Controller decodes and selects register
13	1	SELECT-DR-SCAN	DATA_ACCESS	Second pass through SELECT-DR-SCAN path
14	0	CAPTURE-DR	DATA_ACCESS	Internal shifter loaded with current value of register
15	0	SHIFT-DR	DATA_ACCESS	TDO becomes active, and outputs current value of register while new value is shifted in through TDI
31 TCKs				
47	1	EXIT1-DR	DATA_ACCESS	Last bit of current value shifted out TDO. Last bit of new value shifted in TDI.
48	1	UPDATE-DR	DATA_ACCESS	Value written to register
49	0	RUN-TEST/IDLE	REG_SELECT	Controller returned to idle state. It could also return to SELECT-DR-SCAN to write another register.

72.6.12 Trace memory bus controller

The purpose of the trace memory bus is to transfer trace data from main queue to external overlay memory. This port works on a modified AHB protocol that supports early write. It has AHB interface signals as defined in AMBA specification (Rev 2.0). In addition, there are side-band signals for added functionality.

Key features of the module include:

- AHB-EW Interface

- Early Write (for higher BW in special module)
- 32-bit address bus width
- 64-bit data bus width
- Transfer Types
- IDLE, NONSEQ, SEQ
- Single Transfers
- Burst Transfers
- Configurable support for INCR
- Configurable support for INCR4, INCR8, INCR16, WRAP4
- Response Type
- OKAY, ERROR
- Transfer Size
- Byte, Half Word, Word, Double-Word
- Protection Control
- Cacheable/ Non Cacheable Access Control
- User/Privilege Access

- Endianess Support
  - Configurable Little Endian/Big Endian support on AMBA-AHB interface
- Pipeline Support
  - Total of two transactions (One plus one ongoing)

72.6.12.1 Operation

The trace memory bus controller allows all read/write operations to be cut through. The controller has a pipeline depth of two. While the data phase of one transaction is ongoing, it can accept one more read/write request from the internal bus master and initiate the address phase on the AHB interface during the last data cycle of the ongoing transaction.

72.6.12.2 Write operation

When the trace memory bus initiator asserts a request for a write operation, it can find the acknowledge signal parked asserted if the controller is ready to accept the transaction. If the pipeline is full or in case of an ongoing read transaction, the controller inserts wait states by keeping the acknowledge low. The trace memory bus controller initiates the address phase on AHB interface once it accepts the transaction by asserting the acknowledge on the trace memory bus interface. The write data from the trace memory bus initiator is accepted by the gasket by asserting the acknowledge only on completion of address phase at AHB interface, which is signified by receiving the ready signal asserted. Simultaneously, the data is sent to the data bus. Once the requisite number of bytes have been accepted from the trace memory bus initiator, the gasket generates end of data and transfer according to the Trace memory bus protocol.

The AHB protocol supports data transactions of byte, half-word, word and double-word (when both trace memory bus and AHB data bus width is 64 bits). A write transaction from the trace memory bus initiator take place as single/multiple transactions on the AHB side.

72.6.12.3 Read operation

When the trace memory bus initiator asserts a request signal to request for a read operation, it can find the acknowledge signal parked asserted if the gasket is ready to accept the transaction. If the pipeline is full, the controller inserts wait states by keeping the acknowledge low. The trace memory bus controller initiates the address phase on AHB-EW interface once it accepts the transaction by asserting the acknowledge on trace memory bus interface. The controller reads the data from the bus when the ready signal is sensed asserted. The data is transferred on the trace memory bus data bus with the data acknowledge asserted. The gasket asserts end of data and transfer at the end of transaction as per trace memory bus protocol.

The AHB protocol supports data transactions of byte, word, half-word and double-word (when both trace memory bus and AHB data bus width is 64-bits). A read transaction from trace memory bus initiator takes place as single/multiple transaction on the AHB interface before the read data is merged and sent on the trace memory bus read data bus.

In case of variable data bus width on trace memory bus and AHB interface (32-bit data bus on one interface and 64-bit data bus on the other interface), a maximum of 64 bits is read on each beat.

72.6.13 Legacy client interface controller

This block converts the legacy client protocol into internal client protocol that is accepted by the internal NPC block. The Nexus beat size must be same for both interfaces. The Nexus beat is composed of MDO bits along with two MSEO bits. The trace data width from the legacy client is fixed at one beat. The architecture of this block is shown in Figure 72-6.

The legacy client sends each message after arbitrating the bus. It requests the gasket with a 2-bit request signal whenever it has data to send. A 00 means no request, 01 a low-priority request, 10 a medium-priority request, and 11 a high-priority request. The legacy client can send one maximum message sized data on receiving a grant from the block. There is no backpressure mechanism during transfer of a message from the client to this block. The block asserts a grant if it has at least one max message size space in its FIFO. Seeing the grant the client asserts busy signal and holds it until it wants to send data, it may hold it up to max message size data is transferred.

The following architecture describes the legacy client to internal client protocol conversion block. There is a small FIFO of paramaterizeable depth used to store the data from client. The block asserts a grant only when at least one max message sized space is available in FIFO. The write happens in the client's clock domain. The write pointer is passed to other domain which is NPC clock domain.

The logic on other side compares read and write pointer to check the data availability in the block's FIFO and space availability in NPC's receive queue. If space and data both are available it tries to send message to the NPC.

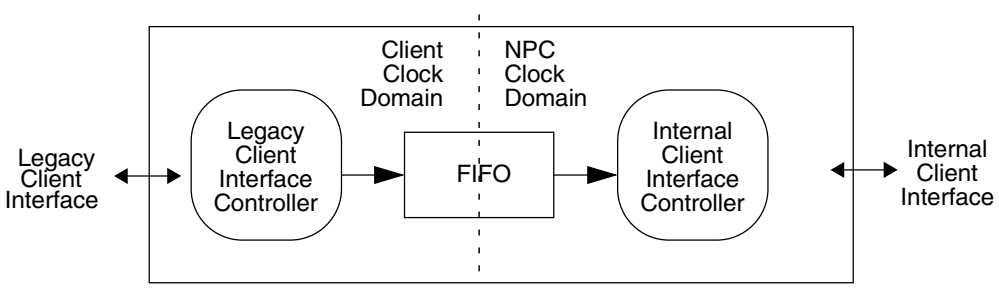

Figure 72-6. Legacy client Interface controller

The size of the receive queue of the corresponding client at NPC must be known to the block. The block drives a not empty signal whenever it has data in FIFO and looks for a ready signal. It can send as many Nexus beats as receive queue can store. It operates on decrements a counter after sending data to the NPC so that it can track how much data it can send. The counter is incremented by the value of acknowledge from NPC which tells how may spaces are freed in receive queue.

72.7 Application information

The base application for the NAR is collecting and collating Nexus trace data.

Example flow of NAR configuration for different cases.

Configuration with Two output port enabled

1. For Two port enabled one port must be Message Select (MSP) and other Alternate (ALT); Trace Memory and Aurora ports with multiple clients

   Selection of MSP port depends on user choice. One option could be based on the requirement of Filtering. If Messages from some known sources with some specific type (if any) is required to be sent to a particular port then select user can select that port as MSP. All other messages will go to the Alternate port. The filter can be used as inverted manner where unmatched messages will go to MSP. (Please see section “Output arbitration” for details)
   - Configure the Source Filter register (NAR_SFR), To enable proper filtering of messages based on Message source going to MSP or ALT port
   - Configure the Type Filter register (NAR_TFR), To enable proper filtering of messages based on Message Type going to MSP or ALT port
   - Configure Trace Memory port attributes : (This step is not required if Trace memory port is not used)
     - Start Address (base address) in NAR_TBALO & NAR_TBAHI register
     - Transfer mode, Block size, Threshold in %, Wrapping enable and Total size of memory
   - Configure Client disable register NAR_CDR (disable clients which are not required)
   - Configure NPC suppress trigger registers NAR_STCR[x] (x=0-3) (suppress the clients for which data is not to be forwarded at output) (Difference between suppressing and disabling is that suppressing can be done dynamically during NAR operation but disabling can’t be done this way which may leads to system hang)
   - Configure the Event generation register (NAR_AHFPAR) for programmable fill level event generation
   - Configure the NAR control register for other controls and Enable NAR
     - Set the MSP as Nexus Out and ALT as Trace memory
     - Set AQP for partitioning the Main Queue for ALT and MSP ports
     - Set time stamp controls
     - Enable NAR to start operation
     - Configuration for Single Output port with single partition in NAR central Message Queue

2. Only Trace Memory port is enabled with multiple client
    - Configure Trace Memory port attributes : (This step is not required if Trace memory port is not used)
        - Start Address (base address) in NAR_TBALO & NAR_TBAHI register
        - Transfer mode, Block size, Threshold in %, Wrapping enable and Total size of memory
    - Configure Client disable register NAR_CDR (disable clients which are not required)
    - Configure the Event generation register (NAR_AHFPAR) for programmable fill level event generation
    - Configure the NAR control register for other controls and Enable NAR
        - Set the Trace Memory port as ALT port (Alternate port is only the main port in single out port application)
        - Set AQP for disabling partitioning
        - Set time stamp controls
        - Set watch point controls
        - Enable NAR to start operation

Chapter 73
Nexus Module

73.1 Introduction

The Nexus 3 module provides real-time development capabilities for corresponding core processors in compliance with the IEEE-ISTO 5001 standard. This module provides development support capabilities without requiring the use of address and data pins for internal visibility.

A portion of the pin interface (the JTAG port) is also shared with the OnCE / Nexus 1 unit. The IEEE-ISTO 5001 standard defines an extensible auxiliary port which is used in conjunction with the JTAG port in these processors.

73.1.1 General Description

This chapter defines the auxiliary pin functions, transfer protocols and standard development features of a Class 3 device in compliance with the IEEE-ISTO 5001 standard. The development features supported are Program Trace, Data Trace, Watchpoint Messaging, Ownership Trace, Data Acquisition Messaging, and Read/Write Access via the JTAG interface. The Nexus 3 module also supports two Class 4 features: Watchpoint Triggering, and Processor Overrun Control.

73.1.2 Terms and Definitions

The following table contains a set of terms and definitions associated with the Nexus 3 module.

Table 73-1. Terms and Definitions

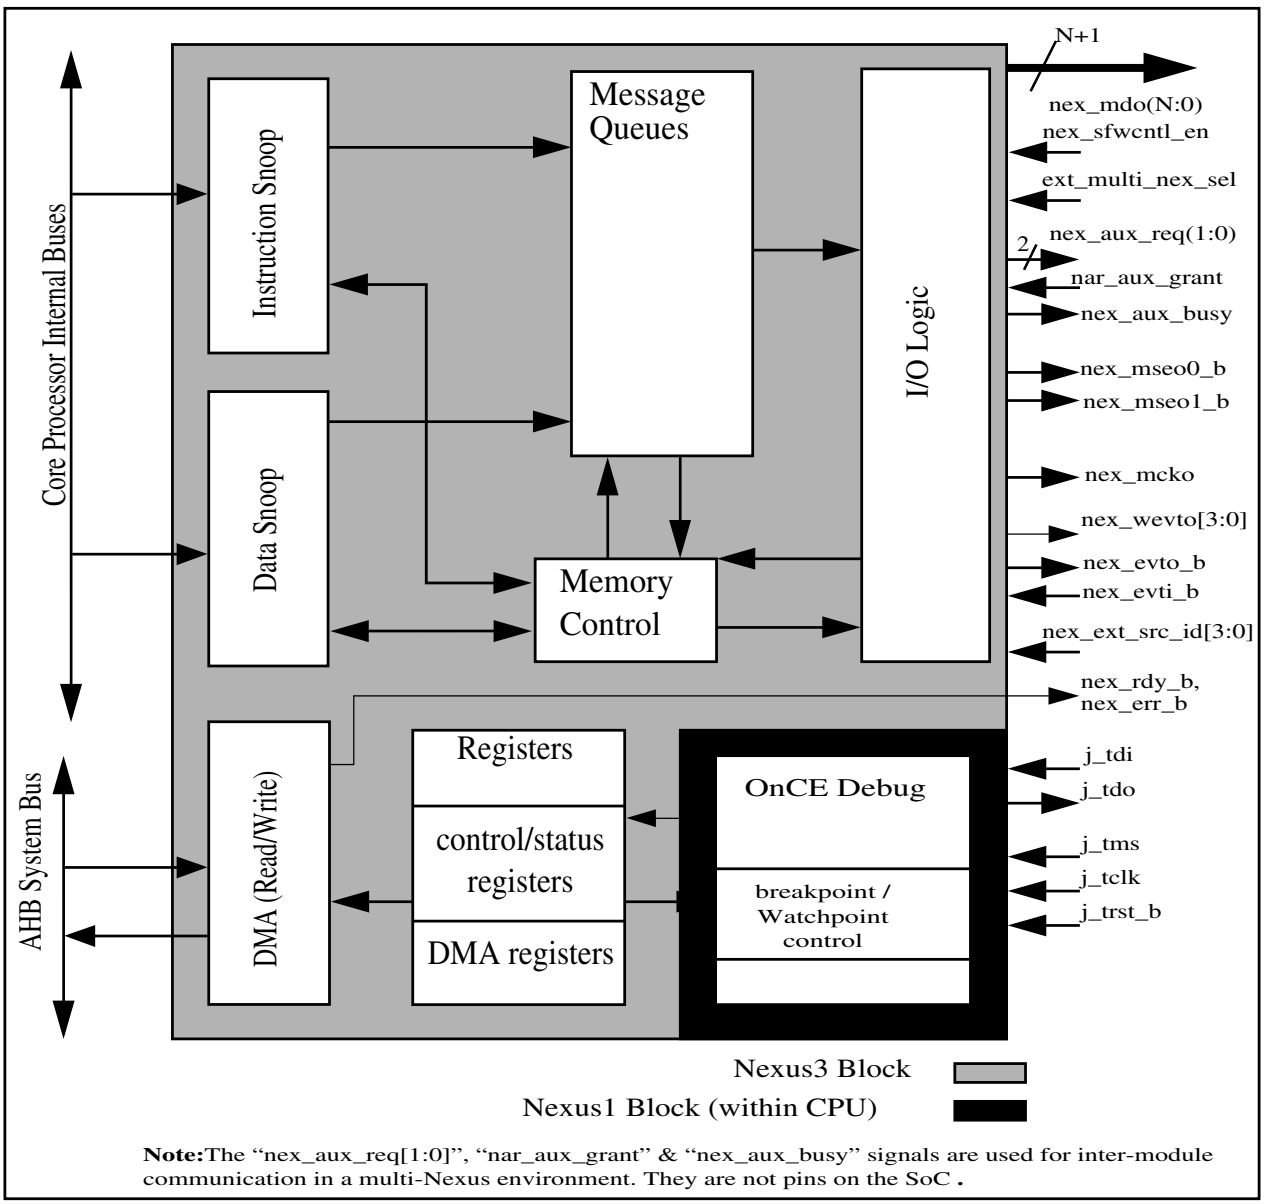
Term	Description
IEEE-ISTO 5001	Consortium & standard for real-time embedded system design. World wide Web documentation at http://www.ieee-isto.org/Nexus5001
Auxiliary Port	Refers to Nexus auxiliary port. Used as auxiliary port to the IEEE 1149.1 JTAG interface.
Branch Trace Messaging (BTM)	Visibility of addresses for taken branches and exceptions, and the number of sequential instructions executed between each taken branch.
Data Read Message (DRM)	External visibility of data reads to memory-mapped resources.
Data Write Message (DWM)	External visibility of data writes to memory-mapped resources.
Data Trace Messaging (DTM)	External visibility of how data flows through the embedded system. This may include DRM and/or DWM.
Data Acquisition Messaging (DQM)	Data Acquisition Messaging (DQM) allows code to be instrumented to export customized information to the Nexus Auxiliary Output Port.
JTAG Compliant	Device complying to IEEE 1149.1 JTAG standard
JTAG IR & DR Sequence	JTAG Instruction Register (IR) scan to load an opcode value for selecting a development register. The JTAG IR corresponds to the OnCE command register (OCMD). The selected development register is then accessed via a JTAG Data Register (DR) scan.
Nexus1	The (OnCE) debug module. This module integrated with each processor provides all static (core halted) debug functionality. This module is compliant with Class1 of the IEEE-ISTO 5001 standard.
Ownership Trace Message (OTM)	Visibility of process/function that is currently executing.
Public Messages	Messages on the auxiliary pins for accomplishing common visibility and controllability requirements
SoC	"System-on-a-Chip". SoC signifies all of the modules on a single die. This generally includes one or more processors with associated peripherals, interfaces & memory modules.
Standard	The phrase "according to the standard" is used to indicate according to the IEEE-ISTO 5001 standard.
Transfer Code (TCODE)	Message header that identifies the number and/or size of packets to be transferred, and how to interpret each of the packets.
Watchpoint	A Data or Instruction Breakpoint or other debug event that does not cause the processor to halt. Instead, a pin is used to signal that the condition occurred. A Watchpoint Message may also be generated.

73.1.3 Feature List

The Nexus 3 module is compliant with Class 3 of the IEEE-ISTO 5001 standard, with additional Class 4 features available. The following features are implemented:

- Program Trace via Branch Trace Messaging (BTM). Branch trace messaging displays program flow discontinuities (direct and indirect branches, exceptions, etc.), allowing the development tool to interpolate what transpires between the discontinuities. Thus static code may be traced.
- Data Trace via Data Write Messaging (DWM) and Data Read Messaging (DRM). This provides the capability for the development tool to trace reads and/or writes to selected internal memory resources.
- Ownership Trace via Ownership Trace Messaging (OTM). OTM facilitates ownership trace by providing visibility of which process ID or operating system task is activated. An Ownership Trace Message is transmitted when a new process/task is activated, allowing the development tool to trace ownership flow.
- Run-time access to embedded processor memory map via the JTAG port. This allows for enhanced download/upload capabilities.
- Watchpoint Messaging via the auxiliary pins
- Watchpoint Trigger enable of Program and/or Data Trace Messaging
- > External hardware trigger inputs to independently enable/disable Program Trace, Data Trace, Ownership Trace, and Watchpoint Trace Messaging
- Auxiliary interface for higher data
  - Message Data Out pins (**nex_mdo[29:0]**)
  - One (1) or two (2) Message Start/End Out pins (**nex_mseo_b[1:0]**)
  - One (1) Read/Write Ready pin (**nex_rdy_b**) pin
  - One (1) Read/Write Error pin (**nex_err_b**) pin
  - One (1) Watchpoint Event output pin (**nex_evto_b**)
  - Four (4) additional Watchpoint Event output pins (**nex_wevto[3:0]**) for SoC use
  - One (1) Event In pin (**nex_evti_b**)
  - One (1) MCKO (Message Clock Out) pin
- Registers for Program Trace, Data Trace, Ownership Trace and Watchpoint Trigger.
- All features controllable and configurable via the JTAG port
- Conditional software control of the module via SoC signaling input (**nex_sfwcntl_en**)

Note



For multi-Nexus implementations, the configuration of the Message Data Out pins is controlled by the Port Control Register (@ the SoC level). For single Nexus implementations (not normally implemented on an SoC), this configuration is controlled by Development Control Register 1 (DC1) within the Nexus 3 module.

In either implementation, Full Port Mode (FPM - maximum number of MDO pins) or Reduced Port Mode (RPM - minimum number of MDO pins) are supported. This setting should not be changed while the system is running.

Note

The configuration of the Message Start/End Out pins (1 or 2) is determined at the SOC integration level. This option will be hard-wired based on SOC bandwidth requirements.

73.1.4 Functional Block Diagram

Note: The "nex_aux_req[1:0]", "nar_aux_grant" & "nex_aux_busy" signals are used for inter-module communication in a multi-Nexus environment. They are not pins on the SoC .

73.2 Enabling Nexus 3 Operation

The Nexus module is enabled by loading a single instruction (*NEXUS3-ACCESS*) into the JTAG Instruction Register (IR) (OnCE OCMD register). For the Nexus3 module, the OCMD value is 0b0001111100. The Nexus 3 module may alternately be enabled if the nex_evti_b input signal is asserted at the time that j_trst_b is initially negated, or is asserted during the Test-Logic-Reset TAP state. Once enabled, the module will be ready to accept control input via the JTAG/OnCE pins.

Enabling the Nexus 3 module automatically enables the generation of Debug Status Messages.

The Nexus 3 module is disabled when the JTAG state machine initially reaches the Test-Logic-Reset state from any other state. This state can be reached by the assertion of the **j_trst_b** pin or by cycling through the state machine using the **j_tms** pin. The Nexus module will also be disabled if a Power-on-Reset (POR) event occurs. If the Nexus 3 module is disabled, no trace output will be provided, and the module will disable (drive inactive) auxiliary port output pins (**nex_mdo[29:0]**, **nex_mseo[1:0]**, **nex_mcko**). Nexus registers will not be available for reads or writes.

In order to support software control of the Nexus 3 module when no external development tool is present, the Nexus 3 module is not forced to be disabled when the JTAG state remains in the Test-Logic-Reset state. Software is allowed to control the Nexus 3 module when the input signal **nex_sfwcntl_en** is asserted by the SoC. This signal is intended to provide a mechanism for allowing software to use the Nexus 3 module to fill on-chip trace buffers or other visibility mechanisms. It is up to the SoC to determine whether a top-level Nexus 3 controller has been enabled by a hardware debugger, or whether appropriate security mechanisms have granted the capability for software to use these resources, and to drive the appropriate value to the **nex_sfwcntl_en** input. Software can enable the module by a write to any of the module's DCRs when **nex_sfwcntl_en** is asserted.

Reset of the Nexus 3 module is accomplished by a transition on **j_trst_b**, on initial entry into the Test_Logic_Reset state from another state, or if a Power-on-Reset (POR) event occurs. The module is not reset by the CPU's **p_reset_b** signal, even when software has control of the module.

73.2.1 Interaction with Low Power Modes

The Nexus 3 module will continue to operate in the Waiting and Halted states, as long as **nex_clk** remains active. In the Stopped state, **nex_clk** is gated off internally to the Nexus 3 logic, therefore watchpoint or hardware triggering recognition, message generation, and Nexus 3 read-write access to memory is suspended. The Nexus 3 logic will wait to enter the Stopped state until the message FIFOs are empty and any in-progress Nexus R/W transfer has completed. If a block transfer has been requested, the remainder of the block transfer is not completed, and the RWCS AC bit is cleared, and the ERR bit is set. Once the Stopped state has been entered, no further messages are queued and no triggering conditions are monitored. Also, Nexus R/W accesses are no longer available. Upon exiting the Stopped state, normal functions will resume assuming **nex_clk** is active.

73.3 TCODEs supported

The Nexus 3 pins allow for flexible transfer operations via Public Messages. A TCODE defines the transfer format, the number and/or size of the packets to be transferred, and the purpose of each packet. The IEEE-ISTO 5001 2003 standard defines a set of public messages and allocates additional TCODEs for vendor-specific features outside the scope of the public messages. The Nexus 3 block supports the TCODEs shown in Table 73-2.

Table 73-2. Supported TCODEs

Message Name	Min Field Size (bits)	Max Field Size (bits)	Field Name	Field Type	Field Description
Debug Status	6	6	TCODE	fixed	TCODE number = 0
	4	4	SRC	fixed	source processor identifier
	8	8	STATUS	fixed	Development Status Register (DS[31:24])
Ownership Trace Message	6	6	TCODE	fixed	TCODE number = 2
	4	4	SRC	fixed	source processor identifier
	1	32	PROCESS	variable	Task/Process ID tag
Program Trace - Direct Branch Message	6	6	TCODE	fixed	TCODE number = 3
	4	4	SRC	fixed	source processor identifier
	1	8	ICNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
Program Trace - Indirect Branch Message	6	6	TCODE	fixed	TCODE number = 4
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	1	8	ICNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
	1	32	U-ADDR	variable	unique part of target address for taken branches/ exceptions
Data Trace - Data Write Message	6	6	TCODE	fixed	TCODE number = 5
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	4	4	DSZ	fixed	data size (Refer to Table 73-7)
	1	32	U-ADDR	variable	unique portion of the data write address
	1	64	DATA	variable	data write value(s) (see Data Trace section for details)

Table continues on the next page...

Table 73-2. Supported TCODEs (continued)

Message Name	Min Field Size (bits)	Max Field Size (bits)	Field Name	Field Type	Field Description
Data Trace - Data Read Message	6	6	TCODE	fixed	TCODE number = 6
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	4	4	DSZ	fixed	data size (Refer to Table 73-7)
	1	32	U-ADDR	variable	unique portion of the data read address
	1	64	DATA	variable	data read value(s) (see Data Trace section for details)
Data Acquisition Message	6	6	TCODE	fixed	TCODE number = 7
	4	4	SRC	fixed	source processor identifier
	8	8	DQTAG	fixed	identification tag taken from $DEVENT_{DQTAG}$ register field
	1	32	DQDATA	variable	exported data taken from DDAM register
Error Message	6	6	TCODE	fixed	TCODE number = 8
	4	4	SRC	fixed	source processor identifier
	4	4	ETYPE	fixed	error type
	8	8	ECODE	fixed	error code
Program Trace - Synchronization Message	6	6	TCODE	fixed	TCODE number = 9
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	1	8	I-CNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow. Cleared for most sync conditions.
	1	32	F-ADDR	variable	full target address (leading zero (0) truncated)
Program Trace - Direct Branch Message w/ Sync	6	6	TCODE	fixed	TCODE number = 11
	4	4	SRC	fixed	source processor identifier
	1	8	ICNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
	1	32	F-ADDR	variable	full target address (leading zeros truncated)
Program Trace - Indirect Branch Message w/Sync	6	6	TCODE	fixed	TCODE number = 12
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	1	8	ICNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
	1	32	F-ADDR	variable	full target address (leading zeros truncated)

Table continues on the next page...

Table 73-2. Supported TCODEs (continued)

Message Name	Min Field Size (bits)	Max Field Size (bits)	Field Name	Field Type	Field Description
Data Trace - Data Write Message w/ Sync	6	6	TCODE	fixed	TCODE number = 13
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	4	4	DSZ	fixed	data size (Refer to Table 73-7)
	1	32	F-ADDR	variable	full access address (leading zeros truncated)
	1	64	DATA	variable	data write value(s) (see Data Trace section for details)
Data Trace - Data Read Message w/ Sync	6	6	TCODE	fixed	TCODE number = 14
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	4	4	DSZ	fixed	data size (Refer to Table 73-7)
	1	32	F-ADDR	variable	full access address (leading zeros truncated)
	1	64	DATA	variable	data read value(s) (see Data Trace section for details)
Watchpoint Message	6	6	TCODE	fixed	TCODE number = 15
	4	4	SRC	fixed	source processor identifier
	1	32	WPHIT	variable	Field indicating watchpoint source(s) (leading zeros truncated)
Resource Full Message	6	6	TCODE	fixed	TCODE number = 27
	4	4	SRC	fixed	source processor identifier
	4	4	RCODE	fixed	resource code (Refer to Table 73-5) - indicates which resource is the cause of this message
	1	32	RDATA	variable	branch / predicate instruction history (See Section Resource Full Messages.)
Program Trace - Indirect Branch History Message	6	6	TCODE	fixed	TCODE number = 28 (see Note below)
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	1	8	I-CNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
	1	32	U-ADDR	variable	unique part of target address for taken branches/ exceptions
	1	32	HIST	variable	branch / predicate instruction history (see Branch Trace Messaging types)

Table continues on the next page...

Table 73-2. Supported TCODEs (continued)

Message Name	Min Field Size (bits)	Max Field Size (bits)	Field Name	Field Type	Field Description
Program Trace - Indirect Branch History Message w/ Sync	6	6	TCODE	fixed	TCODE number = 29 (see Note below)
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	1	8	I-CNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
	1	32	F-ADDR	variable	full target address (leading zero (0) truncated)
	1	32	HIST	variable	branch / predicate instruction history (See Branch Trace Messaging types.)
Program Trace - Program Correlation Message	6	6	TCODE	fixed	TCODE number = 33
	4	4	SRC	fixed	source processor identifier
	4	4	EVCODE	fixed	event correlated w/ program flow (Refer to Table 73-6)
	2	2	CDF	fixed	# fields of information in CDATA. 00 - reserved, 01 - one field (CDATA1) (reserved), 10 - two fields (CDATA1 + CDATA2), 11 - three fields (reserved)
	1	8	I-CNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
	1	32	CDATA1	variable	correlation data field 1 - [branch / predicate instruction history] (See Program Correlation Messages.)
	0	32	CDATA2	variable	correlation data field 2- PID info (See Program Correlation Messages.)

Note

Program Trace can be implemented using either Branch History/Predicate Instruction Messages, or traditional Direct/ Indirect Branch Messages. The user can select between the two types of Program Trace. The advantages for each are discussed in Branch Trace Messaging types. If the Branch History method is selected, the shaded TCODES above will not be messaged out.

Table 73-3 shows the error code encodings used when reporting an error via the Nexus 3 Error Message.

Table 73-3. Error Code (ECODE) Encoding (TCODE = 8)

Error Code	Description
xxxxxxx1	Watchpoint Trace Message(s) Lost
xxxxxx1x	Data Trace Message(s) Lost

Table continues on the next page...

Table 73-3. Error Code (ECODE) Encoding (TCODE = 8) (continued)

Error Code	Description
xxxxx1xx	Program Trace Message(s) Lost
xxxx1xxx	Ownership Trace Message(s) Lost
xxx1xxxx	Status Message(s) Lost (Debug Status messages, etc.)
xx1xxxxx	Data Acquisition Message(s) Lost
x1xxxxxx	Reserved
1xxxxxxx	Reserved

Table 73-4 shows the error type encodings used when reporting an error via the Nexus 3 Error Message.

Table 73-4. Error Type (ETYPE) Encoding (TCODE = 8)

Error Type	Description
0000	Message Queue Overrun caused one or more messages to be lost
0001	Contention with higher priority messages caused one or more messages to be lost
0010	Reserved
0011	Reserved
0100	Reserved
0101	Invalid access opcode (Nexus Register unimplemented)
0110 - 1111	Reserved

Table 73-5 shows the encodings used for resource codes for certain messages.

Table 73-5. Resource Code (RCODE) values (TCODE = 27)

Resource Code	Description
0000	Program Trace Instruction counter reached 255 and was reset.
0001	Program Trace, Branch / Predicate Instruction History full. This type of packet is terminated by a stop bit set to 1 after the last history bit.

Table 73-6 shows the event code encodings used for certain messages.

Table 73-6. Event Code (EVCODE) Encoding (TCODE = 33)

Event Code	Description
0000	Entry into Debug Mode
0001	Entry into Low Power Mode (CPU only)
0010-0011	Reserved for future functionality
0100	Disabling Program Trace
0101	Process ID value is established in PID0/NPIDR via **mtspr PID0/NPIDR**
0110-1000	Reserved for future functionality

Table continues on the next page...

Table 73-6. Event Code (EVCODE) Encoding (TCODE = 33) (continued)

Event Code	Description
1001	Begin masking of program trace messages due to MSR_{PMM}=0 and $DC4_{PTMARK}$=1
1010	Branch and link occurrence (direct branch function call)
1011-1111	Reserved for future functionality

Table 73-7 shows the data trace size encodings used for certain messages.

Table 73-7. Data Trace Size (DSZ) Encodings (TCODE = 5,6,13,14)

DTM Size Encoding	Transfer Size
0000	0 - no data
0001	Byte
0010	Halfword (2 bytes)
0011	Three bytes
0100	Word (4 bytes)
0101	Five bytes
0110	Six bytes
0111	Seven bytes
1000	Doubleword (8 bytes)
1001-1111	Reserved

73.4 Nexus 3 Programmer's Model

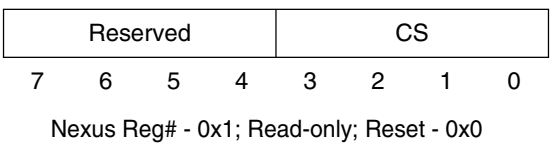
This section describes the Nexus 3 programmers model. Nexus 3 registers are accessed using the JTAG/OnCE port in compliance with IEEE 1149.1, or by software via DCRs. See Nexus 3 Register Access via JTAG/OnCE and Nexus 3 Register Access via Software for details on Nexus 3 register access.

Note

Nexus 3 registers and output signals are numbered using bit 0 as the least significant bit. This bit ordering is consistent with the ordering defined by the IEEE-ISTO 5001 standard.

The following table details the register map for the Nexus 3 module.

Table 73-8. Nexus 3 Register Map



Nexus Register	Nexus Access Opcode	Read/ Write	Read Address	Write Address	DCR #[1]
Client Select Control (CSC)[2, 2]	0x1	R	0x02	-	
Port Configuration Register (PCR)[3]	PCR_INDEX[2]	R/W	-	-	
Development Control 1 (DC1)	0x2	R/W	0x04	0x05	368
Development Control 2 (DC2)	0x3	R/W	0x06	0x07	369
Development Control 3 (DC3)	0x4	R/W	0x08	0x09	370
Development Control 4 (DC4)	0x5	R/W	0x0A	0x0B	371
Reserved	0x6	R/W	0x18	0x19

Reserved	0x8	R/W	0x18	0x19	
Read/Write Access Address (RWA)	0x9	R/W	0x12	0x13	-
Read/Write Access Data (RWD)	0xA	R/W	0x14	0x15	-
Watchpoint Trigger (WT)	0xB	R/W	0x16	0x17	375
Reserved	0xC	R/W	0x18	0x19	
Data Trace Control (DTC)	0xD	R/W	0x1A	0x1B	376
Data Trace Start Address 1 (DTSA1)	0xE	R/W	0x1C	0x1D	377
Data Trace Start Address 2 (DTSA2)	0xF	R/W	0x1E	0x1F	378
Data Trace Start Address 3 (DTSA3)	0x10	R/W	0x20	0x21	379
Data Trace Start Address 4 (DTSA4)	0x11	R/W	0x22	0x23	380
Data Trace End Address 1 (DTEA1)	0x12	R/W	0x24	0x25	381
Data Trace End Address 2 (DTEA2)	0x13	R/W	0x26	0x27	382
Data Trace End Address 3 (DTEA3)	0x14	R/W	0x28	0x29	383
Data Trace End Address 4 (DTEA4)	0x15	R/W	0x2A	0x2B	408
Reserved	0x16 -> 0x2F	-	0x28->0x5E	0x29->5F	
Development Status (DS)	0x30	R	0x60	-	409
Reserved	0x31	R/W	0x62	0x63	
Overrun Control (OVCR)	0x32	R/W	0x64	0x65	410
Watchpoint Mask (WMSK)	0x33	R/W	0x66	0x67	411
Reserved	0x34	-	0x68	0x69	
Program Trace Start Trigger Control (PTSTC)	0x35	R/W	0x6A	0x6B	412
Program Trace End Trigger Control (PTETC)	0x36	R/W	0x6C	0x6D	413
Data Trace Start Trigger Control (DTSTC)	0x37	R/W	0x6E	0x6F	414
Data Trace End Trigger Control (DTETC)	0x38	R/W	0x70	0x71	415
Reserved	0x39 -> 0x3F	-	0x72->0x7E	0x73->7F	

1. Software access via the **mfdcr** and **mtdcr** instructions use these values for the DCR number. Software writes to these registers via **mtdcr** when **nex_sfwcntl_en** is negated are ignored.
2. The CSC and PCR registers are shown in this table as part of the Nexus programmer's model. They are only present at the top level SoC Nexus controller in a multi-Nexus implementation, not in the Nexus 3 module. The SoC's CSC Register is readable through Nexus, but the PCR is shown for reference only here.

3. The "PCR_INDEX" is a parameter determined by the SoC.

73.4.1 Client Select Control (CSC) register

The CSC Register determines which Nexus client is under development. This register is present at the top-level SOC Nexus 3 controller to select one of multiple on-chip Nexus 3 units.

Nexus Reg# - 0x1; Read-only; Reset - 0x0

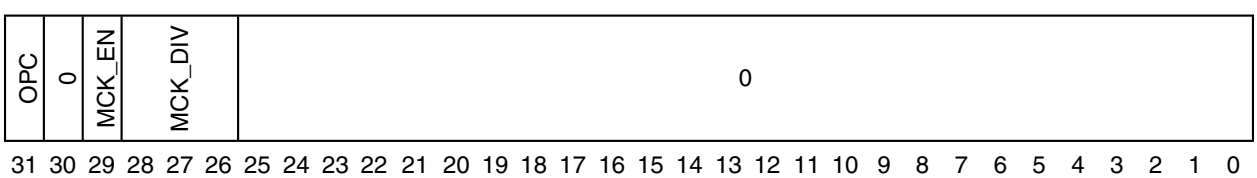

Figure 73-1. Client Select Control (CSC) register

Table 73-9. CSC field descriptions

Bits	Description
CSC[7:4]	Reserved for future Nexus Clients (read as 0)
CSC[3:0]	Client Select Control 0xx - Nexus client (SoC level)

73.4.2 Port Configuration Register (PCR) - reference only

The Port Configuration Register (PCR) controls the basic port functions for all Nexus modules in a multi-Nexus environment. This includes clock control and auxiliary port width. All bits in this register are writable only once after system reset.

Nexus Reg# - PCR_INDEX; Read/Write; Reset - 0x0

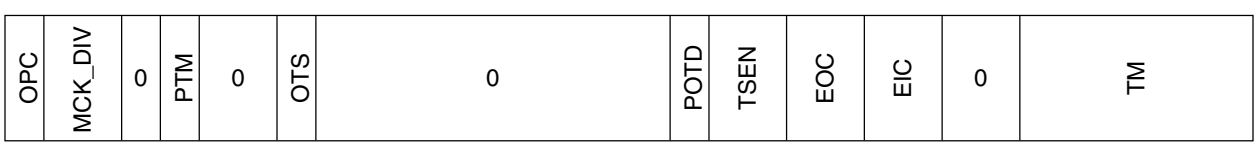
Figure 73-2. Port Configuration Register

Table 73-10. PCR field descriptions

Bit	Name	Description
31	OPC	Output Port Mode Control (SoC Level)
		0 Reduced Port Mode configuration (min# **nex_mdo[n:0]** pins defined by SOC)
		1 Full Port Mode configuration (max# **nex_mdo[n:0]** pins defined by SOC)

Table continues on the next page...

Table 73-10. PCR field descriptions (continued)



Bit	Name	Description
30	—	Reserved for future functionality
29	MCK_EN	MCKO Clock Enable (SoC Level)
		0 **nex_mcko** is disabled
		1 **nex_mcko** is enabled
28:26	MCK_DIV	MCKO Clock Divide Ratio (see note below) (SoC Level)
		000 **nex_mcko** is 1x processor clock freq.
		001 **nex_mcko** is 1/2x processor clock freq.
		010 Reserved (default to 1/2x processor clock freq.)
		011 **nex_mcko** is 1/4x processor clock freq.
		100 Reserved (default to 1/2x processor clock freq.)
		101 Reserved (default to 1/2x processor clock freq.)
		110 Reserved (default to 1/2x processor clock freq.)
		111 **nex_mcko** is 1/8x processor clock freq.
25:0	—	Reserved for future functionality

Note

The CSC and PCR Registers exist in a separate module at the SoC level in a multi-Nexus environment. If the core Nexus 3 module is the only Nexus module, these registers are not implemented and the Nexus 3 defined Development Control Register 1 (DC1) is used to control the SoC-level Nexus port functionality.

73.4.3 Nexus Development Control Register 1 (DC1)

Nexus Development Control Register 1 is used to control the basic development features of the Nexus 3 module. Development Control Register 1 is shown in Figure 73-3 and its fields are described in Table 73-11.

Nexus Reg# - 0x2; DCR - 368; Read/Write; Reset - 0x0

Figure 73-3. Development Control Register 1

Table 73-11. DC1 field descriptions

Bits	Name	Description
31	OPC	Output Port Mode Control
		0 Reduced Port Mode configuration (min# **nex_mdo[n:0]** pins defined
		1 Full Port Mode configuration (max# **nex_mdo[n:0]** pins defined
30:29	MCK_DIV	MCKO Clock Divide Ratio (see note below)
		00 **nex_mcko** is 1x processor clock freq.
		01 **nex_mcko** is 1/2x processor clock freq.
		10 **nex_mcko** is 1/4x processor clock freq.
		11 **nex_mcko** is 1/8x processor clock freq.
28	—	Reserved for future functionality
27	PTM	Program Trace Method
		0 Program Trace uses traditional Branch Messages
		1 Program Trace uses Branch History Messages
26:25	—	Reserved for future functionality
24	OTS	Ownership Trace PID Select
		0 PID0 data is transmitted within Ownership Trace Messages
		1 Nexus PID Register (NPIDR) data is transmitted within Ownership Trace Messages
26:15	—	Reserved for future functionality
14	POTD	Periodic Ownership Trace Disable
		0 Periodic Ownership Trace message events are enabled
		1 Periodic Ownership Trace message events are disabled
13:12	TSEN	Timestamp Enable - (not implemented, write to 00)
		00 Timestamp is disabled
11:10	EOC	EVTO Control
		00 **nex_evto_b** upon occurrence of Watchpoints (configured in DC2 and DC3)
		01 **nex_evto_b** upon entry into Debug Mode
		1x Reserved
9:8	EIC	EVTI Control
		00 **nex_evti_b** is used for synchronization (Program Trace Sync msg is generated)
		01 **nex_evti_b** is used for Debug request
		10 **nex_evti_b** is disabled
		1X Reserved
7:6	—	Reserved for future functionality
5:0	TM	Trace Mode[1]
		000000 All Trace Disabled
		XXXXX1 Ownership Trace enabled
		XXXX1X Data Trace enabled
		XXX1XX Program Trace enabled
		XX1XXX Watchpoint Trace enabled
		X1XXXX Reserved
		1XXXXX Data Acquisition Trace enabled

1. This field may be updated by hardware in response to watchpoint triggering or external hardware trigger inputs if not already enable for tracing by a previous direct write to DC1. Direct writes to this field to enable one or more trace types take precedence over hardware updates. Refer to Watchpoint Trigger (WT, PTSTC, PTETC, DTSTC, DTETC) registers for more information on watchpoint triggering. Refer to External Hardware Trigger Controls for more information on external hardware triggering.

Note

The Output Port Mode Control bit (OPC) and MCKO Clock Divide Ratio bits (MCK_DIV) MUST ONLY be modified during system reset or debug mode to insure correct output port and output clock functionality. It is also recommended that all other bits of the DC1 also only be modified in one of these two modes.

73.4.4 Nexus Development Control Registers 2 & 3 (DC2, DC3)

Nexus Development Control Registers 2 and 3 are used to control output signaling on the Nexus 3 module. A table of watchpoints can be found in the Core Debug Support chapter.

Development Control Register 2 is shown in Figure 73-4 and its fields are described in Table 73-12.

1. Refer to Table 73-6 for implemented EVCODEs.

73.4.6 Development Status Register (DS)

The Development Status Register is used to report system debug status. When Debug Mode is entered or exited, or an SoC- or core-defined Low Power Mode is entered (see note below), a Debug Status Message is transmitted with DS[31:24]. The external tool can read this register at any time.

Nexus Reg# - 0x4; DCR - 409; Read-only; Reset - 0x0

25:0	—	Reserved for future functionality (read as 0)

73.4.7 Watchpoint Trigger (WT, PTSTC, PTETC, DTSTC, DTETC) registers

The Watchpoint Trigger Registers allows the watchpoints defined within the Nexus1 logic to trigger actions. These watchpoints can control Program and/or Data Trace enable and disable. The control bits can be used to produce a related "window" for triggering Trace Messages. Watchpoint trigger register WT is used to control triggering by a single selected watchpoint. The Program Trace Start Trigger Control (PTSTC), Program Trace End Trigger Control (PTETC), Data Trace Start Trigger Control (DTSTC), and Data Trace End Trigger Control (DTETC) are used for extended trigger controls for the respective function. If multiple watchpoints are desired for triggering, or a watchpoint beyond watchpoint #13 is required, then one or more of the extended watchpoint trigger registers may be used. A field encoding of 4'b1111 in one of the WT register fields enables the corresponding extended trigger register. For all other WT field encodings, the corresponding extended trigger register is disabled and the contents are ignored. Note that

direct writes to enable program trace and/or data trace in DC1 will override these controls, and trace will remain enabled until another direct write to DC1 to disable program and/or data trace occurs.

When a start trigger is detected, the designated trace features become enabled, and the corresponding enable bits of the DC1 register are set. Whenever a stop trigger is detected, the designated trace features become disabled, and the corresponding enable bits of the DC1 register are cleared. If the same trigger condition is used for both start and stop triggering, then the designated trace features will toggle between being enabled and disabled at each occurrence of the trigger condition. Similarly, if start and stop triggers for a trace feature occur simultaneously, then the designated trace feature will toggle between enabled and disabled depending on the enable state at the time of the trigger events. For example, if tracing is enabled, and a start and stop trigger occur simultaneously, then tracing will be disabled. Direct writes of the DC1 register take precedence over any trace feature enable state that is derived from watchpoint triggering. A table of watchpoints can be found in the Core Debug Support chapter.

Nexus Reg# - 0xB; DCR - 375; Read/Write; Reset - 0x0

0	STEN	Stall Enable 0 - Stalling is disabled 1 - Stalling is enabled

Figure 73-15. Nexus Overrun Control Register Fields

73.4.10 Data Trace Control Register (DTC) register

The Data Trace Control Register controls whether DTM Messages are restricted to reads, writes, or both for a user programmable address range. In addition, control is provided to restrict data trace message generation to only those load or store accesses that are not stack-related, in order to minimize required data trace message bandwidth.

There are four Data Trace channels controlled by the DTC for the Nexus 3 module. Channels can be programmed to trace data accesses or instruction accesses, but not independently.

Nexus Reg# - 0xD; DCR - 376; Read/Write; Reset - 0x0

Figure 73-16. Data Trace Control Register

The following table details the Data Trace Control register fields.

Table 73-22. DTC field descriptions

Bits	Name	Description
31:30	RWT1	Read/Write Trace 1
		00 No trace enabled
		X1 Enable Data Read Trace
		1X Enable Data Write Trace
29:28	RWT2	Read/Write Trace 2
		00 No trace enabled
		X1 Enable Data Read Trace
		1X Enable Data Write Trace
27:26	RWT3	Read/Write Trace 3
		00 No trace enabled
		X1 Enable Data Read Trace
		1X Enable Data Write Trace
25:24	RWT4	Read/Write Trace 4
		00 No trace enabled
		X1 Enable Data Read Trace
		1X Enable Data Write Trace
23:16	—	Reserved for future functionality (read as 0)

Table continues on the next page...

Table 73-22. DTC field descriptions (continued)

Bits	Name	Description
15	STDC1	Stack Trace Disable Control 1
		0 Tracing of stack accesses are not disabled for range 1
		1 Tracing of stack accesses are disabled for range 1; data accesses using GPR R1 in effective address computations are not traced and do not generate data range watchpoint outputs
14	STDC2	Stack Trace Disable Control 2
		0 Tracing of stack accesses are not disabled for range 2
		1 Tracing of stack accesses are disabled for range 2; data accesses using GPR R1 in effective address computations are not traced and do not generate data range watchpoint outputs
13	STDC3	Stack Trace Disable Control 3
		0 Tracing of stack accesses are not disabled for range 3
		1 Tracing of stack accesses are disabled for range 3; data accesses using GPR R1 in effective address computations are not traced and do not generate data range watchpoint outputs
12	STDC4	Stack Trace Disable Control 4
		0 Tracing of stack accesses are not disabled for range 4
		1 Tracing of stack accesses are disabled for range 4; data accesses using GPR R1 in effective address computations are not traced and do not generate data range watchpoint outputs
11:8	—	Reserved for future functionality (read as 0)
7	RC1	Range Control 1
		0 Condition trace on address within range
		1 Condition trace on address outside of range
6	RC2	Range Control 2
		0 Condition trace on address within range
		1 Condition trace on address outside of range
5	RC3	Range Control 3
		0 Condition trace on address within range
		1 Condition trace on address outside of range
4	RC4	Range Control 4
		0 Condition trace on address within range
		1 Condition trace on address outside of range
3	DI	Data Access / Instruction Access Trace
		0 Condition trace on data accesses
		1 Condition trace on instruction accesses
		The support for monitoring instruction accesses is not guaranteed to be present in all versions of the Nexus 3 module.
		The setting of the DI bit also affects the information provided on the data trace port outputs (See the "Data Trace Port Signals" section in the Core Debug Support chapter.)
2:0	—	Reserved for future functionality (read as 0)

73.4.11 Data Trace Start Address Registers (DTSA1-4)

The Data Trace Start Address Registers define the start addresses for each trace channel.

Data Trace Start Address																															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Nexus Reg# - 0x15; DCR - 408; Read/Write; Reset - 0x0

Figure 73-24. Data Trace End Address 4 (DTEA4) register

Table 73-23 illustrates the range that will be selected for Data Trace for various cases of DTSA being less than, greater than, or equal to DTEA.

Table 73-23. Data trace - address range options

Programmed values	Range Control Bit Value	Range Selected	
DTSA < DTEA	0	DTSA ->	<- DTEA
DTSA < DTEA	1	<- DTSA	DTEA ->
DTSA > DTEA	N/A	Invalid Range - no trace	
DTSA = DTEA	N/A	Invalid Range - no trace	

Note

DTSA must be less than DTEA in order to guarantee correct Data Write/Read Traces. Data Trace ranges are *inclusive* of the DTSA and DTEA addresses for Range Control settings indicating "within range," and are *exclusive* of the DTSA and DTEA addresses for Range Control settings indicating "outside of range."

Accesses that meet the range and access type qualifiers will cause assertion of a watchpoint output for Ranges 1, 2, and 3. There are three dedicated watchpoint outputs, one for each DTSA/DTEA sets 1, 2, and 3. Range 4 does not provide a watchpoint output. Note that when DTC_{DI}=1, all instruction fetches and prefetches (including discarded prefetches) are monitored, and thus these range watchpoints differ from the IACx watchpoint outputs, which are not asserted for instructions that are not executed (i.e. when the instruction prefetch is discarded).

73.4.13 Read/Write Access Control/Status (RWCS) register

The Read Write Access Control/Status Register provides control for Read/Write Access. Read/Write access provides DMA-like access to memory-mapped resources on the AHB System bus either while the processor is halted, or during runtime. Control is provided over access type, size, count, and certain bus attributes.

Note that the internal CPU interfaces to the caches and local memory are not accessible or utilized by this mechanism. Since the external interface is used, base address port settings are used to access local memory, and not the settings of local memory control register base address values.

0The RWCS Register also provides Read/Write Access Status information per Table 73-25.

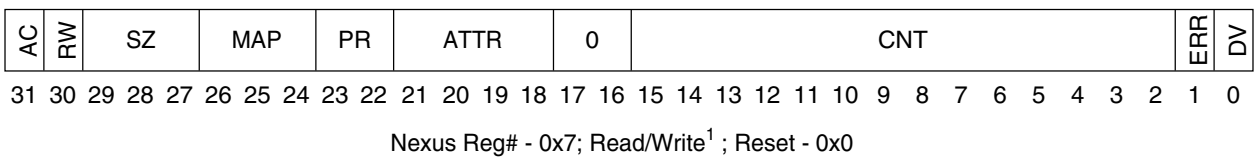

Figure 73-25. Read/Write Access Control/Status (RWCS) register

NOTES:

[1]ERR and DV are read-only

Table 73-24. RWCS field description

Bits	Name	Description
RWCS[31]	AC	Access Control
		0 End access/ Access has completed
		1 Start access
RWCS[30]	RW	Read/Write Select
		0 Read access
		1 Write access
RWCS[29:27]	SZ	Word Size
		000 8-bit (byte)
		001 16-bit (half-word)
		010 32-bit (word)
		011 64-bit (doubleword, requires two passes through RWD)
		100 - 111 Reserved (default to word)
RWCS[26:24]	MAP	MAP Select
		000 Primary memory map
		001-111 Reserved

Table continues on the next page...

Table 73-24. RWCS field description (continued)

Bits	Name	Description
RWCS[23:22]	PR[1]	Read/Write Access Priority
		00 Reserved (default to highest priority)
		01 Reserved (default to highest priority)
		10 Reserved (default to highest priority)
		11 Highest access priority
RWCS[21:18]	ATTR	Access Attributes
		0xxx Reserved
		1xxx Reserved
		x0xx **p_d_hprot[4]** driven to 0 for accesses

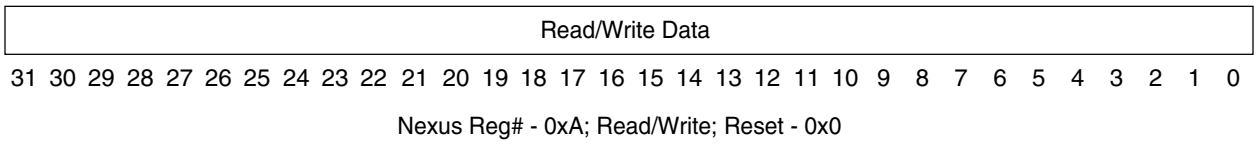
		xx1x **p_d_hprot[3]** driven to 1 for accesses
		xxx0 **p_d_hprot[2]** driven to 0 for accesses
		xxx1 **p_d_hprot[2]** driven to 1 for accesses
RWCS[17:16]	—	RES - Reserved for future functionality
RWCS[15:2]	CNT	Access Control Count
		hhhh Number of accesses of word size SZ
RWCS[1]	ERR[2, 2]	Read/Write Access Error (see Table 73-25)
RWCS[0]	DV[2]	Read/Write Access Data Valid (see Table 73-25)



1. The priority functionality is not currently implemented.
2. ERR and DV are read-only.

Table 73-25. Read/Write Access Status Bit Encoding

Read Action	Write Action	ERR	DV
Read Access has not completed	Write Access completed without error	0	0
Read Access error has occurred	Write Access error has occurred	1	0
Read Access completed without error	Write Access has not completed	0	1
Not Allowed	Not allowed	1	1

73.4.14 Read/Write Access Data (RWD) register

The Read/Write Access Data (RWD) register provides the data to/from system bus memory-mapped locations when initiating a read or a write access.

Nexus Reg# - 0xA; Read/Write; Reset - 0x0

Figure 73-26. Read/Write Access Data (RWD) register

Read/Write accesses to the AHB require that the debug firmware properly retrieve/place the data in the RWD. Table 73-26 shows the proper placement of data into the RWD. Note that doubleword transfers require two passes through RWD.

Table 73-26. RWD data placement for ransfers

Transfer Size and byte offset	RWA(2:0)	RWCS[SZ]	RWD			
			31:24	23:16	15:8	7:0
Byte	x x x	0 0 0	-	-	-	X
Half	x x 0	0 0 1	-	-	X	X
Word	x 0 0	0 1 0	X	X	X	X
Doubleword	0 0 0	0 1 1				
first RWD pass (low order data)			X	X	X	X
second RWD pass (high order data)			X	X	X	X

Table Notes:

"X" indicates byte lanes with valid data

"-" indicates byte lanes that will contain unused data.

Table 73-27 shows the mapping of RWD bytes to byte lanes of the AHB read and write data buses.

Table 73-27. RWD byte lane mapping

Transfer Size and byte offset	RWA(2:0)	RWD			
		31:24	23:16	15:8	7:0

Doubleword @000	0 0 0				
first RWD pass		AHB[31:24]	AHB[23:16]	AHB[15:8]	AHB[7:0]
second RWD pass		AHB[63:56]	AHB[55:48]	AHB[47:40]	AHB[39:32]

Table Notes:

"-" indicates byte lanes that will contain unused data.

73.4.15 Read/Write Access Address (RWA)

The Read/Write Access Address Register provides the system bus address to be accessed when initiating a read or a write access.

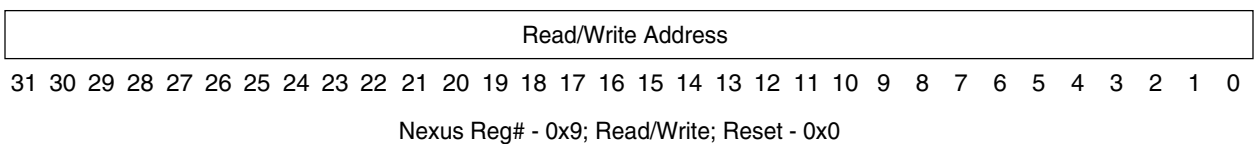

Figure 73-27. Read/Write Access Address (RWA) register

73.5 Nexus 3 Register Access via JTAG/OnCE

Access to Nexus 3 register resources is enabled by loading a single instruction ("*NEXUS3-ACCESS*") into the JTAG Instruction Register (IR) (OnCE OCMD register). For the Nexus 3 block, the OCMD value is 0b0001111100.

Once the NEXUS3-ACCESS instruction has been loaded, the JTAG/OnCE port allows tool/target communications with all Nexus 3 registers according to the register map in Table 73-8.

Reading/writing of a Nexus 3 register then requires two (2) passes through the Data-Scan (DR) path of the JTAG state machine. (See IEEE 1149.1 (JTAG) RD/WR sequences.)

1. The first pass through the DR selects the Nexus 3 register to be accessed by providing an index (see Table 73-8), and the direction (read/write). This is achieved by loading an 8-bit value into the JTAG Data Register (DR). This register has the following format:

(7bits)	(1 bit)
Nexus Register Index	R/W

RESET Value: 0x00

Nexus Register Index	Selected from values in Table 73-8
Read/Write (R/W):	0 - Read 1 - Write

2. The second pass through the DR then shifts the data in or out of the JTAG port, LSB first.
   a. During a read access, data is latched from the selected Nexus register when the JTAG state machine passes through the "Capture-DR" state.
   b. During a write access, data is latched into the selected Nexus register when the JTAG state machine passes through the "Update-DR" state.

73.6 Nexus 3 Register Access via Software

Access to most Nexus 3 register resources by software is supported by mapping the Nexus 3 registers to privileged DCRs (device control registers) that are accessible via the **mfdcr** and **mtdcr** instructions. It is intended that these access only occur when no possible conflicts with hardware-based accesses are possible. A conflict between hardware and software accesses will produce undefined results. Table 73-8 shows the mappings of Nexus 3 registers to DCR numbers. Software writes to Nexus 3 register resources are blocked when the **nex_sfwcntl_en** input signal is negated, without signaling an exception. Note that the Nexus 3 Read/Write Access functionality is not available to software, since software can use load and store instructions to access memory.

73.7 Nexus Message Fields

Nexus messages are comprised of fields. Each field contains a distinct piece of information within a message, and each message contains multiple fields. Messages are transferred in packets over the Auxiliary Output protocol. A packet is a collection of fields. A packet may contain any number of fixed length fields, but may contain at most one variable length field. The variable length field must be the last field in a packet. The following sub-sections describe a subset of the message field types.

73.7.1 TCODE Field

The TCODE field is a 6-bit fixed length field that identifies the type of message and its format. The field encodings are assigned by IEEE-ISTO 5001.

73.7.2 Source ID Field (SRC)

Each Nexus module in a device is identified by a unique Client Source Identification Number. The number assigned to each Nexus module is determined by the SoC integrator, and is provided on the **nex3_ext_src_id[0:3]** input signals. Multi-threaded processors may assign additional source ID information to indicate which thread a message is associated with. The Nexus 3 module implements a 4-bit fixed length Source ID field consisting of a Client Source ID.

73.7.3 Relative Address Field (U-ADDR)

The non-sync forms of the Program and Data Trace messages include addresses that are relative to the address that was transmitted in the previous Program or Data Trace message, respectively. The relative address format is compliant with IEEE-ISTO 5001 and is designed to reduce the number of bits transmitted for address fields.

The relative address is generated by XORing the new address with the previous, and then using only the results up to the most significant '1'. To recreate the original address, the relative address is XORed with the previously decoded address.

The relative address of a Program Trace message is calculated with respect to the previous Program Trace message, regardless of any address information that may have been sent in any other trace messages in the interim between the two Program Trace messages.

The relative address of a Data Trace message is calculated with respect to the previous Data Trace message, regardless of any address information that may have been sent in any other trace messages in the interim between the two Data Trace messages.

Program trace messages also provide the execution mode status in the least significant bit of the **reconstructed** address field. A value of '0' indicates that preceding instruction count and history information should be interpreted in a non-VLE context. A value of '1' indicates that the preceding instruction count and history information should be interpreted in a VLE context.

Previous Address (A1) =0x0003FC01, New Address (A2) = 0x0003F365

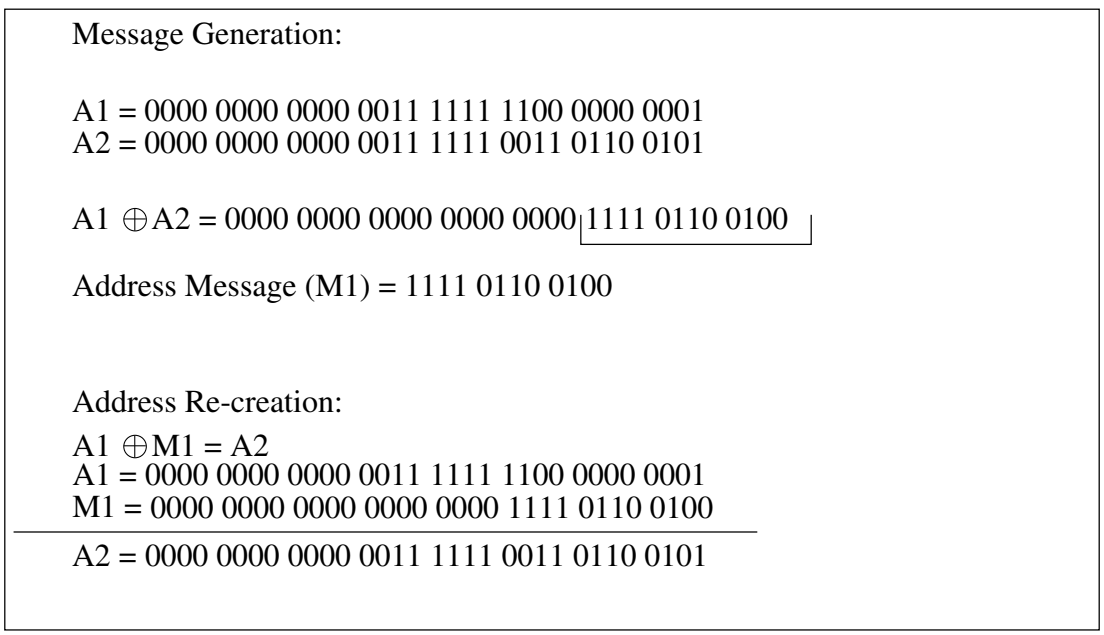

Figure 73-28. Relative address generation and recreation

73.7.4 Full Address Field (F-ADDR)

Program Trace synchronization messages provide the full address associated with the trace event (leading zeroes may be truncated) with the intent of providing a reference point for development tools to operate from when reconstructing relative addresses. Synchronization messages are generated at significant mode switches and are also generated periodically to ensure that development tools are guaranteed to have a reference address given a sufficiently large sample of trace messages. Program trace messages also provide the execution mode status in the least significant bit of the **reconstructed** address field. A value of '0' indicates that preceding instruction count and

history information should be interpreted in a non-VLE context. A value of '1' indicates that the preceding instruction count and history information should be interpreted in a VLE context.

73.8 Nexus Message Queues

The Nexus 3 module implements internal message queues capable of storing up to three messages per cycle into a small initial queue, which then fills a larger queue at up to two messages per cycle. Messages that enter the queues are transmitted in the order in which they are received.

If more than three messages attempt to enter the queue in the same cycle, the highest priority messages are stored and the remaining message(s) will be dropped due to a collision. Collision events are expected to be rare.

The Overrun Control register (OVCR) controls the Nexus behavior as the message queue fills. The Nexus block may be programmed to:

- Allow the queue to overflow, drain the contents, queue an overrun error message and resume tracing.
- Stall the processor when the queue utilization reaches the selected threshold.
- Suppress selected message types when the queue utilization reaches the selected threshold.

73.8.1 Message Queue Overrun

In this mode, the message queue will stop accepting messages when an overrun condition is detected. The contents of the queues will be allowed to drain until empty. Incoming messages are discarded until the queue is emptied. Once empty, an overrun error message is enqueued that contains information about the types of messages that were discarded due to the overrun condition.

73.8.2 CPU Stall

In this mode, processor instruction issue is stalled when the queue utilization reaches the selected threshold. The processor is stalled long enough to drop one threshold level below the level that triggered the stall. For example, if stalling the processor is triggered at 1/4 full, the stall will stay in effect until the queue utilization drops to empty. There may be

significant skid from the time that the stall request is made until the processor is able to stop completing instructions. This skid should be taken into consideration when programming the threshold. Refer to Nexus Overrun Control Register (OVCR) for complete programming options.

73.8.3 Message Suppression

In this mode, the message queue will disable selected message types when the queue utilization reaches the selected threshold. This allows lower bandwidth tracing to continue and possibly avoid an overrun condition. If an overrun condition occurs despite this message suppression, the queue will respond according to the behavior described in Message Queue Overrun. Suppressed message types are reported in the error message if they occur after overrun in addition to other discarded message types. Once triggered, message suppression will remain in effect until queue utilization drops to the threshold below the level selected to trigger suppression.

73.8.4 Nexus Message Priority

Nexus messages may be lost due to contention with other message types under the following circumstances:

- TBD - need examples
- More than three messages are generated in the same cycle

Table 73-28 lists the various message types and their relative priority from highest to lowest.

Up to three message requests can be queued into the message buffer in a given cycle. If more than three message requests exist in a given cycle, the three highest priority message classes are queued into the message buffer. The remaining messages that did not successfully queue into the message buffer in that cycle will generate subsequent responses, as detailed in Table 73-28.

The CPU is capable of completing two instructions per cycle. If multiple trace messages need to be queued at the same time, they will be queued with the following priority: Instruction 0 (oldest instruction) (WPM ->DQM -> PCM_{PIDMSG} -> OTM -> BTM -> DTM)-> Instruction1 (newer instruction) (WPM -> DQM -> OTM -> BTM -> DTM). As many as three messages may be simultaneously queued. Note that for the cycle following a dropped PTM, non-periodic OTM, or DQM message, only two other messages may be queued in addition to the dropped Error Message.

Watchpoint Messages from instructions that complete at the same time or events that occur during the same cycle will be combined.

Table 73-28. Message Type Priority and Message Dropped Responses

Message Type	Message	Priority	Message Dropped Response
Error	Error	0 (highest)	N/A[1, 1]
WP (Watchpoint Trace)	WPM (Watchpoint Message)	1	N/A[1]
DQ (Data Acquisition)	DQM (Data Acquisition Message)	2	DQM Error Message
Program Trace (PID MSG)	PCM - PID/NPIDR update (Program Correlation Message)	2	OTM Error Message
OT (Ownership)	OTM - PID/NPIDR update (Ownership Trace Message)	2	OTM Error Message[2]
Program Trace	BTM (Branch Trace Message)	2	BTM Error Message, Sync upgrade next BTM
	Sync (Program Sync Message)	3	Sync upgrade next BTM
	RFM (Resource Full for Instruction counter or history buffer)	4	BTM Error Message Sync upgrade next BTM
	DS (Debug Status Message)	5	Sync upgrade next BTM
	PCM (Program Correlation Message)	6	BTM Error Message Sync upgrade next BTM
DT (Data Trace)	DTM (Data Trace Message)	7	Sync upgrade next DTM
OT (Ownership)	OTM - Periodic update (Ownership Trace Message)	8 (lowest)	none

1. Error and Watchpoint messages are not dropped due to collisions, due to their priority.
2. Message will always be dropped if program trace is enabled, and program correlation messages for PID messages are not masked (Event Code = 0101). No error message is sent for this case since the PID value is contained in the higher priority message.

73.8.5 Data Acquisition Message Priority Loss Response

If a Data Acquisition Message (DQM) loses arbitration due to contention with higher priority messages, an error message will be generated to indicate that a DQM has been lost due to contention.

73.8.6 Ownership Trace Message Priority Loss Response

If an Ownership Trace message (OTM) due to software updates to the Process ID state loses arbitration due to contention with higher priority messages other than a program correlation message with EVCODE = 0101 (PID update), an error message will be generated to indicate that a OTM has been lost due to contention. If the pending OTM is a periodic update, the event is dropped without generating an error message.

73.8.7 Program Trace Message Priority Loss Response

If a Program Trace message (PTM) loses arbitration due to contention with higher priority messages, and the discarded PTM is a Program Correlation message, a Resource Full message for instruction count or history buffer, or a Branch Trace message, then an Error message is generated to indicate that branch trace information has been lost, and the next Branch Trace message will be upgraded to a sync-type message.

If the discarded PTM is a Program Correlation message with PID information (EVCODE=0101), the Error message will indicate a dropped OTM and a dropped Program Trace (Error code = xxxx11xx).

73.8.8 Program Trace Sync Message Priority Loss Response

If a Program Trace Sync message (SYNC) loses arbitration due to contention with higher priority messages, the Sync event is discarded, and the next Branch Trace message will be upgraded to a sync-type message.

73.8.9 Data Trace Message Priority Loss Response

If a Data Trace message (DTM) loses arbitration due to contention with higher priority messages, the DTM event is discarded, and the next DTM will be upgraded to a sync-type message.

73.9 Debug Status messages

Debug Status Messages report low power mode and debug status. Debug Status messages are enabled when Nexus 3 is enabled. Entering/exiting Debug Mode as well as entering, exiting, or changing Low Power Mode(s) will trigger a Debug Status message, indicating the value of the most significant byte in the Development Status register. Debug status information is sent out in the following format:

(8 bits)	(4 bits)	(6 bits)
DS[31:24]	Src. Proc.	TCODE (000000)

Fixed length = 18 bits

Figure 73-29. Debug Status message format

73.10 Error messages

Error messages are enabled whenever the debug logic is enabled. There are two conditions that will produce an error message, each receiving a separate error type designation:

- A message is discarded due to contention with other (higher priority) message types. These errors will have an Error Type value of 1.
- The message queue overruns. After the queue is drained, an error message is enqueued with an error code that indicates what types of messages were discarded during the interim. These errors will have an Error Type value of 0.

Note

The OVCR Register can be used in order to alleviate potential overrun situations.

Error information is messaged out in the following format (also see Table 73-3 and Table 73-4):

(6 bits)	(4 bits)	(4 bits)	(6 bits)
Error Code	Error Type	Src. Proc.	TCODE (001000)

Fixed length = 20 bits

Figure 73-30. Error message format

73.11 Ownership trace

This section details the ownership trace features of the Nexus 3 module.

73.11.1 Overview

Ownership trace provides a macroscopic view, such as task flow reconstruction, when debugging software written in a high level (or object-oriented) language. It offers the highest level of abstraction for tracking operating system software execution. This is especially useful when the developer is not interested in debugging at lower levels.

73.11.2 Ownership Trace Messaging (OTM)

Ownership trace information is messaged via the auxiliary port using an Ownership Trace Message (OTM). processors contain a *PowerISA 2.06* defined "Process ID" register within the CPU. It is updated by the operating system software to provide task/process ID information. The contents of this register are replicated on the pins of the processor and connected to Nexus. The Process ID (PID) register value can be accessed using the **mfspr/mtspr** instructions.

Note

The CPU includes a Process ID register (PID0), thus the Nexus UBA functionality is not implemented.

In addition, to decouple trace information from the PID0 register and to provide a full independent 32-bit process ID for debug use, the Nexus PID Register (NPIDR) may be used instead of PID0 to provide OTM process ID information. It is updated by the operating system software to provide task/process ID information. The Nexus Process ID (NPIDR) register value can be accessed using the **mfspr/mtspr** instructions. This register is accessible in user or supervisor mode.

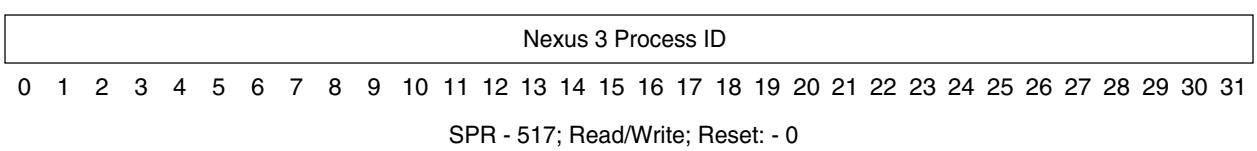

Figure 73-31. Nexus 3 Process ID Register (NPIDR)

Note

OS updates to NPIDR should be performed in addition to normal PID0 updates when a process switch occurs, in order to properly generate OTM messages with new process ID information when NPIDR is selected for OTM use.

The process ID source (PID0 or NPIDR) is selected by the setting of the $DC1_{OTS}$ control bit.

There are two conditions that will cause an Ownership Trace Message when Ownership Trace is enabled:

- When the PID0 register is written to by the processor and $DC1_{OTS}$ indicates PID0 should be used, or when the NPIDR register is written to by the processor and $DC1_{OTS}$ indicates NPIDR should be used, the data is latched within Nexus, and is messaged out via the auxiliary port, allowing development tools to trace ownership flow. However, if Program Trace is enabled, and program correlation messages for PID updates are not masked (Event Code = 0101), then an OTM will not be generated for an update to the selected process ID register, since the program correlation message will provide this process ID update information.
- Periodically, at least once every 256 messages, the most recent state of the selected process ID register is messaged out. The resulting Ownership Trace message will indicate in the PID Index sub-field that PID0/NPIDR status is being reported and the most recent value of the PID0/NPIDR register will be conveyed in the Process ID value sub-field. These periodic Ownership Trace message events can be disabled by setting $DC1_{POTD}$.

Ownership trace information is messaged out in the following format:

(1-32 bits)	(4 bits)	(4 bits)	(6 bits)
Process ID	PID Index (0000)	Src. Proc.	TCODE (000010)

Variable length = 15-46 bits

Figure 73-32. Ownership Trace Message format

73.12 Program trace

This section details the program trace mechanism supported by Nexus3 for the processor. Program trace is implemented via Branch Trace Messaging (BTM) as per the **IEEE-ISTO 5001** standard definition. Branch Trace Messaging for processors is accomplished by snooping the internal address bus (between the CPU and Cache), attribute signals, and CPU Status (**p_mode[0:3]**, **p_pstat_pipe{0,1}[0:5]**).

73.12.1 Branch Trace Messaging types

Traditional Branch Trace Messaging facilitates program trace by providing the following types of information:

- Messaging for taken direct branches includes how many sequential instructions were executed since the last taken branch or exception, including the taken direct branch. Branch instructions are included in the count of sequential instructions.
- Messaging for taken indirect branches and exceptions includes how many sequential instructions were executed since the last taken branch or exception and the unique portion of the branch target address or exception vector address. Branch instructions are included in the count of sequential instructions. For taken indirect branches that trigger generation of a message, the branch is also included in the count.

Branch History Messaging facilitates program trace by providing the following information.

- Messaging for taken indirect branches and exceptions includes a) how many sequential instructions (I-CNT) were executed since the last predicate instruction, taken/not taken direct branch, taken/not-taken indirect branch, or exception, b) the unique portion of the branch target address or exception vector address, and c) a branch/predicate instruction history field. Each bit in the history field represents a direct branch or predicated instruction where a value of one (1) indicates taken, and a value of zero (0) indicates not taken. Certain instructions (**zvselh**) generate a pair of predicate bits that are both reported as consecutive bits in the history field. Not-taken indirect branches will generate a history bit with a value of zero (0). Instructions that generate history bits are not included in instruction counts. For taken indirect branches that trigger generation of this message type, the branch is included in the count, but not in the history field.

73.12.1.1 Indirect Branch Message instructions

Table 73-29 shows the types of instructions and events that cause Indirect Branch Messages or Branch History Messages to be encoded.

Table 73-29. Indirect Branch Message sources

Source of Indirect Branch Message	Instructions / Detail
Taken branch relative to a register value	**bcctr, bcctrl, bclr, bclrl, se_bctr, se_bctrl, se_blr, se_blrl**
System Call / Trap exceptions taken	**se_sc, tw**
Return from interrupts / exceptions	**se_rfi, se_rfci, se_rfdi**
Exit from reset with Program Trace Enabled	**Indirect branch with Sync, target address is initial instruction, count = 1**

73.12.1.2 Direct Branch Message Instructions

Table 73-30 shows the types of instructions that will cause Direct Branch Messages or will toggle a bit in the instruction history buffer to be messaged out in a Resource Full Message or Branch History Message.

Table 73-30. Direct Branch Message sources

Source of Direct Branch Message	Instructions
Taken direct branch instructions Instruction Synchronize	**b, ba, bl, bla, bc, bca, bcl, bcla, se_b. se_bc, se_bl, e_b, e_bc, e_bl, e_bcl, se_isync**

73.12.1.3 BTM using Branch History Messages

Traditional BTM Messaging can accurately track the number of sequential instructions between branches, but cannot accurately indicate which instructions were conditionally executed, and which were not.

Branch History Messaging solves this problem by providing a predicated instruction history field in each Indirect Branch Message. Each bit in the history represents a predicated instruction or direct branch, or a not-taken indirect branch. A value of one (1) indicates the conditional instruction was executed or the direct branch was taken. A value of zero (0) indicates the conditional instruction was not executed or the branch was not taken. Certain instructions (**zvselh**) generate a pair of predicate bits that are both reported as consecutive bits in the history field.

Branch History Messages solve predicated instruction tracking and save bandwidth since only indirect branches cause messages to be queued.

73.12.1.4 BTM using Traditional Program Trace Messages

Based on the PTM bit in the DC1 Register, Program Tracing can utilize either Branch History Messages (PTM = 1) or traditional Direct/Indirect Branch Messages (PTM = 0).

Branch History will save bandwidth and keep consistency between methods of Program Trace, yet may lose temporal order between BTM messages and other types of messages. Since direct branches are not messaged, but are instead included in the history field of the Indirect Branch History Message, other types of messages may enter the FIFO between Branch History Messages. The development tool cannot determine the ordering of "events" that occurred with respect to direct branches simply by the order in which messages are sent out.

Traditional BTM messages maintain their temporal ordering because each event that can cause a message to be queued will enter the FIFO in the order it occurred and will be messaged out maintaining that order.

73.12.2 BTM Message For mats

The Nexus 3 block supports three types of traditional BTM Messages - Direct, Indirect, and Synchronization Messages. It supports two types of branch history BTM Messages - Indirect Branch History, and Indirect Branch History with Synchronization Messages.

73.12.2.1 Indirect branch messages (history)

Indirect branches include all taken branches whose destination is determined at run time, interrupts, and exceptions. If $DC1_{PTM}$ is set to '1', indirect branch information is messaged out in the following format:

(1-32 bits)	(1-32 bits)	(1-8 bits)	(1 bit)	(4 bits)	(6 bits)
Branch History	Relative Address	Sequence Count	(0)	Source Proc.	TCODE (011100)

Max length = 83 bits; Min length = 14 bits

Figure 73-33. Indirect branch message (history) format

73.12.2.2 Indirect branch messages (traditional)

If $DC1_{PTM}$ is cleared to '0', indirect branch information is messaged out in the following format:

(1-32 bits)	(1-8 bits)	(1 bit)	(4 bits)	(6 bits)
Relative Address	Sequence Count	(0)	Source Proc.	TCODE (000100)

Max length = 51 bits; Min length = 13 bits

Figure 73-34. Indirect branch message format

73.12.2.3 Direct branch messages (traditional)

Direct branches (conditional or unconditional) are all taken branches whose destination is fixed in the instruction opcode. Direct branch information is messaged out in the following format:

(1-8 bits)	(4 bits)	(6 bits)
Sequence Count	Src. Proc.	TCODE (000011)

Max length = 18 bits; Min length = 11bits

Figure 73-35. Direct Branch message format

Note

When $DC1_{PTM}$ is set, Direct Branch Messages will not be transmitted. Instead, each direct branch, not-taken indirect branch, or predicated instruction will be recorded in the history buffer.

73.12.3 Program Trace Message Fields

The following subsections describe specific fields used for Program Trace messages.

73.12.3.1 Sequential Instruction Count Field (ICNT)

Most of the program trace messages include an instruction count field. For traditional Branch messages, ICNT represents the number of sequential instructions including non-taken branches since the last Direct/Indirect Branch messages. Branch instructions that trigger message generation are included in the ICNT.

For Branch History messages, ICNT represents the number of instructions executed since the last taken/non-taken direct branch, predicate instruction, last taken/not-taken indirect branch, or exception. Branch instructions that trigger message generation are included in the ICNT. Instructions that generate history bits are not included in the ICNT.

The sequential instruction counter overflows after its value reaches 255 and is reset to 0. In addition, the next BTM Message (corresponding to the 256th or later instruction) will be converted to a w/sync type message.

The instruction counter is reset every time the instruction count is transmitted in a message or whenever there is a branch/predicate history event, as well as on exiting from debug mode.

73.12.3.2 Branch/Predicate Instruction History (HIST)

If $DC1_{PTM}$ is set, BTM messaging will use the Branch History format. The branch history (HIST) field in these messages provides a history of branch execution used for reconstructing the program flow. The branch/predicate history buffer stores information about branch and predicate instruction execution. The buffer is implemented as a left-shifting register. The buffer is preloaded with a one (1), which acts as a stop bit (the most significant 1 in the history field is a termination bit for the field). The pre-loaded bit itself is not part of the history, but is transmitted with the packet.

A value of one (1) is shifted into the history buffer for each taken direct branch (program counter relative branch) or predicate instruction whose condition evaluates to true. A value of zero (0) is shifted into the history buffer for each not-taken branch (including indirect branch instructions) or predicate instruction whose condition evaluates to false. For the **zvselh** instruction, two bits are shifted in, corresponding to the low element (shifted in first) and the high element (shifted in second) conditions.

This history buffer information is transmitted as part of an Indirect Branch with History message, as part of a Program Correlation message, or as part of a Resource Full message if the history buffer becomes full. The history buffer is reset every time the history information is transmitted in a message, as well as on exiting from debug mode.

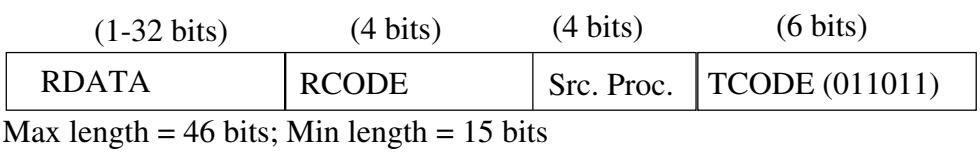
Table 73-31. Branch/Predicate history events

Branch/Predicate History Event	History Bit(s)	Relevant Instructions
Not taken register indirect branches	0	**bcctr, bcctrl, bclr, bclrl**
Not taken direct branches	0	**b, ba, bc, bca, bla, bcla, bl, bcl**
Taken direct branches	1	**b, ba, bc, bca, bla, bcla, bl, bcl**[1]
zvselh instruction	00,01,10, or 11	**zvselh**

1. If the EVCODE for direct branch function calls is not masked in DC4, taken **bl** and **bcl** instructions will generate Program Correlation Messages and will not be logged in the history buffer.1

73.12.3.3 Execution Mode Indication

In order for a development tool to properly interpret instruction count and history information, it must be aware of the execution mode context of that information. VLE instructions will be interpreted differently from non-VLE instructions.



Program trace messages provide the execution mode status in the least significant bit of the **reconstructed** address field. A value of '0' indicates that preceding instruction count and history information should be interpreted in a non-VLE context. A value of '1' indicates that the preceding instruction count and history information should be interpreted in a VLE context.

73.12.4 Resource Full Messages

The Resource Full Message is used in conjunction with Branch Trace and Branch History Messages. The Resource Full Message is generated when either the internal branch/ predicate history buffer is full, or if the BTM Instruction sequence counter (I-CNT) overflows. If synchronization is needed at the time this message is generated, the synchronization is delayed until the next Branch Trace Message that is not a Resource Full Message.

For history buffer overflow, the Resource Full Message transmits a Resource Code (RCODE) of 0b0001 and the current contents of the history buffer, including the stop bit, are transmitted in the Resource Data (RDATA) field. This history information can be concatenated by the development tool with the branch/predicate history information from subsequent messages to obtain the complete branch/predicate history between indirect changes of flow.

For instruction counter overflow, the Resource Full Message transmits an RCODE of 0b0000 and a value of 0xFF is transmitted in the RDATA field, indicating that 255 sequential instructions have been executed since the last change of flow, or, if program trace is in history mode, since the last instruction that recorded history information.

Max length = 46 bits; Min length = 15 bits

Figure 73-36. Resource Full Message format

The following table shows the RCODE encodings and RDATA information used for Resource Full Messages.

Table 73-32. RCODE encoding

RCODE	Description	RDATA field
0000	Program Trace Instruction counter reached 255 and was reset.	0xFF
0001	Program Trace, Branch / Predicate Instruction History full.	Branch HIstory. This type of packet is terminated by a stop bit set to 1 after the last history bit.

73.12.5 Program Correlation Messages

Program Correlation Messages (PCMs) are used to correlate events to the program flow that may or may not be associated with the instruction stream. The following events will result in a PCM when program trace is enabled:

- When the CPU enters debug mode, a PCM is generated. The instruction count and history information provided by the PCM can be used to determine the last sequence of instructions executed prior to debug mode entry.
- When the CPU first enters a low power mode in which instructions are no longer executed, a PCM is generated. The instruction count and history information provided by the PCM can be used to determine the last sequence of instructions executed prior to low power mode entry.
- Whenever program trace is disabled by any means, a PCM is generated. The instruction count and history information provided by the PCM can be used to determine the last sequence of instructions executed prior to disabling program trace.
- When a "Branch and Link" instruction executes (direct branch function call — **bl/bcl/bla/bcla**-type instructions)
- When program trace becomes masked due to MSR_{PMM}='0' and $DC4_{PTMARK}$='1'.
- When a write to the process ID register selected by $DC1_{OTS}$ (PID0 or NPIDR) is made via a **mtspr** PID0 or **mtspr** NPIDR.

Refer to Table 73-6 for the event codes that are supported in this implementation. Event code masking is available via the EVCDM field of the DC4 register to allow for control over generation of Program Correlation messages for each event type.

Program Correlation is messaged out in the following formats:

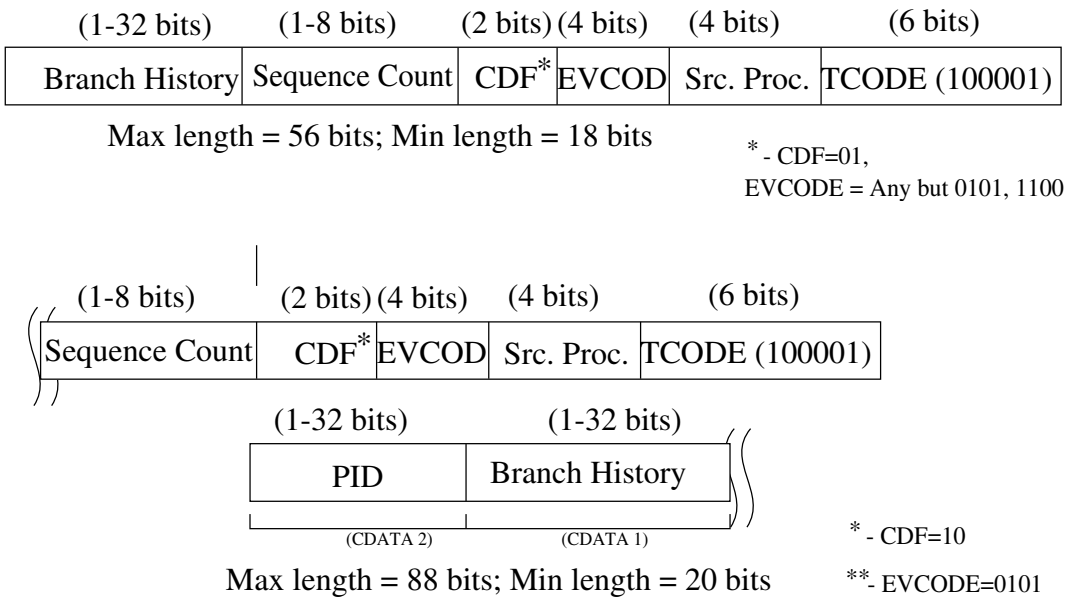


Figure 73-37. Program Correlation message formats

73.12.5.1 Program Correlation message generation for PID updates

When a (potentially) new value is established in the selected process ID register via a **mtspr** PID0/NPIDR, a Program Correlation message is generated containing the information regarding the new process ID value. This PCM also contains the current history and instruction count. The message is provided so that address translation information can be processed by the development tool in the proper program flow. The **mtspr** PID0/NPIDR is included in the instruction count information. Note that Ownership Trace Messages (other than the periodic OTM) are redundant with the information provided, and may be disabled to avoid unnecessary message bandwidth or collisions.

73.12.6 Program Trace Overflow Error messages

An Error Message occurs when a new message cannot be queued due to the message queue being full. The FIFO will discard incoming messages until it has completely emptied the queue. Once emptied, an Error Message will be queued. The error encoding will indicate which type(s) of messages attempted to be queued while the FIFO was being emptied.

73.12.7 Program Trace Synchronization messages

By default, program trace messages will perform XOR compression on the branch target address to produce the address field for the message. This compression is consistent with the specification in IEEE-ISTO 5001.

Under some conditions an uncompressed address is sent to provide development tools with a baseline reference address. A Program Trace Synchronization message is messaged via the auxiliary port (provided Program Trace is enabled) for the following conditions (see Table 73-33):

- Initial Program Trace message after exit from system reset or whenever program trace is enabled.
- Upon exiting from a CPU Low Power state.
- Upon exiting from Debug Mode.
- Upon occurrence of queue overrun (can be caused by any trace message), provided Program Trace is enabled.
- Upon assertion of the Event In (**nex_evti_b**) pin if the EIC bits within the DC1 Register have enabled this feature.
- When program trace becomes unmasked due to $MSR_{PMM} \rightarrow$ '1' with $DC4_{PTMARK}$='1'.

Note that the ICNT information for these messages is driven to zero, thus will not always be meaningful for some of these cases.

The format for Program Trace Synchronization messages is as follows:

(1-32 bits)	(1-8 bits)	(1 bit)	(4 bits)	(6 bits)
Full Target Address	Seq. Count (0)	(0)	Source Proc.	TCODE (001001)

Max length = 51 bits; Min length = 13 bits

Exception conditions that result in Program Trace Synchronization are summarized in Table 73-33.

Table 73-33. Program Trace exception summary

Exception Condition	Exception Handling
System Reset Negation	At the negation of JTAG reset (**j_trst_b**), queue pointers, counters, state machines, and registers within the Nexus 3 module are reset. Upon exiting system reset (**p_reset_b**), if Program Trace is already enabled, a Program Trace Sync Message is sent.
Program Trace Enabled	The first Program Trace Message (after Program Trace has been enabled or re-enabled) is a synchronization message.
Exit from Low Power/Debug	Upon exit from a Low Power mode or Debug mode, a Program Trace Sync Message is sent.

Table continues on the next page...

Table 73-33. Program Trace exception summary (continued)

Exception Condition	Exception Handling
Queue Overrun	An Error Message occurs when a new message cannot be queued due to the message queue being full. The FIFO will discard messages until it has completely emptied the queue. Once emptied, an Error Message will be queued. The error encoding will indicate which type(s) of messages attempted to be queued while the FIFO was being emptied. The next BTM message in the queue will be a Program Trace Sync Message.
Event In	If the Nexus module is enabled, a **nex_evti_b** assertion initiates a Program Trace Sync Message if Program Trace is enabled and the EIC bits of the DC1 Register have enabled this feature.

Note that for cases where program trace sync messages are generated due to program trace being enabled, the address contained in the sync message may either be the address of the instruction that caused program trace to be enabled, or may be the address of the first instruction of an exception handler that is executed in response to unsuccessful completion of that instruction.

73.12.8 Program Trace Direct/Indirect Branch with Sync messages

Under some conditions an uncompressed address is sent to provide development tools with a baseline reference address. A Program Trace Synchronization or a Direct/Indirect Branch with Sync message is messaged via the auxiliary port (provided Program Trace is enabled) for the following conditions (see Table 73-33):

- Upon direct/indirect branch after a Program Sync Message was lost due to a collision while attempting to enter the message queue.
- Upon direct/indirect branch after the sequential instruction counter has expired indicating 255 instructions have occurred since the last change of flow.
- When the periodic program trace counter has expired indicating 255 *without-sync* Program Trace messages have occurred since the last *with-sync* message occurred.

Note that the ICNT and History information for the first message will not always be meaningful, since the temporary masking of program trace may result in ambiguous values. Subsequent w/sync messages will not have this issue.

The format for Program Trace Direct/Indirect Branch with Sync Messages is as follows:

(1-32 bits)	(1-8 bits)	(1 bit)	(4 bits)	(6 bits)
Full Target Address	Sequence Count	(0)	Source Proc.	TCODE (001011 or 001100)

Max length = 51 bits; Min length = 13 bits

Figure 73-38. Direct/Indirect Branch with Sync message format

The format for Program Trace Indirect Branch History with Sync. messages is as follows:

(1-32 bits)	(1-32 bits)	(1-8 bits)	(1 bit)	(4 bits)	(6 bits)
Branch History	Full Target Address	Sequence Count	(0)	Source Proc.	TCODE (011101)

Max length = 83 bits; Min length = 14 bits

Figure 73-39. Indirect Branch History w/ Sync. message format

Exception conditions that result in Program Trace Synchronization using a w/Sync message type are summarized in Table 73-34.

Table 73-34. Program Trace Exception Summary for w/Sync BTM messages

Exception Condition	Exception Handling
Periodic Program Trace Sync.	A forced synchronization occurs periodically after 255 non-sync Program Trace Messages have been queued. A Direct/Indirect Branch w/ Sync. Message is queued. The periodic program trace message counter then resets.
Sequential Instruction Count Overflow	After the sequential instruction counter reaches its maximum count (up to 255 sequential instructions may be executed), a forced synchronization occurs. The sequential counter then resets. A Program Trace Direct/Indirect Branch w/ Sync.Message is queued upon execution of the next branch. A Resource Full Message is Queued on the overflow event. If a branch instruction is the 255th instruction to occur, and causes a Program Trace message to be queued, then no Resource Full Message is queued, and the w/Sync message will be queued for the *next* Program Trace Direct/Indirect Branch Message.
Collision Priority	All Messages have the following priority: Instruction 0 (WPM -> DQM -> PCM_{PIDMSG} → OTM → BTM → DTM) → Instruction1 (WPM → DQM → OTM → BTM → DTM), where instruction0 is the oldest instruction. A BTM Message from Instruction1 that attempts to enter the queue at the same time as three higher priority messages from either instruction will be lost. An Error Message will be sent indicating the BTM was lost. The following direct/indirect branch will queue a Direct/Indirect Branch w/ Sync. Message. The count value within this message will reflect the number of sequential instructions executed after the last successful BTM Message was generated. This count will include the branch that did not generate a message due to the collision.

73.12.9 Enabling Program Trace

Program Trace Messaging can be enabled in one of three ways:

- Setting the TM field of the DC1 Register to enable Program Trace

- Using the PTS field of the WT Register to enable Program Trace on Watchpoint hits (watchpoints are configured within the CPU)
- Using the external hardware trace enable input signal (nex_ptm_starttr)
- Filtering of Program Trace messages may be performed using the MSR_{PMM} bit and the setting of $DC4_{PTMARK}$

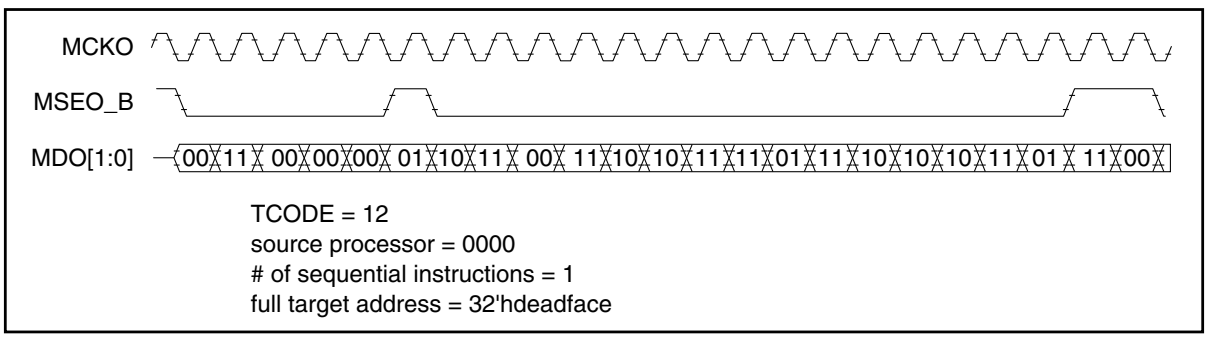

Figure 73-43. Program Trace - Indirect Branch w/ Sync. message

73.13 Data Trace

This section deals with the Data Trace mechanism supported by the Nexus 3 module. Data Trace is implemented via Data Write Messaging (DWM) and Data Read Messaging (DRM), as per the **IEEE-ISTO 5001** standard.

73.13.1 Data Trace Messaging (DTM)

Data Trace Messaging is accomplished by snooping the internal address and data buses, and storing the information for qualifying accesses (based on enabled features and matching target addresses). The Nexus 3 module traces all data access that meet the selected range and attributes.

Note

Data Trace is only performed on the internal data buses. This allows for data visibility for processors that incorporate a data cache. Only CPU initiated accesses will be traced. No DMA accesses to the AHB system bus will be traced.

Data Trace Messaging can be enabled in one of three ways.

- Setting the TM field of the DC1 Register to enable Data Trace.
- Using the DTS field of the WT Register to enable Data Trace on Watchpoint hits (watchpoints are configured within the Nexus1 module).
- Using the external hardware trace enable signal (**nex_dtm_starttr**)

73.13.2 DTM Message formats

The Nexus 3 block supports five types of DTM Messages — Data Write, Data Read, Data Write Synchronization, Data Read Synchronization and Error Messages.

73.13.2.1 Data Write messages

The Data Write message contains the data write value and the address of the write access, relative to the previous Data Trace Message. Data Write message information is messaged out in the following format:

(1-64 bits)	(1-32 bits)	(4 bits)	(1 bit)	(4 bits)	(6 bits)
Data Value(s)*	Relative Address	Data Size	(0)	Src. Proc	TCODE (000101)

Max length = 111 bits; Min length = 17 bits

Figure 73-44. Data Write message format

73.13.2.2 Data Read messages

The Data Read message contains the data read value and the address of the read access, relative to the previous Data Trace message. Data Read message information is messaged out in the following format:

(1-64 bits)	(1-32 bits)	(4 bits)	(1 bit)	(4 bits)	(6 bits)
Data Value(s)*	Relative Address	Data Size	(0)	Src. Proc	TCODE (000110)

Max length = 111 bits; Min length = 17 bits

Figure 73-45. Data Read fessage format

Note

* -based CPUs are capable of generating two (2) reads or writes per clock cycle in cases where multiple registers are accessed with a single instruction (lmw/stmw). These will have a double word pair size encoding (**p_tsiz** = 0b000). In these cases, the Nexus 3 module will send one (1) Data Trace Message with the two 32-bit data values as one combined 64-bit value for each message.

For -based CPUs, the doubleword encoding (**p_tsiz** = 0b000) may also indicate a doubleword access and will be sent out as a single Data Trace Message with a single 64-bit data value.

The debug/development tool will need to distinguish the two cases based on the family of processor.

73.13.2.3 Data Trace Synchronization messages

A Data Trace Write/Read with Sync. message is messaged via the auxiliary port (provided Data Trace is enabled) for the following conditions (see Table 73-35):

- Initial Data Trace Message after exit from system reset or whenever Data Trace is enabled.
- Upon returning from a CPU Low Power state.
- Upon returning from Debug Mode.
- After occurrence of queue overrun (can be caused by any trace message), provided Data Trace is enabled.
- After the periodic data trace counter has expired indicating 255 *without-sync* Data Trace messages have occurred since the last *with-sync* message occurred.
- Upon assertion of the Event In (**nex_evti_b**) pin, the first Data Trace Message will be a synchronization message if the EIC bits of the DC1 Register have enabled this feature.

- Upon Data Trace Write/Read after the previous DTM message was lost due to an attempted access to a secure memory location (for SOC's w/ security).
- Upon Data Trace Write/Read after the previous DTM message was lost due to a collision entering the FIFO between the DTM message and any two of the following: Watchpoint message, Ownership Trace message, or Program Trace message.

Data Trace Synchronization Messages provide the full address (without leading zeros) and insure that development tools fully synchronize with Data Trace regularly. Synchronization messages provide a reference address for subsequent DTMs, in which only the unique portion of the Data Trace address is transmitted. The format for Data Trace Write/Read with Sync. Messages is as follows:

(1-64 bits)	(1-32 bits)	(4 bits)	(1 bit)	(4 bits)	(6 bits)
Data Value	Full Address	Data Size	(0)	Source Proc.	TCODE (001101 or 001110)

Max length = 111 bits; Min length = 17 bits

Figure 73-46. Data Write/Read with Sync. message format

Exception conditions that result in Data Trace Synchronization are summarized in Table 73-35.

Table 73-35. Data Trace Exception summary

Exception Condition	Exception Handling
System Reset Negation	At the negation of JTAG reset (**j_trst_b**), queue pointers, counters, state machines, and registers within the Nexus 3 module are reset. If Data Trace is enabled, the first Data Trace Message is a Data Write/Read w/ Sync. Message.
Data Trace Enabled	The first Data Trace Message (after Data Trace has been enabled) is a synchronization message.
Exit from Low Power/Debug	Upon exit from a Low Power mode or Debug mode the next Data Trace Message will be converted to a Data Write/Read with Sync. Message.
Queue Overrun	An Error Message occurs when a new message cannot be queued due to the message queue being full. The FIFO will discard messages until it has completely emptied the queue. Once emptied, an Error Message will be queued. The error encoding will indicate which type(s) of messages attempted to be queued while the FIFO was being emptied. The next DTM message in the queue will be a Data Write/Read w/ Sync. Message.
Periodic Data Trace Sync.	A forced synchronization occurs periodically after 255 Data Trace Messages have been queued. A Data Write/Read w/ Sync. Message is queued. The periodic data trace message counter then resets.
Event In	If the Nexus module is enabled, a **nex_evti_b** assertion initiates a Data Trace Write/Read w/ Sync. Message upon the next data write/read (if Data Trace is enabled and the EIC bits of the DC1 Register have enabled this feature).
Collision Priority	All Messages have the following priority: Instruction 0 (WPM → DQM → PCM_{PIDMSG} → OTM → BTM → DTM) → Instruction1 (WPM → DQM → OTM → BTM → DTM), where instruction0 is the oldest instruction. A DTM Message that attempts to enter the queue at the same time as three other higher priority messages will be lost. A subsequent read/write will queue a Data Trace Read/Write w/ Sync. Message.

73.13.3 DTM Operation

73.13.3.1 Data Trace windowing

Data Write/Read Messages are enabled via the RWT field in the Data Trace Control Register (DTC) for each DTM channel. Data Trace windowing is achieved via the address range defined by the DTEA and DTSA Registers and by the RC field in the DTC register. All CPU initiated read/write accesses that fall inside or outside these address ranges, as programmed, are candidates to be traced.

73.13.3.2 Data Access / Instruction Access Data Tracing

The Nexus3 module is capable of tracing either instruction access data or data access data and can be configured for either type of data trace by setting the DI1 field within the Data Trace Control Register. This setting applies to all DTM channels.

73.13.3.3 Data Trace filtering

Data Trace filtering is available base on the settings of MSR_{PMM} and $DC4_{DTMARK}$.

73.13.3.4 Bus Cycle special cases

Table 73-36. Bus Cycle Special Cases

Special Case	Action
Bus cycle aborted	Cycle ignored
Bus cycle with data error ($\overline{TEA}$)[1, 1]	Data Trace Message discarded
Bus cycle completed without error[1]	Cycle captured & transmitted
AHB bus cycle initiated by Nexus 3	Cycle ignored
Bus cycle is an instruction fetch	Cycle selectively ignored based on DTC_{DI} setting
Bus cycle accesses misaligned data (across 64-bit boundary) - both 1st & 2nd transactions within data trace range	1st & 2nd cycle captured & a single or a pair of DTM(s) is (are) transmitted (see Note)
Bus cycle accesses misaligned data (across 64-bit boundary) - 1st transaction within data trace range; 2nd transaction out of data trace range	1st & 2nd cycle captured & a single or a pair of DTM(s) is (are) transmitted (see Note)
Bus cycle accesses misaligned data (across 64-bit boundary) - 1st transaction within data trace range; 2nd transaction (regardless of within range or not) receives a bus error	Data Trace Message discarded
Bus cycle accesses misaligned data (across 64-bit boundary) - 1st transaction out of data trace range; 2nd transaction within data trace range	1st & 2nd cycle captured & a single or a pair of DTM(s) is (are) transmitted (see Note)

Table continues on the next page...

Table 73-36. Bus Cycle Special Cases (continued)

Special Case	Action
Bus cycle accesses misaligned data (across 64-bit boundary) - 1st transaction out of data trace range; 2nd transaction within range, receives a bus error	Data Trace Message discarded

1. Buffering of stores in the CPU store buffer may generate a DTM prior to the actual memory access, regardless of an error termination condition from memory.

Note

For misaligned accesses (crossing 64-bit boundary), the access is broken into two accesses by the CPU. If either access is within the data trace range, a single DTM will be sent with a size encoding indicating the size of the original access (i.e. word), and the address indicating the original misaligned accesses, unless the misaligned access wraps into the doubleword at address 0, or unless the misaligned access wraps over the end of a circular buffer when using the LSP specialized load or store with circular addressing. In this case, since the two portions of the misaligned access are not contiguous, two DTMs will be sent, one for each portion. The size encodings and the addresses of the DTMs will indicate the accessed bytes of data. The data trace port handles these cases in the same manner. (See the Data Trace Port section in the Core Debug Support chapter.)

Note

A store to the store buffer within the data trace range may initiate a DTM message prior to completion of the actual memory access.

73.13.4 Data Trace Timing Diagrams (8 MDO / 2 MSEO configuration)

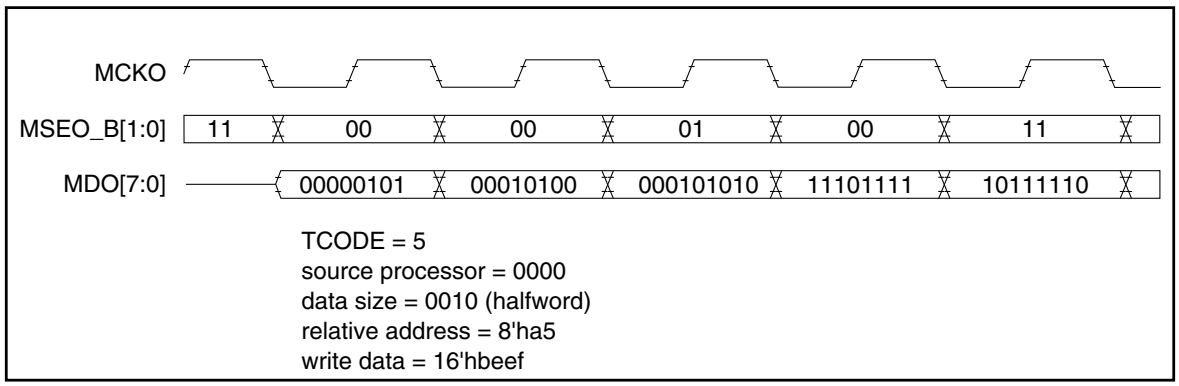

Figure 73-47. Data Trace - Data Write Message

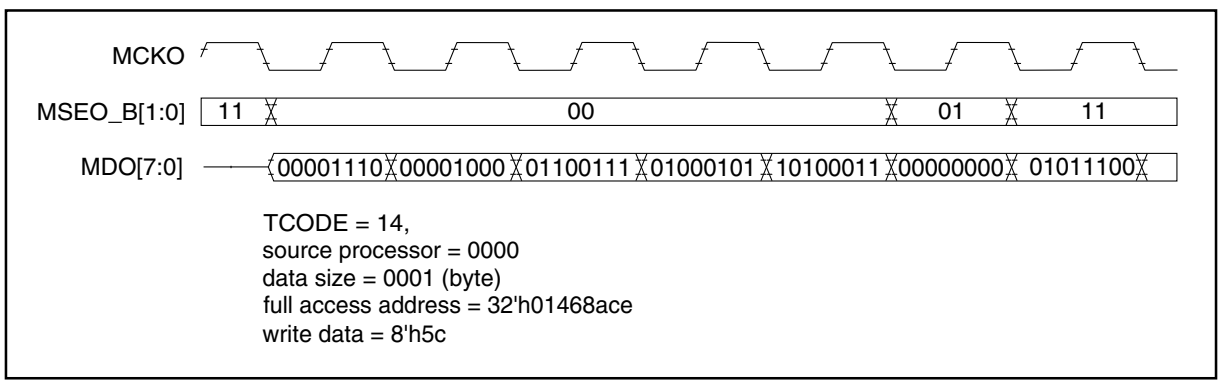

Figure 73-48. Data Trace — Data Read w/ Sync message

73.14 Data Acquisition messaging

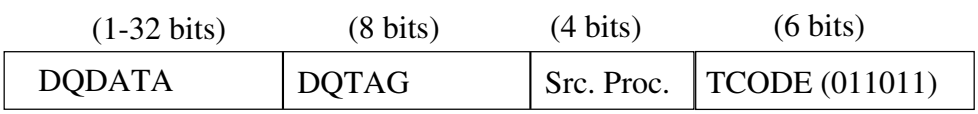
This section details the Data Acquisition mechanisms supported by the Nexus 3 module. Data Acquisition Trace is implemented using Data Acquisition Trace Messages in accordance with IEEE-ISTO 5001 definitions. The control mechanism to export the data is different from the recommendations of the standard, however.

Data Acquisition Trace provides a convenient and flexible mechanism for the debugger to observe the architectural state of the machine through software instrumentation.

73.14.1 Data Acquisition ID Tag field

The DQTAG Tag field (DQTAG) is an 8-bit value specifying control or attribute information for the data included in the Data Acquisition message. DQTAG is sampled from $DEVENT_{DQTAG}$ when a write to DDAM is performed via **mtspr** operations. The usage of the DQTAG is left to the discretion of the development tool to be used in whatever manner is deemed appropriate for the application.

73.14.2 Data Acquisition Data field



The Data Acquisition Data field (DQDATA) is the data captured from the DDAM write operation via **mtspr** operations. Leading zeros are omitted from the message.

73.14.3 Data Acquisition Trace event

For DQM, a dedicated SPR has been allocated (DDAM). It is expected that the general use case is to instrument the software and use **mtspr** operations to generate Data Acquisition messages.

There is no explicit error response for failed accesses as a result of contention between an internal and external debugger. Software may be blocked or given ownership of DDAM and the DQTAG field of the DEVENT register via control in EDBRAC0 while in External Debug Mode. Hardware always has access to these registers. Refer to the "External Debug Resource Allocation Control Register (EDBRAC0)" section in the Core Debug Support chapter for more detail on EDBRAC0.

Reads from the Data Acquisition channel do not generate a Data Acquisition event and will return zeroes for the read data.

Max length = 50 bits; Min length = 19 bits

Figure 73-49. Data Acquisition message format

73.15 Watchpoint Trace messaging

Enabling Watchpoint messaging is done by setting the Watchpoint Trace Enable bit in the DC1 Register. Setting the individual Watchpoint sources is supported through the Nexus1 module and the Performance Monitor unit. The Nexus1 module is capable of setting multiple types of watchpoints. Please refer to the Core Debug Support chapter for details on watchpoint initialization.

When watchpoints occur due to one or more asserted watchpoint event signals and Watchpoint Trace Messaging is enabled, a Watchpoint Trace message will be sent to the message queue to be messaged out. This message includes the watchpoint number indicating which watchpoint(s) caused the message. If more than one enabled watchpoint occurs in a single cycle, only one Watchpoint Trace message is generated and multiple bits of the watchpoint hit field will be set. The settings of the $WMSK_{WEM}$ field control which watchpoints are enabled to generate watchpoint trace messages.

The occurrence of any of the defined watchpoints can also be programmed to assert the Event Out (**nex_evto_b**) pin for one (1) period of the output clock (**nex_mcko**) based on settings in the DC2 and DC3 registers. See Table 73-40 for details on **nex_evto_b**.

Watchpoint information is messaged out in the following format:

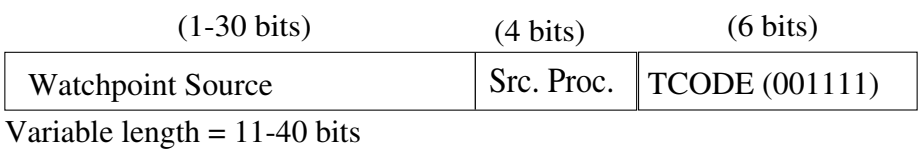


Figure 73-50. Watchpoint message format

The Watchpoint Source message field will contain a '1' for each asserted watchpoint. Leading zeros are truncated.

Table 73-37. Watchpoint Source Encoding

Watchpoint Source (1-30 bits)	Watchpoint Description
00000000000000000000000000000 - No Watchpoints enabled for Watchpoint Trace Messaging	
XXXXXXXXXXXXXXXXXXXXXXXXXXXXX1 - Watchpoint #0 enabled for WTM	
XXXXXXXXXXXXXXXXXXXXXXXXXXXX1X - Watchpoint #1 enabled for WTM	
XXXXXXXXXXXXXXXXXXXXXXXXXXX1XX - Watchpoint #2 enabled for WTM	
XXXXXXXXXXXXXXXXXXXXXXXXXX1XXX - Watchpoint #3 enabled for WTM

XXX1XXXXXXXXXXXXXXXXXXXXXXXXXX - Watchpoint #26 enabled for WTM	
XX1XXXXXXXXXXXXXXXXXXXXXXXXXXX - Watchpoint #27 enabled for WTM	
X1XXXXXXXXXXXXXXXXXXXXXXXXXXXX - Watchpoint #28 enabled for WTM	
1XXXXXXXXXXXXXXXXXXXXXXXXXXXXX - Watchpoint #29 enabled for WTM	

73.15.1 Watchpoint Timing Diagram (2 MDO / 1 MSEO configuration)

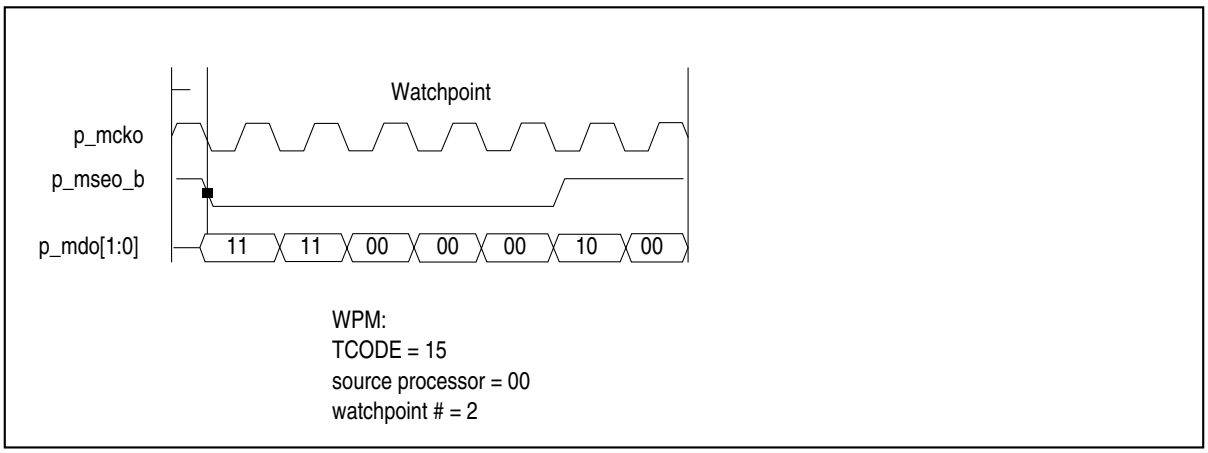

Figure 73-51. Watchpoint Message & Watchpoint Error message

73.16 External Hardware Trigger Controls

The Nexus 3 module provides a set of hardware trigger inputs to allow for external hardware to also independently control enabling/disabling of Program Trace, Data Trace, Ownership Trace, and Watchpoint Trace messaging. These signals can be used to produce a "window" for trace messaging for each type.

When a start trigger condition is detected for one of the trace types, and the corresponding trace type has not already been enabled by a software write to the DC1 register, the designated trace features become enabled, and the corresponding enable bit(s) of the DC1 register is set. When a stop trigger condition is detected and the corresponding trace type has not already been enabled by a software write to the DC1 register, the designated trace feature becomes disabled, and the corresponding enable bit of the DC1 register is cleared. If a simultaneous trigger condition is received for both start and stop triggering, then the designated trace feature will toggle between enabled and disabled depending on the enable state at the time of the trigger events. For example, if tracing is enabled, and a start and stop trigger condition occur simultaneously, then tracing will be disabled. Direct writes of the DC1 register take precedence over any trace feature control action that is derived from external hardware triggering, and if the corresponding trace feature has been enabled by a direct write to DC1, then the corresponding hardware trigger signals will have no effect. The following table details the external hardware trigger signals.

Table 73-38. External Hardware Trigger Signals

Name	Description
nex_dtm_starttr	Data Trace Messaging start trigger input. A transition from 0 → 1 on this input signals a start trace condition.
nex_dtm_stoptr	Data Trace Messaging stop trigger input. A transition from 0 → 1 on this input signals a stop trace condition.
nex_otm_starttr	Ownership Trace Messaging start trigger input. A transition from 0 → 1 on this input signals a start trace condition.
nex_otm_stoptr	Ownership Trace Messaging stop trigger input. A transition from 0 → 1 on this input signals a stop trace condition.
nex_ptm_starttr	Program Trace Messaging start trigger input. A transition from 0 → 1 on this input signals a start trace condition.
nex_ptm_stoptr	Program Trace Messaging stop trigger input. A transition from 0 → 1 on this input signals a stop trace condition.
nex_wtm_starttr	Watchpoint Trace Messaging start trigger input. A transition from 0 → 1 on this input signals a start trace condition.
nex_wtm_stoptr	Watchpoint Trace Messaging stop trigger input. A transition from 0 → 1 on this input signals a stop trace condition.

These signals are active-high inputs and are transition sensitive. A 0 → 1 transition on the signal indicates the corresponding condition is requested. These signals are not synchronized, and must meet setup and hold requirements relative to **nex_clk**.

73.17 Nexus 3 Read/Write access to memory-mapped resources

The Read/Write access feature allows access to memory-mapped resources via the JTAG/ OnCE port. The Read/Write mechanism supports single as well as block reads and writes to AHB resources.

The Nexus 3 module is capable of accessing resources on the system bus (AHB). Memory-mapped registers and other non-cached memory can be accessed via the standard memory map settings.

All accesses are setup and initiated by the Read/Write Access Control/Status Register (RWCS), as well as the Read/Write Access Address (RWA) and Read/Write Access Data Registers (RWD). Nexus 3 read/write accesses are run as privileged data non-cacheable accesses by default, and drive the **p_d_hprot[5:0]** bus access attributes to 6'b000011 accordingly. The $RWCS_{ATTR}$ field is provided to allow a portion of these default values to be modified when performing read or write accesses using the Nexus 3 Read/Write access mechanism.

Using the Read/Write Access Registers (RWCS/RWA/RWD), memory mapped AHB resources can be accessed through Nexus 3. The following subsections describe the steps required to access memory-mapped resources.

Note

Read/Write Access can only access memory mapped resources when system reset is de-asserted and clocks are running.

Misaligned accesses are NOT supported in the Nexus 3 module.

Uncorrectable ECC errors on Nexus 3 read access will result in the RWD register being updated with the raw data received.

73.17.1 Single write access

1. Initialize the Read/Write Access Address Register (RWA) through the access method outlined in Nexus 3 Register Access via JTAG/OnCE. Configure as follows:
   - Write Address → 32h'xxxxxxxx (write address)
2. Initialize the Read/Write Access Control/Status Register (RWCS) through the access method outlined in Nexus 3 Register Access via JTAG/OnCE. Configure the bits as follows:
   - Access Control (AC) → 1b'1 (to indicate start access)
   - Map Select (MAP) → 3b'000 (primary memory map)
   - Access Priority (PR) → 2b'11 (highest priority)
   - Read/Write (RW) → 1b'1 (write access)
   - Word Size (SZ) → 3b'0xx (32-bit, 16-bit, 8-bit)
   - Access Count (CNT) → 14h'0000 or 14h'0001(single access)

   Note

   Access Count (CNT) of 14'h0000 or 14'h0001 will perform a single access.

3. Initialize the Read/Write Access Data Register (RWD) through the access method outlined in Nexus 3 Register Access via JTAG/OnCE. Configure as follows:
   - Write Data → 32h'xxxxxxxx (write data)

4. The Nexus block will then arbitrate for the AHB system bus and transfer the data value from the data buffer RWD Register to the memory mapped address in the Read/Write Access Address Register (RWA). The nex_ahb_start output will be asserted during the first clock of the address phase of the transfer. When the access has completed, Nexus clears the AC and DV bits in the RWCS Register. If the access has completed without error, (ERR=1'b0), Nexus asserts the **nex_rdy_b** pin (see Table 73-40 for details) and clears the ERR bit in the RWCS Register. Otherwise, if the access completes with an error, the **nex_err_b** pin will be asserted and the ERR bit will be set to indicate an error has occurred, and the **nex_rdy_b** pin will not be asserted. Once DV has been cleared, this indicates that the device is ready for the next access, or that an error has occurred.

Note

Only the **nex_ahb_start, nex_rdy_b,** and **nex_err_b** pins as well as the AC, DV, and ERR bits within the RWCS provide Read/Write Access status to the external development tool.

73.17.2 Block write access

1. For a block write access, follow Steps 1, 2, and 3 outlined in Single write access to initialize the registers, but using a value greater than one (14'h0001) for the CNT field in the RWCS Register.
2. The Nexus block will then arbitrate for the AHB system bus and transfer the first data value from the RWD Register to the memory mapped address in the Read/Write Access Address Register (RWA). The nex_ahb_start output will be asserted during the first clock of the address phase of the transfer. When the transfer has completed without error, the address from the RWA Register is incremented to the next word size (specified in the SZ field), the number from the CNT field is decremented, and the **nex_rdy_b** pin is asserted. If the access has completed without error, Nexus clears the ERR and DV bits in the RWCS Register, otherwise the ERR bit will be set and the DV bit will be cleared to indicate an error has occurred, the **nex_err_b** pin is asserted, the block transfer is aborted, and the AC bit in the RWCS register is cleared. Once DV has been cleared, this indicates that the device is ready for the next access in the block transfer, or an error has occurred.

3. If AC has not been cleared due to an error, repeat Step 3 in Single write access until the internal CNT value is zero (0). When this occurs, the AC bit within the RWCS will be cleared to indicate the end of the block write access.

Note

The actual RWA value as well as the CNT field within the RWCS are not changed when executing a block write access. The original values can be read by the external development tool at any time.

73.17.3 Single read access

1. Initialize the Read/Write Access Address Register (RWA) through the access method outlined in Nexus 3 Register Access via JTAG/OnCE. Configure as follows:
   - Read Address → 32h'xxxxxxxx (read address)
2. Initialize the Read/Write Access Control/Status Register (RWCS) through the access method outlined in Nexus 3 Register Access via JTAG/OnCE. Configure the bits as follows:
   - Access Control (AC) → 1b'1 (to indicate start access)
   - Map Select (MAP) → 3b'000 (primary memory map)
   - Access Priority (PR) → 2b'11 (highest priority)
   - Read/Write (RW) → 1b'0 (read access)
   - Word Size (SZ) → 3b'0xx (32-bit, 16-bit, 8-bit)
   - Access Count (CNT) → 14h'0000 or 14h'0001(single access)

Note

Access Count (CNT) of 14'h0000 or 14'h0001 will perform a single access.

3. The Nexus block will then arbitrate for the AHB system bus and the read data will be transferred from the AHB to the RWD Register. The nex_ahb_start output will be asserted during the first clock of the address phase of the transfer. When the access has completed without error, Nexus clears the ERR bit and sets the DV bit in the RWCS Register and asserts the **nex_rdy_b** pin (see Table 73-40 for detail on **nex_rdy_b**). Otherwise, if the access has completed with an error, the **nex_err_b** pin

will be asserted, the ERR bit will be set and the DV bit will be cleared to indicate an error has occurred, and the **nex_rdy_b** pin will not be asserted. Once ERR or DV has been set, this indicates that the device is ready for the next access, or that an error has occurred. The AC bit will be cleared in either case.

4. The data can then be read from the Read/Write Access Data Register (RWD) through the access method outlined in Nexus 3 Register Access via JTAG/OnCE.

Note

Only the **nex_ahb_start, nex_rdy_b,** and **nex_err_b** pins as well as the AC, DV and ERR bits within the RWCS provide Read/Write Access status to the external development tool.

73.17.4 Block read access

1. For a block read access, follow Steps 1 and 2 outlined in Single read access to initialize the registers, but using a value greater than one (14'h0001) for the CNT field in the RWCS Register.
2. The Nexus block will then arbitrate for the AHB system bus and the read data will be transferred from the AHB to the RWD Register. The nex_ahb_start output will be asserted during the first clock of the address phase of the transfer. When the access has completed without error, Nexus clears the ERR bit and sets the DV bit in the RWCS Register and asserts the **nex_rdy_b** pin (see Table 73-40 for detail on **nex_rdy_b**). Otherwise, if the access has completed with an error, the **nex_err_b** pin will be asserted, the ERR bit will be set and the DV bit will be cleared to indicate an error has occurred, and the **nex_rdy_b** pin will not be asserted. Once ERR or DV has been set, this indicates that the device is ready for the next access, or that an error has occurred. The AC bit will be cleared in either case.
3. When the transfer has completed without error, the address from the RWA Register is incremented to the next word size (specified in the SZ field), the number from the CNT field is decremented, Nexus clears the ERR bit and sets the DV bit in the RWCS Register, and asserts the **nex_rdy_b** pin (see Table 73-40 for detail on **nex_rdy_b**). Otherwise, if the access has completed with an error, the **nex_err_b** pin will be asserted, the ERR bit will be set and the DV bit will be cleared to indicate an error has occurred, the AC bit is cleared and the block transfer is aborted, and the **nex_rdy_b** pin will not be asserted. Once ERR or DV has been set, this indicates that

the device is ready for the next access, or that an error has occurred. Once DV has been set, this indicates that the device is ready for the next access in the block transfer, or if ERR is set (AC will be cleared), the block transfer has been aborted.

4. The data can then be read from the Read/Write Access Data Register (RWD) through the access method outlined in Nexus 3 Register Access via JTAG/OnCE.
5. If AC has not been cleared due to an error, repeat Steps 3 and 4 in Single read access until the CNT value is zero (0). When this occurs, the AC bit within the RWCS is cleared to indicate the end of the block read access.

Note

The data values must be shifted out 32 bits at a time LSB first (i.e. doubleword read = two word reads from the RWD).

Note

The actual RWA value as well as the CNT field within the RWCS are not changed when executing a block read access. The original values can be read by the external development tool at any time.

73.17.5 Error handling

The Nexus 3 module handles various error conditions as follows:

73.17.5.1 AHB Read/Write error

All address and data errors that occur on read/write accesses to the AHB system bus will return a transfer error encoding on the **p_hresp[1:0]** signals. If this occurs:

1. The access is terminated without retrying (AC bit is cleared)
2. The ERR bit in the RWCS Register is set
3. The Error Message is sent (TCODE = 8) indicating Read/Write error

73.17.5.2 Access termination

The following cases are defined for sequences of the Read/Write protocol that differ from those described in the above sections.

1. If the AC bit in the RWCS Register is set to start Read/Write accesses and invalid values are loaded into the RWD and/or RWA, then an AHB access error may occur. This is handled as described above.
2. If a block access is in progress (all cycles not completed), and the RWCS Register is written, then the original block access is terminated at the boundary of the nearest completed access.
    a. If the RWCS is written with the AC bit set, the next Read/Write access will begin and the RWD can be written to/ read from.
    b. If the RWCS is written with the AC bit cleared, the Read/Write access is terminated at the nearest completed access. This method can be used to break (early terminate) block accesses.

73.17.6 Read/Write access error message

The Read/Write Access Error Message is sent out when an AHB system bus access error (read or write) has occurred.

Error information is messaged out in the following format:

(5 bits)	(4 bits)	(6 bits)
Error Code (00011)	Src. Proc.	TCODE (001000)

Fixed length = 15 bits

Figure 73-52. Error message format1

73.18 Nexus 3 pin interface

This section details information regarding the Nexus 3 pins and pin protocol.

The Nexus 3 pin interface provides the function of transmitting messages from the messages queues to the external tools. It is also responsible for handshaking with the message queues.

73.18.1 Pins implemented

The Nexus 3 module implements an auxiliary port consisting of one (1) **nex_evti_b** and one (1) **nex_mseo_b** or two (2) **nex_mseo_b[1:0]**. It also implements a configurable number of **nex_mdo[n:0]** pins, (1) **nex_rdy_b** pin, (1) **nex_err_b** pin, (1) **nex_evto_b** pin, (4) **nex_wevto[3:0]** pins, and one (1) clock output pin (**nex_mcko**), as well as additional configuration pins described in Table 73-40. The output pins are synchronized to the Nexus 3 output clock (**nex_mcko**).

All Nexus 3 input functionality may be controlled through the JTAG/OnCE port in compliance with IEEE 1149.1 (see Nexus 3 Register Access via JTAG/OnCE for details). The JTAG pins are incorporated as I/O to the processor, and are further described in the "JTAG/OnCE Pins" section of the Core Debug Support chapter.

Table 73-39. JTAG Pins for Nexus 3

JTAG Pins	Input/ Output	Description of JTAG Pins (included in Nexus 1)
j_tdo	O	The Test Data Output (**j_tdo**) pin is the serial output for test instructions and data. **j_tdo** is three-stateable and is actively driven in the "Shift-IR" and "Shift-DR" controller states. **j_tdo** changes on the falling edge of **j_tclk**.
j_tdi	I	The Test Data Input (**j_tdi**) pin receives serial test instruction and data. TDI is sampled on the rising edge of **j_tclk**.
j_tms	I	The Test Mode Select (**j_tms**) input pin is used to sequence the OnCE controller state machine. **j_tms** is sampled on the rising edge of **j_tclk**.
j_tclk	I	The Test Clock (**j_tclk**) input pin is used to synchronize the test logic, and control register access through the JTAG/OnCE port.
j_trst_b	I	The Test Reset (**j_trst_b**) input pin is used to asynchronously initialize the JTAG/OnCE controller.

The auxiliary pins are used to send and receive messages and are described in Table 73-40.

Table 73-40. Nexus 3 Auxiliary pins

Auxiliary pins	Input/ Output	Description of auxiliary pins
nex_mcko	O	Message Clock Out (**nex_mcko**) is a free running output clock to development tools for timing of **nex_mdo[n:0]** & **nex_mseo_b[1:0]** pin functions. **nex_mcko** is programmable through the DC1 Register.
nex_mdo[n:0]	O	Message Data Out (**nex_mdo[n:0]**) are output pins used for OTM, BTM, and DTM. External latching of **nex_mdo[n:0]** shall occur on the rising edge of the Nexus3 clock (**nex_mcko**).
nex_mseo_b[1:0]	O	Message Start/End Out (**nex_mseo_b[1:0]**) are output pins that indicate when a message on the **nex_mdo[n:0]** pins has started, when a variable length packet has ended, and when the message has ended. External latching of **nex_mseo_b[1:0]** shall occur on the rising edge of the Nexus3 clock (**nex_mcko**). One or two pin MSEO functionality is determined at integration time per SOC implementation.

Table continues on the next page...

Table 73-40. Nexus 3 Auxiliary pins (continued)

Auxiliary pins	Input/ Output	Description of auxiliary pins
nex_ahb_start	O	AHB Start (**nex_ahb_start**) is an output pin used to indicate to the external tool or SoC that the Nexus block is requesting the next Read/Write Access on the system bus. If Nexus is enabled, this signal is asserted upon an acknowledged request to start an AHB system bus transfer (Nexus read or write) and is pulsed asserted for one **nex_clk** clock period, corresponding to the first clock of the address phase of the transfer. Upon exit from system reset or if Nexus is disabled, **nex_ahb_start** remains de-asserted.
nex_rdy_b	O	Ready (**nex_rdy_b**) is an output pin used to indicate to the external tool that the Nexus block is ready for the next Read/Write Access. If Nexus is enabled, this signal is asserted upon successful (without error) completion of an AHB system bus transfer (Nexus read or write) & is held asserted until the JTAG/OnCE state machine reaches the "Capture_DR" state. Upon exit from system reset or if Nexus is disabled, **nex_rdy_b** remains deasserted.
nex_err_b	O	Error (**nex_err_b**) is an output pin used to indicate to the external tool that the Nexus block is ready for the next Read/Write Access and an error has occurred on the previous access. If Nexus is enabled, this signal is asserted upon unsuccessful (with error) completion of an AHB system bus transfer (Nexus read or write) & is held asserted until the JTAG/OnCE state machine reaches the "Capture_DR" state. Upon exit from system reset or if Nexus is disabled, **nex_err_b** remains deasserted.
nex_evto_b	O	Event Out (**nex_evto_b**) is an output that, when asserted, indicates one of two events has occurred based on the EOC bits in the DC1 Register. **nex_evto_b** is held asserted for one (1) cycle of **nex_mcko**: 1. One (or more) watchpoints has occurred (from Nexus1) & EOC = 2'b00 2. Debug mode was entered (jd_debug_b asserted from Nexus1) & EOC = 2'b01
nex_evti_b	I	Event In (**nex_evti_b**) is an input that, when asserted, will initiate one of two events based on the EIC bits in the DC1 Register (if the Nexus module is enabled at reset): 1. Program Trace & Data Trace synchronization messages (provided Program Trace & Data Trace are enabled & EIC = 2'b00). 2. Debug request to Nexus1 module (provided EIC = 2'b01 and this feature is implemented).
nex_wevto[3:0]	O	Watchpoint Event Out 3:0 (**nex_wevto[3:0]**) are outputs that, when asserted, indicates one or more watchpoint events has occurred based on the settings in the DC2 and DC3 registers. **nex_wevto[3:0]** is held asserted for one (1) cycle of **nex_mcko**.
nex_ext_src_id[0:3]	I	**nex_ext_src_id[0:3]** is used to provide the SRC field value used in each message. These pins are tied to a predetermined value at SoC integration time.
nex_sfwcntl_en]	I	**nex_sfwcntl_en** is used to allow software to control the module resources via the DCR register mappings. SoC logic should drive this signal appropriately in a semi-static manner based on the presence of an external hardware debugger and appropriate security precautions.

The Nexus auxiliary port arbitration pins are used when the Nexus 3 module is implemented in a multi-Nexus SoC that shares a single auxiliary output port. The arbitration is controlled by an SoC level Nexus Aurora Router (NAR). Refer to Auxiliary port arbitration for detail on Nexus port arbitration.

Table 73-41. Nexus port arbitration signals

Nexus port arbitration pins	Input/ Output	Description of arbitration pins
nex_aux_req[1:0]	O	Nexus Auxiliary Request (**nex_aux_req[1:0]**) output signals indicate to an SoC level Nexus arbiter a request for access to the shared Nexus auxiliary port in a multi-Nexus implementation. The priority encodings are determined by how many messages are currently in the message queues (See Table 73-43.)
nex_aux_busy	O	Nexus Auxiliary Busy (**nex_aux_busy**) is an output signal to an SoC level Nexus arbiter indicating that the Nexus 3 module is currently transmitting its message after being granted the Nexus auxiliary port.
nar_aux_grant	I	Nexus Auxiliary Grant **(nar_aux_grant)** is an input from the SoC level NAR that the auxiliary port has been granted to the Nexus 3 module to transmit its message.
ext_multi_nex_sel	I	Multi-Nexus Select (**ext_multi_nex_sel**) is a static signal indicating that the Nexus 3 module is implemented within a multi-Nexus environment. If set, port control and arbitration is controlled by the SoC level arbitration module (NAR).

73.18.2 Pin protocol

The protocol for the processor transmitting messages via the auxiliary pins is accomplished with the MSEO pin function outlined in Table 73-42. Both single and dual pin cases are shown.

nex_mseo_b[1:0] is used to signal the end of variable-length packets, and not fixed length packets. **nex_mseo_b[1:0]** is sampled on the rising edge of the Nexus 3 clock (**nex_mcko**).

Single pin MSEO is not supported on the .

Table 73-42. MSEO pin(s) protocol

nex_mseo_b function	Single nex_mseo_b data (serial)	Dual nex_mseo_b[1:0] data
Start of message	1-1-0	11-00
End of message	0-1-1-(more 1's)	00 (or 01)-11-(more 1's)
End of variable length packet	0-1-0	00-01
Message transmission	0's	00's
Idle (no message)	1's	11's

Figure 73-53 illustrates the state diagram for single pin MSEO transfers.

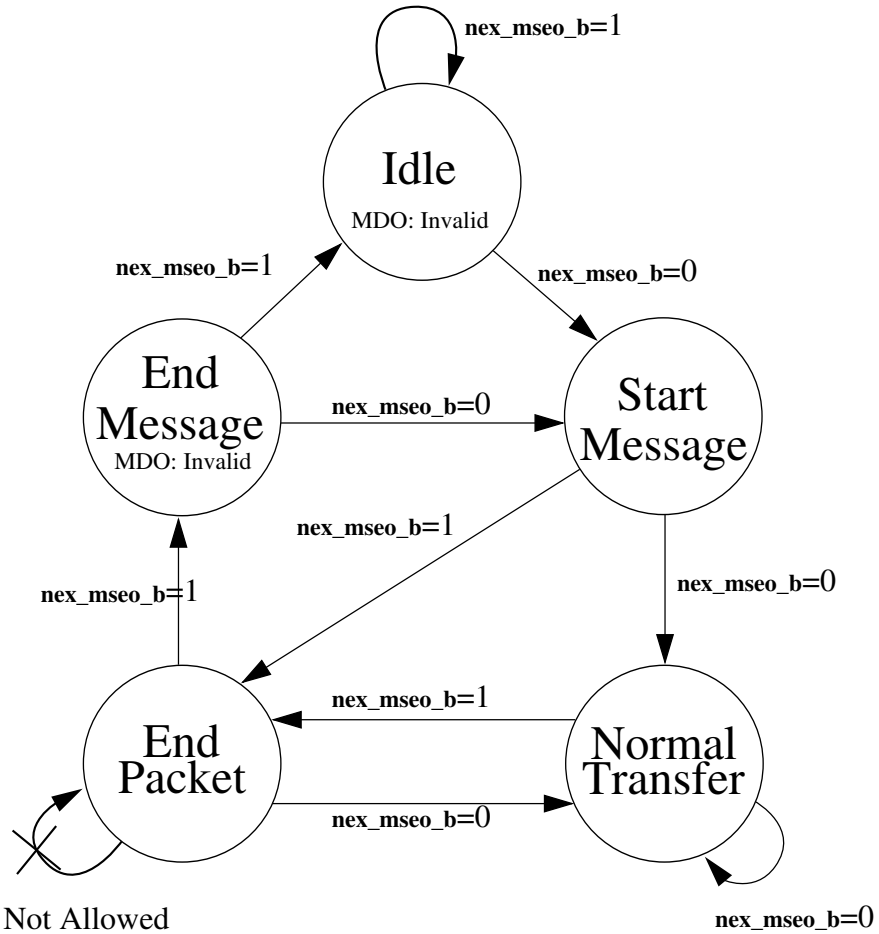

Figure 73-53. Single pin MSEO transfers

Note that the "End Message" state does not contain valid data on the **nex_mdo[n:0]** pins. Also, It is not possible to have two consecutive "End Packet" messages. This implies the minimum packet size for a variable length packet is 2x the number of **nex_mdo[n:0]** pins. This ensures that a false end of message state is not entered by emitting two consecutive '1's on the **nex_mseo_b** pin before the actual end of message.

Figure 73-54 illustrates the state diagram for dual pin MSEO transfers.

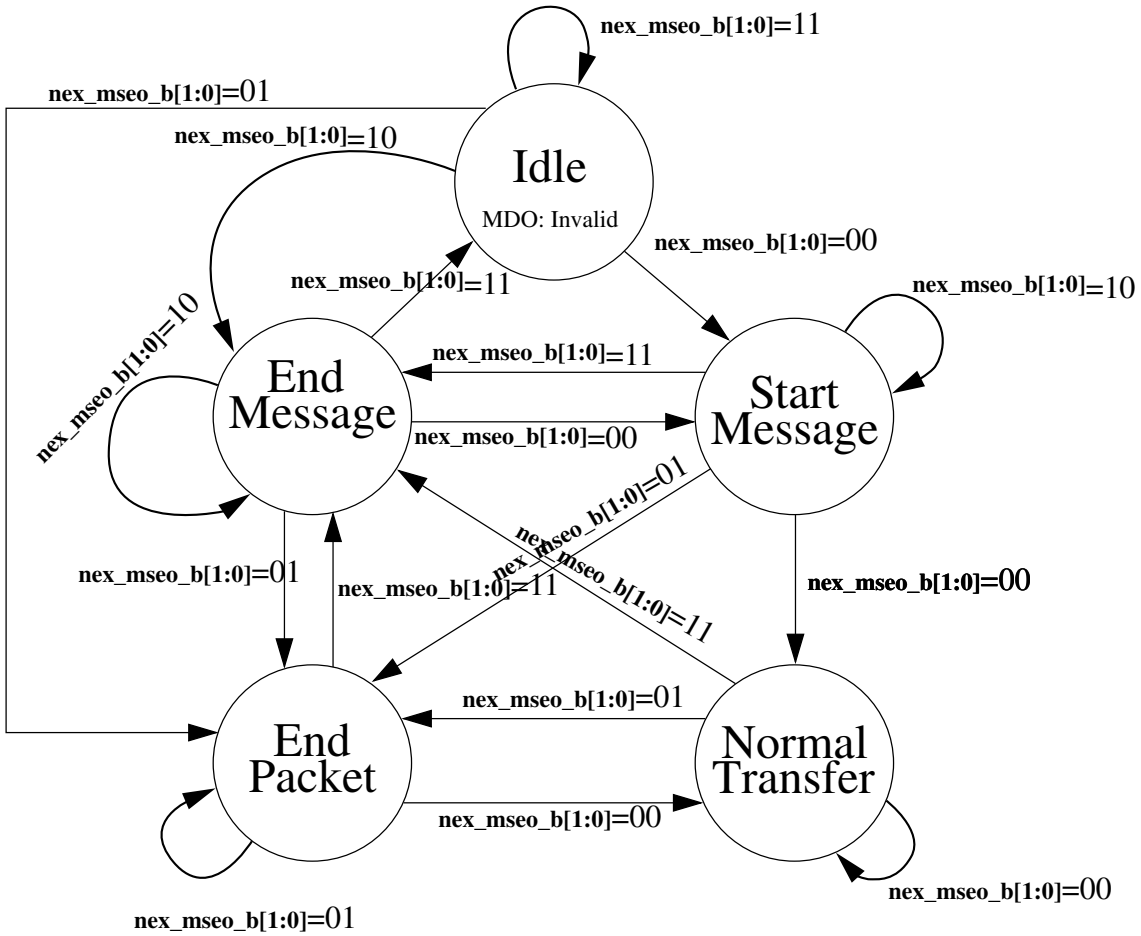

Figure 73-54. Dual pin MSEO transfers

The dual pin MSEO option is more robust that the single pin option. Termination of the current message may immediately be followed by the start of the next message on the consecutive clocks. An extra clock to end the message is not necessary as with the one MSEO pin option. The dual pin option also allows for consecutive "End Packet" states. This can be an advantage when small, variable sized packets are transferred.

Note

The "End Message" state may also indicate the end of a variable-length packet as well as the end of the message when using the dual pin option.

73.19 Rules for output messages

Class 3 compliant embedded processors must provide messages via the auxiliary port in a consistent manner as described below:

- A variable-sized packet within a message must end on a port boundary.
- A variable-sized packet may start within a port boundary only when following a fixed length packet. (If two variable-sized packets end and start on the same clock, it is impossible to know which bit is from the last packet and which bit is from the next packet.)
- Whenever a variable-length packet is sized such that it does not end on a port boundary, it is necessary to extend and zero fill the remaining bits after the highest-order bit so that it can end on a port boundary.

  For example, if the **nex_mdo[n:0]** port is 2 bits wide, and the unique portion of an indirect address TCODE is 5 bits, then the remaining 1 bit of **nex_mdo[n:0]** must be packed with a 0.

73.20 Auxiliary port arbitration

In a multi-Nexus environment, the Nexus 3 module must arbitrate for the shared Nexus port at the SoC level.The request scheme is implemented as a 2-bit request with various levels of priority. The priority levels are defined in Table 73-43 below. The Nexus 3 module will receive a 1-bit grant signal (**nar_aux_grant**) from the SoC level arbiter. When a grant is received, the Nexus 3 module will begin transmitting its message following the protocol outlined in Pin protocol. The Nexus 3 module will maintain control of the port, by asserting the **nex_aux_busy** signal, until the $\overline{\text{MSEO}}$ state machine reaches the "End Message" state.

Table 73-43. MDO Request Encodings

Request level	MDO request encoding (nex_aux_req[1:0])	Condition of queue
No Request	00	No message to send
Low Priority	01	Message queue less than 1/2 full
—	10	Reserved
High Priority	11	Message queue 1/2 full or more

73.21 Examples

The following are examples of Program Trace and Data Trace Messages.

Table 73-44 illustrates an example Indirect Branch Message with 2 MDO / 1MSEO configuration. Table 73-45 illustrates the same example with an 8 MDO / 2 MSEO configuration.

Note that T0 and S0 are the least significant bits where:

- Tx = TCODE number (fixed)
- Sx = Source processor (fixed)
- MAP = (always set to 0)
- Ix = Number of instructions (variable)
- Ax = Unique portion of the address (variable)

Note that during clock 13, the **nex_mdo[n:0]** pins are ignored in the single MSEO case.

Table 73-44. Indirect Branch Message Example (2 MDO / 1 MSEO)

Clock	nex_mdo[1:0]		nex_mseo_b	State
0	X	X	1	Idle (or end of last message)
1	T1	T0	0	Start Message
2	T3	T2	0	Normal Transfer
3	T5	T4	0	Normal Transfer
4	S1	S0	0	Normal Transfer
5	S3	S2	0	Normal Transfer
6	I0	MAP	0	Normal Transfer
7	I2	I1	0	Normal Transfer
8	I4	I3	1	End Packet
9	A1	A0	0	Normal Transfer
10	A3	A2	0	Normal Transfer
11	A5	A4	0	Normal Transfer
12	A7	A6	1	End Packet
13	0	0	1	End Message
14	T1	T0	0	Start Message

Table 73-45. Indirect branch message example (8 MDO / 2 MSEO)

Clock	nex_mdo[7:0]								nex_mseo_b[1:0]		State
0	X	X	X	X	X	X	X	X	1	1	Idle (or end of last message)
1	S1	S0	T5	T4	T3	T2	T1	T0	0	0	Start Message

Table continues on the next page...

Table 73-45. Indirect branch message example (8 MDO / 2 MSEO) (continued)

Clock	nex_mdo[7:0]								nex_mseo_b[1:0]		State
2	I4	I3	I2	I1	I0	MAP	S3	S2	0	1	End Packet
3	A7	A6	A5	A4	A3	A2	A1	A0	1	1	End Packet/End Message
4	S1	S0	T5	T4	T3	T2	T1	T0	0	0	Start Message

Table 73-46 and Table 73-47 illustrate examples of Direct Branch Messages: one with 2 MDO / 1 MSEO, and one with 8 MDO / 2 MSEO.

Note that T0 and I0 are the least significant bits where:

- Tx = TCODE number (fixed)
- Sx = Source processor (fixed)
- Ix = Number of Instructions (variable)

Table 73-46. Direct branch message example (2 MDO / 1 MSEO)

Clock	nex_mdo[1:0]		nex_mseo_b	State
0	X	X	1	Idle (or end of last message)
1	T1	T0	0	Start Message
2	T3	T2	0	Normal Transfer
3	T5	T4	0	Normal Transfer
4	S1	S0	0	Normal Transfer
5	S3	S2	0	Normal Transfer
6	I1	I0	1	End Packet
7	0	0	1	End Message

Table 73-47. Direct branch message example (8 MDO / 2 MSEO)

Clock	nex_mdo[7:0]								nex_mseo_b[1:0]		State
0	X	X	X	X	X	X	X	X	1	1	Idle (or end of last message)
1	S1	S0	T5	T4	T3	T2	T1	T0	0	0	Start Message
2	0	0	0	0	I1	I0	S3	S2	1	1	End Packet/End Message
3	S1	S0	T5	T4	T3	T2	T1	T0	0	0	Start Message

Table 73-48 illustrates an example Data Write Message with 8 MDO / 1 MSEO configuration, and Table 73-49 illustrates the same DWM with 8 MDO / 2 MSEO configuration

Note that T0, A0, D0 are the least significant bits where:

- Tx = TCODE number (fixed)
- Sx = Source processor (fixed)
- MAP = (always set to 0)
- Zx = Data size (fixed)
- Ax = Unique portion of the address (variable)
- Dx = Write data (variable 8-, 16- or 32-bit)

Table 73-48. Data write message example (8 MDO / 1 MSEO)

Clock	nex_mdo[7:0]								nex_mseo_b	State
0	X	X	X	X	X	X	X	X	1	Idle (or end of last message)
1	S1	S0	T5	T4	T3	T2	T1	T0	0	Start Message
2	A0	Z3	Z2	Z1	Z0	0	S3	S2	1	End Packet
3	D7	D6	D5	D4	D3	D2	D1	D0	0	Normal Transfer
4	0	0	0	0	0	0	0	0	1	End Packet
5	0	0	0	0	0	0	0	0	1	End Message

Table 73-49. Data write message example (8 MDO / 2 MSEO)

Clock	nex_mdo[7:0]								nex_mseo_b[1:0]		State
0	X	X	X	X	X	X	X	X	1	1	Idle (or end of last message)
1	S1	S0	T5	T4	T3	T2	T1	T0	0	0	Start Message
2	A0	Z3	Z2	Z1	Z0	0	S3	S2	0	1	End Packet
3	D7	D6	D5	D4	D3	D2	D1	D0	1	1	End Packet/ End Message

73.22 Electrical characteristics

For all electrical characteristics related to core processor and Nexus 3 operation, please refer to the Data Sheet.

73.23 IEEE 1149.1 (JTAG) RD/WR sequences

This section contains example JTAG/OnCE sequences used to access resources.

73.23.1 JTAG sequence for accessing internal Nexus registers

Table 73-50. Accessing internal Nexus 3 registers via JTAG/OnCE

Step #	TMS Pin	Description
1	1	IDLE -> SELECT-DR_SCAN
2	0	SELECT-DR_SCAN -> CAPTURE-DR (Nexus Command Register value loaded in shifter)
3	0	CAPTURE-DR -> SHIFT-DR
4	0	(7) TCK clocks issued to shift in direction (rd/wr) bit and first 6 bits of Nexus reg. addr.
5	1	SHIFT-DR -> EXIT1-DR (7th bit of Nexus reg. shifted in)
6	1	EXIT1-DR -> UPDATE-DR (Nexus shifter is transferred to Nexus Command Register)
7	1	UPDATE-DR -> SELECT-DR_SCAN
8	0	SELECT-DR_SCAN -> CAPTURE-DR (Register value is transferred to Nexus shifter)
9	0	CAPTURE-DR -> SHIFT-DR
10	0	(31) TCK clocks issued to transfer register value to TDO pin while shifting in TDI value
11	1	SHIFT-DR -> EXIT1-DR (MSB of value is shifted in/out of shifter)
12	1	EXIT1-DR -> UPDATE -DR (if access is write, shifter is transferred to register)
13	0	UPDATE-DR -> RUN-TEST/IDLE (transfer complete - Nexus controller to Reg. Select state)

73.23.2 JTAG sequence for read access of memory-mapped resources

Table 73-51. Accessing memory-mapped resources (reads)

Step #	TCLK clocks	Description
1	13	Nexus Command = write to Read/Write Access Address Register (RWA)
2	37	Write RWA (initialize starting read address — data input on TDI)
3	13	Nexus Command = write to Read/Write Control/Status Register (RWCS)
4	37	Write RWCS (initialize read access mode and CNT value — data input on TDI)
5	—	Wait for falling edge of **nex_rdy_b** or **nex_err_b** pin
6	13	Nexus Command = read Read/Write Access Data Register (RWD)
7	37	Read RWD (data output on TDO)
8	—	If CNT > 0, go back to Step #5

73.23.3 JTAG sequence for write access of memory-mapped resources

Table 73-52. Accessing memory-mapped resources (writes)

Step #	TCLK clocks	Description
1	13	Nexus Command = write to Read/Write Access Control/Status Register (RWCS)
2	37	Write RWCS (initialize write access mode and CNT value - data input on TDI)
3	13	Nexus Command = write to Read/Write Address Register (RWA)
4	37	Write RWA (initialize starting write address - data input on TDI)
5	13	Nexus Command = read Read/Write Access Data Register (RWD)
6	37	Write RWD (data output on TDO)
7	—	Wait for falling edge of **nex_rdy_b** or **nex_err_b** pin
8	—	If CNT > 0, go back to Step #5

Chapter 74
Nexus Crossbar Multi-Master Client (NXMC)

74.1 NXMC chip-specific module information

74.1.1 Generating In Circuit Trace Messages (ICTM)

To generate In Circuit Trace Messages (ICTM) on this chip, follow the steps below.

1. Configure the Nexus trace memory path in NAR:

   - Trace memory port base addresses-NAR_TBALO, NAR_TBAHI
   - Trace memory bus Control register-NAR_TCR (Transfer mode, Block Size, Threshold, Wrap around and Max transfer size)
   - Trace memory fill level and partition-NAR_AHFPAR
   - Nexus Aurora PHY Control (if available and used)-NAR_NAPCR
   - NAR Control Register-NAR_CR (to start NAR module with other attributes)

2. Configure the NXMC[x] to enable trace from peripheral module:

   - Development control register 1 - DC1 (Example: 0x0000_0002 ; Data trace enabled)
   - Development control register 2 - DC2 (Example: 0x0000_FFFF ; Enable peripheral interface)

3. Configure the SPU to enable trigger event to NXMC[x]:

   - Configure sequence-Sequence Control (SCTRL) (start, end and enable; example 0x0000_0011)
   - Configure connects between states:
     - State0 Goto Control (S0GC) (Enable Go to control (TE, NF), Next State on True Condition (Go to State 1), Next State on False Condition (Go to State 0))
     - State1 Goto Control (S1GC) (Enable Go to control (NF), Next State on False Condition (Go to State 1))

4. Configure actions for timestamp message into trace stream :

- State0 True Action 0 (S0TA0) (Action1: group = system, client = 0 , action = Timestamp0_NXMC0)
- State0 True Action 0 (S0TA0) (Action2: group = counter, client = 1 , action = Reset Counter)
- State0 True Action 1 (S0TA1) (Action3: group = counter, client = 2 , action = Reset Counter)
- State1 True Action 0 (S1TA0) (Action1: group = system, client = 0 , action = Timestamp0_NXMC1)
- State1 True Action 0 (S1TA0) (Action2: group = counter, client = 1 , action = Capture)
- State1 True Action 1 (S1TA1) (Action3: group = counter, client = 2 , action = Capture)

Configure Input triggers:

- Level1 Mux Selection 0 (L1SEL0)
- Level1 Mux Selection 1 (L1SEL1)

Map inputs to state inputs:

- Level2 Mux state n selection 0 (L2nSEL0)

Configure counters:

- Counter Control 0 (CCTRL0) (enable, increment)
- Counter Control 1 (CCTRL1) (enable, increment)

74.2 Introduction

The Nexus Crossbar Multi-master Client (NXMC) module provides real-time trace capabilities in compliance with the IEEE-ISTO Nexus 5001-2012 standard. This module provides development support capabilities for devices without requiring address and data pins for internal visibility. A portion of the pin interface is also compliant with the IEEE 1149.1 JTAG standard. The IEEE-ISTO 5001 standard defines an extensible auxiliary port which is used in conjunction with the JTAG port.

Many bus masters start accesses to internal address locations via the system bus. The NXMC module monitors the system bus and provides real-time trace information to debug or development tools. This also provides the capability of sending user defined messages for the peripherals attached to it.

74.2.1 Features

The NXMC module is compliant with the IEEE-ISTO 5001-2012 standard. The following features are implemented:

- Data trace via Data Write Messaging (DWM) and Data Read Messaging (DRM). This provides the capability for the development tool to trace reads and/or writes to (selected) internal memory resources.
- Multi-master tracing capability for multiple master accesses
- Watchpoint messaging based on internal/external triggers, via the auxiliary pins
- Watchpoint trigger events out based on internal/external triggers
- Watchpoint trigger enable of data trace messaging

- Peripheral interface for data message transfers based on In Circuit Trace Message (ICTM) format
- Start or stop of Tracing (Data Trace, Watchpoint Trace) based on external triggers.
- Optional timestamping of the messages based on timer value and controls received at the interface
- Nexus Auxiliary port for higher data throughput
  - One $\overline{\text{EVTO}}$ (Watchpoint Event) pin
  - One $\overline{\text{EVTI}}$ (Event In) pin
- Registers for data trace, watchpoint generation, and watchpoint trigger
- All features controllable and configurable via the JTAG port

74.3 External signal description

This section details information regarding the standard ports and protocol. The NXMC pin interface provides the function of transmitting messages from the messages queues to NAR. It is also responsible for handshaking with the message queues.

The NXMC module implements the following signals:

- One $\overline{\text{EVTI}}$
- One $\overline{\text{EVTO}}$

These pins are described in Table 74-2.

All NXMC input functionality is controlled through the JTAG port in compliance with IEEE 1149.1 (see IEEE 1149.1 (JTAG) Test Access Port for details). A separate JTAG TAP controller is instantiated within the NXMC. The following table describes the JTAG pins.

Table 74-1. JTAG pins for NXMC

JTAG port	Input/ output	Description
TDO	O	The Test Data Output (TDO) pin is the serial output for test instructions and data. TDO is three-stateable and is actively driven in the shift-IR and shift-DR controller states. TDO changes on the falling edge of TCK.
TDI	I	The Test Data Input (TDI) pin receives serial test instruction and data. TDI is sampled on the rising edge of TCK and has an internal pull-up resistor.
TMS	I	The Test Mode Select (TMS) input pin is used to sequence the JTAG test controllers' state machine. TMS is sampled on the rising edge of TCK and has an internal pull-up resistor.
TCK	I	The Test Clock (TCK) input pin is used to synchronize the test logic, and control register access through the JTAG port.
TRST	I	The Test Reset ($\overline{\text{TRST}}$) input pin is used to asynchronously initialize the JTAG controller. The $\overline{\text{TRST}}$ pin has an internal pull-down resistor.

Table 74-2. NXMC auxiliary pins

Auxiliary port	Input/ output	Description
EVTO	O	Event Out ($\overline{\text{EVTO}}$) is an output which, when asserted, indicates one of two events has occurred based on the EOC bits in the DC Register: • one of the internal or external watchpoints has occurred and EOC = 2'b00 • system-level debug mode was entered (ipg_debug) and EOC = 2'b01 $\overline{\text{EVTO}}$ is held asserted for one cycle.
EVTI	I	Event In ($\overline{\text{EVTI}}$) is an input which initiates synchronization messages. If the Nexus module is enabled at reset, (see Enabling NXMC operation), assertion initiates data trace synchronization messages (provided data trace is enabled).

74.4 Supported messages and TCODEs

The NXMC pins allow for flexible transfer operations via public messages. A TCODE defines the transfer format, the number and/or size of the packets to be transferred, and the purpose of each packet. The IEEE-ISTO 5001-2012 standard defines a set of public messages. The NXMC block supports the public TCODEs listed in the following table. The SRC and MASTER field values are described in the device-specific chapter that describes how the modules are configured.

Table 74-3. Supported public TCODEs

Message name	Min packet size (bits)	Max packet size (bits)	Packet name	Packet type	Packet description
Data Trace - Data Write Message	6	6	TCODE	fixed	TCODE number = 58
	4	4	SRC	fixed	Source processor identifier (multiple Nexus configuration)
	4	4	MASTER	fixed	Indicates which master (ID) initiated the data access
	3	3	DSZ	fixed	Data size (See Table 74-4)
	1	32	U-ADDR	variable	Unique portion of the data write address
	8	64	DATA	fixed	Data write value (size fixed based on DSZ field)
	1	26	TSTAMP	variable	Timestamp (Optional)

Table continues on the next page...

Table 74-3. Supported public TCODEs (continued)

Message name	Min packet size (bits)	Max packet size (bits)	Packet name	Packet type	Packet description
Data Trace - Data Read Message	6	6	TCODE	fixed	TCODE number = 59
	4	4	SRC	fixed	Source processor identifier (multiple Nexus configuration)
	4	4	MASTER	fixed	Indicates which master (ID) initiated the data access
	3	3	DSZ	fixed	Data size (See Table 74-4)
	1	32	U-ADDR	variable	Unique portion of the data read address
	8	64	DATA	fixed	Data read value (size fixed based on DSZ field)
	1	26	TSTAMP	variable	Timestamp (Optional)
Error Message	6	6	TCODE	fixed	TCODE number = 8
	4	4	SRC	fixed	Source processor identifier (multiple Nexus configuration)
	4	4	ETYPE	fixed	Error type (See Table 74-5)
	14	14	ECODE	fixed	Error code (See Table 74-6)
	1	26	TSTAMP	variable	Timestamp (Optional)
Data Trace - Data Write Message w/ Sync	6	6	TCODE	fixed	TCODE number = 60
	4	4	SRC	fixed	Source processor identifier (multiple Nexus configuration)
	4	4	MASTER	fixed	Indicates which master (ID) initiated the data access
	3	3	DSZ	fixed	Data size (See Table 74-4)
	1	32	F-ADDR	variable	Full access address (leading zero (0) truncated)
	8	64	DATA	fixed	Data write value (size fixed based on DSZ field)
	1	26	TSTAMP	variable	Timestamp (Optional)
Data Trace - Data Read Message w/ Sync	6	6	TCODE	fixed	TCODE number = 61
	4	4	SRC	fixed	Source processor identifier (multiple Nexus configuration)
	4	4	MASTER	fixed	Indicates which master (ID) initiated the data access
	3	3	DSZ	fixed	Data size (See Table 74-4)
	1	32	F-ADDR	variable	Full access address (leading zero (0) truncated)
	8	64	DATA	fixed	Data read value (size fixed based on DSZ field)
	1	26	TSTAMP	variable	Timestamp (Optional)

Table continues on the next page...

Table 74-3. Supported public TCODEs (continued)

Message name	Min packet size (bits)	Max packet size (bits)	Packet name	Packet type	Packet description
Watchpoint Message	6	6	TCODE	fixed	TCODE number = 15
	4	4	SRC	fixed	Source processor identifier (multiple Nexus configuration)
	1	8	WPHIT	variable	Watchpoint source(s) number (See Table 74-22)
	1	26	TSTAMP	variable	Timestamp (Optional)
Peripheral Message (In circuit Trace Message: ICTM	6	6	TCODE	fixed	TCODE number = 34
	4	4	SRC	fixed	Source processor identifier (multiple Nexus configuration)
	6	6	CKSRC	fixed	Peripheral source identifier
	1	44	CKDATA	variable	Peripheral data
	1	26	TSTAMP	variable	Timestamp (Optional)

Table 74-4. Data trace size (DSZ) encodings (TCODE = 58, 59, 60, 61)

DSZ	Transfer size
001	8-bit
010	16-bit
011	32-bit
100	64-bit
000, 101-111	Reserved

Table 74-5. Error Type (ETYPE) encodings (applicable to all error messages)

ETYPE	Description
0000	Queue overrun caused message (one or more) to be lost
0001	Contention with higher priority message caused message(s) to be lost
0010	Reserved
0011	Reserved
0100	Reserved
0101	Invalid access opcode (Nexus register unimplemented)
0110–1111	Reserved

Table 74-6. Error Code (ECODE) encodings (applicable based on error source)

ECODE		Description[1]

CKSRCn	XXXX1XXX	Reserved
CKSRCn	XXX1XXXX	Reserved
CKSRCn	XX1XXXXX	Reserved
CKSRCn	X1XXXXXX	In-Circuit Trace Message(s) Lost
CKSRCn	1XXXXXXX	Reserved

1. The SRC field values are described in the device-specific chapter that describes how the modules are configured.

74.5 Register description

This section describes the NXMC register definition. Nexus registers are accessed using the JTAG port in compliance with IEEE 1149.1. See IEEE 1149.1 (JTAG) Test Access Port for details. The complete list of registers is shown in this table.

Table 74-7. NXMC registers

Nexus register	Nexus access opcode (hex)	Read/ write	Read address (hex)	Write address (hex)
Development Control 1 (DC1)	2	R/W	04	05
Development Control 2 (DC2)	3	R/W	06	07
Watchpoint Trigger (WT)	B	R/W	16	17
Data Trace Control (DTC)	D	R/W	1A	1B
Data Trace Start Address1 (DTSA1)	E	R/W	1C	1D
Data Trace Start Address2 (DTSA2)	F	R/W	1E	1F
Data Trace End Address1 (DTEA1)	12	R/W	24	25
Data Trace End Address2 (DTEA2)	13	R/W	26	27

Table continues on the next page...

Table 74-7. NXMC registers (continued)

Nexus register	Nexus access opcode (hex)	Read/ write	Read address (hex)	Write address (hex)
Breakpoint/Watchpoint Control Register1 (BWC1)	16	R/W	2C	2D
Breakpoint/Watchpoint Control Register2 (BWC2)	17	R/W	2E	2F
Breakpoint/Watchpoint Address Register1 (BWA1)	1E	R/W	3C	3D
Breakpoint/Watchpoint Address Register2 (BWA2)	1F	R/W	3E	3F

74.5.1 Development control register 1 (DC1)

The Development Control Registers control the basic development features of the NXMC module. This table shows the format of the DC1.

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

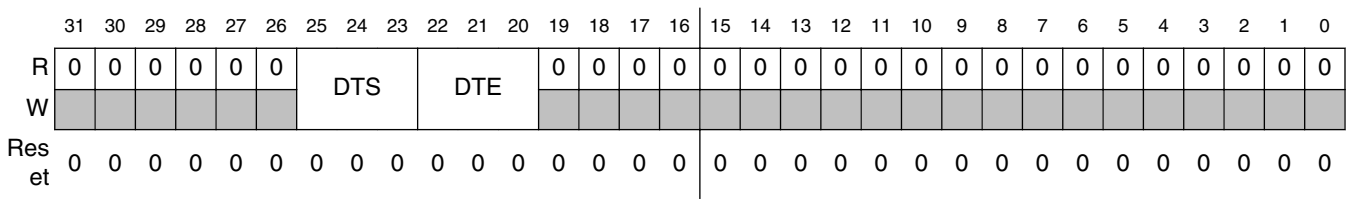
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	PME0
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The DC2 is described in this table.

Table 74-9. DC2 register field description



Field	Description	
31:24	$\overline{\text{EVTO}}$ Watchpoint Configuration[1].	
EWC	00000000	No Watchpoints trigger $\overline{\text{EVTO}}$
	1XXXXXXX	External Watchpoint #1 triggers $\overline{\text{EVTO}}$
	X1XXXXXX	External Watchpoint #2 triggers $\overline{\text{EVTO}}$
	XX1XXXXX	Reserved
	XXX1XXXX	Reserved
	XXXX1XXX	Internal Watchpoint #1 triggers $\overline{\text{EVTO}}$
	XXXXX1XX	Internal Watchpoint #2 triggers $\overline{\text{EVTO}}$
	XXXXXX1X	Reserved
	XXXXXXX1	Reserved
23:1	Reserved for future functionality (read as 0)	
0	Peripheral Messaging Enable for the In-Circuit Trace (ICT) feature. [2]	
PME0	0	Peripheral Interface disabled
	1	Peripheral Interface enabled

1. The EOC bits in DC1 must be programmed to trigger EVTO on watchpoint occurrence for the EWC bits to have any effect.
2. The peripheral details are described in the device-specific chapter that describes how the modules are configured.

74.5.3 Watchpoint trigger register (WT)

The Watchpoint Trigger Register allows the watchpoints defined either internally to the NXMC module or by an external module to trigger actions. These watchpoints can control data trace enable and disable.

The WT bits can be used to produce an address related window for triggering trace messages. This table shows the format of the WT register.

The WT register is described in this table.

Table 74-10. WT register field description

Field	Description[1]	
31:26	Reserved for future functionality (read as 0)	
25:23 DTS	Data Trace Start Control.	
	000	Trigger disabled
	001	Use External Watchpoint #1
	010	Use External Watchpoint #2
	011	Reserved
	100	Reserved
	101	Use Internal Watchpoint #1 (BWA1 Register)
	110	Use Internal Watchpoint #2 (BWA2 Register)
	111	Reserved
22:20 DTE	Data Trace End Control.	
	000	Trigger disabled
	001	Use External Watchpoint #1
	010	Use External Watchpoint #2
	011	Reserved
	100	Reserved
	101	Use Internal Watchpoint #1 (BWA1 Register)
	110	Use Internal Watchpoint #2 (BWA2 Register)
	111	Reserved
19:0	Reserved for future functionality (read as 0)	

1. The WT bits only enable data trace if the TM bits in the Development Control Register (DC) have not already been set to enable data trace.

74.5.4 Data trace control register (DTC)

The Data Trace Control Register controls whether DTM messages are restricted to reads, writes or both for a user programmable address range. There are two data trace channels controlled by the DTC for the NXMC module. This table shows the format of the DTC register.

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	RWT1		RWT2		0	0	0	MME	0	0			MID				0	0	0	0	0	0	0	0	RC1	RC2	0	0	0	0	0	0
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The DTC register is described in this table.

Table 74-11. DTC field description

Field	Description	
31:30 RWT1	Read/Write Trace 1.	
	00	No trace messages generated
	x1	Enable data read trace
	1x	Enable data write trace
29:28 RWT2	Read/Write Trace 2.	
	00	No trace messages generated
	x1	Enable data read trace
	1x	Enable data write trace
27:25	Reserved for future functionality	
24 MME	Multi Master Tracing enable.	
	0	Tracing enabled only for Master with ID = MID (DTC[19:16])
	1	Tracing enabled for all the Masters
23:20	Reserved for future functionality	
19:16 MID	ID of the system bus Master to be traced[1]	
15:8	Reserved for future functionality	
7 RC1	Range Control 1.	
	0	Condition trace on address within range (endpoints inclusive)
	1	Condition trace on address outside of range (endpoints exclusive)

Table continues on the next page...

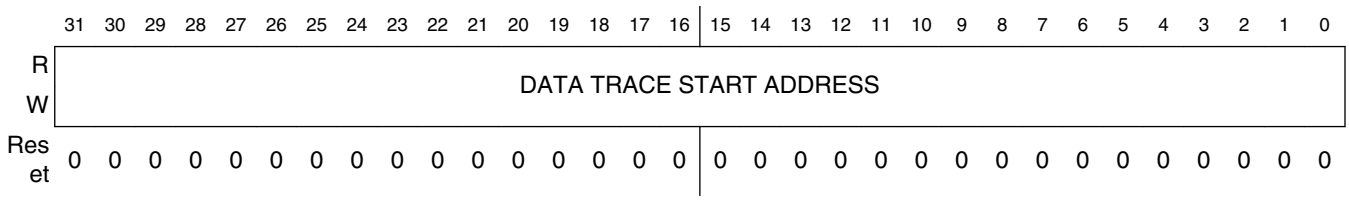


Table 74-11. DTC field description (continued)

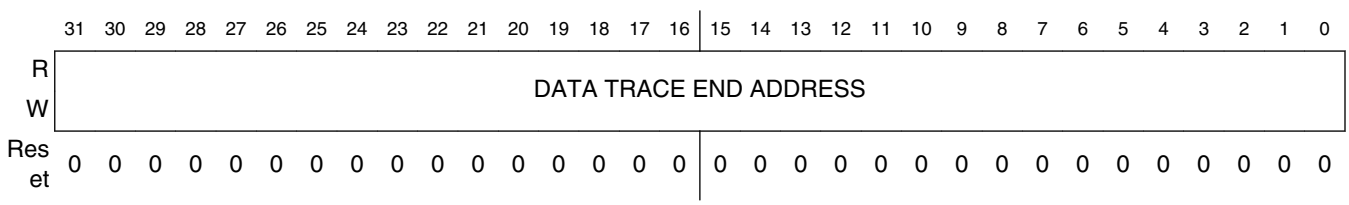
Field	Description	
6 RC2	Range Control 2.	
	0	Condition trace on address within range (endpoints inclusive)
	1	Condition trace on address outside of range (endpoints exclusive)
5:0	Reserved for future functionality	

1. The MASTER field values are described in the device-specific chapter that describes how the modules are configured.



74.5.5 Data trace start address registers 1 and 2 (DTSA1 and DTSA2)

The Data Trace Start Address Registers define the start addresses for each trace channel. This table shows the format of the DTSA1 and DTSA2 registers.

74.5.6 Data trace end address registers 1 and 2 (DTEA1 and DTEA2)

The Data Trace End Address Registers define the end addresses for each Trace channel. This table shows the format of the DTEA1 and DTEA2 registers.

This table illustrates the range that are selected for data trace for various cases of DTSA being less than, greater than, or equal to DTEA.

Table 74-12. Data trace address range options

Programmed values	Range control bit value	Range selected
DTSA ≤ DTEA	0	DTSA -> <- DTEA

Table continues on the next page...

Table 74-12. Data trace address range options (continued)

Programmed values	Range control bit value	Range selected
DTSA ≤ DTEA	1	<- DTSA DTEA ->
DTSA > DTEA	N/A	Invalid range—no trace

Note

DTSA must be less than (or equal to) DTEA in order to guarantee correct data write/read traces.

When the range control bit is 0 (internal range), accesses to DTSA and DTEA addresses are traced. When the range control bit is 1 (external range), accesses to DTSA and DTEA are not traced.

74.5.7 Breakpoint/watchpoint control register 1 (BWC1)

Breakpoint/watchpoint control register 1 controls the attributes for generation of NXMC watchpoint#1. This table shows the format of the BWC1 register.

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	BWE1		BRW1		0	0	0	0	0	0	0	0	0	0	BWR1		BWT1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The BWC1 register is described in this table.

Table 74-13. BWC1 field description

Field	Description	
31:30	Breakpoint/Watchpoint #1 Enable.	
BWE1	00	Internal Nexus Watchpoint #1 disabled
	01	Reserved
	10	Reserved
	11	Internal Nexus Watchpoint #1 enabled
29:28	Breakpoint/Watchpoint #1 Read/Write Select.	
BRW1	00	Watchpoint #1 hit on read accesses
	01	Watchpoint #1 hit on write accesses
	10	Watchpoint #1 on read or write accesses
	11	Reserved

Table continues on the next page...

Table 74-13. BWC1 field description (continued)

Field	Description	
27:18	Reserved for future functionality (read as 0)	
17:16	Breakpoint/Watchpoint #1 Register Compare.

	0	Reserved
	1	Watchpoint #2 on data accesses
14:0	Reserved for future functionality (read as 0)	

74.5.9 Breakpoint/watchpoint address registers 1 and 2 (BWA1 and BWA2)

The Breakpoint/Watchpoint Address Registers are compared with system bus addresses in order to generate internal watchpoints. This table shows the format of the BWA1 and BWA2 registers.

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	BREAKPOINT / WATCHPOINT ADDRESS																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

74.5.10 Unimplemented registers

Unimplemented registers are those with client select and index value combinations other than those listed in Table 74-7. For unimplemented registers, the NXMC module drives TDO to zero during the SHIFT-DR state. It also transmits an error message with the invalid access opcode encoding (ETYPE = 0101).

74.6 Programming considerations (RESET)

If NXMC register configuration is to occur during system reset (as opposed to debug mode), all NXMC configuration should be completed between the negation of $\overline{\text{TRST}}$ and system reset de-assertion. The JTAG ID register should be read by the tool after negation of $\overline{\text{TRST}}$ and should be programmed before deassertion of system reset.

74.6.1 IEEE 1149.1 (JTAG) Test Access Port

The NXMC module uses the IEEE 1149.1 TAP controller for accessing Nexus resources. The JTAG signals themselves are shared by all TAP controllers on the device. The NXMC module implements a 4-bit Instruction Register (IR). The valid instructions and method for register access are outlined in NXMC register access via JTAG.

74.6.2 Enabling NXMC operation

The Nexus module is enabled by loading a single instruction into the JTAG Instruction Register (IR). Once enabled, the module is ready to accept control input via the JTAG pins.

The Nexus module is disabled when the JTAG state machine reaches the Test-Logic-Reset state. This state can be reached by the assertion of the $\overline{\text{TRST}}$ pin or by cycling through the state machine using the TMS pin. The Nexus module is also disabled if a Power-on-Reset (POR) event occurs.

If the NXMC module is disabled, no trace output is provided. Nexus registers are not available for reads or writes.

74.6.3 Enabling NXMC TAP controller

Assertion of a Power-on-Reset signal or assertion of the $\overline{\text{TRST}}$ pin resets all TAP controllers. Upon exit from the Test-Logic-Reset state, the IR value is loaded with the JTAG ID. When the NXMC TAP is accessed, this information helps the development tool obtain information about the Nexus module it is accessing, such as version, sequence, feature set, etc.

74.6.4 NXMC register access via JTAG

Access to Nexus register resources is enabled by loading a single instruction into the JTAG Instruction Register (IR).

Once the JTAG NEXUS-ACCESS instruction has been loaded, the JTAG port allows tool/target communications with all Nexus registers according to the map in Table 74-7.

Reading/writing of a Nexus register then requires two passes through the Data-Scan (DR) path of the JTAG state machine.

1. The first pass through the DR selects the Nexus register to be accessed by providing an index (see Table 74-7), and the direction (read/write). This is achieved by loading an 8-bit value into the JTAG Data Register (DR). This register has the format shown below.

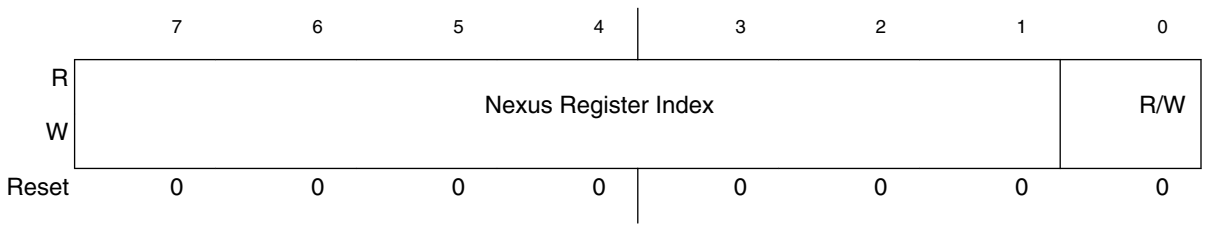

Table 74-15. JTAG DR field description for Nexus register access

Field	Description	
Nexus Register Index	Selected from values in Table 74-7	
Read/Write (R/W)	0	Read
	1	Write

2. The second pass through the DR then shifts the data in or out of the JTAG port, LSB first.
   a. During a read access, data is latched from the selected Nexus register when the JTAG state machine passes through the Capture-DR state.
   b. During a write access, data is latched into the selected Nexus register when the JTAG state machine passes through the Update-DR state.

74.7 Functional description

The following sections describe the functionality of the NXMC module.

74.7.1 Data trace

This section describes the data trace mechanism supported by the NXMC module. Data trace is implemented via Data Write Messaging (DWM) and Data Read Messaging (DRM), as per the IEEE-ISTO 5001-2012 standard.

74.7.1.1 Data trace messaging (DTM)

NXMC data trace messaging is accomplished by snooping the system bus and storing the information for qualifying accesses (based on enabled features and matching target addresses). The NXMC module traces all data access that meet the selected range and attributes.

74.7.1.2 DTM message formats

The NXMC block supports five types of DTM messages:

- Data write
- Data read
- Data write synchronization
- Data read synchronization
- Error messages

74.7.1.2.1 Data write and data read messages

The data write and data read messages contain the data write/read value and the address of the write/read access, relative to the previous data trace message. The DATA field is considered fixed based on the DSZ encodings to either 8, 16, 32 , 64. The TSTAMP field is 26 bits. Data write message and data read message information is messaged out in the format shown in the following figure. The SRC field values are described in the device-specific chapter that describes how the modules are configured.

Table 74-16. DTM message format for DATA width = 64 bits

8/16/32/64 bits	1–32 bits	3 bits	4 bits	4 bits	6 bits
DATA	U-ADDR	DSZ	MASTER	SRC	TCODE (111010 or 111011)

TSTAMP is another optional field which is inserted based on the controls received from the NAR, see Timestamping feature.

74.7.1.2.2 Data trace with non-contiguous byte strobes asserted

The v6 extensions to AMBA 2.0 allow system bus transfers with bytes non-asserted byte strobes in between asserted byte strobes. The NXMC does not support transfers with non-contiguous byte strobes asserted. In such a condition, the invalid bytes in the DATA packet are driven to the value of 0xFF.

74.7.1.2.3 DTM overflow error messages

An error message occurs when a new message cannot be queued due to the message queue being full. The FIFO discards incoming messages until it has completely emptied the queue. Once emptied, an error message is queued. The error encoding indicates which type(s) of messages attempted to be queued while the FIFO was being emptied.

If only a data trace message attempts to enter the queue while it is being emptied, the error message incorporates the data trace only error encoding (ECODE = 00000000000010). If a watchpoint also attempts to be queued while the FIFO is being emptied, then the error message incorporates error encoding (ECODE = 00000000000011).

Error information is messaged out in the format shown in this figure. The SRC field values are described in the device-specific chapter that describes how the modules are configured.

Table 74-17. DTM error message format (fixed length = 28 bits)

14 bits	4 bits	4 bits	6 bits
ECODE	ETYPE	SRC	TCODE (001000)

74.7.1.2.4 Data trace synchronization messages

A data trace write/read with synchronization message is messaged via the auxiliary port (provided data trace is enabled) for the following conditions (see Table 74-19):

- Initial data trace message upon exit from system reset or whenever data trace is enabled is a synchronization message.
- Upon returning from a low power state, the first data trace message is a synchronization message.

- Upon returning from debug mode, the first data trace message is a synchronization message.
- After occurrence of queue overrun (can be caused by any trace message), the first data trace message is a synchronization message.
- After the periodic data trace counter has expired indicating 255 without-sync data trace messages have occurred since the last with-sync message occurred.
- Upon assertion of the event in (EVTI) pin, the first data trace message is a synchronization message if the EIC bits of the DC Register have enabled this feature.
- Upon data trace write/read after the previous DTM Message was lost due to a collision while entering the FIFO between the DTM message and any of the following: error message, or watchpoint message or peripheral message.This is a very rare occurrence and possible only in case of continuous burst on the system bus as well as watchpoint events which is unrealistic.

Data trace synchronization messages provide the full address (without leading zeros) and ensure that development tools fully synchronize with data trace regularly. Synchronization messages provide a reference address for subsequent DTMs, in which only the unique portion of the data trace address is transmitted. The format for data trace write/read with synchronization messages is shown in the following figure. The SRC and MASTER field values are described in the device-specific chapter that describes how the modules are configured.

Table 74-18. Data write/read with synchronization message format

8-64 bits	1–32 bits	3 bits	4 bits	4 bits	6 bits
DATA	F-ADDR	DSZ	MASTER	SRC	TCODE (111100 or 111101)

Exception conditions that result in data trace synchronization are summarized in this table.

Table 74-19. Data trace exception summary

Exception condition	Exception handling
System Reset Negation	At the negation of JTAG reset ($\overline{\text{TRST}}$), queue pointers, counters, state machines, and registers within the NXMC module are reset. If data trace is enabled, the first data trace message is a data write/read with synchronization message.
Data Trace Enabled	The first data trace message (after data trace has been enabled) is a synchronization message.
Exit from Low Power/Debug	Upon exit from a low power mode or debug mode the next data trace message is converted to a data write/read with synchronization message.

Table continues on the next page...

Table 74-19. Data trace exception summary (continued)

Exception condition	Exception handling
Queue Overrun	An error message occurs when a new message cannot be queued due to the message queue being full. The FIFO discards messages until it has completely emptied the queue. Once emptied, an error message is queued. The error encoding indicates which type(s) of messages attempted to be queued while the FIFO was being emptied. The next DTM message in the queue is a data write/read with synchronization message.
Periodic Data Trace Synchronization	A forced synchronization occurs periodically after 255 data trace messages have been queued. A data write/read with synchronization message is queued. The periodic data trace message counter then resets.
Event In	If the Nexus module is enabled, an $\overline{\text{EVTI}}$ assertion initiates a data write/read with synchronization message upon the next data write/read (if data trace is enabled and the EIC bits of the DC Register have enabled this feature).
Collision Priority	All messages have the following priority: Error > WPM > ICTM > DTM. Although a very rare occurrence, during simultaneous burst lower priority messages can be lost due to burst of high priority messages. Proper error messages are generated and in case of DTM lost a subsequent read/write queues a data write/read with synchronization message.

74.7.1.3 Enabling data trace messaging operation

Data trace messaging can be enabled in one of three ways:

- Setting the TM field of the DC Register via JTAG to enable data trace (DC[1]).
- Using the DTS field of the WT Register to enable data trace on watchpoint hits (either watchpoints configured within the NXMC module or external watchpoint inputs controlled by the device).
- By toggling the external start control, which in turn sets the TM field of the DC register to enable data trace. (The TM bit clears and hence the data tracing stops on the toggle of external stop control. In case of conflict between JTAG write and external start/stop control, JTAG write takes precedence.

Note

When enabling the DTM, either via JTAG or external start/stop control, it is important to make sure that all the other controls (i.e. DTC, DTSA/E1/2 and WT register fields) are correctly configured to ensure correct DTM functionality.

74.7.1.4 DTM queueing

The NXMC implements a programmable depth queue for queuing all messages. Messages that enter the queue are transmitted via the auxiliary pins in the order in which they are queued.

Note

If multiple trace messages need to be queued at the same time, watchpoint messages have the highest priority (WPM > ICTM > DTM).

74.7.1.5 Relative addressing

The relative address feature is compliant with IEEE-ISTO 5001-2012 and is designed to reduce the number of bits transmitted for addresses of data trace messages. The address transmitted is relative to the address of the previous data trace message. It is generated by XORing the new address with the previous address, and then using only the results up to the most significant 1 in the result. To recreate this address, an XOR of the (most-significant 0-padded) message address with the previously decoded address gives the current address.

For example, if the previous address (A1) = 0x0003FC01, the new address (A2) = 0x0003F365 as shown in this figure.

Message Generation:

A1 = 0000 0000 0000 0011 1111 1100 0000 0001
A2 = 0000 0000 0000 0011 1111 0011 0110 0101

A1 ⊕ A2 = 0000 0000 0000 0000 0000 1111 0110 0100

Address Message (M1) = 1111 0110 0100

Address Re-creation:

A1 ⊕ M1 = A2
A1 = 0000 0000 0000 0011 1111 1100 0000 0001
M1 = 0000 0000 0000 0000 0000 1111 0110 0100

A2 = 0000 0000 0000 0011 1111 0011 0110 0101

Figure 74-1. Relative addressing example

74.7.1.6 Data trace windowing

Data write/read messages are enabled via the RWT1(2) field in the Data Trace Control Register (DTC) for each DTM channel. Data trace windowing is achieved via the address range defined by the DTEA and DTSA Registers and by the RC1(2) field in the DTC. All system bus DMA initiated read/write accesses which fall inside or outside these address ranges, as programmed, are candidates to be traced.

74.7.1.7 System bus cycle special cases

The system bus cycle special cases are shown in this table.

Table 74-20. System Bus cycle special cases

Special case	Action
System bus cycle with data error	Data trace message discarded
System bus cycle completed without error	Cycle captured and transmitted
System bus cycle is an instruction fetch	Cycle ignored

74.7.1.8 System bus multi-master tracing

DTM tracing can be done either for all the masters or for a single master (indicated by the MID field of the DTC register) based on the DTC register MME field. In case of single master, the correct value needs to be configured in the MID register before enabling the data trace operation.

The MASTER field of the DTM message (see figure in Data write and data read messages for an example) indicates the system bus master for which the trace has been generated. For each masters (0 to 15) there is a parameter associated (MSID0-15) for indicating its actual ID, which finally gets inserted in the MASTER field. The MASTER field values are described in the device-specific chapter that describes how the modules are configured.

74.7.2 Watchpoint support

The NXMC module provides watchpoint messaging via the auxiliary pins, as defined by IEEE-ISTO 5001-2012. Watchpoint messages can be generated by either using the NXMC defined internal watchpoints or by externally defined watchpoint signals.

74.7.2.1 Watchpoint messaging

Enabling watchpoint messaging is accomplished by setting the WEN bit in the DC Register. This bit is set either via JTAG write 1 access or external start indication, and cleared via JTAG write 0 access or external start indication. In case of conflict between JTAG write and external start/stop control, JTAG write takes precedence.

Note

In case of enabling the watchpoint messaging, either via JTAG or external start/stop control, it is important to make sure that all the other Watch Point Message (WPM) controls (i.e. BWC1/2, BWA1/2 register fields) are configured with the correct values in order to ensure correct WPM operation.

Watchpoint setting is supported through two methods:

- Internal watchpoints—Using the BWC1(2) registers, two independently controlled internal watchpoints can be initialized. When a system bus access address matches on BWA1(2), a watchpoint message is transmitted. The system bus multi-master or single master controls applies here too as explained for DTM (in System bus multi-master tracing).
- External watchpoints—The NXMC module supports two external watchpoint inputs. The optional logic to generate these watchpoint signals is implemented at the device level. The watchpoints are described in the device-specific chapter that describes how the modules are configured. If either of these signals asserts (i.e, on 0-to-1 transition), a watchpoint message is transmitted.

The Nexus module provides watchpoint messaging using the IEEE-ISTO 5001 defined TCODE. When any of the four possible watchpoint sources asserts, a message is sent to the queue to be messaged out. This message indicates the watchpoint number as shown in Table 74-21 and Table 74-22.

Table 74-21. Watchpoint message format (fixed length = 18 bits)

8 bits	4 bits	6 bits
WPHIT (RRRRXXXX)	SRC	TCODE (001111)

Table 74-22. Watchpoint source description

Watchpoint source (8-bits)	Watchpoint description
RRRRXXX1[1]	External Watchpoint #1(device defined)
RRRRXX1X	External Watchpoint #2 (device defined)
RRRRX1XX	Internal Watchpoint #1 (BWA1 match)

Table continues on the next page...

Table 74-22. Watchpoint source description (continued)

Watchpoint source (8-bits)	Watchpoint description
RRRR1XXX	Internal Watchpoint #2 (BWA2 match)

1. R = reserved for future use (insert 0s).

74.7.2.2 Watchpoint error message

An error message occurs when a new message cannot be queued due to the message queue being full. The FIFO discards messages until it has completely emptied the queue. Once emptied, an error message is queued. The error encoding indicates which type(s) of messages attempted to be queued while the FIFO was being emptied.

If only a watchpoint message attempts to enter the queue while it is being emptied, the error message incorporates the watchpoint only error encoding (ECODE = 00000000000001). If a data trace message also attempts to enter the queue while it is being emptied, the error message incorporates error encoding (00000000000011). Error information is messaged out in the format shown in this figure.

Table 74-23. Error message format (fixed length = 28 bits)

14 bits	4 bits	4 bits	6 bits
ECODE	ETYPE	SRC	TCODE (001000)

74.7.3 Peripheral interface

The NXMC provides an asynchronous interface to peripherals for sending data messages. The NXMC can back pressure or delay the data transfer using a data accept signal. A round-robin scheme is followed between the peripherals for forwarding received data to the queue; therefore, each peripheral has an equal priority and hence bandwidth for data transfers.

To enable messaging from peripherals there are controls present in the DC2 register for individual peripherals: DC2[PME0]. There are no message generated and hence data accepted from a peripheral unless the corresponding enable bit is set to 1.

Table 74-24. Peripheral DATA bus fields

MSB	6 bits	(54-6) bits			LSB
CKSRCn		DATAn			
54-1	54-6	54-6-1	2	1	0

n = peripheral number

Another input port is present which indicates data loss inside the peripheral itself due to over-run, the module in turn generates error message to communicate such events to the debugger.

74.7.3.1 Peripheral data message format (ICTM)

The message formats for the peripheral data messages (formatted as ICTM) is shown in the following figure. The SRC field values are described in the device-specific chapter that describes how the modules are configured. The CKSRC field is received from the MSB 6 bits of the individual peripheral data bus, and CKDATA is a variable field and contains 44 LSBits received on the databus of the peripheral interface.

Table 74-25. Peripheral message format (max length = 60 bits, min length = 17 bits)

1–44 bits	6 bits	4 bits	6 bits
CKDATAn	CKSRCn	SRC	TCODE (100010)

74.7.3.2 Peripheral error message format

The error messages are generated based data over-run indication from a peripheral. Error information is messaged out in the format shown in this figure.

Table 74-26. Error message format (fixed length = 28 bits)

14 bits	4 bits	4 bits	6 bits
ECODE(CKSRCn,ErrCODE)	ETYPE	SRC	TCODE (001000)

The SRC field values are described in the device-specific chapter that describes how the modules are configured. ETYPE and ECODE encoding are listed in Table 74-5 and Table 74-6.

74.7.4 Timestamping feature

This feature allows a timestamp packet to be appended to all messages, based on the timer value and controls received externally from the NAR. If enabled, this packet is added as the last field to all the outgoing messages. The TSTAMP packet width is 26 bits.

The TSTAMP packet is appended at the end of a message during message formatting, before transfer. This figure shows an example of ICTM message with a TSTAMP field.

Table 74-27. Message with TSTAMP field example

26 bits	1–44 bits	6 bits	4 bits	6 bits
TSTAMP	CKDATAn	CKSRCn	SRC	TCODE (100010)

The enable or disable indication should remain static for the complete debug session. Dynamically enabling or disabling of the timestamping is not allowed during running debug tracing. The following steps allow seamless enabling/disabling of the timestamping:

1. All tracing (DTM/WPM/ICTM) must be disabled
2. Wait for the internal queues to be emptied (no further request is asserted at the auxiliary interface)
3. Change the timestamp enable indication to assert/deassert
4. Enable the required tracing controls (via TM, PME0 etc. control bits)

Chapter 75
Functional Safety

75.1 Introduction

The MPC5746R offers a set of features to support applications that need to fulfill functional safety requirements as defined by automotive safety integrity level ASIL-D of ISO26262. This chapter gives an overview of the safety implementation for the MPC5746R and discusses the operation of the safety mechanisms.

75.2 Safety overview

The MPC5746R has been designed for automotive applications executing safety-relevant tasks that require either a fail-silent or fail-indicate MCU. The MPC5746R supports a Fault Tolerant Time Interval (FTTI) of at least 10 ms. Shorter intervals are possible depending on the actual combination of failure detection and signaling mechanisms as documented in the Safety Manual (SM), but, in general, the MPC5746R supports an FTTI of 10 ms.

75.3 Module categorization

The definition of the MPC5746R safety concept and its validation (particularly the computation of Probabilistic Metric for Random Hardware Failures (PMHF)) has been done by splitting system modules into four categories as shown in the following table.

Table 75-1. PMHF module categories

Module category	Category abbreviation	Description
Vital system modules	ViMo	All modules that can directly influence the correct operation of the software execution (by influence of the correct function of CPU, RAM, flash, and the bus interconnect). Examples of ViMo are the core, the cache, the crossbar, and the interrupt controller (INTC), as well as clock or power generation.
Peripheral modules	PeMo	All microcontroller modules involved in I/O operation, specifically including the I/O bridge.
Non-safety modules	NoSaMo	Modules that belong in one of the above categories but that do not require hardware-level safety measures. Only their non-interference with modules from the other categories is ensured by hardware. In case they are used in a safety-relevant way, application measures are necessary to ensure their safe operation.
Other support modules	SuMo	These are modules which, although safety-relevant and in principle potential members of the ViMo category, cannot lead to a violation of the safety goal on their own. Typically, these will only have multiple point faults, but not single point faults. Example SuMo's are the RCCU and Clock Monitoring Unit (CMU).

75.4 System implementation

75.4.1 General concept

In general, safety integrity is achieved in the following ways:

- For the Safety Core, and its closely related periphery, safety is ensured by a delayed lockstep approach (see section "Dual-core lockstep" in this chapter).
- The safety of storage and of the data path to storage and periphery is ensured by End-to-End ECC (E2E ECC) with address encoding and selected additional measures for individual modules. For the periphery, end-to-end ECC ends at the I/O bridges (see section "End-to-End protection on data path" in this chapter).
- Clock and power, generation and distribution, are supervised by dedicated monitors (see section "Clock and power monitoring" in this chapter).
- The safety of the periphery is ensured by application-level measures (such as connecting one sensor to different I/O modules, sensor validation by sensor fusion, and so on). Hardware supports this application-level redundancy by providing redundant I/O modules connected to different peripheral bridges (PBRIDGE) to maximize the independence between the monitored and monitoring resources (see sections "I/O peripherals" and "Communication controllers" in this chapter).
- MBIST and LBIST are provided to avoid the accumulation of latent faults in the functional logic as well as the safety integrity mechanisms (see section "Built-In Self Tests (BIST)" in this chapter). Dedicated mechanisms are provided to check the

availability of safety mechanisms and the functionality of each error reaction path (such as by fake fault injection). The MPC5746R Safety Manual includes detailed information on BISTs implemented on the device.

- The Fault Collection and Control Unit (see "Fault Collection and Control Unit (FCCU)" chapter for FCCU details) is responsible for collecting and reacting to failure notifications (see section "FCCU and failure monitoring" in this chapter). MEMU (see section "Memory Error Management Unit (MEMU)" in this chapter) is responsible for the collection and reporting (to the FCCU) of error events in system memories, flash memories, and peripheral memories, as well as E2E ECC errors caused by the XBAR, or RAM or flash memory controllers. Error events include ECC corrections and detections as well as faults detected by memory BISTs.
- Common Cause Failures (CCF) are handled by measures for control and avoidance of CCFs, including system-level approaches (such as temperature and nonfunctional signal monitoring) and back-end techniques (such as isolated silicon areas and routing constraints) (see section "Common Cause Failure measures" in this chapter).

75.4.1.1 End-to-End protection on data path

Connections between XBAR masters and slaves (clients) are denoted as data paths. Data corruption on all data paths between the Safety Core and any client is detected via two main safety mechanisms: data from the replicated cores is encoded using Error Correcting Code (ECC), which is implemented with a Single-Error Correction, Double-Error Detection (SECDED) code with a Hamming distance of 4 and includes coverage of addressing information; control signals and address decoding are monitored to verify the data reaches all of the intended clients, from all possible connections to these clients and the intended operation is performed on the target address. The following figure shows a general view of ECC schema.

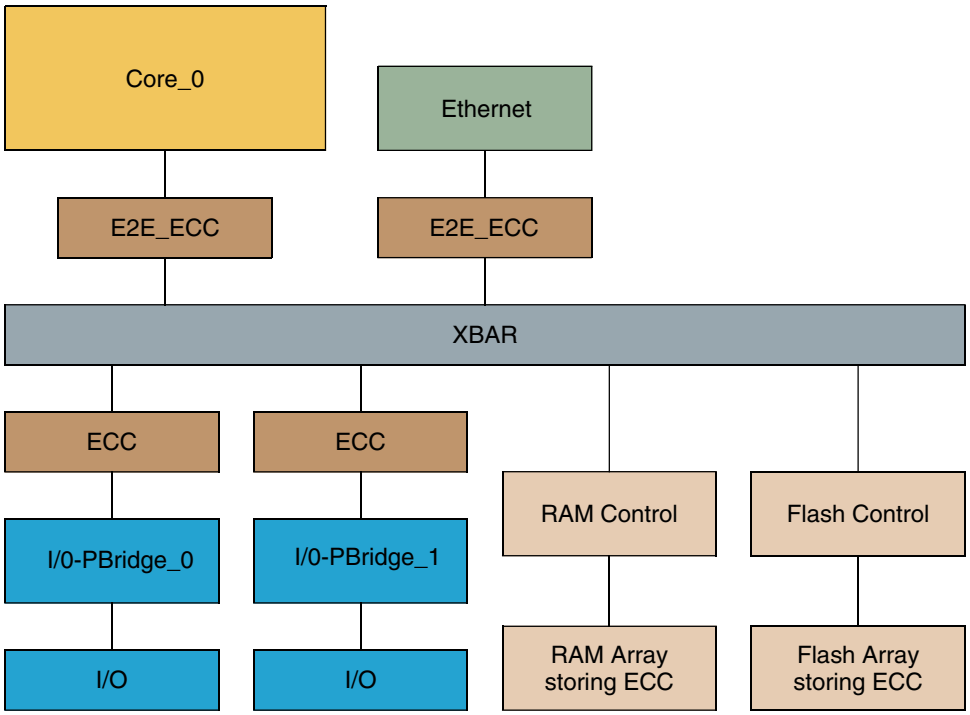

Figure 75-1. General view of E2E ECC

NOTE

Specific implementation for the MPC5746R may vary depending on the special requirements of RAM and flash memory concerning ECC handling.

ECC bits are generated on writes by XBAR masters (including, but not limited to the Safety Core) and checked on reads. The ECC correction bits are stored alongside the data in flash memory and RAM so, in principle, no ECC logic is necessary at the memories themselves. For this reason the ECC schema is referred to as End-to-End ECC (E2E ECC) in the following sections. For XBAR slaves, other than memories, new ECC logic is added as these clients cannot store or produce the ECC correction bits. This resolves the problem where ECC needs to be calculated in real time before entering or exiting the ECC-protected data path. This is particularly true with peripherals connected to the I/O bridges. This setup is considered sufficient to fulfill safety requirements because the data path not protected by ECC, which is downstream from the I/O bridges, is replicated and is used redundantly by the application (see section "I/O peripherals" in this chapter).

The E2E ECC schema provides high detection capabilities against failures affecting the data content of the transaction. The inclusion of the target address in the computation of the redundancy bits (8 ECC bits) allows the partial detection of addressing faults as well. To reach the desired integrity level, additional dedicated safety mechanisms are implemented in the data path particularly to:

- Improve the detection capability over addressing failures (no/multiple/wrong address selected), considering faults affecting address transmission (from master to client) as well as the decoding of the address;
- Provide coverage for control failures affecting, for example, the type (read vs. write) or size of a transaction.

Though safety mechanisms protecting the XBAR, the RAM controller, or the flash memory controller are different, they are all based on the feedback of address and control information from the target to the source of the transaction, which is responsible for checking for consistency with respect to the intended transaction. Depending on the portion of the data path covered by the specific safety mechanism, the source can be an XBAR master port rather than the XBAR interface of the RAM or Flash Memory Controllers; the target is respectively an XBAR slave port, the RAM array, or the flash memory module. See the separate chapters dedicated to the Crossbar Switch (XBAR), Flash Memory Controller, and RAM Controller (PRAM) for details.

75.4.1.2 Clock and power monitoring

75.4.1.2.1 Clock

Clocks in the MPC5746R are supervised by Clock Monitor Units (CMUs). The CMUs are driven by the IRCOSC (16 MHz internal oscillator) for independent operation from the monitored clocks. CMUs flag errors associated with conditions due to loss of clock, clock out of a programmable bound (over and under frequency), and loss of reference. If a supervised clock leaves the specified range for the device, a signal is sent to the FCCU.

Please see the Clock Management Unit chapter for the clocks that are supervised.

The clock tree for Core_0 and Core_0 - Checker (the two lock step cores comprising the Safety Core) consists of separate clock branches that are not shared with any other module.One CMU (CMU_1) is connected to the RCCU clock path, downstream from the common part of the clock tree for the Master and Checker Cores. In this way any frequency failure affecting the RCCU clock or the common clock (SYS_CLK) is detected by the CMU, and any frequency failure affecting the Main or Checker Core clock is detected by the Redundancy Control and Checker Units (RCCUs) (see "Clocking" chapter for detailed clocking information).

75.4.1.2.2 Power

There are two types of voltage supervisors on the MPC5746R, Low Voltage Detect (LVD) and High Voltage Detect (HVD) monitors. Safety relevant voltages (recommended operating voltages), are supervised for voltage levels that are out of correct operating voltage ranges. Since any voltage running outside of the correct operating voltage range has the potential to disable the failure indication mechanisms of the MCU, the indication of these voltage variations can be used to cause a direct transition of the MCU into the safe state (reset assertion) (see "Power Management Controller digital interface (PMC_dig)" and "Power Control Unit (MC_PCU)" chapters for details on power monitoring).

75.4.1.3 I/O peripherals

To allow a safety application to use redundant I/O peripherals, each individual peripheral from a pair of redundant peripherals is connected to a different PBRIDGE. For example, if DSPI is provided by the MCU, two DSPI modules (DSPIn, DSPIm) are included and connected externally through different pins. Internally, DSPIn is connected to PBRIDGE_0 and DSPIm is connected to PBRIDGE_1 and is accessible via different addresses.

The arrangement of I/O peripherals onto two PBRIDGEs, as well as further CCF prevention measures, allow redundant use of peripherals while limiting possible causes of CCFs. Redundant usage includes usage of equivalent peripherals in a replicated way as well as usage of functionally different peripherals in, for example, feedback measurement loops. Comparison of redundant operation is the responsibility of the application software, not the safety hardware mechanism.

75.4.1.4 Communication controllers

Communication controllers provide the ability to exchange information with external components and therefore fall under the same safety requirements as I/O peripherals. High bandwidth communication controllers require additional software measures which provide mechanisms for adhering to functional safety requirements.

The following communication controllers do not contain special safety mechanisms (above what is included in their protocol specifications) nor are they duplicated or spread over the PBRIDGE (in contrast to other I/Os, see section "I/O peripherals" in this chapter):

- FlexCAN Communication Controller

- Universal Asynchronous Communication Controller (LINFlexD)
- Fast Ethernet Controller (FEC)

Typically, software measures for the communication controllers (also called fault-tolerant communication layer) can include E2E CRC data protection, sender identification, sequence numbering, and an acknowledgement mechanism.

75.4.1.5 Built-In Self Tests (BIST)

BIST is a mechanism that permits a device to perform self-test. BIST can be used (typically at startup) to ensure the absence of latent faults. On the MPC5746R, BIST provides a mechanism for meeting this requirement for avoiding latent faults as defined by the ISO 26262 standard. Different BIST mechanisms are implemented in the MPC5746R: LBIST for digital logic and MBIST for memories. LBIST and MBIST execution is managed by the STCU2 (see "Self-Test Control Unit (STCU2)" chapter).

75.4.1.5.1 BIST during boot

A device BIST is performed every time the device boots. BIST is performed transparently for the application while the device is still under reset. In case the BIST fails, the device is held in reset, but the BIST continues running, if possible, and informs the system of the failure. Application software can start executing when the BIST finishes successfully without detecting a fault. The boot time BIST comprises:

- Memory BIST for all RAMs and ROM
- Scan-based Logic BIST for digital logic, which is divided into multiple partitions that can be configured to be tested in parallel or sequentially to find the best time versus power consumption trade off.

75.4.1.6 Redundancy Control and Checker Units (RCCUs)

The RCCU compares a set of equivalent input signals provided by different sources and issues an alarm in case of a mismatch. For example, an RCCU compares the output of the checker core against the output of the Master core and issues an alarm if they do not match. In case of a compare mismatch the fault stays stable until it is explicitly cleared.

75.4.1.7 FCCU and failure monitoring

The FCCU offers a hardware mechanism to aggregate error notifications and a configurable means to bring the device to a safe state. No CPU intervention is required for collection and control operation. Error indications are passed from the individual hardware components to the FCCU where the appropriate action is decided (according to the FCCU configuration).

For a list of fault inputs see section "FCCU failure inputs from other modules" in the FCCU chapter.

75.4.1.7.1 External error indication

Failure of the MCU is signaled to one or two pins, FCCU_F[0] and FCCU_F[1]. See the "Fault Collection and Control Unit (FCCU)" chapter for details on the fault output signals.

The error indication on pins FCCU_F[0] and FCCU_F[1] is controlled by the FCCU.

The error status flag (FCCU_STAT[ESTAT]) can be read to determine whether the FCCU is in an error state. This flag can be written by software to either a 1 (fault) or 0 (operational) when the FCCU is in operational state. Another flag, FCCU_STAT[PhysicErrorPin], is accessible through the register interface. It mirrors the physical state of the FCCU_F[n] external pin's value, though this might differ from the logical state if a toggling protocol is used.

75.4.1.7.2 Failure handling

The FCCU is an autonomous module that is responsible for reacting to failure indicators. A different reaction can be configured for each failure source. Overall failure reaction time requires time for detecting, processing, and indicating the error. During this time, the MPC5746R could provide incorrect results to the system.

Failure sources include:

- All failure indication signals from modules within the MCU
- Control logic and signals monitored by the FCCU itself. See the "Fault Collection and Control Unit (FCCU)" chapter for details.
- Software-initiated failure indications. For example, software signals the FCCU that it has evidence of a failure. Keep in mind that software can also directly influence the state of the FCCU_F[n] pins.
- External failure input

Available failure reactions are:

- Assertion of an interrupt (maskable or non-maskable)
- Resetting the chip
- Changing the state of the failure indication pins, ERRORn
- Disabling the transmission capabilities of communication controllers (Ethernet, CAN) (note: possible only in conjunction with changing the state of the failure indication pins and the SMC bit of the corresponding pad's MSCR register)
- No reaction

Software can read the failure source that caused a fault, and can do so either before, or after, a functional reset (the condition indicators are not volatile). Software can also reset the failure, but the external failure indication will stay in failure mode for a configurable minimum time. If necessary, software can also reset the MCU.

75.4.1.8 Operational interference protection

Being a multi-master system, MPC5746R provides safety mechanisms to prevent non-safety masters from interfering with the operation of the Safety Core, as well as mechanisms to handle the concurrent execution of software with different (lower) ASIL. Interference freedom is guaranteed via a hierarchical memory protection schema including:

- MPUs
- PBRIDGEs
- Register protection.

There are two Memory Protection Unit levels included in the MPC5746R. The Core Memory Protection Unit (CMPU) is a mechanism included in each core to protect address ranges against access by software developed according to lower ASIL. It will typically be used by the operating system to ensure inter-task interference protection.

The second MPU level is provided by the System MPUs (SMPU) located in each XBAR. They will prevent access of different bus masters to address ranges and will typically be used by the safety application to prevent NoSaMos to access the application's safety-relevant resources.

Furthermore, the PBRIDGE can restrict read and write access to individual I/O modules based on the origin of the access and its state (user mode/supervisor mode).

Finally, the register protection included allows individual registers to be "locked" against any manipulation without unlocking.

These safety mechanisms are further described in "System Memory Protection Unit (SMPU)".

75.4.1.9 FCCU supervision (FOSU)

As the FCCU is a central component in reacting to errors, it is itself supervised even though an error in it can only cause a latent failure. This supervision is provided by the FOSU (FCCU Output Supervision Unit). The FOSU receives failure indications at the same time as the FCCU. Unless the respective failure is switched off, the FOSU will observe the outputs of the FCCU (IRQ, RESET, FCCU_F[n]). If the FCCU does not react—within a predefined interval—on one of those outputs to the incoming failure indication, the FOSU assumes the FCCU has failed and causes a reset.

The FOSU does not require any configuration by software.

75.4.2 Dual-core lockstep

The MPC5746R duplicates its safety-relevant processing elements and compares their operation in Lockstep mode (LSM). This Safety core consists of two cores, Checker Core_0 and Master Core_0, and as far as software is concerned they behave as one core. Main Core_0 is the main execution core of the pair, where Checker Core_0 follows the execution of the Master core in lockstep.

The processing elements which are replicated contain:

- Core
- Cache control
- Local memory control
- Core Memory Protection Unit (CMPU)
- Core System Bus Interface, including E2E ECC logic
- eDMA controller

Together each set of replicated elements forms a channel (for example, the Main channel and the Checker channel).

Elements that are not replicated are:

- Cache and local memory arrays
- INTC
- Interconnect (XBAR)
- RAM controller
- Flash memory controller

NOTE

This is not a complete list of all non-replicated elements. But the elements listed are sometimes replicated in similar lockstep architectures.

Equivalent operation of replicated resources is supervised by comparators on all functional signals leaving the channels for the rest of the MCU. Any operational deviations between the supervised signals will cause the FCCU to be notified of the discrepancy.

The Checker Core does not have a direct connection to the XBAR. All of the outputs of Checker Core_0 that target the XBAR (as well as any other non-duplicated resource, like local memories) will end in an RCCU for verification, and all the inputs to Checker Core_0 from the XBAR will be split off from the Main Core_0 XBAR inputs.

An abstract view of the implementation including delays and RCCUs is shown in the following figure, but it does not show the local memory.

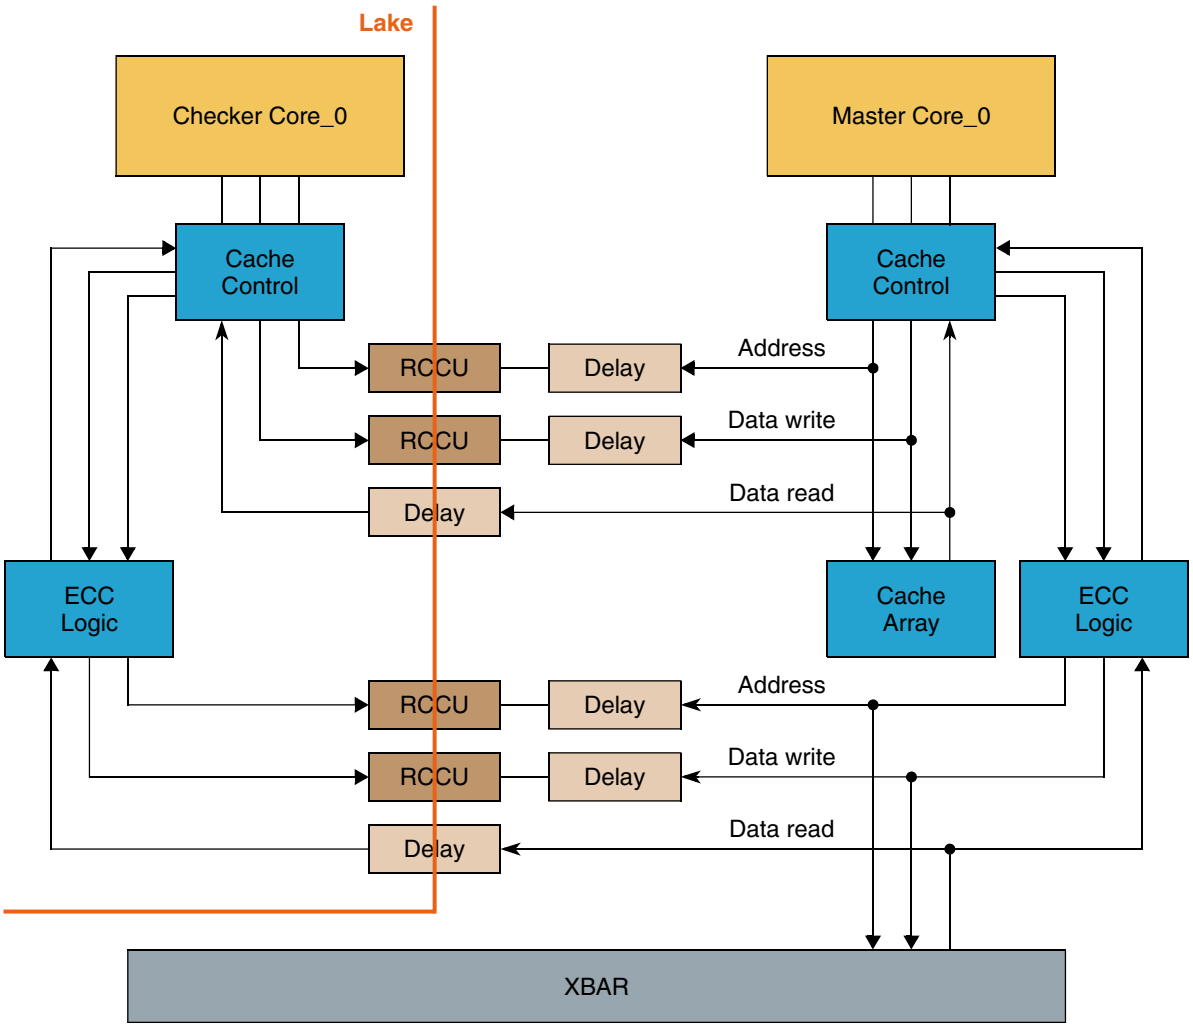

Figure 75-2. Dual core concept

A delay of two clock cycles exists between the Master and Checker channel to reduce their susceptibility to CCFs caused by power and clock disturbances. Outputs of the Master core (such as XBAR addresses) are registered and delayed before being forwarded to the RCCUs while inputs signals (such as XBAR read data) are registered and delayed before being fed to the Checker channel.

LSM can be disabled during boot by reprogramming the flash memory. LSM is not guaranteed when Core_0 is in debug mode; cores (main and checker) are working, but the RCCUs are disabled. If disabled, the Checker Core (Core_0 - Checker) and the RCCUs are constantly off. No dynamic switching is possible between lockstep on/off, a reset is needed to reestablish LSM. No Decoupled Parallel Mode (DPM) is available (Main Core_0 and Checker Core_0 cannot operate as two independent cores running different software). Main Core_0 is able to operate as an independent core if Checker Core_0 is disabled. The status of LSM for the Safety core can be verified by checking the

Core Status register (ME_CS) in the Mode Enable module (MC_ME). If both Main Core_0 and Checker Core_0 are on, or both off, the Safety Core is in LSM. See the "Core Status Register (ME_CS)" section in the "Mode Entry Module (MC_ME)" chapter.

75.4.3 Common Cause Failure measures

Various measures are included to prevent CCFs from endangering the effectiveness of the replication of the Safety Core or of the peripherals. These measures include physical separation of the components on the die, routing restrictions and supervision of clock, power, temperature, test and debug signals. In general these measures are independent from the software.

Also, there are several functional configuration registers throughout the MCU where, if they erroneously change, they can affect the execution of the MCU's safety function and, at the same time, disable the respective safety mechanism. These registers in particular are either protected against bit flips or those flips are detected by independent measures. These same registers are also protected against accidental software writes by employing as well the register protection safety feature.

75.4.4 ECC

Error correcting codes are used for end-to-end protection from cores to system storage as well as for individual protection of peripheral RAMs.

75.4.4.1 ECC for storage

All storage (System RAM, local memory, flash memory, peripheral RAM) used in normal operation is protected by ECC with SECDED (Single Error Correct and Double Error Detect). Exceptions to this are noted below:

- The caches in the cores are protected by EDC (Error Detection Code), which detects but does not correct errors.

Some memories, particularly system storage, use an ECC computed over data and address to detect data and addressing faults (no/wrong/multiple selection). In addition, these same memories include dedicated measures against addressing and control faults (such as address/control feedback). This is different for storage related to PeMos. PeMos in general use an ECC without address error protections and also do not include additional measures to detect them.

75.4.4.2 All-x words and ECC

There is a special case for legal ECC values in the MPC5746R. Memory entries that are all zeros (All-0) or all ones (All-1), including the ECC parity bits, are not legal for memory that is checked by ECC. The flash memory allows All-1, corresponding to the status of an erase block, as a valid codeword.

Memories that include addresses in the ECC calculation do not specifically protect against All-0 or All-1. This means that for some addresses All-0 or All-1 may be legal.

All-0 and All-1 memory content is indicated in different ways. For memories that do not include address into the ECC calculation, All-0 and All-1 will be uncorrectable errors. For all memories that include address into the ECC code-bit calculation, since the ECC checkbits depend on the address, it is not possible to generate an uncorrectable error indication for all the possible addresses. Therefore, an All-x content may result in a correctable error.

Notice that for flash memory, additional dedicated safety mechanisms exist to detect failures that have the potential of leading to an All-1 word (see the "Flash memory controller" chapter for more details on flash memory safety mechanisms).

75.4.4.3 ECC failure handling

Single-bit and double-bit errors (correctable and uncorrectable errors) are signaled to the FCCU unless filtered by the MEMU. The MEMU (see section "Memory Error Management Unit (MEMU)" in this chapter) may filter ECC error notification for known ECC error addresses (known permanent correctable errors). Actual implementation will signal errors, not to the FCCU, but to the MEMU which filters, then forwards unfiltered notifications in an aggregated manner to the FCCU.

75.4.4.4 Memory Error Management Unit (MEMU)

The MEMU is responsible for the collection and reporting of error events associated with ECC logic used on SRAM (system RAMs in this context are those RAMs with "System RAM" memory classification), peripheral RAM, and flash memory. When ECC error events occur, the MEMU receives an error signal that causes an event to be recorded, and possibly sets corresponding error flags that are reported to the FCCU.

The MEMU stores the addresses of ECC errors that have occurred in a table as follows:

- Uniqueness of the addresses in the table is ensured. For example, if an address is already stored in the MEMU's table, correctable errors at that address will no longer be reported to the FCCU.
- Software can read and modify the MEMU table and remove individual entries (by marking them as invalid). For example, this allows software to invalidate a new entry in the MEMU table and wait for a repeat occurrence of the ECC error indicating a permanent error in memory.
- If the MEMU table overflows, an additional signal (instead of the ECC error signal) is sent to the FCCU.

As the MEMU aggregates address information from several sources, it might not be able to process all simultaneously arriving reports. This is called a simultaneous overflow and is signaled to the FCCU as a buffer overflow (see "Memory Error Management Unit (MEMU)" chapter for details).

75.4.4.4.1 Interface to ECC units

The MEMU receives data according to the following interface per ECC unit connected:

- Whether the error is a Single-Bit-Error (SBE) or Uncorrectable Error (UCE) type
- Address of the memory where the error occurred
- A configuration specifying whether the ECC unit is attached to a vital memory (SRAM, local memory, and system RAM of Safety Core), to flash memory, or to a peripheral RAM

If an error is signaled, it is compared against all errors known for that storage:

NOTE

If a previously known error has been marked invalid by software, no comparison against the address will occur.

- If no entry of that address is already in the buffer, it will be added into the appropriate table depending on the SBE versus UCE indicator

NOTE

For this comparison the bit position will not be taken into account. This is in contrast to MBIST reporting.

- If there is no free entry left in that buffer, the overflow flag is set.

If a valid entry of that address is in the buffer, the following occurs:

- If the entry indicates an SBE in that address, and the error indicated is correctable, a new entry is added in the MEMU buffer.
- In all other cases, nothing is changed in the entry.

Chapter 76
Cyclic Redundancy Check (CRC) Unit

76.1 Introduction

The Cyclic Redundancy Check (CRC) computing unit is dedicated to the computation of CRC, off-loading the CPU. Each context has a separate CRC computation engine in order to allow the concurrent computation of the CRC of multiple data streams. The CRC computation is performed at speed without wait-state insertion. Bit-swap and bit-inversion operations can be applied on the final CRC signature. Each context can be configured with one of three hard-wired polynomials, normally used for most of the standard communication protocols. The data stream supports multiple data width (byte/halfword/word) formats.

76.2 Main features

- Single context is supported
- Zero-wait states during the CRC computation (pipeline scheme)
- Four hard-wired polynomials (two CRC-8, CRC-32 Ethernet, and CRC-16-CCITT)
- Support for byte, halfword, or word width of the input data stream

76.2.1 Standard features

- Peripheral bus interface
- CRC-8 VDA CAN
- CRC-16-CCITT

- CRC-32 Ethernet (see note below)
- CRC-8-H2F Autosar polynomial

NOTE

Although the CRC-32 Ethernet polynomial is used for CRC generation, the generation algorithm differs (MISR) from the one used by the Ethernet protocol (IEEE 802).

76.3 Block diagram

The top level diagram of the CRC module is given in the following figure. Refer to Main features for number of contexts in this module.

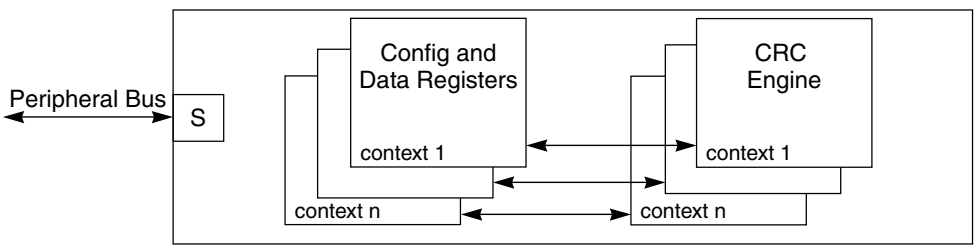

Figure 76-1. CRC top level diagram

76.4 External signal description

The CRC module does not generate any external signals.

76.4.1 Peripheral bus interface

The peripheral bus interface is a slave bus used for configuration and data streaming (CRC computation) purposes via CPU or DMA. The following bus operations (contiguous byte enables) are supported:

- Word (32 bits) data write/read operations to any registers
- Low and high halfword (16 bits, data[31:16] or data[15:0]) data write/read operations to any registers

- Byte (8 bits, data[31:24], data[23:16], data[15:8], or data[7:0]) data write/read operations to any registers
- Any other operation (free byte enables or other operations) must be avoided.

The CRC module generates a transfer error in the following cases:

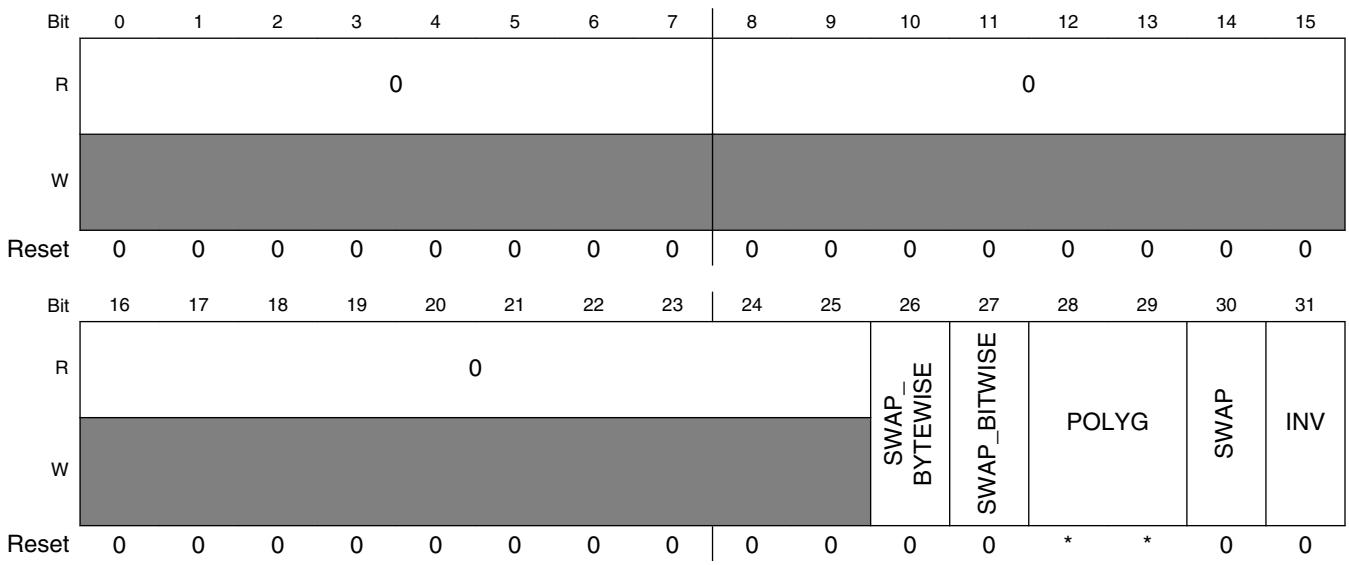
- Any write/read access to the register addresses not mapped on the peripheral but included in the address space of the peripheral
- Any write/read operation different from byte/halfword/word (free byte enables or other operations) on each register

The registers of the CRC module are read/write accessible in each access mode:
- user
- supervisor

The following summarizes bus operation performance:

- Zero wait states (single bus cycle) for each write/read operation to the CRC_CFG and CRC_INP registers
- Zero wait states (single bus cycle) for each write operation to the CRC_ CSTAT register
- Double wait states (3 bus cycles) for each read operation to the CRC_ CSTAT or CRC_OUTP registers immediately following (next clock cycle) a write operation to the CRC_CSTAT, CRC_INP, or CRC_CFG registers belonging to the same context; in all the other cases, no wait states are inserted

76.5 CRC memory map and registers



CRC memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	Configuration Register (CRC_CFG)	32	R/W	See section	76.5.1/3232
4	Input Register (CRC_INP)	32	R/W	0000_0000h	76.5.2/3233
8	Current Status Register (CRC_CSTAT)	32	R/W	FFFF_FFFFh	76.5.3/3234
C	Output Register (CRC_OUTP)	32	R	FFFF_FFFFh	76.5.4/3234

76.5.1 Configuration Register (CRC_CFG)

Access: User read/write.

Address: 0h base + 0h offset = 0h

* Notes:

- POLYG field: Reset value is a function of the number of contexts, N. When N%2 = 0, reset value = 01b. When N%2 = 1, reset value = 00b.

CRC_CFG field descriptions

Field	Description

CRC_CSTAT field descriptions

Field	Description
0–31 CSTAT	CRC signature status This register includes the current status of the CRC signature. No bit swap and inversion are applied to this register. In the case of the CRC-CCITT polynomial, only the 16 least-significant bits are significant. The 16 most-significant bits are set to 0 during the computation. In the case of the CRC-8 polynomial, only the 8 least-significant bits are significant. The 24 most-significant bits are set to 0 during the computation. The CSTAT register can be written at byte, halfword, or word. This register can be written only during the configuration phase.

76.5.4 Output Register (CRC_OUTP)

Access: User read-only.

Address: 0h base + Ch offset = Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

CRC_OUTP field descriptions

Field	Description
0–31 OUTP	Final CRC signature This register includes the final signature corresponding to the CRC_CSTAT register value eventually swapped and inverted. In the case of the CRC-CCITT polynomial, only the 16 least-significant bits are significant. The 16 MSB bits are set to 0 during the computation. In the case of the CRC-8 polynomial, only the 8 least-significant bits are significant. The 24 most-significant bits are set to 0 during the computation.

76.6 Functional description

The CRC module supports the CRC computation for each context. Each context has its own complete set of registers, including the CRC engine. The data flow of each context can be interleaved. The data stream can be structured as a sequence of bytes, halfwords, or words. The input data sequence is provided, eventually mixing the data formats (byte, halfword, and word), writing to the input data register (CRC_INP).

The data stream is generally executed by *n* concurrent DMA data transfers (mem2mem) where *n* is less or equal to the number of contexts.

The standard generator polynomials are given in Figure 76-6, Figure 76-7, and Figure 76-8 for the CRC computation of each context. Two separate registers are available: CRC_INP for writing data and CRC_CSTAT for retrieving the (accumulated up to now) CRC.

$$x^8 + x^4 + x^3 + x^2 + 1$$

Figure 76-6. CRC8 VDA CAN

$$x^{16} + x^{12} + x^5 + 1$$

Figure 76-7. CRC-CCITT (x.25 protocol)

$$x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x + 1$$

Figure 76-8. CRC-32 (Ethernet protocol)

$$x^5 + x^3 + x^2 + x + 1$$

Figure 76-9. CRC-8-H2F (Autosar 4.0 protocol)

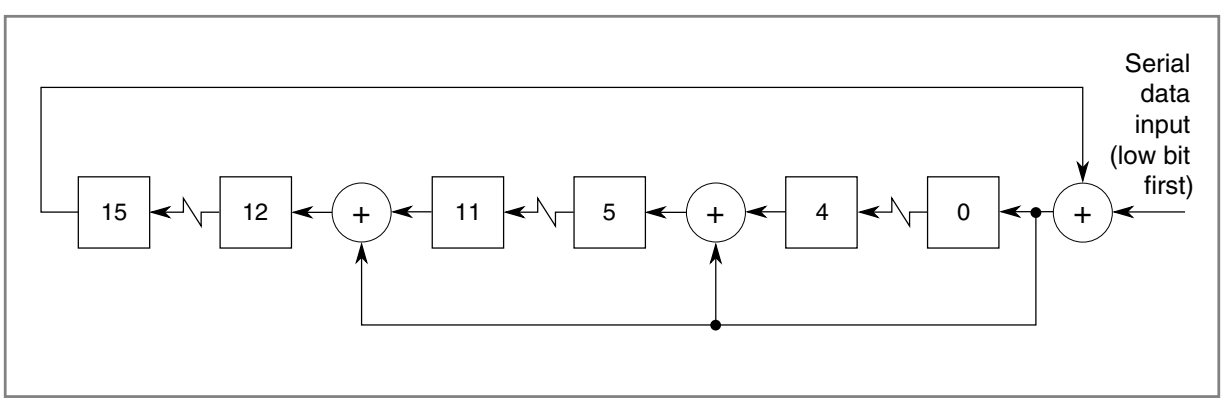

Figure 76-10. CRC-CCITT engine concept scheme

The initial seed value of the CRC can be programmed by initializing the CRC_CSTAT register. A diagram illustrating serial data loading of the CRC engine is shown in Figure 76-10 for the CRC-CCITT. Note that, conceptually, the least-significant, or "right-most," bit shown in Input Register (CRC_INP), is fed first into the engine. The actual implementation executes the CRC computation in a single clock cycle (parallel data loading). A pipeline scheme has been adopted to decouple the IPS bus interface from the CRC engine in order to allow the computation of the CRC at speed (zero wait states).

If the CRC signature is used for encapsulation in the data frame of a communication protocol (for example, SPI, etc.), a bit swap (high bit for low bit or low bit for high bit) and/or bit inversion of the final CRC signature can be applied to CRC_OUTP before transmitting the CRC.

Use of the CRC module is summarized in the flow chart given in Figure 76-11.

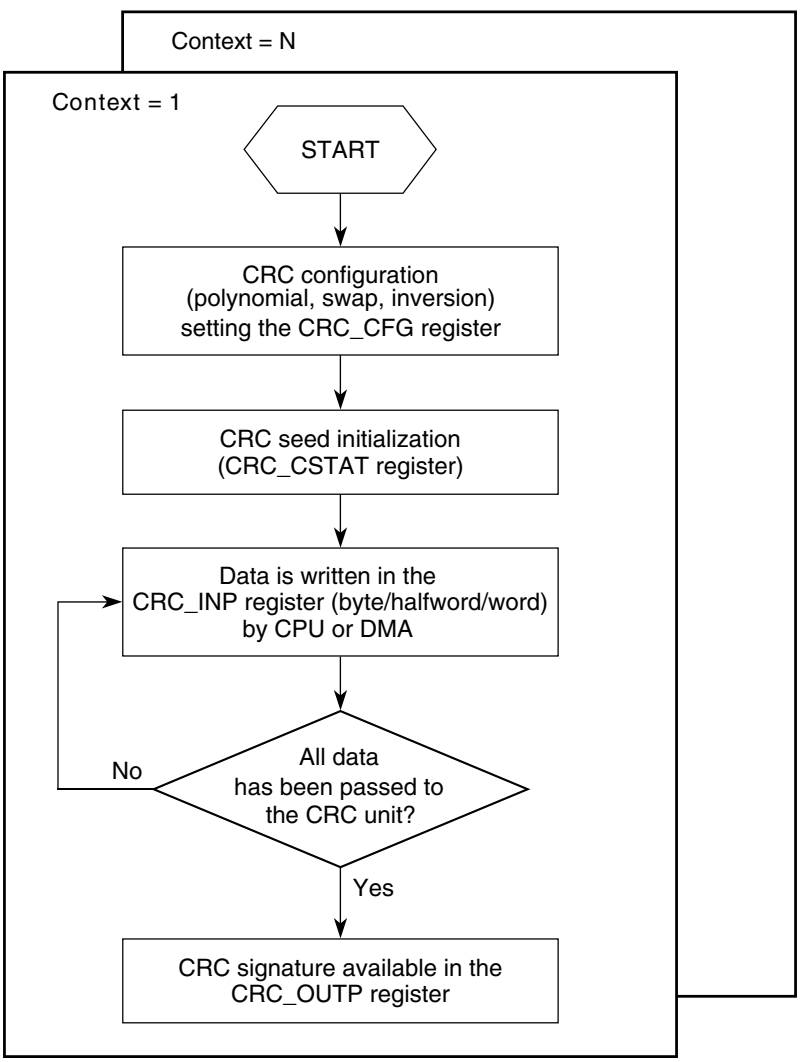

Figure 76-11. CRC computation flow

76.7 Use cases

76.7.1 Programming example

The number of contexts depends on the application. The overall number of contexts for the CRC peripheral depends on the number of peripherals that concurrently require intervention by the CRC module. Two main use cases are considered:

- Calculation of the CRC of the configuration registers during the process safety time
- Calculation of the CRC on the incoming/outcoming frames for the communication protocols (not protected with CRC by definition of the protocol itself) used as a safety-relevant peripheral

The signature of the configuration registers is computed correctly only if these registers do not contain any status bit.

Assuming that the DMA engine has *n* channels (greater than or equal to the number of contexts) configurable for the following types of data transfer—mem2mem, periph2mem, mem2periph—the following sequence, as shown in the following figure, is applied to manage the transmission data flow:

1. DMA/CRC module configuration (context x, channel x) by CPU
2. Payload transfer from the MEM to the CRC module (CRC_INP register) after MSB-to-LSB change (input mirroring) to calculate the CRC signature (phase1) by DMA (mem2mem data transfer, channel x)
3. CRC signature copy from the CRC module (CRC_OUTP register) to the MEM (phase 2) by CPU
4. Data block (payload + CRC) transfer from the MEM to the PERIPH module (for example, SPI Tx FIFO) (phase 3) by DMA (mem2periph data transfer, channel x)

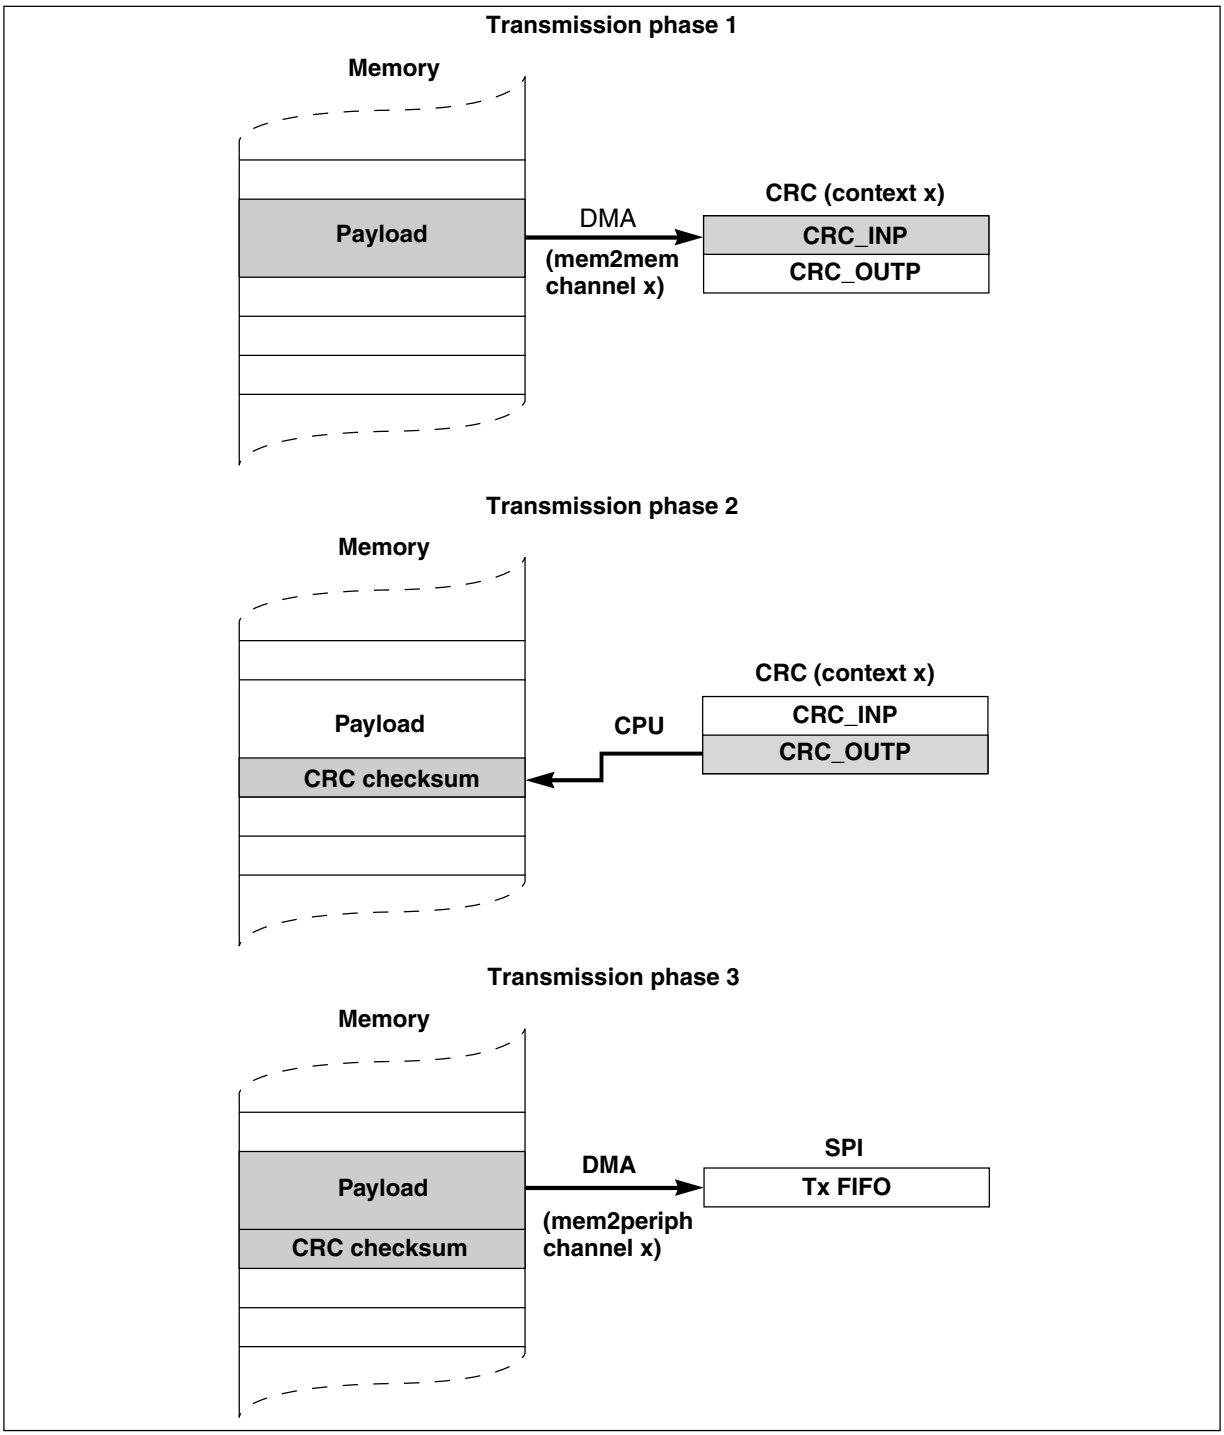

Figure 76-12. DMA-CRC transmission sequence

76.7.2 Register programming

- INV and/or SWAP (affecting the output only) can be applied to CRC-8, CRC-16, and CRC-32. Both can be applied together.

- SWAP_BITWISE (affecting the input only) can be applied for all polynomials if required by an application.
- SWAP_BYTEWISE (affecting the input only) can be applied for CRC-16 and CRC-32 polynomials only.
- SWAP_BITWISE has priority over SWAP_BYTEWISE when both are applied together.
- When generating CRC-32 for the Ethernet standard the user needs to set SWAP_BYTEWISE together with INV and SWAP.
- When generating CRC-16 the user needs to set SWAP_BITWISE bit.

Chapter 77
Memory Error Management Unit (MEMU)

77.1 Memory Error Management Unit (MEMU) chip-specific module information

77.1.1 MEMU system connections

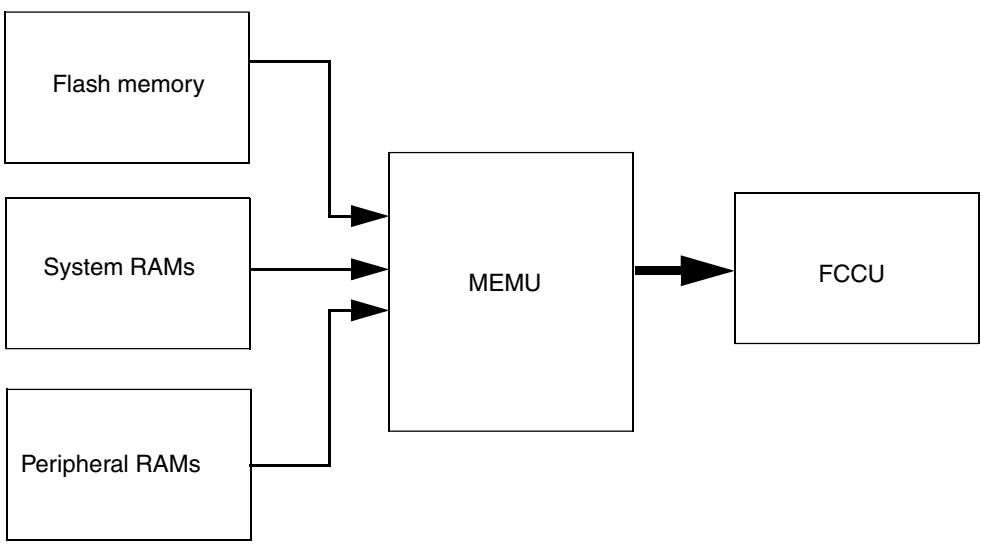

Figure 77-1. MEMU system connections

77.1.2 MEMU error sources

The following table shows the MEMU error sources for each instance configured on this chip.

Table 77-1. MEMU error sources

Instance	Value
Number of system RAM unique error sources	18
Number of peripheral RAM unique error sources	12
Number of flash memory unique error sources	2

77.1.3 Reporting table implementation

MEMU establishes the following categories of error reporting:

- Flash memory error reporting
- System RAM error reporting (for errors when System RAM is accessed by CPUs)
- Peripheral RAM error reporting (for errors in any RAM that is not CPU accessible as well as errors when System SRAM is accessed by peripherals connected to concentrators - Ethernet, SIPI, or eDMA)

Each category of error reporting has two tables associated with it, these are:

- Correctable error reporting table
- Uncorrectable error reporting table

Each entry in a reporting table corresponds to a unique error event. The number of entries supported by each table depends upon the error source.

The table below describes the number of entries in each reporting table for the different error sources.

Table 77-2. Number of entries in each reporting table

Error source	Number of entries in correctable error reporting table	Number of entries in un-correctable error reporting table
Flash memory	20	1
System RAM	10	1
Peripheral RAM	2	1

77.1.4 Concurrent overflow register (OFLW) implementation

Errors are reported to the MEMU from these categories:

- Flash memory
- System RAM
- Peripheral RAM

In an overflow condition, it is possible to identify the unique error source that caused the overflow. Corresponding error sources for the OFLW register details the corresponding error source to the respective bit-field in the Concurrent Overflow registers.

Positions not explicitly listed in the tables below are reserved.

Table 77-3. Corresponding error sources for system RAM OFLW0 register

Bit number	Error source
0	Core0 d-ahb error
1	Core0 i-ahb error
2	Core0 Data TCM error
3	Core0 Instruction TCM error
5	Core0 Instruction cache error
6	Core1 d-ahb error
7	Core1 i-ahb error
8	Core1 Data TCM error
9	Core1 Instruction TCM error
11	Core1 Instruction cache error
12	PRAM
13	PBRIDGE_0 Decorated storage
14	PBRIDGE_1 Decorated storage
15	PRAM decorated storage
16	Core0 backdoor TCM decorated storage
17	Core1 backdoor TCM decorated storage

10	CAN2
11	CAN3

Table 77-5. Corresponding error sources for flash memory OFLW0 register

Bit number	Error source
0	Flash Port0 ECC Error
1	Flash Port1 ECC Error

77.1.5 Uncorrectable error in flash memory can cause uncorrectable error in SRAM

Be aware of the following scenario where an uncorrectable error in flash memory can cause an uncorrectable error in SRAM to be reported. Each error triggers a separate FCCU response.

1. An uncorrectable error in flash memory occurs, and C55FMC_MCR[EER] sets to 1.
2. MEMU_FLASH_UNCERR_STS[VLD] sets to 1, and MEMU_ERR_FLAG[F_UCE] sets to 1. MEMU_FLASH_UNCERR_ADDR[ERR_ADD] records the address on which the error was detected.
3. The FCCU responds to a fault on NCF[29].

When the core register field E2ECTL0[DECCEN] is 1, these events follow:

1. The detected error in flash memory results in an exception/machine check.
2. MEMU_SYS_RAM_UNCERR_STS[VLD] sets to 1, and MEMU_ERR_FLAG[SR_UCE] sets to 1. MEMU_SYS_RAM_UNCERR_ADDR[ERR_ADD] records the address on which the error was detected.
3. The FCCU responds to a fault on NCF[23].

77.2 Introduction

The MEMU is responsible for collection and reporting of error events associated with ECC (Error Correction Code) logic used on:

- System RAM

- Peripheral RAM
- Flash memory

When any of the following events occur the MEMU receives an error signal which causes an event to be recorded and corresponding error flags to be set and reported to FCCU (Fault Collection and Control Unit).

- Correctable Error: It comprises the following:
  - Single Bit error in the data part that is detected via ECC for:
    - System RAM
    - Peripheral RAM
    - Flash memory
- Uncorrectable Error: It comprises the following:
  - Multiple bit error that is detected via ECC for:
    - System RAM
    - Peripheral RAM
    - Flash memory
  - Addressing errors and unused data bit errors detected by ECC logic.

The MEMU system connections are chip-specific; see the chip-specific MEMU information.

When multiple errors are indicated from various sources at same instant, an Overflow can be indicated by the MEMU to the FCCU. Overflow can also be indicated if the reporting table entries are full and a new unique error is reported by the system.

MEMU processes the errors based on whether they are correctable or uncorrectable (from ECC logic), independent of the source generating these errors.

The MEMU has multiple instances of the basic reporting block; one each for:

- System RAM ECC
- Peripheral RAM ECC
- Flash memory ECC

Each instance has two reporting tables. Correctable errors are reported in one table, and the uncorrectable errors are reported in the other.

See Design overview for the reporting block details.

77.3 Features

The MEMU has the following features:

- Supports up to 128 error sources per the following reporting blocks (the number of error sources are chip-specific; see the chip-specific MEMU information):
  - System RAM ECC
  - Peripheral RAM ECC
  - Flash memory ECC
- Support for error reporting from the following category of error sources (for ECC):
  - System RAM
  - Peripheral RAM
  - Flash memory
- Unique reported errors are logged into the module's reporting table which is accessible to CPU via memory mapped CPU register programming interface.
- MEMU handles overflow during error assertion and reports status accordingly.
- Unique errors are stored in correctable and non correctable section of the reporting table and corresponding indication is generated to the FCCU.
- CPU can program the known errors into the reporting table to avoid their re-reporting by MEMU.
- CPU can clear the reporting table errors.
- The reporting table for uncorrectable errors supports only 1 entry.

77.4 Block diagram

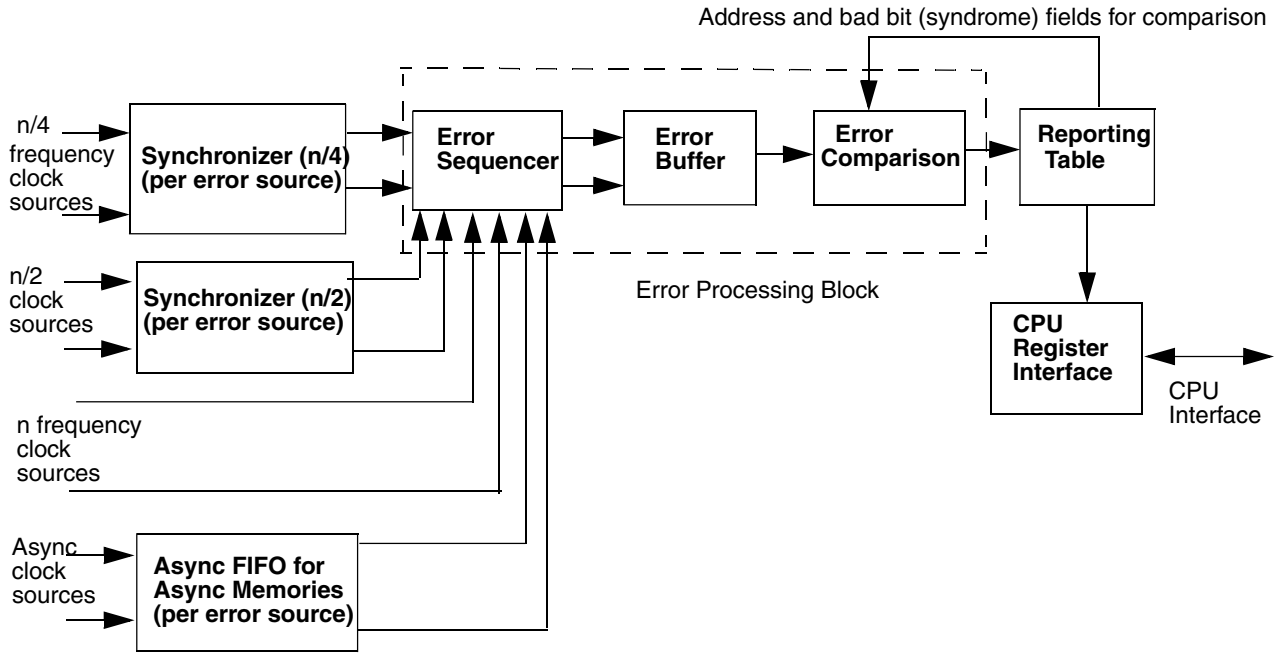

Figure 77-2. MEMU block diagram

77.5 Design overview

The MEMU should be enabled on power-on reset. The user software can write known error addresses into the reporting table to prevent reporting of those errors addresses to FCCU should they later be accessed in operation. All writes into the reporting table by the CPU that assert the Valid Bit (of the respective reporting table entry) will be indicated as a new error detected and will be reported to the FCCU. This feature can also be used as self-checking option of the MEMU and the MEMU-FCCU connection.

The MEMU design does not limit any particular sequence or errors. See Handling overflows (Multiple error reporting), for details on overflow behaviors.

The basic algorithm flow/architecture for error reporting in the MEMU is summarized below:

1. Synchronizer block

   For asynchronous inputs, a FIFO-based structure (per asynchronous channel) is implemented. All the error inputs (correctable error reported, uncorrectable error reported, error address and bad bits/syndrome) are concatenated and stored in the

FIFO. While storing the entry in the FIFO, a duplicity check is performed with the previously stored entry (the entry which was stored in the last cycle). If both the entries are duplicate the new entry is deleted and the pointers are rolled back to the old value, otherwise the new entry is stored. Whenever there is an overflow (FULL condition) in the Asynchronous FIFO, it is denoted by setting the Error Buffer Overflow or the EBO flag to the FCCU and the corresponding bit in the Concurrent Overflow Register is set.

For synchronous inputs, inputs are sampled whenever the corresponding clock synchronizing signal is asserted for a particular channel.

NOTE

On this chip, all error inputs are synchronous.

2. Error Processing block

   This block is used to process the incoming errors coming from the device.

   - Error Sequencer is used for sequencing the errors so that these are processed one per clock. In case of more than one errors detected by the sequencer logic, one is sent for the processing (error comparison block), the other is stored in the error buffer and the rest are marked as overflows in the Concurrent overflow register.
   - All the sequences of incoming errors are supported. However, in case of multiple errors being asserted in back to back clock cycles, MEMU will process the errors being forwarded by the sequencer logic and register the rest of the errors as Concurrent Overflows in the Concurrent Overflow Register.
   - While storing the error in the error buffer, uniqueness is determined by comparing the error address, correctable or uncorrectable error type and the bad bit/syndrome (depending on ECC logic) of the incoming error with the one stored in buffer. If the error buffer is full, and the incoming error to be stored in the error buffer is not yet in the error table, Error Buffer Overflow (EBO) is registered and the corresponding bit in the Concurrent Overflow Register is set., else the incoming error is dropped.
   - While doing the error buffer uniqueness check, the type of error i.e Correctable Error (CE) or Uncorrectable Error UCE) is also compared, hence even if the Error Address and the Bad bit/syndrome fields (Depending on whether the incoming error is generated from ECC logic) of the incoming error matches with the error buffer, if the type of errors (CE and UCE) differ they are treated as unique

- Determine the type and uniqueness of errors in the error comparison block and store them in the correct reporting table (correctable or uncorrectable)
- Generate signals to assert the necessary flags. Be aware that it takes several MEMU clock cycles (<=5 unless the error gets temporarily stored in the error buffer due to a collision) for an error report to cause a signal to be sent to the FCCU.

3. Reporting table

   This is a pre-defined table in the MEMU to store the details for the device. For the reporting table if the entry is unique it is stored in the reporting table. If the entry is not unique it is not stored and discarded.

   The MEMU asserts proper flags when error is stored in the reporting table or an overflow is asserted. Flags are also asserted when the software writes the VLD bit to the reporting table.

   The CPU can clear the flags signaling errors or overflows to the FCCU directly by writing 1 at the corresponding valid bit of the status register (i.e. ..._CERR_STS or ..._UNCERR_STS). The clearing of flags is totally independent from the status of VLD bits in the reporting table.

   The reporting table sizes are chip-specific; see the chip-specific MEMU information.

4. Register block

   The CPU register programming interface provides the memory-mapped registers necessary for the CPU to access the reporting table and other control and status registers for the modules. Flags to FCCU will be asserted on write by CPU to the valid bit or by MEMU itself if a unique error is stored. However, in the situation when both MEMU and the CPU are accessing the same Register location, a wait cycle will be signaled to the CPU and the CPU command will be completed in the next clock cycle.

   The software, in principle, is not supposed to write VLD to 1 if it is already 1.

   The CPU register interface provides the decoding of the peripheral signals to allow access to the reporting table and other registers in module.

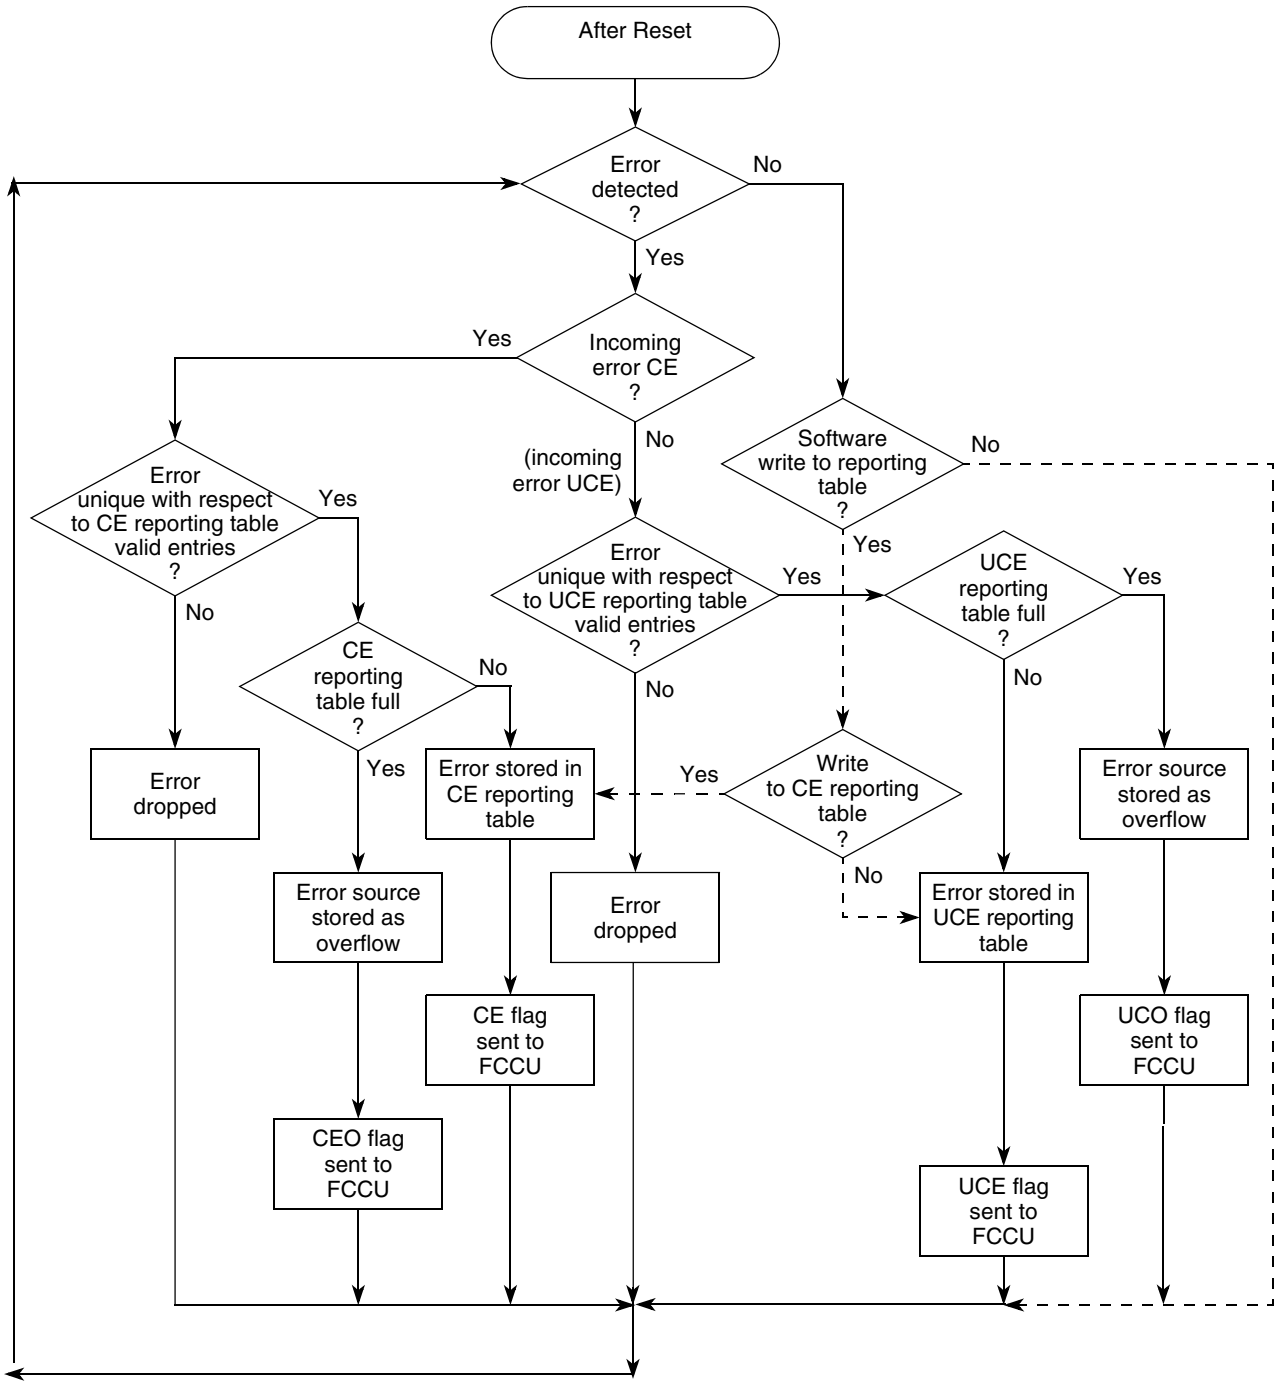

Figure 77-4. MEMU reporting table uniqueness check flow chart

77.6 External signal description

MEMU has no external signals.

77.7 Memory map and register definition

This section describes the registers on this module.

77.7.1 Overview

The memory map comprises 32-bit aligned registers that can be accessed via 8-bit,16-bit, or 32-bit accesses. Write access to reserved address locations will generate a transfer error. Read data from reserved locations will also generate a transfer error and the read data bus will return all 0's.

NOTE

The module does not check for correctness of the programmed values in registers. Software must ensure that the correct values are being written.

NOTE

The memory map in this section shows all the possible registers on this module and the associated offsets (which vary depending on the number of registers actually implemented). The actual availability, number and addresses of registers, and number of reported errors in the reporting table are chip-specific; see the Device Configuration chapter that describes how modules are configured and connected.

MEMU memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	Control register (MEMU_CTRL)	32	R/W	0000_0000h	77.7.2/3256
4	Error flag register (MEMU_ERR_FLAG)	32	w1c	0000_0000h	77.7.3/3256

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

MEMU_CTRL field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 SWR	Software Reset bit. Setting this will clear status flags and overflow register. However, the reporting table registers are not cleared. This bit will auto clear on next clock cycle. 0 No reset. 1 Reset asserted.
17–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

77.7.3 Error flag register (MEMU_ERR_FLAG)

Bits in the ERR_FLAG register indicate:

- A new entry in an error reporting table has been made (indicated by PR_CE, PR_UCE, F_CE, F_UCE, SR_CE, and SR_UCE)

- An overflow condition has been encountered when attempting to make a new entry in an error reporting table (indicated by SR_UCO, SR_CEO, F_UCO,F_CEO, PR_UCO, and PR_CEO)
- An overflow condition has been encountered in the internal error processing buffer of a MEMU reporting block.

Individual flags can be cleared by writing a '1'. This also resets the corresponding error indication to FCCU. Flags will not automatically reset if entries are removed from the reporting table. They have to be explicitly cleared by SW.

Bits SR_UCO, SR_CEO, F_UCO, F_CEO, PR_UCO, and PR_CEO are asserted when an overflow in the uncorrectable error reporting table is detected.

Access: User read/write

Address: 0h base + 4h offset = 4h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

MEMU_ERR_FLAG field descriptions

Field	Description
0–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11 PR_CE	Peripheral RAM ECC Correctable Error detect flag. Indicates that a new and unique Peripheral RAM ECC correctable error is detected. Asserted when a new entry is inserted into the correctable error reporting table (either by CPU or module).

Table continues on the next page...

MEMU_ERR_FLAG field descriptions (continued)

Field	Description
	0 No new and unique error detected. 1 New entry in correctable error reporting table is made.
12 PR_UCE	Peripheral RAM ECC Uncorrectable Error Detect flag. Asserted when a new Peripheral RAM ECC uncorrectable error was detected or a new entry is inserted into the uncorrectable error reporting table (either by CPU or module). 0 No new and unique error detected. 1 New entry in uncorrectable error reporting table is made.
13 PR_CEO	Peripheral RAM ECC Correctable error Overflow flag. Asserted when the Peripheral RAM ECC correctable error reporting table is full and a new entry is attempted to be made to this table. 0 No Overflow. 1 Overflow in the correctable error reporting table detected.
14 PR_UCO	Peripheral RAM ECC Uncorrectable error Overflow flag. Asserted when the Peripheral RAM ECC uncorrectable error reporting table is full and a new entry is made to this table. 0 No Overflow. 1 Overflow in the uncorrectable error reporting table detected.
15 PR_EBO	Peripheral RAM ECC Error buffer Overflow flag. Asserted when the internal error processing buffer of Peripheral RAM ECC MEMU reporting block has overflowed. This can happen when too many errors are reported in a short interval of time for processing by MEMU. The channel(s) from which error reports were dropped due to the overflow are indicated in the XXXXX_OFLW registers. This field will also be set to 1 if the input ASYNC FIFOs overflow. 0 No Overflow. 1 Overflow in the internal error processing buffer detected.
16–18 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
19 F_CE	Flash ECC Correctable Error Detect flag. Indicates that a new and unique Flash ECC correctable error was detected. Asserted when a new entry to the correctable error reporting table is done (either by CPU or module). 0 No new and unique error detected. 1 New entry in correctable error reporting table is made.
20 F_UCE	Flash ECC Uncorrectable Error Detect flag. Asserted when: • a new Flash ECC uncorrectable error was detected. • a new entry to the uncorrectable error reporting table is done (either by CPU or module) 0 No new and unique error detected. 1 New entry in uncorrectable error reporting table is made.
21 F_CEO	Flash ECC Correctable Error Overflow flag. Asserted when the Flash ECC correctable error reporting table is full and a new entry is made to this table.

Table continues on the next page...

MEMU_ERR_FLAG field descriptions (continued)

Field	Description
	0 No Overflow. 1 Overflow in the correctable error reporting table detected.
22 F_UCO	Flash ECC Uncorrectable Error Overflow flag. Asserted when the Flash ECC uncorrectable error reporting table is full and a new entry is made to this table. 0 No Overflow. 1 Overflow in the uncorrectable error reporting table detected.
23 F_EBO	Flash ECC Error buffer Overflow. Flag Asserted when the internal error processing buffer of Flash ECC MEMU reporting block has overflowed. This can happen when too many errors are reported in a short interval of time for MEMU to process them all. The channel(s) from which error reports were dropped due to the overflow are indicated in the XXXXX_OFLW registers. This field will also be set to 1 if the input ASYNC FIFOs overflow. 0 No Overflow. 1 Overflow in the internal error processing buffer detected.
24–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 SR_CE	System RAM ECC Correctable Error detect flag. Indicates that a new and unique System RAM ECCcorrectable error is detected. Asserted when a new entry to the correctable error reporting table is done (either by CPU or module). 0 No new and unique error detected. 1 New entry in correctable error reporting table is made.
28 SR_UCE	System RAM ECC Uncorrectable Error Detect flag. Asserted when: • A new System RAM ECC uncorrectable error is detected • A new entry to the uncorrectable error reporting table is done (either by CPU or module) 0 No new and unique error detected. 1 New entry in uncorrectable error reporting table is made.
29 SR_CEO	System RAM ECC Correctable error Overflow flag. Asserted when the System RAM ECC correctable error reporting table is full and a new entry is made to this table. 0 No Overflow. 1 Overflow in the correctable error reporting table detected.
30 SR_UCO	System RAM ECC Uncorrectable error Overflow flag. Asserted when the System RAM ECC uncorrectable error reporting table is full and a new entry is made to this table. 0 No Overflow. 1 Overflow in the uncorrectable error reporting table detected.
31 SR_EBO	System RAM ECC Error buffer Overflow.

Table continues on the next page...

MEMU_ERR_FLAG field descriptions (continued)

Field	Description
	Flag asserted when the internal error processing buffer of System RAM ECC MEMU reporting block has overflowed. This can happen when too many errors are reported in a short interval of time for processing by MEMU. The channel(s) from which error reports were dropped due to the overflow are indicated in the XXXXX_OFLW registers. This field will also be set to 1 if the input ASYNC FIFOs overflow. 0 No Overflow. 1 Overflow in the internal error processing buffer detected.

77.7.4 Debug register (MEMU_DEBUG)

This register is used to check the connections between MEMU & FCCU.

The error output of the MEMU towards FCCU shall stay set if forced until reset by SW via the MEMU in the normal way.

Access: User read/write

Address: 0h base + Ch offset = Ch

MEMU_FLASH_OFLW*n* field descriptions

Field	Description
0–31 OFLW	Overflow Bit. Each bit corresponds to an error source and is asserted when any of the conditions mentioned in Handling overflows (Multiple error reporting) occurs.

77.8 Functional description

In this section, the term “bad bit” and “syndrome” are equivalent, and are used to indicate the position of the bit in error.

77.8.1 Initializing MEMU

MEMU is always enabled and can be configured by user software for known faults which the system/application has collected over a period of time. The MEMU logic will not update the reporting table corresponding to the programmed values which have the VLD bit SET.

The user software can write into the reporting table and must make VLD bit ='1' for the programmed entry to be valid. Any write by the CPU that asserts the VLD bit will cause a corresponding flag to FCCU.

The software can program the table with known error addresses by setting the valid bit and storing the corresponding error address. The sequence of programming to prevent a collision of reporting table entries written by the HW and the SW is as follows:

1. Check that the VLD bit is not set,
2. Write an invalid address/bad bit information,
3. Set VLD bit,
4. Check that the address still has an invalid value,
5. Write address/bad bit information to desired address.

If the FCCU is programmed to cause an IRQ on new MEMU table entries, steps 3 to 5 should be executed with interrupts disabled to prevent any fault handling SW to read the invalid address written in step 2). Note that in the case the software is in between the 3rd and the 5th step, and the MEMU writes a fault with the same address that Software wants to program, both the faults will be stored in the reporting table (i.e. duplicate entries).

77.8.2 Reading the reporting table

The software at any time can read the reporting table via the software programming interface. It should read the entries with the valid bit set and take necessary action. To invalidate any entry, the valid bit must be cleared. Reading an entry which does not have the VLD bit set will return invalid data.

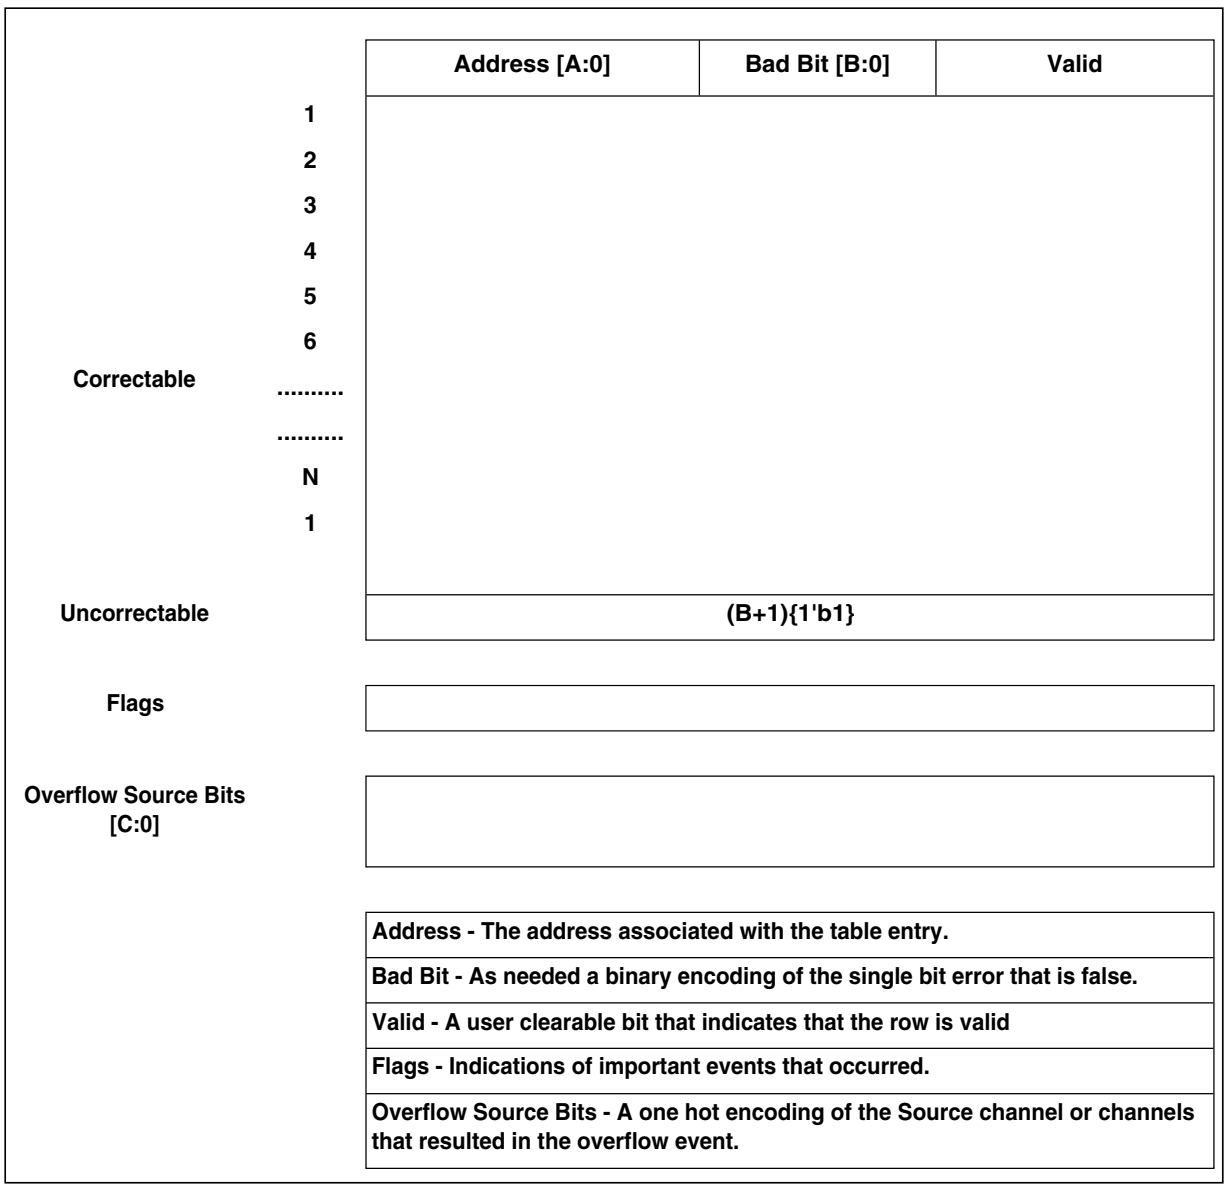

Figure 77-90. Generic representation of the reporting table of one MEMU reporting block

77.8.3 Handling overflows (Multiple error reporting)

When a bit in the overflow registers (either error buffer or reporting table though the overflow registers are same) is asserted it can indicate the occurrence of one of the following conditions:

1. Fault buffer overflow–More than two memories reporting a fault at the same instant or the input ASYNC FIFOs reach the FULL level (overflow)
    - More than 2 faults detected at same time. This would lead to overflow in the fault buffer. MEMU can process only one fault at a time while storing the other in the fault buffer. So this would be indicated as an overflow. The uniqueness check in the input buffer does not "guarantee" that an ECC-supervised memory with only one fault will not be marked as overflow source. If that one fault occurs together with two (or more) additional faults at the same cycle it can get flagged as an overflow.
2. Correctable/Uncorrectable Fault Overflow–Overflow in correctable and uncorrectable reporting table occurs only when a unique entry is to be stored but the tables are already full (all entries have valid bit set).
3. The Overflows will be stored in the bit-wise order i.e., if the fault bit 31 reports a fault, the bit 31 of the overflow register will be set to '1'.

Chapter 78
Fault Collection and Control Unit (FCCU)

78.1 FCCU chip-specific module information

This section describes the implementation of this module in the device.

78.1.1 FCCU fault recovery after NMI reaction

When an NMI (Non-Maskable Interrupt) is configured as the internal FCCU reaction for a specific NCF (fault state), the application software should not clear the core's MCSR[NMI] bit field during the execution of the NMI interrupt service routine, unless the FCCU fault source which generated the respective NMI reaction is cleared.

For details on MCSR[NMI] bit field clearing, see Machine Check Syndrome Register (MCSR). For details on FCCU Fault recovery see Fault recovery.

78.1.2 FCCU chip-specific register reset values

The following table shows FCCU registers whose reset values are specific to this chip.

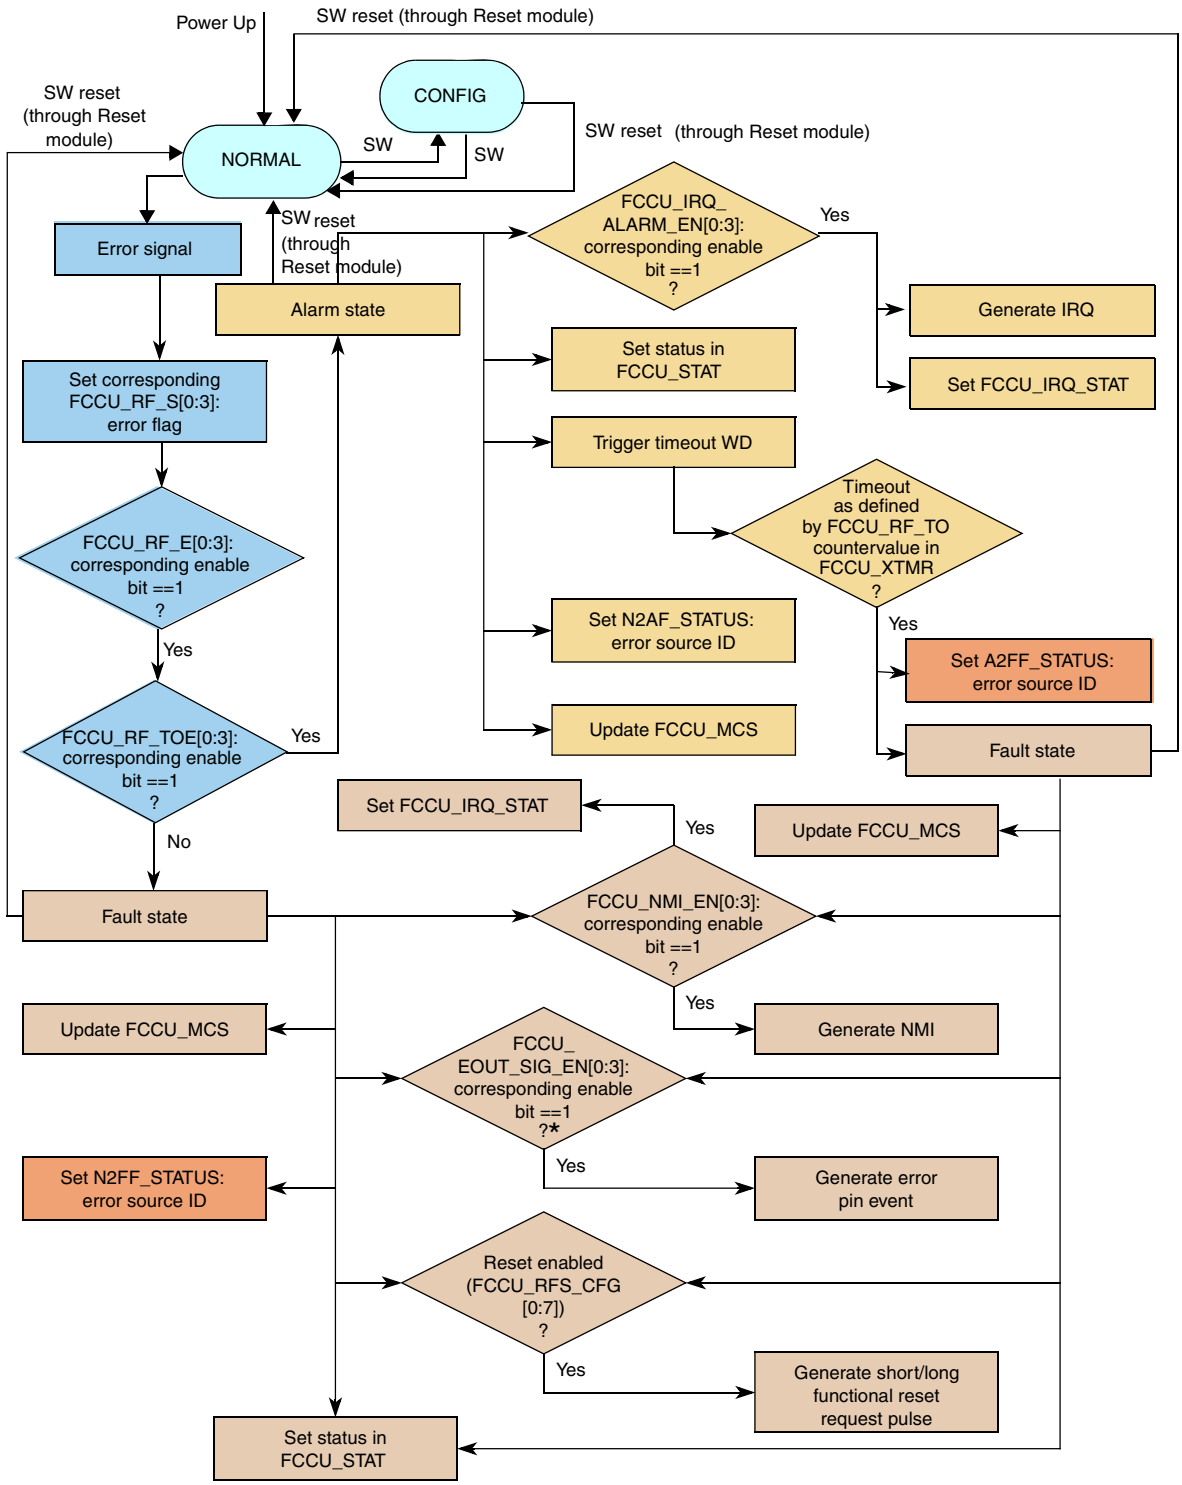
Table 78-1. FCCU chip-specific register reset values

Register	Reset value
FCCU_CFG	0x00000008
FCCU_NCF_CFG0	0xFFFFFFFF
FCCU_NCF_CFG1	0xFFFFFFFF
FCCU_NCF_CFG2	0xFFFFFFFF
FCCU_NCFS_CFG0	0x00002000
FCCU_NCFS_CFG1	0x00000080
FCCU_NCFS_CFG2	0x00000000
FCCU_NCFS_CFG3	0x00000000

Table continues on the next page...

Table 78-1. FCCU chip-specific register reset values (continued)

Register	Reset value
FCCU_NCFS_CFG4	0x00000000
FCCU_NCFS_CFG5	0x00000000
FCCU_NCF_E0	0x00080040
FCCU_NCF_E1	0x00000000
FCCU_NCF_E2	0x00000000
FCCU_NCF_TOE0	0x00000000
FCCU_NCF_TOE1	0x00000000
FCCU_NCF_TOE2	0x00000000
FCCU_NCF_TO	0x0000_FFFF
FCCU_CFG_TO	0x0000_0006



78.1.3 Available FCCU output signals

The following table shows the available FCCU output signals implemented on this chip.

Table 78-2. FCCU output signals

FCCU output signal name	Chip-top signal name
EOUT[0]	ERROR0
EOUT[1]	ERROR1

78.1.4 Error signal flow diagram

* This condition must be satisfied only when FCCU is configured for Bistable fault-output mode (FCCU_CFG[FOM]).

Figure 78-1. Error signal flow

78.1.5 FCCU failure inputs from other modules

The following table shows the different failure input signals of the FCCU, how they can be tested, and their default configuration after reset.

NOTE

All the faults shown in the following table require a long functional reset.

NOTE

FCCU Fault Channels 51, 52, 69 through 84, 92, and 93 may be asserted during the execution of MBIST and LBIST. Before running MBIST or LBIST, these channels should be configured to NO REACTION. If any of these channels become asserted during MBIST or LBIST testing, the fault should simply be cleared and no further action should be taken.

Table 78-3. FCCU Fault Inputs

NCF Index	Default Reaction Configuration at POR or Destructive Reset	Source	Error Reaction Path Check	Description
0	No Reaction	Temp sensor	Using PMC_TS_FIR register to set the fault at source + Via FCCU Fake bit	Temperature Sensor Event Triggered by PMC_ESR_TD[TEMP1_2, TEMP1_0, TEMP0_2, TEMP0_0] and PMC_TS_FIR[TSNS_FAULT] . For details, see the descriptions of the PMC_ESR_TD and PMC_TS_FIR registers.
1	No Reaction	PMC	Using PMC FIR register to set the fault at source + Via FCCU Fake bit	LVD event to FCCU Triggerred by PMC_LVD_HVD_EVENT_STATUS[LVD_PMC, LVD_SAR_ADC, LVD_IO, LVD_FLASH, LVD_CORE_HOT, LVD_CORE_COLD] and PMC_FIR[LVD_FAULT]. For details, see the descriptions of the PMC_LVD_HVD_EVENT_STATUS and PMC_FIR registers.
2	No Reaction	PMC	Using PMC FIR register to set the fault at source + Via FCCU Fake bit	HVD Event to FCCU Triggered by PMC_LVD_HVD_EVENT_STATUS[HVD_FLASH, HVD_HV, HVD_CORE]. For details, see the descriptions of the PMC_LVD_HVD_EVENT_STATUS register.

Table continues on the next page...

Table 78-3. FCCU Fault Inputs (continued)

NCF Index	Default Reaction Configuration at POR or Destructive Reset	Source	Error Reaction Path Check	Description
3	No Reaction	PMC	Using PMC FIR register to set the fault at source + Via FCCU Fake bit	PMC Self Test Failure Event PMC hard/soft self-test failed: LVD/HVD **NOTE:** When this occurs, single LVD or HVD self-tests should be executed to identify which detection mechanism failed in the SOC: LVD or HVD. For details, see the description of the PMC_SELF_TEST_UM_VD_REG register as well as the flag bits associated to NCF3 (PMC_SELF_TEST_UM_VD_REG [ST_RESULT]). Self test bit definition indicates all valid values for PMC_SELF_TEST_UM_VD_REG[VD_ST_CTRL] while executing single self-tests. LVD-HVD self test mechanism provides details about the available PMC self-tests
4	No Reaction	SSCM	write wrong data to address + Via FCCU Fake bit to set the fault at error path	See SSCM_STATUS[CERS] field description.
5	No Reaction	SSCM	write wrong data to address + Via FCCU Fake bit to set the fault at error path	See SSCM_STATUS[CER] field description.
6	long reset	STCU	SW check of BIST MISR + Via FCCU Fake bit to set the fault at source	Critical Fault of STCU. Set when STCU2_ERR_STAT[UFSF] is set.
7	No Reaction	STCU	SW check of BIST MISR + Via FCCU Fake bit to set fault at source	Non critical Fault of STCU. Set when STCU2_ERR_STAT[RFSF] is set.
8	No Reaction	STCU	STCU activation during user application run Via FCCU Fake bit to set the fault at source	Critical Fault in case LBIST or MBIST control signals go to wrong condition during User application. This fault is set when the self-test was triggered without STCU2_RUN[RUN] bit programming.
9	No Reaction	Checker Shell	Via FCCU Fake bit	out of lockstep fault detected for miscellaneous safety core output
10	No Reaction	Checker Shell	Via FCCU Fake bit to set the fault at error source	out of lockstep fault detected for safety Core dtcm array interface signal
11	No Reaction	Checker Shell	Via FCCU Fake bit to set the fault at error source	out of lockstep fault detected for safety Core I Cache array interface signals
12	Reserved	Reserved		Reserved
13	No Reaction	Checker Shell	Via FCCU Fake bit to set the fault at error source	out of lockstep fault detected for safety Core Amba interface signals
14	No Reaction	DMA Checker Shell	Via FCCU Fake bit to set the fault at error source	out of lockstep fault detected for DMA

Table continues on the next page...

Table 78-3. FCCU Fault Inputs (continued)

NCF Index	Default Reaction Configuration at POR or Destructive Reset	Source	Error Reaction Path Check	Description
15	No Reaction	DMC Checker	Via FCCU Fake bit to set the fault at error source	out of lockstep fault detected for core0 TCM DMC
16	RESERVED	RESERVED		RESERVED
17	No Reaction	SWT3	Emulate fault using functionality + Via FCCU Fake bit to set the fault at error path	Software watchdog timer reset request
18	RESERVED	RESERVED		RESERVED
19	Long Reset	SWT1	Emulate fault using functionality (SW test by not triggering SWT during startup) + Via FCCU Fake bit to set the fault at error path	Software watchdog timer reset request
20	No Reaction	SWT0	Emulate fault using functionality (SW test by not triggering SWT during startup) + Via FCCU Fake bit to set the fault at error path	Software watchdog timer interrupt
21	No Reaction	SWT0	Emulate fault using functionality (SW test by not triggering SWT during startup) +Via FCCU Fake bit to set the fault at error path	Software watchdog timer reset request
22	No Reaction	MEMU	Injection of RAM ECC error via ECC bit access and later reading + Via FCCU Fake bit to set the fault at error path+ LBIST	System RAM Correctable Error detected
23	No Reaction	MEMU	Injection of RAM ECC error via ECC bit access and later reading + Via FCCU Fake bit to set the fault at error path + LBIST	System RAM Un-Correctable Error detected
24	No Reaction	MEMU	Via FCCU Fake bit to set the fault at error path + LBIST	System RAM error Overflow
25	No Reaction	MEMU + eTPU Memory Error Correction Interrupt	Via FCCU Fake bit to set the fault at error path + LBIST	Peripheral RAM Correctable error detected. Set eTPU_MESR_MECR[MECIE] to enable this error.
26	No Reaction	MEMU + eTPU Global Exception	Via FCCU Fake bit to set the fault at error path + LBIST	Peripheral RAM UN-Correctable error detected. Set eTPU_MESR_MECR[MECIE] to enable this error.
27	No Reaction	MEMU	Via FCCU Fake bit to set the fault at error path + LBIST	Periph RAM error Overflow

Table 78-3. FCCU Fault Inputs (continued)

NCF Index	Default Reaction Configuration at POR or Destructive Reset	Source	Error Reaction Path Check	Description
28	No Reaction	MEMU	Reading preprogrammed correctable ECC error from UTEST flash memory + Via FCCU Fake bit to set the fault at error path + LBSIT	Flash Correctable Error detected NCF correlated to C55FMC_MCR[SBC] bit **NOTE:** From the MEMU perspective this is indicated by MEMU_FLASH_CERR_STSn. For details, see the description of the C55FMC_MCR and MEMU_FLASH_CERR_STSn registers.
29	No Reaction	MEMU	Reading preprogrammed uncorrectable ECC error from UTEST flash memory + Via FCCU Fake bit to set the fault at error path + LBIST	Flash Un-Correctable Error detected NCF correlated to C55FMC_MCR[EER] bit **NOTE:** From the MEMU perspective this is indicated by MEMU_FLASH_UNCERR_STSn. For details, see the description of the C55FMC_MCR and MEMU_FLASH_UNCERR_STS registers.
30	No Reaction	MEMU	Via FCCU Fake bit to set the fault at error path + LBIST	Flash Error Overflow For details on conditions which trigger this NCF, see section Handling overflows (Multiple error reporting). **NOTE:** From the MEMU perspective this is indicated by MEMU_FLASH_OFLWn. For details, see the description of the MEMU_FLASH_OFLWn register.
31	RESERVED	RESERVED		RESERVED
32	No Reaction	PLL0	Forced loss by PLL reconfiguration + Via FCCU Fake bit to set the fault at error path	Loss of Lock detected for NON-FM PLL **NOTE:** This source should be configured to generate a reset instead of an interrupt if the source is used as the system clock.
33	No Reaction	PLL1	Forced loss by PLL reconfiguration + Via FCCU Fake bit to set the fault at error path	Loss of Lock detected for FM PLL **NOTE:** This source should be configured to generate a reset instead of an interrupt if the source is used as the system clock.
34	No Reaction	CMU_PLL	Test by misconfiguration + Via FCCU Fake bit to set the fault at error path	OLR Event from crystal clock monitor circuit of cmu_pll **NOTE:** This source should be configured to generate a reset instead of an interrupt if the source is used as the system clock.

Table continues on the next page...

Table 78-3. FCCU Fault Inputs (continued)

NCF Index	Default Reaction Configuration at POR or Destructive Reset	Source	Error Reaction Path Check	Description
35	No Reaction	CMU_PLL	Test by misconfiguration + Via FCCU Fake bit to set the fault at error path	FLL/FHH event from PLL Clock Monitor circuit. This fault is set when CMU_0 detects an FHH or FLL event **NOTE:** To identify which CMU module raised this NCF, read the CMU_ISR[FHHI/FLLI] bit fields from all relevant CMU instances. For details, see the description of the CMU_ISR register. For available CMU's, see sections Clock input sources and CMU registers and field availability .
36	No Reaction	System clock CMU	Test by misconfiguration + Via FCCU Fake bit to set the fault at error path	FLL/FHH event from System clock monitor circuit. This fault is set when one of CMU_1 to CMU_3 detects an FHH or FLL event. **NOTE:** To identify which CMU module raised this NCF, read the CMU_ISR[FHHI/FLLI] bit fields from all relevant CMU instances. For details, see the description of the CMU_ISR register. For available CMU's, see sections Clock input sources and CMU registers and field availability .
37	No Reaction	Other CMU	Emulate fault using functionality + Via FCCU Fake bit to set the fault at error path	FLL/FHH event from other clock monitor circuit. This fault is set when one of CMU_4 to CMU_12 detects an FHH or FLL event. **NOTE:** To identify which CMU module raised this NCF, read the CMU_ISR[FHHI/FLLI] bit fields from all relevant CMU instances. For details, see the description of the CMU_ISR register. For available CMU's, see sections Clock input sources and CMU registers and field availability .
38	No Reaction	Periph AXBS	Using XBIC_EIR register to set the fault at source+Via FCCU Fake bit to set the fault at error path	Peripheral Crossbar alarm to FCCU
39	No Reaction	Comp AXBS	Using XBIC_EIR register to set the fault at source+Via FCCU Fake bit to set the fault at error path	Computational Crossbar alarm to FCCU
40	No Reaction	Flash	Via FCCU Fake bit to set the fault at error source + LBIST	alarm indicating the flash detected an error in the ECC correction logic through an EDC

Table continues on the next page...

Table 78-3. FCCU Fault Inputs (continued)

NCF Index	Default Reaction Configuration at POR or Destructive Reset	Source	Error Reaction Path Check	Description
41	No Reaction	Flash Controller	Via FCCU Fake bit to set the fault at error path + LBIST	alarm indicating the flash controller detected an error in the address ECC manipulation logic through an EDC
42	No Reaction	Flash	Via FCCU Fake bit to set the fault at error path + LBIST	alarm indicating the Flash Array Controller detected an Encode Address Error, such as multiple address lines selected or no address lines selected **NOTE:** Address Encode Errors detected within Flash Array [FCCU channel 42] will also assert the P-Flash [FCCU channel 43]
43	No Reaction	Flash Controller	Via FCCU Fake bit to set the fault at error path + LBIST	alarm indicating the flash controller detected a transaction monitor mismatch when compared to the flash safety feedback outputs
44	No Reaction	Flash Controller	Via FCCU Fake bit to set the fault at error path + LBIST	alarm indicating the flash controller detected a transaction monitor mismatch when compared to the on-chip calibration RAM safety feedback outputs
45	No Reaction	Flash Controller	Via FCCU Fake bit to set the fault at error path + LBIST	alarm indicating the flash controller detected a transaction monitor mismatch in the pseudo-replicated calibration evaluation hardware
46	RESERVED	RESERVED		RESERVED
47	No Reaction	Platform Gasket	Via FCCU Fake bit to set the fault at error path	2:1 bridging gasket transaction monitor alarm
48	No Reaction	Platform Gasket	Via FCCU Fake bit to set the fault at error path	1:2 bridging gasket transaction monitor alarm
49	No Reaction	SMPU	Via FCCU Fake bit to set the fault at error path + LBIST	Computational MPU alarm to the fault collection unit An access error has happened due to restrictions specified by the MPU region descriptors. This is in addition to the MPU responding to the requesting master with an error response.
50	No Reaction	SMPU	Via FCCU Fake bit to set the fault at error path + LBIST	Peripheral MPU alarm to the fault collection unit An access error has happened due to restrictions specified by the MPU region descriptors. This is in addition to the MPU responding to the requesting master with an error response.

62	No Reaction	DCI	Via FCCU Fake bit to set the fault at error path + LBIST	Debug Fault Condition to MCU • If any JTAG_aux_tms is high from DCI • If Jtag_rst_b is low from DCI • If JTAG mode is high from DCI • If nex_rst_b is high from DCI
63	No Reaction	SAR ADC0/1/2/3	VIA SAR-ADC STCR2[SERR] bit to set the fault at error source + Via FCCU Fake bit to set the fault at error path	Non Critical fault from ALL SARs
64	No Reaction	SAR ADC0/1/2/3	VIA SAR-ADC STCR2[SERR] bit to set the fault at error source + Via FCCU Fake bit to set the fault at error path	Critical Fault from All SARs
69	No Reaction	CoreA Instruction cache	Via FCCU Fake bit to set the fault at error path	IC data0 feedback check alarm
70	No Reaction	CoreA Instruction cache	Via FCCU Fake bit to set the fault at error path	IC data1 feedback check alarm
71	No Reaction	CoreA Instruction cache	Via FCCU Fake bit to set the fault at error path	IC data2 feedback check alarm
72	No Reaction	CoreA Instruction cache	Via FCCU Fake bit to set the fault at error path	IC data3 feedback check alarm
73	No Reaction	CoreA Instruction Tag	Via FCCU Fake bit to set the fault at error path	IC tag feedback check alarm
74	No Reaction	CoreA DMEM Controller	Via FCCU Fake bit to set the fault at error path	DTCM0 feedback check alarm
75	No Reaction	CoreA DMEM Controller	Via FCCU Fake bit to set the fault at error path	DTCM1 feedback check alarm
76	No Reaction	CoreA IMEM Controller	Via FCCU Fake bit to set the fault at error path	ITCM feedback check alarm
77	No Reaction	CoreB Instruction cache	Via FCCU Fake bit to set the fault at error path	IC data0 feedback check alarm
78	No Reaction	CoreB Instruction cache	Via FCCU Fake bit to set the fault at error path	IC data1 feedback check alarm
79	No Reaction	CoreB Instruction cache	Via FCCU Fake bit to set the fault at error path	IC data2 feedback check alarm
80	No Reaction	CoreB Instruction cache	Via FCCU Fake bit to set the fault at error path	IC data3 feedback check alarm

Table continues on the next page...

Table 78-3. FCCU Fault Inputs (continued)

NCF Index	Default Reaction Configuration at POR or Destructive Reset	Source	Error Reaction Path Check	Description
81	No Reaction	CoreB Instruction Tag	Via FCCU Fake bit to set the fault at error path	IC tag feedback check alarm
82	No Reaction	CoreB DMEM Controller	Via FCCU Fake bit to set the fault at error path	DTCM0 feedback check alarm
83	No Reaction	CoreB DMEM Controller	Via FCCU Fake bit to set the fault at error path	DTCM1 feedback check alarm
84	No Reaction	CoreB IMEM Controller	Via FCCU Fake bit to set the fault at error path	ITCM feedback check alarm
85	No Reaction	CoreA/0 interrupt controller	This alarm can be triggered by enabling the INTC_MMR and setting the INTC_TIMER value to be larger than the INTC_LAT value (which itself needs to be non-zero). + Via FCCU Fake bit to set the fault at error path	INTC monitor error
86	No Reaction	CoreB/1 Interrupt controller	This alarm can be triggered by enabling the INTC_MMR and setting the INTC_TIMER value to be larger than the INTC_LAT value (which itself needs to be non-zero). + Via FCCU Fake bit to set the fault at error path	INTC monitor error
87	No Reaction	Decorated memory Controller	Via FCCU Fake bit to set the fault at error path	PRAM decorated storage transaction monitor error
88	No Reaction	Computational SMPU	Via FCCU Fake bit to set the fault at error path + LBIST	MPU alarm to the fault collection unit An internal error has happened in the operation of the MPU. Example: MPU erroneously blocked transactions without a real permissions violation will assert this NCF.
89	No Reaction	peripheral SMPU	Via FCCU Fake bit to set the fault at error path + LBIST	MPU transaction monitor error output An internal error has happened in the operation of the MPU. Example: MPU erroneously blocked transactions without a real permissions violation will assert this NCF.
90	No Reaction	Core0/1 IMEM MBIST	Via FCCU Fake bit to set the fault at error path	Mbist multi bit error of IMEM (Core0 or Core1)
91	No Reaction	Flash	Via FCCU Fake bit to set the fault at error path + LBIST	Flash Read Voltage error or reference current error
92	No Reaction	Core0/1 DMEM MBIST	Via FCCU Fake bit to set the fault at error path	Mbist multi bit error of DMEM (Core0 or Core1)
93	No Reaction	Core0/1 ICACHE/TAG MBIST	Via FCCU Fake bit to set the fault at error path	Mbist multi bit error of ICACHE(Core0 or Core1)

Table continues on the next page...

Table 78-3. FCCU Fault Inputs (continued)

NCF Index	Default Reaction Configuration at POR or Destructive Reset	Source	Error Reaction Path Check	Description
94	No Reaction	SRAM MBIST	Via FCCU Fake bit to set the fault at error path	Mbist Multibit error of SRAM
95	No reaction	All Peripheral RAM MBIST	Via FCCU Fake bit to set the fault at error path	Mbist multi bit error from all peripheral RAM

78.1.6 Lockstep Status

RCCU status is evaluated in FCCU_NCF[57] channel.

In debug mode, the cores do not work in lockstep mode and the RCCUs are disabled. The actual enablement/disablement state of the RCCUs (including any automatic disablement by debug) can be read by software.

78.1.7 FOSU Count Value

The fixed preprogrammed value for FOSU_Count is 0x1F40.

78.1.8 FCCU_CFG[FCCU_SET_AFTER_RESET]

FCCU_CFG[FCCU_SET_AFTER_RESET] is not used to control EOUT pads on this chip and hence there will be no effect of writing to this bit. FCCU EOUT pads OBE are controlled either via SIUL or DCF records.

78.2 Introduction

The Fault Collection and Control Unit (FCCU) offers a hardware channel to collect faults and to place the device into a safe state when a failure in the device is detected. No CPU intervention is requested for collection and control operation.

The FCCU offers a systematic approach to fault collection and control. The distinctive features of the module are:

- Redundant collection of fault information from safety relevant modules on the device
- Collection of test results
- Configurable fault control
- Configurable internal reactions for each NCF:
  - No reaction
  - IRQ
  - Short functional reset
  - Long functional reset
  - NMI
- External reactions via configurable output pins
- Watchdog timer for the reconfiguration phase
- The FCCU's configuration is lockable:
  - Permanently locked until next reset or transiently locked until a specific key is written. FCCU gets transiently locked again if an invalid key is written into FCCU_TRANS_LOCK register (that is, other than 0xBC). Key to lock the FCCU permanently is 0xFF, written in the FCCU_PERMNT_LOCK register.
- Self checking capabilities: FSM redundancy and parity check for the configuration register
- One of the error out pins is high to indicate operational (OK) state (in bi-stable operation mode). The above is not true in case the error out protocol is configured to be a toggling protocol, for example, dual rail and time switching.
- After power on, the EOUT signals have high impedance.[1] They show operational state only on software request.
- In case of a failure event or on software request for Error pin indication, the pin(s) are set to faulty state for a minimum time T_min, even if SW tries to release it before (for the case of error pin configured in Bi-stable mode only).
- The overall fault detection, processing and indication time is less than 10 ms.
- The actual maximum time is 5 CLKSAFE cycles**.**

1. Actual value depends on device specific setting at pad level.

The FCCU circuitry is checked at the start-up by the self-checking procedure. The FCCU is operative with the default configuration immediately after the completion of the self-checking procedure. Internal (short or long functional reset request pulse, interrupt request) and external (EOUT signaling) reactions are statically defined or programmable. The default configuration can be modified only in the CONFIG state. FCCU is designed to function when CLKSYS is faster than the CLKSAFE clocks.

78.2.1 Acronyms and abbreviations

Term	Description
CF	Critical fault
CPU	Central processing unit
EOUT	Error out
FOSU	FCCU output supervision unit
FSM	Finite state machine
INTC	Interrupt controller
intf	Interface
IRQ	Interrupt request
MC_ME	Mode entry module
NCF	Noncritical fault
NMI	Nonmaskable interrupt
SoC	System-on-chip
STCU	Self-test control unit
SW	Software
WKPU	Wake-up unit

78.3 Main features

- Management of non-critical faults
- HW or SW fault recovery management
- Fault detection and collection
- Fault injection (fake faults)
- External reaction (fault state): EOUT signaling. Error indication via the pin(s) is controlled by the FCCU.
- Internal chip reactions (alarm state): interrupt request
- Internal chip reactions (fault state):

- long functional reset request pulse
- short functional reset request pulse
- NMI

- Bi-Stable, Dual-Rail and Time Switching output protocols on EOUT
- Internal (to the FCCU) watchdog timer for the reconfiguration phase
- Configuration lock
- Self-checking capabilities: FSM redundancy and parity check for the configuration registers

78.4 Block diagram

The following figure is a top-level diagram of the FCCU module.

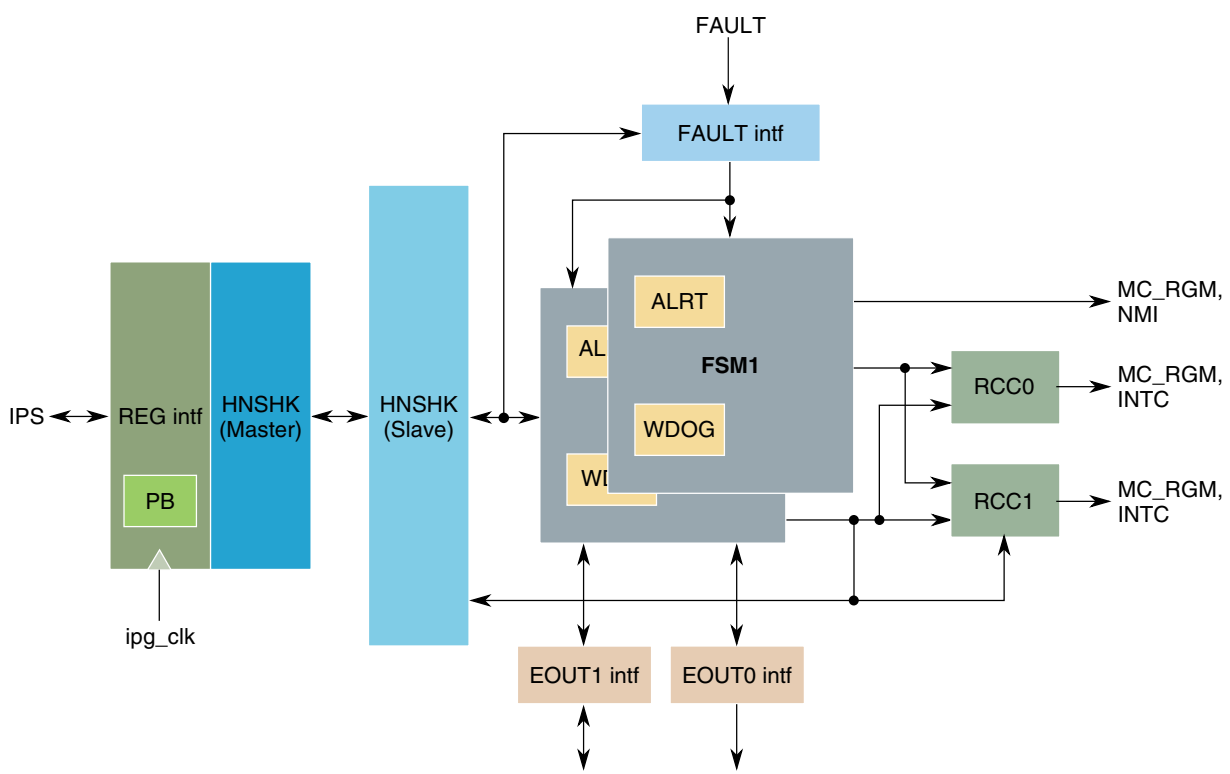

Figure 78-2. FCCU block diagram

This table describes the FCCU submodules.

Table 78-4. FCCU submodules

Submodule	Description
REG intf	Includes the register file, the IPS bus interface, the IRQ interface and the parity block (PB) for the configuration registers
HNSHK blocks (master and slave blocks)	Includes the FSM's ability to support the handshake between the REG interface and the FSM unit due to the usage of 2 asynchronous clocks (IPS system clock and RC oscillator clock)
FSM unit	Implements the main functions of the FCCU. The FSM also includes the: • Watchdog timer (WDG) • Alarm timer (ALRT)
FAULT intf	Implements the interface for the fault conditioning and management
EOUTx units	Implement the output stage to manage the EOUT interfaces
RCCx units	Implement the redundancy control checker to monitor the FSMx unit state and its configuration

78.5 Signal description

78.5.1 Signals

This table describes the signals on the boundary of FCCU.

Signal	Direction	Function	Active level	Clock
Clock and reset				
CLKSYS	Input	System Clock—Supplies the primary clock.	Rising edge	—
CLKSAFE0	Input	Safe Clock 0—Supplies one of two 16 MHz clocks for use by various redundant submodules. This clock and CLKSAFE1 are often referred to as the same clock (CLKSAFE).	Rising edge	—
CLKSAFE1	Input	Safe Clock 1—Supplies one of two 16 MHz clocks for use by various redundant submodules. This clock and CLKSAFE0 are often referred to as the same clock (CLKSAFE).	Rising edge	—
EOUT interface				
EOUT[1:0]	Output	Error Output—Indicate FCCU's condition (Faulty, Nonfaulty, or Configuration) to off-chip logic.	Programmable	CLKSAFE0, CLKSAFE1
FOSU interface				

Table continues on the next page...

Signal	Direction	Function	Active level	Clock
FIF	Output	FCCU In Fault—Indicates to the FOSU module that FCCU is recognizing a fault so that FOSU doesn't mistakenly generate a destructive chip reset. FCCU asserts and then deasserts this signal in two cases: *Case 1* When the EOUT signals are programmed to be always low (FCCU_SET_CLEAR), FCCU asserts this signal until the EOUT signals are programmed not to be always low. *Case 2* When the EOUT signals are programmed not to be always low (FCCU_SET_CLEAR), FCCU asserts this signal when all of the following are true: • FCCU enters Fault state as the result of a fault. • If the fault is a noncritical fault and the EOUT signals are in Bistable fault-output mode (FOM), the EOUT signals are enabled for the fault (EOUTENx). FCCU deasserts this signal when FCCU leaves Fault state.	High	CLKSAFE0, CLKSAFE1
WKPU interface				
NMIWKPU	Input	WKPU Nonmaskable Interrupt Request—Receives nonmaskable interrupt requests from the WKPU module.	Low	CLKSYS
WAKEWKPU	Output	Wake WKPU—Wakes the WKPU module to bring the chip out of dormant state when FCCU enters Fault state as the result of a noncritical fault for which NMI is enabled as the reaction (FCCU_NMI_ENa[NMIENx]).	High	CLKSAFE0, CLKSAFE1
Interrupt interface				
NMIOUT	Output	Nonmaskable Interrupt Output—Sends a nonmaskable interrupt request to the processor core or cores when FCCU enters Fault state as the result of a noncritical fault for which NMI is enabled as the reaction (FCCU_NMI_ENa[NMIENx]).	Low	CLKSYS

78.6 Functional description

78.6.1 Definitions

In general, the following definitions are applicable for the fault management:

- HW recoverable fault: the fault indication is an edge-triggered and level-sensitive signal that remains asserted until the fault cause is deasserted. That is, if logical 0 on the fault signal indicates fault, then the status flags are valid as long as the fault line stays at 0. The status is automatically cleared when the fault signal goes to 1. Typically the fault signal is latched external to the FCCU in the module where the fault occurred. The FCCU state transitions are consequently executed on the state changes of the input fault signal. No SW intervention in the FCCU is required to recover the fault condition.
- SW recoverable fault: the fault indication is a signal asserted without a defined time duration. The fault signal is latched in the FCCU. The fault recovery is executed following a SW recovery procedure (status/flag register clearing).

HW recoverable is an option to exclude the handling of error source/s by FCCU management SW, in case it is known that the fault is recoverable by itself when the fault condition gets corrected.

These type of chip resets reset the FCCU:
- Power-on
- Destructive
- Long functional, when initiated by the assertion of the chip reset pin (RESET_B)

These types of chip resets don’t reset the FCCU:
- Long functional, when initiated by anything other than the assertion of the chip reset pin (RESET_B)
- Short functional reset

For more information on each type of reset, see the MC_RGM and reset chapters.

78.6.2 FSM description

FCCU functionality is depicted by the finite state machine (FSM) state diagram.

Basically four states are identified with the following meaning:

- Configuration: Used only to modify the configuration of FCCU from its default. A subset of the FCCU registers, dedicated to define the FCCU configuration (global configuration, reactions to fault, timeout, noncritical fault masking) can be accessed in write mode only in Configuration state.

  Configuration state is accessible only in Normal state and if the configuration is not locked. The permanent configuration lock can be disabled by a reset which also resets the FCCU., The transient lock register is unlocked by writing BCh into it. FCCU gets transiently locked again if an invalid key is written into FCCU_TRANS_LOCK register (that is, other than BCh). Key to lock FCCU permanently is FFh, written in the FCCU_PERMNT_LOCK register.

  After the release of reset the state of the transient lock will be locked. The state of the permanent lock will be unlocked.

  The locking feature only restricts the FSM movement into Configuration state. Once the user enters Configuration state and then tries to lock the configuration, the locking of configuration will be effective after FCCU moves to Normal state, it will not be effective in the current Configuration state.

  The Configuration to Normal state transition can be executed by SW or automatically following a timeout condition of the watchdog. In case the timeout information and the SW request to mode change to Normal appears at the same time, watchdog timeout has the priority and hence the Configuration registers (those that are writable only in Configuration state) are reset to their default values. The movement to Normal is made.

  The incoming faults, occurring during the configuration phase (Configuration state) are latched in order to process them when FCCU is moved into Normal state, according to the new configuration.

  All pending faults that occur during Configuration state result in both of the following:

  - Highest-priority state transition
  - Interrupt generation (NMI or alarm IRQ)

  If the state transition occurs, it gives the reset reaction corresponding to the worst case based on all the faults (pending or nonpending faults) that occurred during Configuration state.

- Normal: This is FCCU's operating state when no faults are occurring. It is also the default state on the reset exit. Following state transitions occur on one of the following events:

    - unmasked noncritical faults with the timeout disabled → FCCU moves to Fault state
    - unmasked noncritical faults with the timeout enabled → FCCU moves to Alarm state
    - masked noncritical faults → FCCU stays in Normal state
- Alarm: FCCU moves into Alarm state when an unmasked noncritical fault occurs and the timeout is enabled. The transition to Alarm state goes along with an interrupt alarm, if enabled. By definition, this fault may be recovered within a programmable timeout period, before it generates a transition to Fault state. The timeout is reinitialized if FCCU enters Normal state. The timeout restarts following the recovery from Fault state.
- Fault: FCCU moves into Fault state when one of the following condition occurs:
    - timeout related to a noncritical fault when FCCU is in Alarm state
    - unmasked noncritical faults with the timeout disabled

The transition from Normal/Alarm to Fault state goes along with the generation of:

- NMI interrupt (optional)
- EOUT signaling (optional)
- SW option: Soft reaction (Short functional reset request pulse if configured)
- SW option: Hard reaction (Long functional reset request pulse if configured)
- Non Maskable Interrupt (NMI) is routed only to the Safety Core

After moving to Fault state, if there is either a previous pending fault or a new fault for which NMI is enabled, NMI generation takes place.

Multiple faults can occur at the same time. Consider the case where there is a fault for which Alarm state is enabled and IRQ is programmed along with a fault for which Alarm state is disabled. In that case, the FSM moves to Fault state, but with the generation of alarm IRQ for the fault which has IRQ enabled.

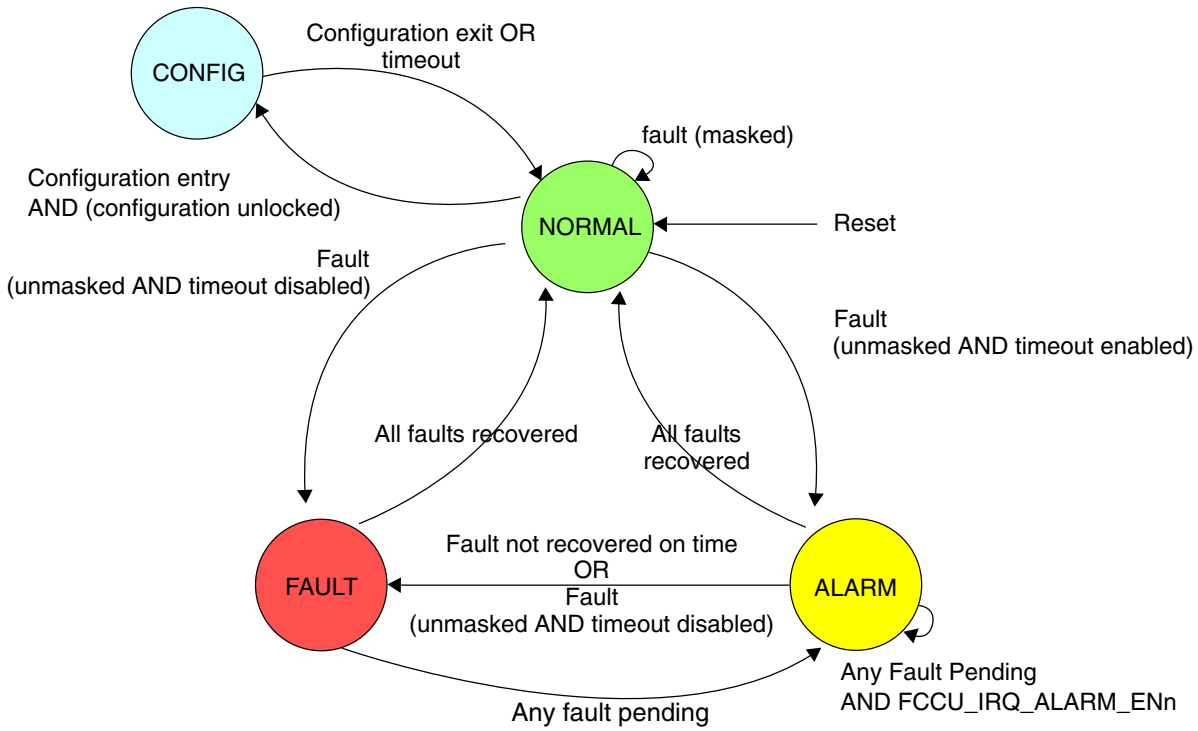

Figure 78-3. FCCU state diagram

78.6.3 Self-checking capabilities

The FCCU includes some features to support self-checking capabilities of the main FSM in running mode. The FSM unit is duplicated and its state (internal state and relevant outputs) is checked by 2 RCCx units (cycle accurate). The following checks (per CLKSAFE cycle) are provided by the RCCx units:

- all the FSM outputs and its internal state for the redundant FSM instances are checked to detect runtime faults on the FSM outputs and its internal state
- parity bits (computed at byte level) on the configuration registers are checked to detect run time faults on the configuration inputs of the FSM
- parity bits (computed at byte level) on the interface used to clear the FCCU_CF_Sx FCCU_UF_Sx and FCCU_RF_Sx status registers
- EOUT protocol state in dual-rail, time-switching and bi-stable mode
- common mode signals (handshake interface signals activated only in CONFIG state) congruence with the FSM state

In case of failure each RCCx unit provides the following reaction:

- an interrupt request to the INTC module.

The RCCx state is freeze in a SC freeze status register (FCCU_SCFS).

To guarantee the self checking capabilities through the FAULT interface, each critical/ unrecoverable fault source must be duplicated on a couple of CF UF inputs.

Two separate clock inputs (CLKSAFE0 and CLKSAFE1) are routed to the redundant modules (FSMx, RCCx, EOUTx, FAULT-if modules). An off-module monitor of the CLKSAFE clocks and an off-module reaction (functional reset to the MC) is required to cover a potential fault on the CLKSAFE clocks.

Self checking capabilities cover the HW reaction of the FCCU due to the assertion of an external fault. The IPS bus interface and the handshake modules are not covered by self-checking capabilities. Any operation executed by SW (configuration, fault recovery) must be cross-verified by congruence checks via SW (registers read following a write/ clear operation, internal FCCU state, ..).

A typical sequence with self checking failure and related reaction is given in Figure 78-4.

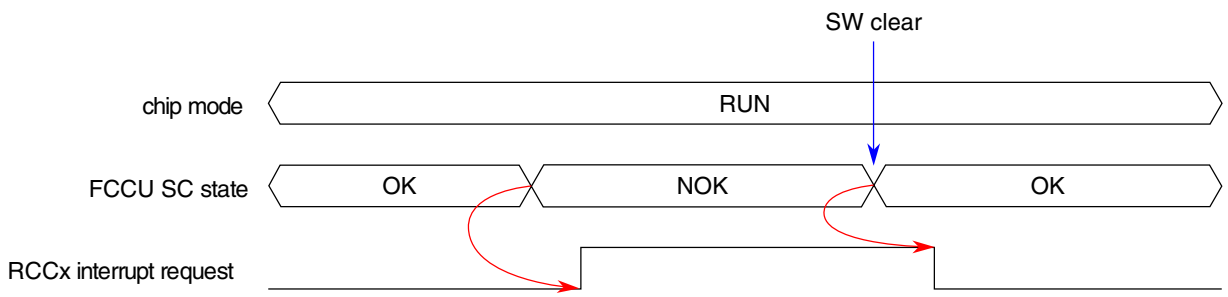

Figure 78-4. Self-checking reaction (interrupt)

For more information about how to enable or disable FCCU Self-checking, see Configuration (FCCU_CFG) and SC Freeze Status (FCCU_SCFS).

78.6.4 Fault priority scheme and nesting

The FAULT state has a higher priority than the ALARM state in case of concurrent fault events (non-critical) that occur in the NORMAL state.

The ALARM to FAULT state transition occurs if a non-critical fault (unmasked and with time-out disabled) is asserted in the ALARM state.

The ALARM to NORMAL state transition occurs only if all the non-critical faults (including the faults that have been collected after the entry in the ALARM state) have been cleared (SW or HW recovery); otherwise the FCCU will remain in the ALARM state.

The FAULT to NORMAL state transition occurs only if all the non-critical faults (including the faults that have been collected after the entry in the FAULT/ALARM state) have been cleared (SW or HW recovery); otherwise the FCCU will move to the ALARM state (if any non-critical fault is still pending and the time-out is not elapsed).

In general, no fault nesting is supported except for the non-critical faults that cause an ALARM to FAULT state transition. In this case the NCF timer is stopped until the FAULT state is recovered. If FCCU is in ALARM state and another fault comes, which has its alarm timeout enabled, then the alarm timer shall not reload and shall not start again.

78.6.5 Fault recovery

The following timing diagrams describe the main use cases of the FCCU in terms of fault events and related recovery.

A typical sequence related to a non-critical FAULT management (ALARM state), see Figure 78-5 and Figure 78-6, is as follows:

- non-critical fault assertion
- FCCU state transition (automatic): NORMAL → ALARM
  - alarm interrupt request (if enabled)
  - time-out running
- system state: RUN
- alarm interrupt management: FAULT recovery (by SW)
  - FCCU state transition ALARM → NORMAL

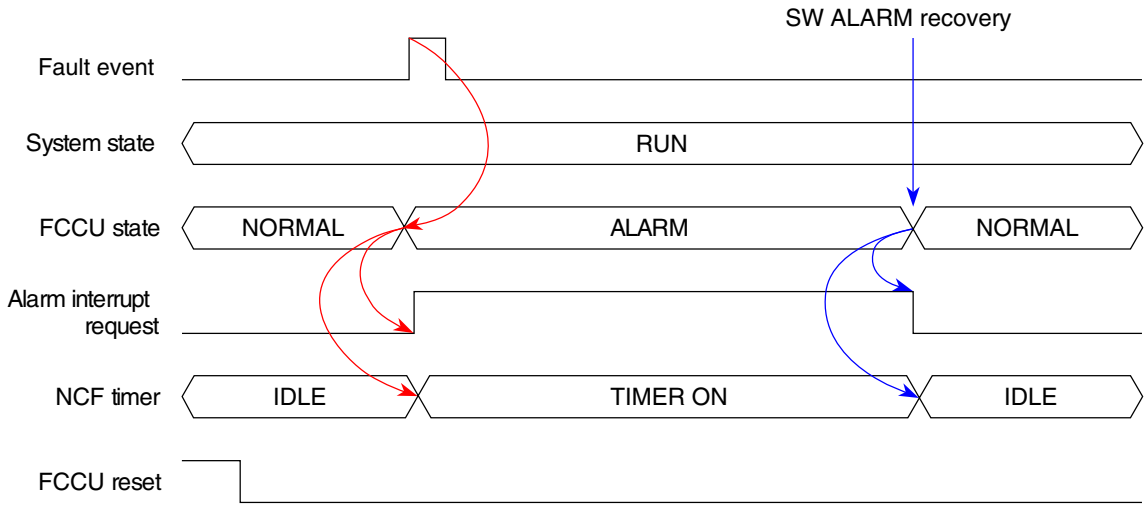

Figure 78-5. Non-critical FAULT (ALARM state) recovery (a)

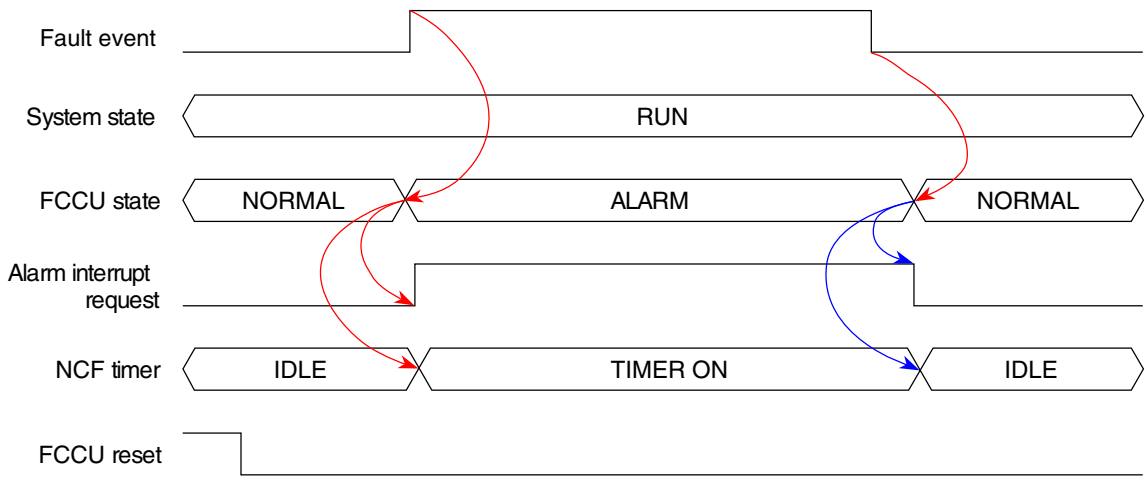

Figure 78-6. Non-critical FAULT (ALARM state) recovery (b)

A typical sequence related to a FAULT management (ALARM → FAULT state), see Figure 78-7, is as follows:

- non-critical fault assertion
- FCCU state transition (automatic): NORMAL → ALARM
  - alarm interrupt request (if enabled)
  - time-out running
- FCCU state transition (following the time-out trigger): ALARM → FAULT
  - NMI assertion (if enabled)
- system state transition: RUN → SAFE
- NMI interrupt management (if enabled)

- FAULT recovery (by SW): FCCU state transition FAULT → NORMAL
- system state transition: SAFE → RUN

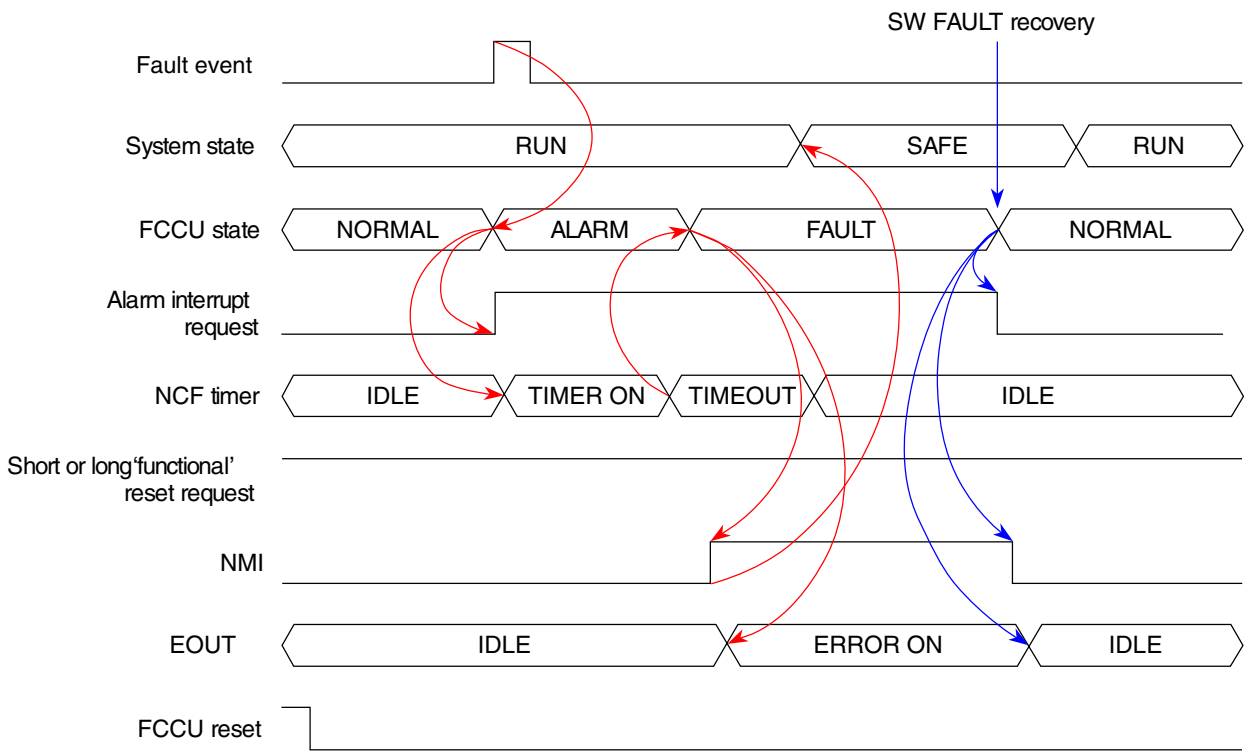

Figure 78-7. FAULT (ALARM → FAULT state) recovery

78.6.6 NMI/WKPU interface

NMIOUT is connected to all processor cores on the chip but is masked when any one of the following is true:

- An FCCU asynchronous reset is in progress.
- The chip is in RESET mode.
- The chip has automatically entered DRUN mode from RESET mode and software has not yet requested another mode.

This figure shows the logical scheme.

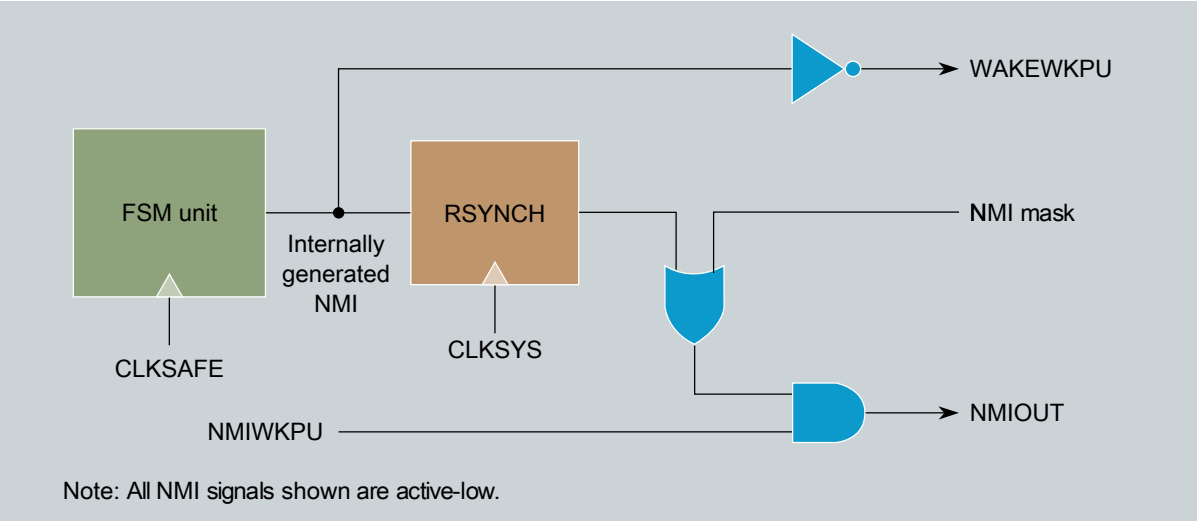

Figure 78-8. NMI/WKPU scheme

78.6.7 STCU interface

The STCU interface includes:

- A set of signals resulting from the self-checking procedure connected externally at the FCCU.

  The STCU fault signals are processed by the FCCU when the SoC is re-booted following the self-testing procedure. The STCU includes a status register that stores the self-testing results (flags).

- a mask that inhibits the EOUT dummy signaling until the STCU self-checking procedure has been completed.

During the self-testing procedure, depending on the STCU results, three cases are applicable:

1. STCU completes the self-testing procedure successfully. The SoC reboots and the FCCU is responsible for fault collection and indication.
2. STCU completes the self-testing procedure with low severity failures. The FCCU records the fault condition but does not, by default, trigger a reset cycle.
3. STCU completes the self-testing procedure with serious failures. The FCCU triggers a reset cycle in response to this fault input from the STCU. Because the fault condition survives reset, new reset cycles are subsequently triggered until the reset escalation feature takes control, freezing the chip in the reset state until a POR. This feature is optionally programmable using MC_RGM.

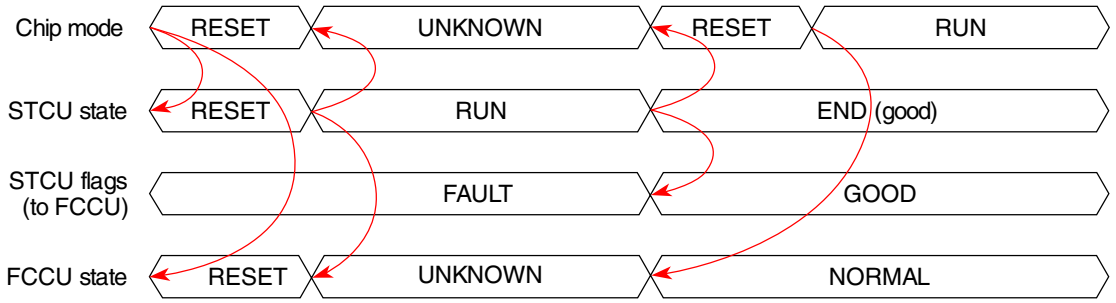

Figure 78-9. STCU-FCCU (case 1)

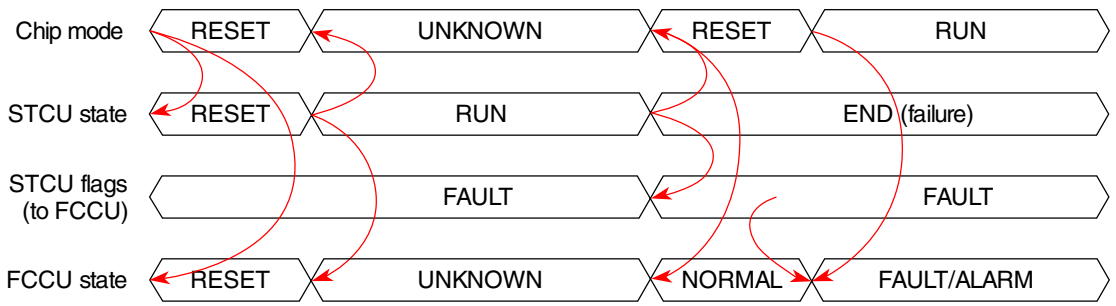

Figure 78-10. STCU-FCCU (case 2)

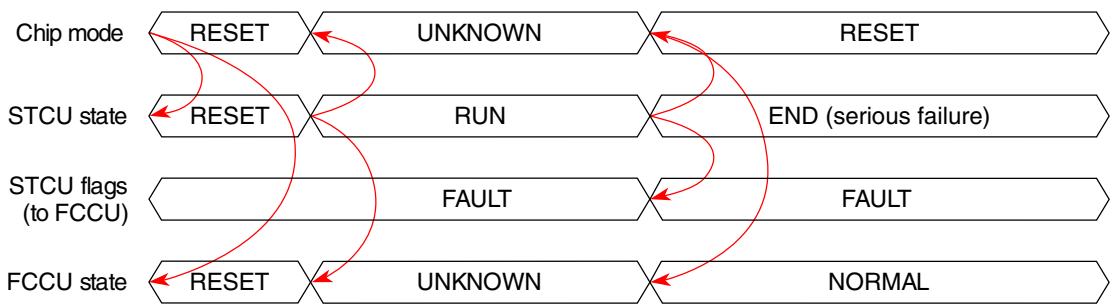

Figure 78-11. STCU-FCCU (case 3)

78.6.8 EOUT interface

The FCCU provides up to two bidirectional signals (EOUT[1:0]) as a failure indication to the external world. For information on the availability and names of these FCCU signals on the boundary of this chip, see the chip-specific FCCU information.

Different fault-output modes (protocols) for the fault-output (EOUT) interface are supported (FCCU_CFG[FOM]):

- Dual-Rail
- Time-Switching

- Bistable
- Test

You can further configure the fault-output modes using the following attributes:

Attribute	Field	Setting used in the example diagrams and tables that follow
Switching mode	FCCU_CFG[SM]	Slow
Polarity selection	FCCU_CFG[PS]	For the faulty indication, EOUT1 is high, and EOUT0 is low.

The EOUT frequency is generated by dividing the CLKSAFE frequency by a fixed factor of 2^{18}.

With a CLKSAFE frequency of 16 MHz, this drives a signal of 61 Hz on EOUT.

The external monitor of the EOUT protocol should oversample the EOUT signals in order to synchronize periodically the external clock (used by the monitor) and CLKSAFE (which detects the edge transition of the EOUT protocol) in Dual-Rail or Time-Switching fault-output mode.

In case of a failure event or on software request for EOUT indication, the signal(s) are set to the faulty state for a minimum time T_min, even if software tries to release it before. If software configures the error pins to OK(1), and if a fault comes trying to drive the pin to NOK(0), then priority is given to the fault indication and the error signals indicate NOK, such as an incoming fault is not masked when software has set the error signal to high. During the T_min by a non-software fault, the FCCU FSM moves independently of this signal state (low), and as soon as the timer expires, the pin behavior is dictated by the state in which the FSM finds itself in, and it is not possible to set the signals to OK by software moving FCCU to Configuration state, as long as this timer is running. No software intervention is needed to bring the signal from the low state.

Software can bring the pin back to OK state by clearing the faults and waiting for the T_min interval to expire, after which the FCCU automatically enters Normal state and the error signal indicates OK.

In case another failure event happens within T_min after a first one, the T_min counter is restarted.

These resets influence the state of the failure indication pins:

- Power on reset
- Destructive reset (including when an FOSU timeout occurs due to FCCU failing to react)
- Chip pin reset (RESET_B)

Other resets should not influence the state of the failure indication pins.

NOTE

The transition from Fault to Configuration state is not possible but is shown to display the behavior in all four states—reset, normal, error, and configuration.

NOTE

FCCU remains in Normal state when a fault is disabled; therefore, NA (not applicable) appears in the following table.

NOTE

The following table is valid only after software has enabled the EOUT signals (FCCU_CFG[FCCU_SET_AFTER_RESET].

Table 78-5. FCCU error pin behavior on state transitions

Fault signaling state	Transition from Normal to Fault state			Normal+Configuration states			Transition from Normal to Alarm state		
	with Fault disabled | enabled						with Fault disabled | enabled		
	Internal error pin	Error pin enable	Error pad	Internal error pin	Error pin enable	Error pad	Internal error pin	Error pin enable	Error pad
Disabled	NA | OK	NA | 1	NA | OK	OK	1	OK	NA | OK	NA | 1	NA | OK
Enabled	NA | NOK	NA | 1	NA | NOK	OK	1	OK	NA | OK	NA | 1	NA | OK

NOTE

The first time FCCU is in Configuration state, the EOUT pads are in a high-impedance state; thereafter, their states reflect the programmed EOUT protocol.

78.6.8.1 Dual-rail protocol

Dual-rail encoding is an alternate method for encoding bits. In contrast with classical encoding, where each signal carries a single-bit value, dual-rail encoded circuits use two wires to carry each bit. The encoding scheme is given in Table 78-6 and the related timing diagram is given in Figure 78-12 and Figure 78-13.

Table 78-6. Dual-rail encoding

Logical state	Dual-rail encoding (output pins EOUT[1:0])	Note
non-faulty	10	toggling
non-faulty	01	

Table continues on the next page...

Table 78-6. Dual-rail encoding (continued)

Logical state	Dual-rail encoding (output pins EOUT[1:0])	Note
faulty	00	toggling
faulty	11	
reset	Hi impedence[1]	no toggling
configuration	same as NORMAL	toggling

1. Final value depends on the SoC setting at pad level.

As long as FCCU is in NORMAL or ALARM state, output will show "non-faulty" signal. Output pins EOUT[0:1] will toggle between 01 and 10 with a given frequency of 61 Hz.

In the RESET phase the output pins are set as "high impedance".

Note

Figure 78-12 and Figure 78-13 are formatted to display the behavior in all four phases (reset, normal, error, and config), not to imply transitions between one phase to another. In particular, transition from error phase to config phase is not possible.

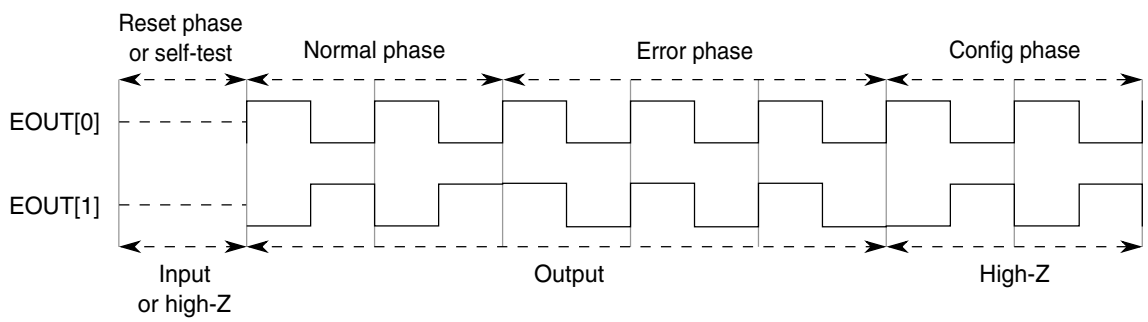

Figure 78-12. Dual-rail protocol (slow switching mode)

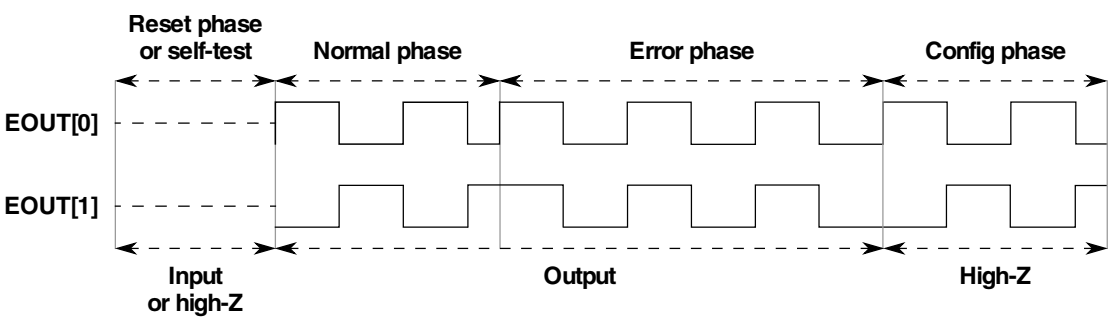

Figure 78-13. Dual-rail protocol (fast switching mode)

78.6.8.2 Time-switching protocol

The encoding scheme is given in Table 78-7 and the related timing diagram is given in Figure 78-14.

Table 78-7. Time-switching encoding

Logical state	Time-switching encoding (output pins EOUT[1:0])	Note
non-faulty	10	toggling
non-faulty	01	
faulty	10	no toggling
reset	high-Z[1]	no toggling
configuration	same as NORMAL	toggling

1. Final value depends on device specific settings at pad level.

As long as FCCU is in NORMAL or ALARM state, outputs will show "non-faulty" signal. Output pins #0, #1 will toggle between 01 and 10 with frequency of 61 Hz.

In the FAULT state, the output pin EOUT[0] is set as low.

In Time Switching mode the second output (EOUT[1]) is the inverted signal of first output (EOUT[0]).

In the RESET phase the output pins are set as "high impedance".[2]

Note

Figure 78-14 is formatted to display the behavior in all four phases (reset, normal, error, and config), not to imply transitions between one phase to another. In particular, transition from error phase to config phase is not possible.

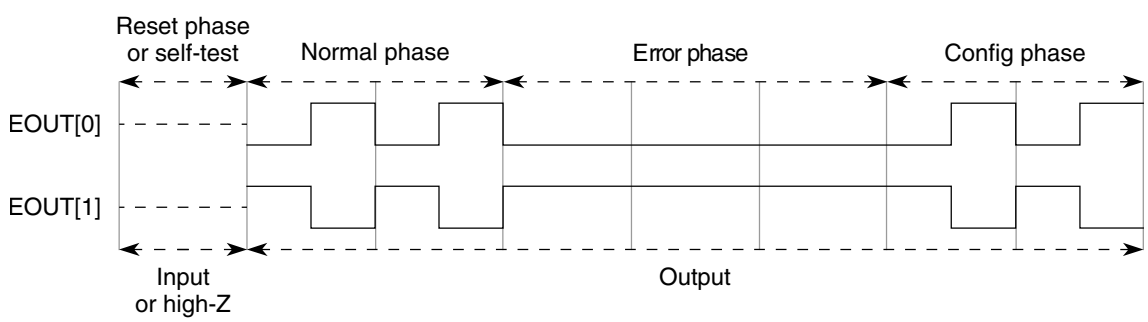

Figure 78-14. Time-switching protocol

2. Actual value depends on device specific settings at pad level.

78.6.8.3 Bi-stable protocol

The encoding scheme is given in Table 78-8 and the related timing diagram is given in Figure 78-15.

Table 78-8. Bi-stable encoding

Logical state	Bi-stable encoding (output pins EOUT[1:0])	Note
non-faulty	01	no toggling
faulty	10	no toggling
reset	high-Z[1]	no toggling
configuration	same as NORMAL	no toggling

1. Final value depends on device specific settings at pad level.

In the FAULT state, the faulty logical state is indicated. In NORMAL or ALARM state, "no-faulty" state is indicated. In Bi-stable mode the second output (EOUT[1]) is the inverted signal of first output (EOUT[0]).

In the RESET phase the output pins are set as "high impedance".[3]

Note

Figure 78-15 is formatted to display the behavior in all four phases (reset, normal, error, and config), not to imply transitions between one phase to another. In particular, transition from error phase to config phase is not possible.

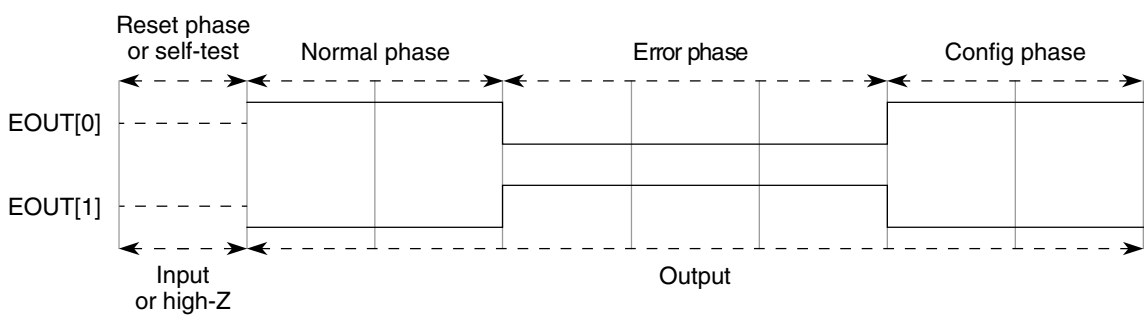

Figure 78-15. Bi-stable protocol

78.6.9 Error signal flow

See the chip-specific FCCU information for the diagram of the signal flow.

3. Actual value depends on device specific settings at pad level.

78.7 Register descriptions

The FCCU registers are listed in the table below. Any address offset not explicitly mentioned in this table is reserved.

The FCCU supports word (32-bit), half-word (16-bit), and byte (8-bit) read and write accesses.

Follow these register-access guidelines:

- Don't read from or write to any addresses that are not shown in the following table. Doing so may result in a transfer error.
- Don't write to any of the configuration registers unless FCCU is in Configuration state. Doing so results in a transfer error.
- Don't write to FCCU_TRANS_LOCK or FCCU_PERMNT_LOCK unless your code runs in Supervisor mode. Doing so results in a transfer error.

All the registers accessible in write mode only in CONFIG state are referred as configuration registers. These configuration registers return to the default value after configuration watchdog timer expires. These are the registers protected by FCCU_TRANS_LOCK and FCCU_PERMNT_LOCK registers. The configuration register setting has effect only when the FCCU state exits from the CONFIG state.

For each possible NCF failure source a different reaction shall be configurable through the use of NMI, IRQ, long/short reset selection registers as well as no reaction by disabling the former registers. It is not possible for a single event upset to switch off all reactions on failures as implementation is per fault source (but it will be possible to switch them all off by SW if intended). Failures themselves are not able to disable all reactions and indications.

The FCCU is not reset by short or long functional resets.

78.7.1 Control (FCCU_CTRL)

The FCCU_CTRL register allows the following operations to be executed:

- moving the FCCU state from the NORMAL state into the CONFIG state
- moving the FCCU state from the CONFIG state into the NORMAL state
- reading or to clear the NCF status register
- reading the FCCU FSM status register
- reading or to clear the FCCU freeze registers
- reading the ALARM timer
- reading the Watchdog timer

Some critical operations require a key as defined in the FCCU_CTRLK register.

Address: 0h base + 0h offset = 0h

FCCU_CTRL field descriptions

Field	Description
0 FILTER_ BYPASS	Filter bypass 0 glitch filter not bypassed 1 glitch filter bypassed
1–2 FILTER_WIDTH	Filter width 00 filters glitches up to 50 µs 01 filters glitches up to 75 µs 10 filters glitches up to 100 µs 11 filters glitches up to 100 µs
3–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22 DEBUG	Debug Mode Enable Specifies whether Debug mode is enabled. If so, FCCU enters Debug mode when the Debug signal is asserted. When FCCU enters Debug mode, it halts operation and remains in the state it was in before it entered Debug mode. **NOTE:** FOSU doesn't halt when FCCU enters Debug mode. Therefore, FOSU can still cause a reset if a fault occurs while FCCU is in Debug mode.

Table continues on the next page...

FCCU_CTRL field descriptions (continued)

Field	Description
	0 Disabled 1 Enabled
23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–25 OPS	Operation status. This bit can be read and cleared (via OP15 operation) by the software. 00 Idle 01 In progress 10 Aborted 11 Successful
26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27–31 OPR	Operation run. The SW application must not modify the OPR field (any write operation will be ignored) until the completion of the operation. Once the operation has been completed, the operation status (OPS) is set and the OPR field is automatically cleared (OPR = 000). The opcode OP12 must not be programmed. The OPR field is automatically set to OP12 when the FCCU_NCF_S registers are cleared by a write-clear operation into the related register. The opcode OP14 must not be programmed. The OPR field is automatically set to OP14 when the timeout occurs (FCCU_CFG_TO) during the configuration procedure => the FCCU state is automatically forced in NORMAL mode setting the default configuration. In this phase any write operation to the FCCU configuration registers is inhibited. In the case of OP15, the operation is successful immediately and OPS/OPR are cleared instantly. The operations OP21-OP30 are forbidden. In case of execution, they return an ABORT response without any side effect. The ABORT response occurs in the following cases: • wrong access (missing or wrong key) to the FCCU_NCF_S register (clear operation OP12) • wrong access (missing or wrong key) to the FCCU_CTRL register (OP1, OP2 operation) • OP1 (CONFIG command) execution when FCCU state /= NORMAL or configuration locked 00000 No operation [OP0] 00001 Set the FCCU into the CONFIG state [OP1] 00010 Set the FCCU into the NORMAL state [OP2] 00011 Read the FCCU state (see the FCCU_STAT register) [OP3] 00100 Read the FCCU frozen status flags (see the N2AF_STATUS register) [OP4] 00101 Read the FCCU frozen status flags (see the A2FF_STATUS register) [OP5] 00110 Read the FCCU frozen status flags (see the N2FF_STATUS register) [OP6] 00111 Read the FCCU frozen status flags (see the F2AF_STATUS register) [OP7] 01000 Read the FCCU frozen status flags (see the FCCU_SCFS register) [OP8] 01001 Reserved 01010 Read the NCF status register (see the FCCU_NCF_S register) [OP10] 01011 Reserved 01100 NCF status clear operation in progress (see the FCCU_NCF_S register) [OP12] 01101 Clear the freeze status registers (see the freeze registers) [OP13]

78.7.2 Control Key (FCCU_CTRLK)

The FCCU_CTRLK register implements the key access for the operations OP1, OP2 according to the following sequence:

1. Write the key into the FCCU_CTRLK register.
2. Write the FCCU_CTRL register (operations OP1 or OP2).

NOTE

The FCCU_CTRLK and FCCU_CTRL registers must be written with consecutive instructions. Both registers must be written as 32-bit values. Do not use read-modify-write instructions, such as bit field instructions, to modify these registers.

The FCCU_CTRLK register is not readable, a 0000_0000h value is always returned in case of read operation. The key must be written by a word (32 bits) data write operation.

Address: 0h base + 4h offset = 4h

Field	Description

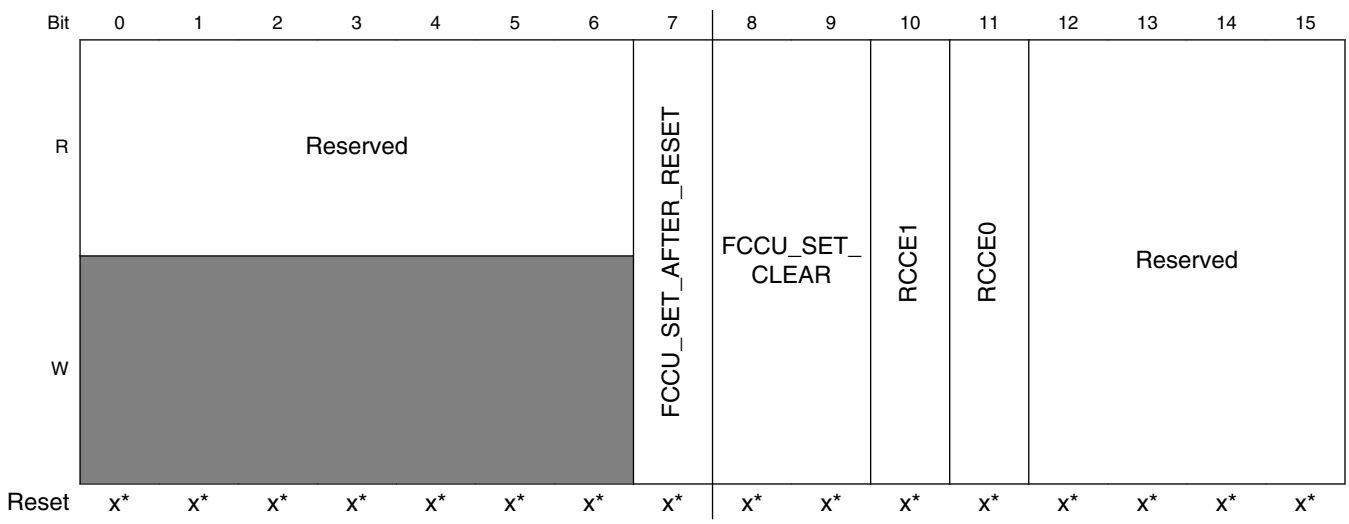
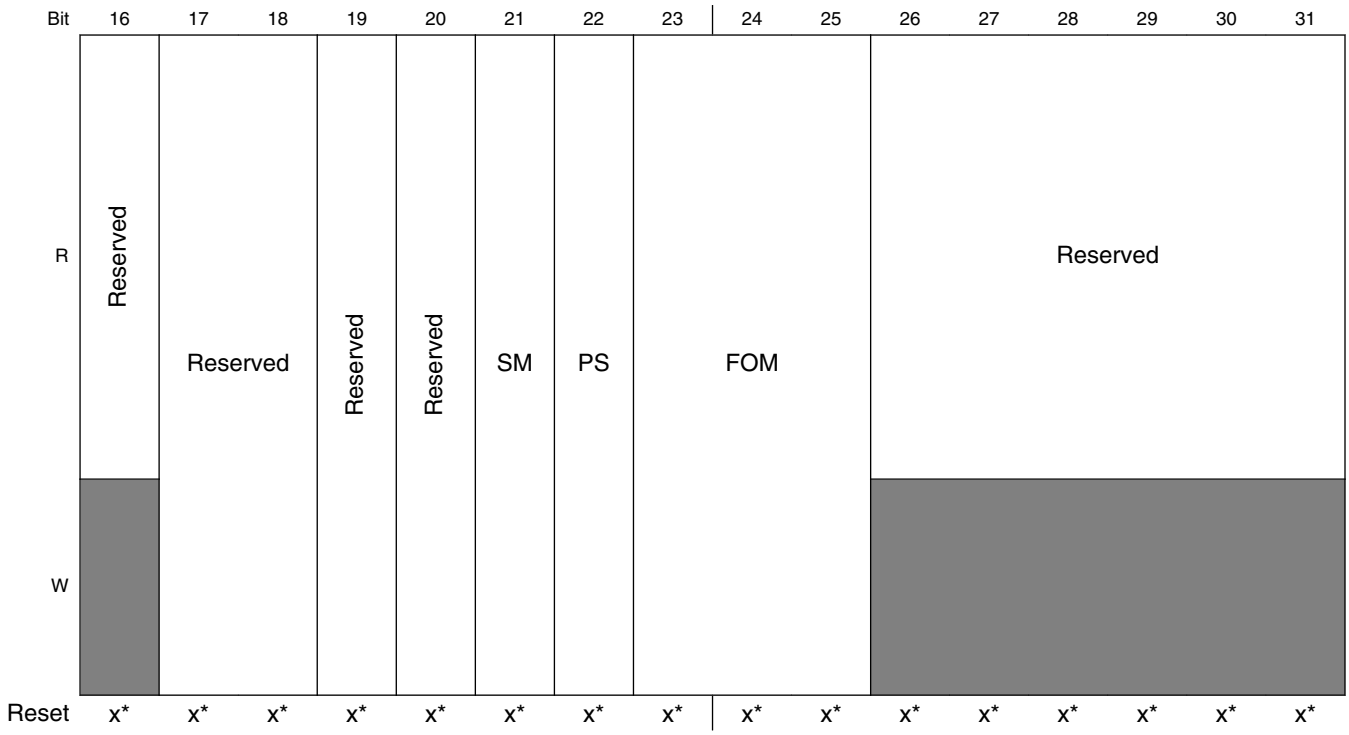
78.7.3 Configuration (FCCU_CFG)

Defines the global configuration for FCCU.



NOTE



This register is writable only when FCCU is in Configuration state.

NOTE

If you specify a new value for any of the fields in this register that affect the EOUT signals while the EOUT fault-indication timer is running (FCCU is indicating a fault on the EOUT signals), FCCU doesn't use the new settings you specified until after the EOUT fault-indication timer expires (FCCU stops indicating a fault on the EOUT signals).

Address: 0h base + 8h offset = 8h

* Notes:
- The reset value is chip-specific. See the chip-specific FCCU information.x = Undefined at reset.

FCCU_CFG field descriptions

Field	Description
0–6 Reserved	This field is reserved.
7 FCCU_SET_ AFTER_RESET	Fault-Output (EOUT) Activate For fault-output (EOUT) signaling, controls whether the EOUT signals are active. 0 Inactive (the EOUT signals are in a high-impedance state) 1 Active (the EOUT signals indicate FCCU's condition)
8–9 FCCU_SET_ CLEAR	Fault-Output (EOUT) Control Applies only when the EOUT signals are active (FCCU_SET_AFTER_RESET). Controls whether the fault-output (EOUT) signals are controlled by FCCU's finite state machine (FSM). 00 Controlled by the FSM 01 Always low 10 Controlled by the FSM 11 High until a fault occurs on a channel, regardless of whether that fault is disabled; thereafter, controlled by the FSM. Note: FCCU ignores an attempt to write this value if the fault-output (EOUT) timer is already running.
10 RCCE1	Redundancy Control Checker 1 Enable For the self-checking feature, controls whether FCCU's redundancy control checker 1 (RCC1) is enabled.

Table continues on the next page...

FCCU_CFG field descriptions (continued)

Field	Description
	NOTE: • Always enable any RCCs in a separate register access after activating the EOUT signals (FCCU_SET_AFTER_RESET). • If only one RCC is enabled and a self-check fails, both RCCs assert an interrupt. 0 Disabled 1 Enabled
11 RCCE0	Redundancy Control Checker 0 Enable For the self-checking feature, controls whether FCCU's redundancy control checker 0 (RCC0) is enabled. **NOTE:** • Always enable any RCCs in a separate register access after activating the EOUT signals (FCCU_SET_AFTER_RESET). • If only one RCC is enabled and a self-check fails, both RCCs assert an interrupt. 0 Disabled 1 Enabled
12–15 Reserved	This field is reserved. Always write the reset value to this field.
16 Reserved	This field is reserved.
17–18 Reserved	This field is reserved. Always write the reset value to this field.
19 Reserved	This field is reserved. Always write the reset value to this field.
20 Reserved	This field is reserved. Always write the reset value to this field.
21 SM	Fault-Output (EOUT) Switching Mode For fault-output (EOUT) signaling, controls how quickly the signals switch between faulty and nonfaulty indication. Applies only to Dual-Rail and Time-Switching fault-output modes. 0 Slow: No EOUT frequency violation during the FCCU state transition (Normal to Fault or vice versa, and Configuration to Normal). The indication transition occurs after a maximum delay equal to the duration of the semiperiod of the EOUT frequency. 1 Fast: The indication transition (Normal to Fault or vice versa, and Configuration to Normal) occurs immediately. A pulse with the minimum duration corresponding to the CLKSAFE period can occur in this mode. It implies a frequency violation of the EOUT protocol.
22 PS	Fault-Output (EOUT) Polarity Selection For fault-output (EOUT) signaling, controls the polarity of the signals for fault-output-mode indications that hold the signals low or high (versus toggling them or placing them in a high-impedance state). Applies only to Time-Switching fault-output mode (for faulty and configuration indications) and Bistable fault-output mode (for all indications). 0 For the faulty indication, EOUT1 is high, and EOUT0 is low. 1 For the faulty indication, EOUT1 is low, and EOUT0 is high.
23–25 FOM	Fault-Output (EOUT) Mode For fault-output (EOUT) signaling, controls the protocol of the signaling. **NOTE:** In the test modes, a simple double-stage resynchronization stage is used to resynchronize the EOUT input/outputs with CLKSAFE.

Table continues on the next page...

26–31 Reserved	This field is reserved. Always write the reset value to this field.

78.7.4 Noncritical Fault Configuration (FCCU_NCF_CFG*n*)

Contains the configuration of noncritical faults in terms of fault-recovery management. The configuration depends on the type of signaling of a fault event. Hardware-recoverable faults should be configured only if a previous latching stage captures and holds the physical fault; otherwise, the fault can be lost. All other faults should be configured as software faults.

NOTE

These registers are writable only when FCCU is in Configuration state.

This table shows the noncritical-fault configuration-register channels.

Table 78-14. Noncritical-fault configuration-register channels

Address offset	Register name	Channel range (x) (bit location [0:31])
1Ch	FCCU_NCF_CFG0	NCFC[31:0]

FCCU_NCF_CFG*n* field descriptions

Field	Description
0–31 NCFCx	Noncritical Fault Configuration. Defines the fault recovery mode. Hardware-recoverable faults are self-recovered (status flag clearing and related) if the root cause (input fault) has been removed. Software-recoverable faults are recovered (status flag clearing) by software clearing of the related status flag. See Table 78-14 for register offset to channel number relationship. 0 Hardware-recoverable fault 1 Software-recoverable fault

78.7.5 Noncritical Fault State Configuration (FCCU_NCFS_CFG*n*)

The FCCU_NCFS_CFGx registers contain the configuration of each non-critical fault in terms of fault reaction (short or long functional reset request pulse) when it is the root cause for the FAULT state transition.

NOTE

These registers are writable only when the FCCU is in the CONFIG state.

NOTE

Do not configure the same channel for both a RESET reaction in the FCCU_NCFS_CFGn register and an NMI reaction in the FCCU_NMI_ENn register at the same time.

Table 78-22 shows FCCU configuration register channels.

Table 78-22. FCCU NCFS configuration register channels

78.7.6 Noncritical Fault Status (FCCU_NCF_S*n*)

The FCCU_NCF_Sx register contains the latched fault indication collected from the non-critical fault sources. Faults are latched also in the CONFIG state and independently from the enabling or reactions programmed for the NCF.

No reactions are executed until the FCCU moves in the NORMAL state.

FCCU reacts and moves from the NORMAL state into the ALARM state only if the respective enable bit for a fault is set in the FCCU_NCF_Ex register and the respective enable bit for the timeout is set in the FCCU_TOEx register.

FCCU reacts and moves from the NORMAL or ALARM state into the FAULT state if the respective enable bit for a fault is set in the FCCU_NCF_Ex register and the respective enable bit for the timeout is disabled in the FCCU_TOEx register.

FCCU reacts and moves from the ALARM state into the FAULT state if the timeout (FCCU_TO register) is elapsed before recovering from the fault.

The timeout is stopped only when the FCCU returns in the NORMAL state.

The FCCU_NCF_Sx register is encoded respectively into the N2FF_STATUS or A2FF_STATUS register to freeze the entry condition in the FAULT state. The status bits of the FCCU_NCF_Sx register, configured as SW recoverable faults, can be cleared by the following locked sequence:

1. Write the proper key into the FCCU_NCFK register.
2. Clear the status (flag) bit NCFSx => the opcode OP12 is automatically set into the FCCU_CTRL.OPR field.
3. Wait for the completion of the operation (FCCU_CTRL.OPS field).
4. Read the FCCU_NCF_Sx register in order to verify the effective deletion and in case of failure to repeat the sequence.

As result of the above sequence, in addition the FAULT interface provides support to clear the external fake FAULT root .

NOTE

There should not be any other operation in between the above steps.

The FCCU moves from the FAULT or ALARM state into the NORMAL state if all the source faults that caused the transition into the FAULT state have been removed (HW recoverable fault) or cleared via SW (SW recoverable fault). In case of nested faults that are not all recovered, the FCCU will remain in the FAULT or ALARM state.

The SW application executes the FCCU_NCF_Sx read operation by the following sequence:

1. Set the OP10 operation into the FCCU_CTRL.OPR field.
2. Wait for the completion of the operation (FCCU_CTRL.OPS field).
3. Read the FCCU_NCF_Sx register.

In case of re-configuration of the FCCU (CONFIG state), before to return in NORMAL state the pending status bits into the FCCU_NCF_Sx must be cleared in order to avoid a false transition in ALARM/FAULT state.

The following faults are ignored:

- to write a wrong key into the FCCU_NCFK register
- to attempt to clear a HW recoverable fault

Table 78-36 shows FCCU NCF status register channels.

Table 78-36. FCCU NCF status register channels

Address offset	Register name	Channel range (x) (bit location [0:31])

FCCU_NCF_S*n* field descriptions

Field	Description
0–31 NCFSx	Non-critical fault status. The status bits related to the non-critical fault configured as HW recoverable faults are read-only and the flag is self cleared when the fault source is removed. See Table 78-36 for register offset to channel number relationship. 0 No "non-critical" fault latched 1 "Non-critical" fault latched

78.7.7 Noncritical Fault Key (FCCU_NCFK)

The FCCU_NCFK register implements the key access to clear the status flags of the FCCU_NCF_Sx register.

The status bits of the FCCU_NCF_Sx register, configured as SW recoverable faults, can be cleared by the following locked sequence:

1. Write the key into the FCCU_NCFK register.
2. Clear the status (flag) bit NCFSx .

The key must be written for each FCCU_NCF_Sx clear operation.

The FCCU_NCFK register is not readable; a 0000_0000h value is always returned in case of read operation.

Address: 0h base + 90h offset = 90h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

FCCU_NCFK field descriptions

Field	Description
0–31 NCFK	Non-critical fault key = AB34_98FEh

78.7.8 Noncritical Fault Enable (FCCU_NCF_E*n*)

The FCCU_NCF_En registers enable the fault sources to allow a transition from the NORMAL into the FAULT or ALARM state. In case of fault masking, the respective status bit into the FCCU_NCF_Sn register is set (for debugging purposes), only the reaction is masked.

NOTE

These registers are writable only when the FCCU is in the CONFIG state.

NOTE

Any enabled fault should be programmed to result in a defined action. For example, set up an ALARM IRQ action by programming the IRQ Alarm Enable Register (FCCU_IRQ_ALARM_ENn).

Table 78-45 shows FCCU NCFE enable register channels.

Table 78-45. FCCU NCF enable register channels

FCCU_NCF_E*n* field descriptions

Field	Description
0–31 NCFEx	Non-critical fault enable See Table 78-45 for register offset to channel number relationship. 0 No actions following the respective non-critical fault assertion 1 FCCU moves to ALARM or FAULT state

78.7.9 Noncritical Fault Timeout Enable (FCCU_NCF_TOE*n*)

The FCCU_NCF_TOEx registers enable a transition from the NORMAL state into the ALARM state if the respective non-critical fault is enabled (NCFEx and NCFTOEx are set). In case the respective timeout is disabled (NCFTOEx is cleared) and the non-critical fault is enabled (NCFEx is set) the FCCU moves into the FAULT state if the related non-critical fault is asserted. The timer (preset with the timeout value defined by FCCU_TO register) is started when the FCCU moves into the ALARM state. If the fault is not recovered within the timeout the FCCU moves from the ALARM state to the FAULT state.

NOTE

These registers are writable only when the FCCU is in the CONFIG state.

Table 78-53 shows FCCU NCF timeout enable register channels.

Table 78-53. FCCU NCF timeout enable register channels

Field	Description
0–31 NCFTOEx	Fault timeout enable See Table 78-53 for register offset to channel number relationship. 0 FCCU moves into the FAULT state if the respective fault is enabled 1 FCCU moves into the ALARM state if the respective fault is enabled

78.7.10 Noncritical Fault Timeout (FCCU_NCF_TO)

Defines the preset value of the timer for the recovery of enabled noncritical faults. Once FCCU enters Alarm state, following the assertion of a noncritical fault that is enabled (NCFEa and NCFTOEa are set), the timer starts the countdown.

If the fault is not recovered within the timeout period, the FCCU moves from the Alarm state to the Fault state. The alarm timeout value should be programmed to be less than FOSU_COUNT, or destructive resets may be generated by FOSU timeouts.

NOTE

This register is writable only when FCCU is in Configuration state.

Address: 0h base + B4h offset = B4h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

FCCU_NCF_TO field descriptions

Field	Description
0–31 TO	Noncritical Fault Timeout Timeout = (TO) × $T_{RC16MHz}$

78.7.11 Configuration-State Timeout (FCCU_CFG_TO)

The FCCU_CFG_TO register defines the preset value of the watchdog timer for the recovery from the CONFIG state. Once FCCU enters in CONFIG state, following a SW request (OP1 opcode), the watchdog timer is initialized and starts the countdown if the reset is not asserted.

If the configuration is not completed within the timeout, the FCCU moves automatically from the CONFIG state to the NORMAL state and the default values for all the configuration register is restored. Configuration registers are those registers which can be written only in CONFIG state. The description for a configuration register will contain a NOTE that it is writable only in the CONFIG state. The watchdog timeout is clocked

with CLKSAFE. The default timeout value is 4.096 ms. Longer activation of CONFIG state can lead to resets if a failure is indicated during the time the FCCU is in CONFIG state due to FOSU.

NOTE

The FCCU_CFG_TO register is writable in any state excluding the CONFIG state as follows the execution of the OP1 opcode (NORMAL to CONFIG state) and until the completion of the OP2 opcode (CONFIG to NORMAL state).

In case of watchdog timeout the FCCU_CFG_TO register is not accessible until the OP14 operation (CONFIG to NORMAL) has been completed.

NOTE

When the configuration watchdog timer expires, FCCU changes the value of this register to its reset value.

Address: 0h base + B8h offset = B8h

FCCU_CFG_TO field descriptions

Field	Description
0–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29–31 TO	Configuration timeout Timeout = $T_{RC16MHz} \times 2^{(TO + 10)}$ 000 Timeout = 64 µs ... 111 Timeout = 8.192 ms

78.7.12 IO Control (FCCU_EINOUT)

The FCCU_EINOUT register allows the following operations typically in NORMAL state:

- to control the EOUT[1] output level when the FCCU is configured in "Test1" or "Test0" fault output mode (FCCU_CFG.FOM)

- to control the EOUT[0] output level when the FCCU is configured in "Test1" or "Test2" fault output mode (FCCU_CFG.FOM)
- to observe the EOUT[1:0] signals in input mode

Table 78-63 shows Bi-stable encoding.

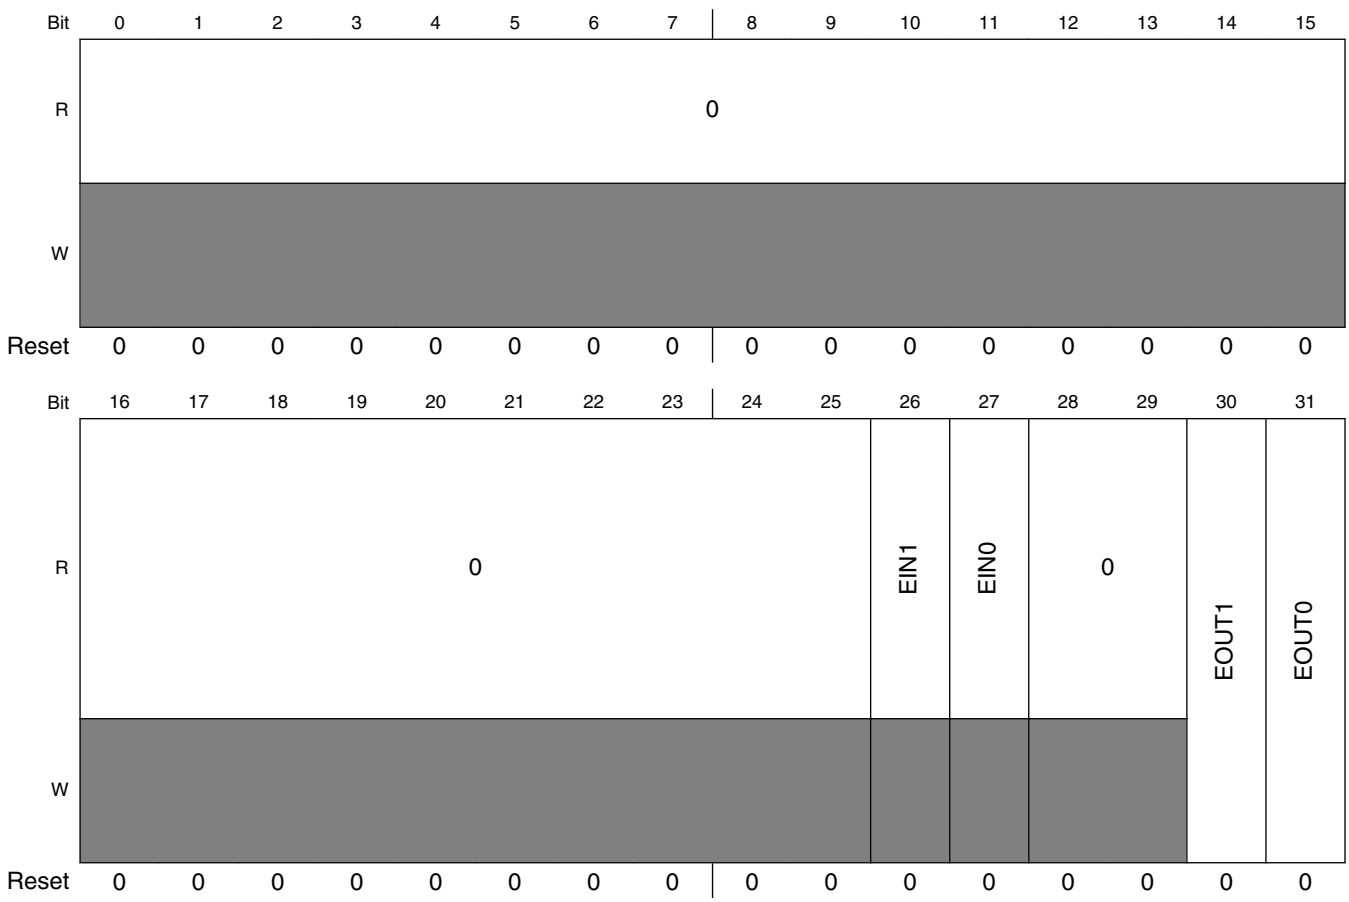

Table 78-63. Bi-stable encoding

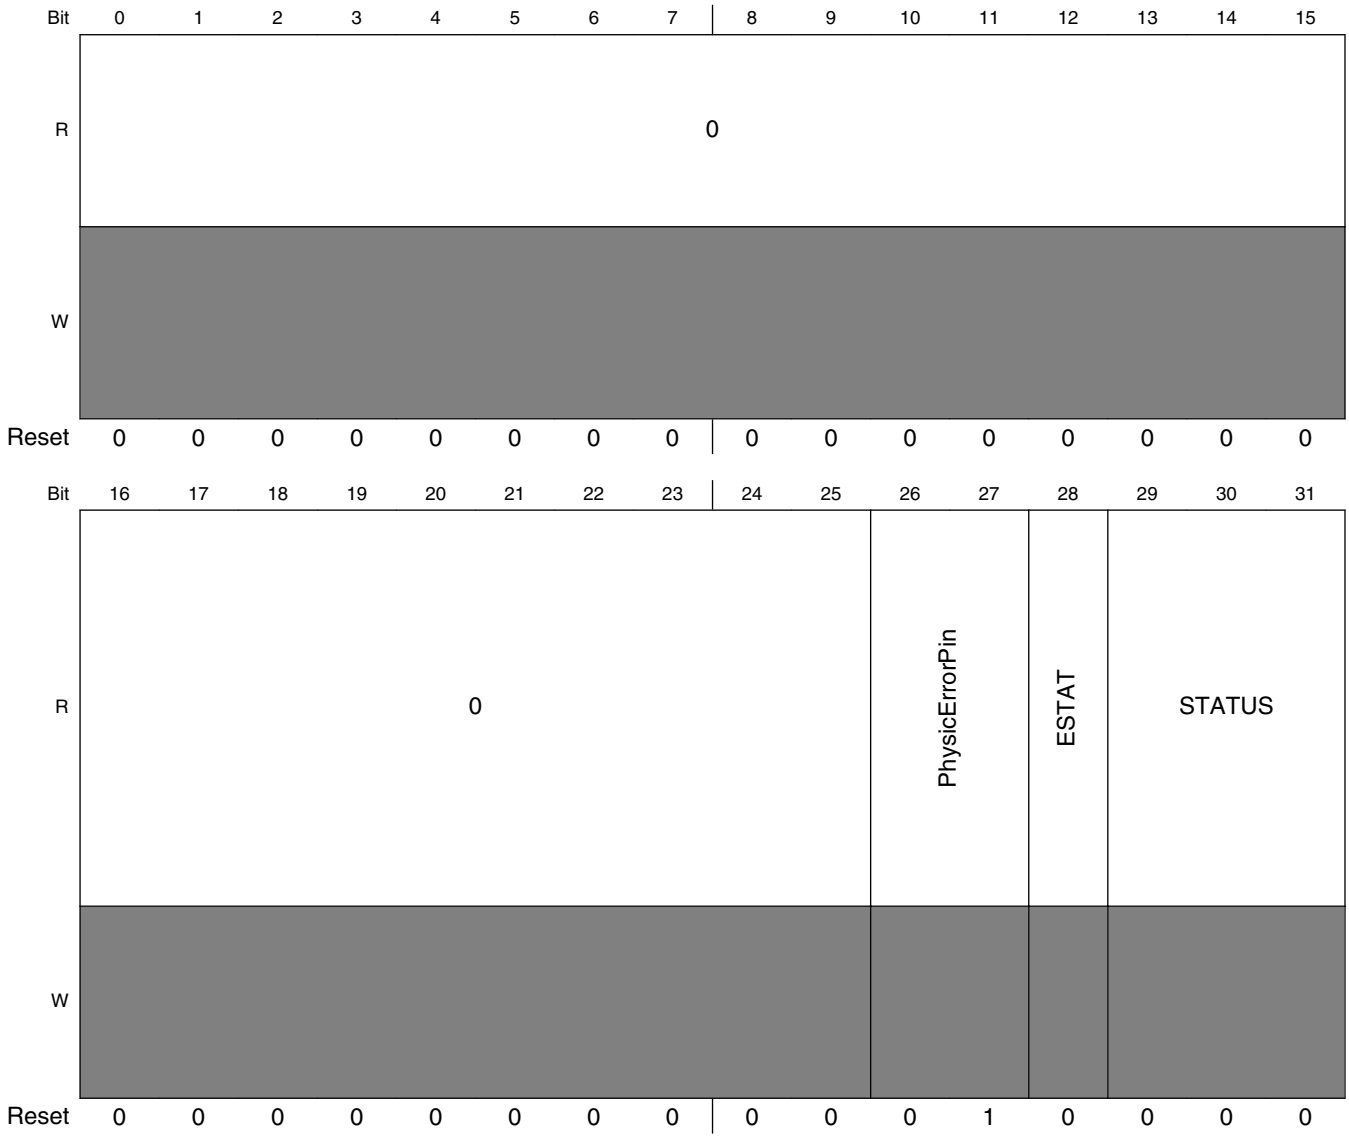
Mode = FCCU_CFG.FOM	EOUT[0]	EOUT[1]
Test1	output	output
Test2	output	input
Test0	input	output

NOTE

Due to the resynchronization stage of the EOUT interface, there is a latency of a few CLKSAFE cycles following a write/read operation of the FCCU_EINOUT register.

Address: 0h base + BCh offset = BCh

FCCU_EINOUT field descriptions



Field	Description
0–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26 EIN1	Error input 1. The EIN1 captures the respective fccu_ein[1] input signal. While this field is set to zero by reset, a read of this field always returns the logic value on the fccu_ein[1] pin. 0 when fccu_ein[1] = 0 1 when fccu_ein[1] = 1
27 EIN0	Error input 0.The EIN0 captures the fccu_ein[0] input signal. While this field is set to zero by reset, a read of this field always returns the logic value on the fccu_ein[0] pin. 0 when fccu_ein[0] = 0 1 when fccu_ein[0] = 1
28–29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30 EOUT1	Error out 1 (significant only if the FCCU_CFG.FOM = Test1 or Test0 => EOUT[1] configured in output mode). The EOUT1 set/clear the respective EOUT[1] output signal if FCCU_CFG.FOM = 110 or 101, otherwise it is a "don't-care" value. **NOTE:** When the configuration watchdog timer expires, FCCU changes the value of this field to its reset value. 0 force EOUT[1] = 0 1 force EOUT[1] = 1
31 EOUT0	Error out 0 (significative only if the FCCU_CFG.FOM = Test1 or Test2 => EOUT[0] configured in output mode). The EOUT0 set/clear the respective EOUT[0] output signal if FCCU_CFG.FOM = 110 or 111, otherwise it is a "don't care" value. **NOTE:** When the configuration watchdog timer expires, FCCU changes the value of this field to its reset value. 0 force EOUT[0] = 0 1 force EOUT[0] = 1

78.7.13 Status (FCCU_STAT)

The FCCU_STAT register includes the FCCU status for debugging/test purposes. The FCCU finite state machine operates by the RC oscillator clock asynchronous with the system clock. The FCCU status read operation requires a safe mechanism operated by a HW/SW synchronization sequence. The SW application executes a FCCU status read operation by the following sequence:

1. Set the OP3 operation into the FCCU_CTRL.OPR field.
2. Wait for the completion of the operation (FCCU_CTRL.OPS field).
3. Read the FCCU status (FCCU_STAT register).

Address: 0h base + C0h offset = C0h

FCCU_STAT field descriptions

Field	Description
0–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26–27 PhysicErrorPin	PhysicErrorPin : Physical Error Pin's state. PhysicErrorPin[0] corresponds to error pin 0 and PhysicErrorPin[1] corresponds to error pin 1. For each of these, the bit values have the following meanings: 0: Error Pin is at logical 0 1: Error Pin is at logical 1 During Fault state, a static or toggling value is observed based on selected protocol. 0 Error Pin is at logical 0 1 Error Pin is at logical 1

Table continues on the next page...

FCCU_STAT field descriptions (continued)

Field	Description
28 ESTAT	Current Error Pin Status 0 The system is operational (OK). 1 The system is in Fault state. This state is taken from the FCCU EOUT logic (that is, as late as possible).
29–31 STATUS	FCCU Status 000 NORMAL state 001 CONFIG state 010 ALARM state 011 FAULT state 100 Reserved 101 Reserved 110 Reserved 111 Reserved

78.7.14 NA Freeze Status (FCCU_N2AF_STATUS)

The N2AF_STATUS register contains a unique code to identify the "non-critical fault" source (fccu_ncf[x]) that caused the state transition from the NORMAL state to the ALARM state. In case of multiple fault conditions the fault source cannot be identified. This register is for test/debug purposes.

The SW application executes the N2AF_STATUS read operation by the following sequence:

1. Set the OP4 operation into the FCCU_CTRL.OPR field.
2. Wait for the completion of the operation (FCCU_CTRL.OPS field).
3. Read the N2AF_STATUS register.

The SW application executes the N2AF_STATUS clear operation by the following sequence:

1. Set the OP13 operation into the FCCU_CTRL.OPR field.
2. Wait for the completion of the operation (FCCU_CTRL.OPS field). (All the freeze registers are cleared by this operation.)

Address: 0h base + C4h offset = C4h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

78.7.15 AF Freeze Status (FCCU_A2FF_STATUS)

The A2FF_STATUS register contains a unique code to identify the timeout trigger (non-critical fault) that caused the state transition from the ALARM state to the FAULT state. In case of multiple fault conditions the fault source cannot be identified. This register is for test/debug purposes.

The SW application executes the A2FF_STATUS read operation by the following sequence:

1. Set the OP5 operation into the FCCU_CTRL.OPR field.
2. Wait for the completion of the operation (FCCU_CTRL.OPS field).
3. Read the A2FF_STATUS register.

The SW application executes the FCCU_AFFS clear operation by the following sequence:

1. Set the OP13 operation into the FCCU_CTRL.OPR field.
2. Wait for the completion of the operation (FCCU_CTRL.OPS field).

All the freeze registers are cleared by this operation.

Address: 0h base + C8h offset = C8h

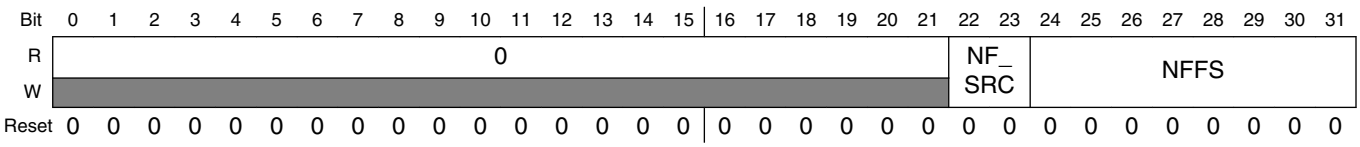
78.7.16 NF Freeze Status (FCCU_N2FF_STATUS)



The N2FF_STATUS register contains a unique code to identify the source of the non-critical fault that caused the state transition from the NORMAL state to the FAULT state. In case of multiple fault conditions the fault source cannot be identified. This register is for test/debug purposes. The SW application executes the N2FF_STATUS read operation by the following sequence:

1. Set the OP6 operation into the FCCU_CTRL.OPR field.
2. Wait for the completion of the operation (FCCU_CTRL.OPS field).
3. Read the N2FF_STATUS register.

The SW application executes the N2FF_STATUS clear operation by the following sequence:

1. Set the OP13 operation into the FCCU_CTRL.OPR field.
2. Wait for the completion of the operation (FCCU_CTRL.OPS field). (All the freeze registers are cleared by this operation.)

Address: 0h base + CCh offset = CCh

FCCU_N2FF_STATUS field descriptions

Field	Description
0–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

78.7.17 FA Freeze Status (FCCU_F2A_STATUS)

The F2AF_STATUS register contains a unique code to identify the source of the non-critical fault (fccu_ncf[x]) that caused the state transition from the FAULT state to the ALARM state. In case of multiple fault conditions the fault source cannot be identified. This register is for test/debug purposes.

The SW application executes the F2AF_STATUS read operation by the following sequence:

1. Set the OP7 operation into the FCCU_CTRL.OPR field.
2. Wait for the completion of the operation (FCCU_CTRL.OPS field).
3. Read the F2AF_STATUS register.

The SW application executes the F2AF_STATUS clear operation by the following sequence:

1. Set the OP13 operation into the FCCU_CTRL.OPR field.
2. Wait for the completion of the operation (FCCU_CTRL.OPS field). (All the freeze registers are cleared by this operation.)

Address: 0h base + D0h offset = D0h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

FCCU_F2A_STATUS field descriptions

Field	Description
0–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23–31 FAFS	Fault to Normal Frozen Status **NOTE:** This field can be read and written but writing 1 has no effect. 00h: No transition from FAULT to ALARM state 01h: FAULT to ALARM state transition cause => fccu_ncf[0]/ fault 02h: FAULT to ALARM state transition cause => fccu_ncf[1]/ fault 03h: FAULT to ALARM state transition cause => fccu_ncf[2]/ fault ... 80h: FAULT to ALARM state transition cause => fccu_ncf[127]/ fault FFh: FAULT to ALARM state transition cause => multiple fccu_ncf[] faults

78.7.18 SC Freeze Status (FCCU_SCFS)

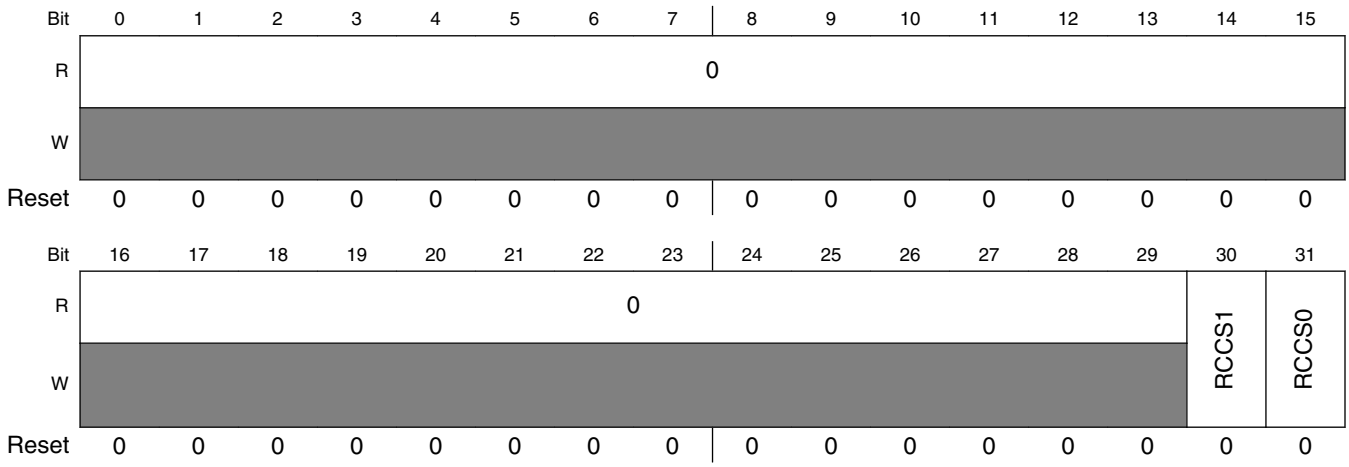
The FCCU_SCFS register contains the status of the RCCx checkers. This register is for test/debug purposes.

Two interrupt lines are asserted by the correspondent status bits (FCCU_SCFS.RCCSx).

The SW application executes the FCCU_SCFS read operation by the following sequence:

1. Set the OP8 operation into the FCCU_CTRL.OPR field.
2. Wait for the completion of the operation (FCCU_CTRL.OPS field).
3. Read the FCCU_SCFS register.

The SW application executes the FCCU_SCFS clear operation by the following sequence:



1. Set the OP13 operation into the FCCU_CTRL.OPR field.
2. Wait for the completion of the operation (FCCU_CTRL.OPS field). All the freeze registers are cleared by this operation. The RCCx checkers must be disabled

(FCCU_CFG.RCCEx = 00b) during a clear operation otherwise the RCCSx flags are asserted again.

NOTE

The INTC will never attend the second interrupt line since RCCS0 and RCCS1 are always cleared together by the operation above. From SW perspective the INTC should be configured to attend RCCS0 or RCCS1 interrupt line only, not the pair.

Address: 0h base + D4h offset = D4h

FCCU_SCFS field descriptions

Field	Description
0–29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30 RCCS1	RCC1 Status **NOTE:** This field can be read and written but writing 1 has no effect. 0 No miscompares 1 A miscompare has been detected. An interrupt line is asserted.
31 RCCS0	RCC0 Status **NOTE:** This field can be read and written but writing 1 has no effect. 0 No miscompares 1 A miscompare has been detected. The interrupt line is asserted.

78.7.19 Noncritical Fault Fake (FCCU_NCFF)

The FCCU_NCFF register contains a unique code to set a non-critical fault in mutually exclusive mode by the external FAULT interface (signal setting). It allows the SW emulation of the non-critical faults, by the injection of the fault directly in the FAULT root, in order to verify the entire path and reaction. The reaction following a fake non-critical fault cannot be masked. The FCCU_NCFF is a write-only register with a set of codes corresponding to each non-critical fault injection.

Address: 0h base + DCh offset = DCh

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

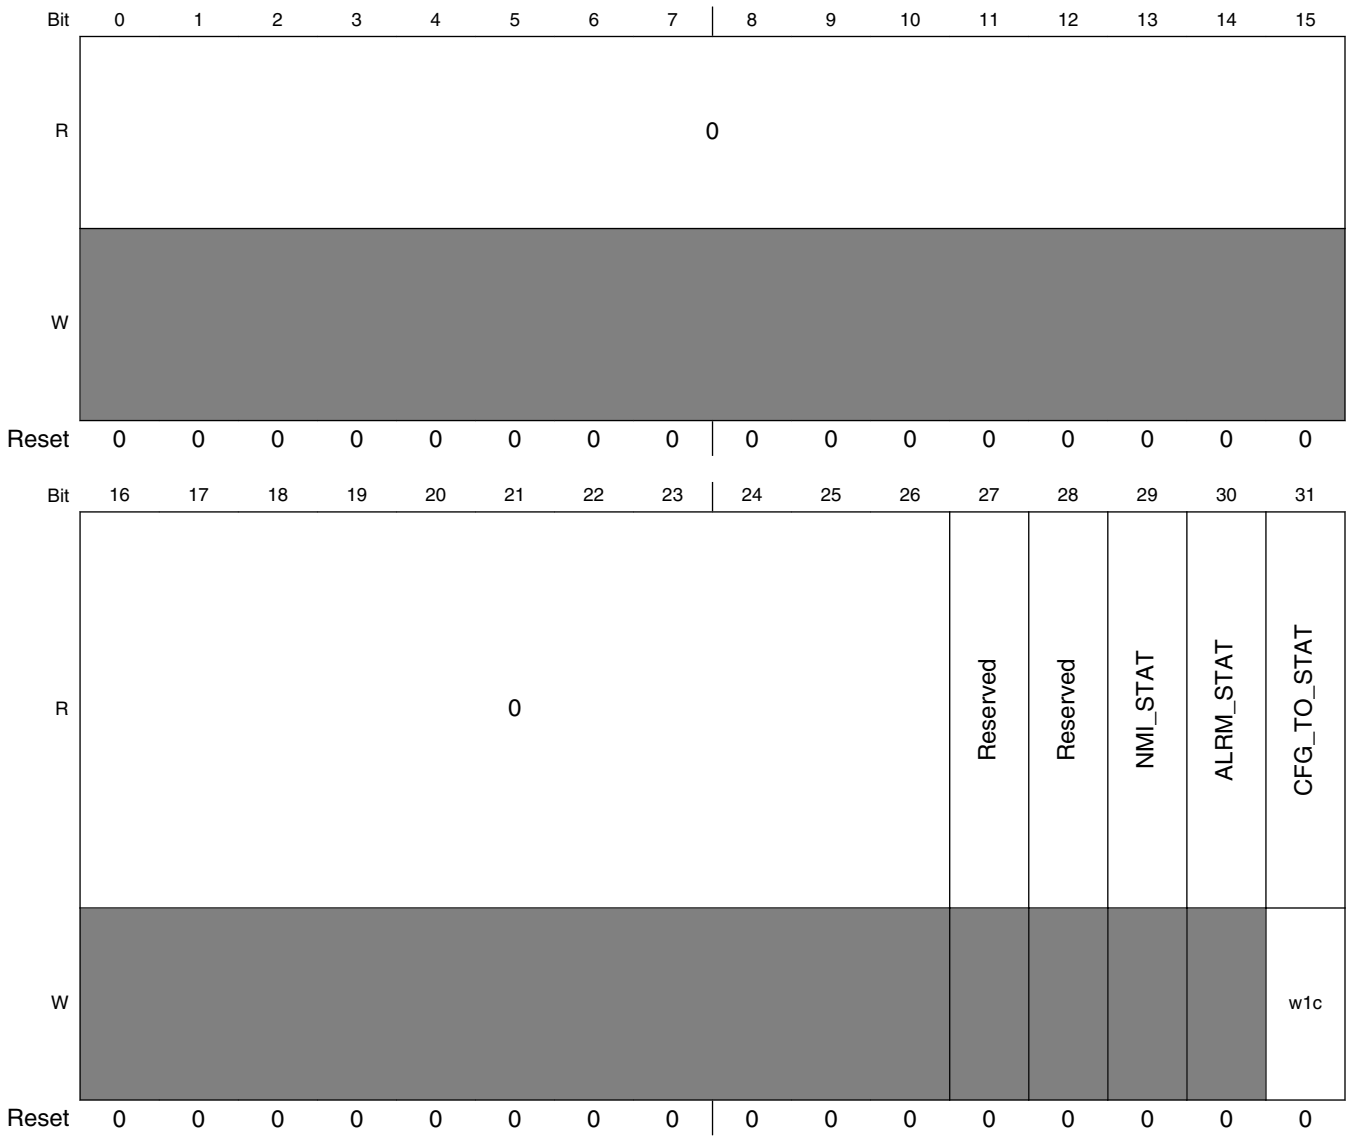
25–31 FNCFC	FNCFC/ : Fake non-critical fault code **NOTE:** Only writing to this register, fake fault injection occurs, writing 00 and default value being zero give different results. 00h: Fake non-criticalfault injection at non-criticalfault source 0 01h: Fake non-criticalfault injection at non-criticalfault source 1 02h: Fake non-criticalfault injection at non-criticalfault source 2 ... 7Fh: Fake non-criticalfault injection at non-criticalfault source 127

78.7.20 IRQ Status (FCCU_IRQ_STAT)



The FCCU_IRQ_STAT register provides the FCCU interrupt status related to the following events:

- Configuration timeout error
- Alarm interrupt
- NMI interrupt

The configuration timeout interrupt is asserted if the CFG_TO_STAT bit of the FCCU_IRQ_STAT register is set and the CFG_TO_IEN bit of the FCCU_IRQ_EN register is also set. It is cleared when a 1 is written to the CFG_TO_STAT bit.

The NMI and ALARM interrupts are asserted and cleared according to the FCCU state. The status bits of the FCCU_IRQ_STAT trace the status of the related interrupt lines.

Address: 0h base + E0h offset = E0h

FCCU_IRQ_STAT field descriptions

Field	Description
0–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 Reserved	This field is reserved.

31 CFG_TO_IEN	Configuration Timeout Interrupt Enable 0 Configuration timeout interrupt disabled 1 Configuration timeout interrupt enabled

78.7.22 XTMR (FCCU_XTMR)

The FCCU_XTMR register contains the read values of the Alarm or Watchdog Timer. These timers are clocked by CLKSAFE.

The SW application executes the timer read operation by the following sequence:

1. Set any of the following operations into the FCCU_CTRL.OPR field:
   - OP17
   - OP19
2. Wait for the completion of the operation (FCCU_CTRL.OPS field).
3. Read the FCCU_XTMR register.

Table 78-74 shows Timer state/value.

Table 78-74. Timer state/value

TIMER	CONFIG state	NORMAL state	ALARM state	FAULT state
ALARM	00000000h	Initial value	Running	Idle/End of count
CFG	Running	0001FFFFh	0001FFFFh	0001FFFFh

Address: 0h base + E8h offset = E8h

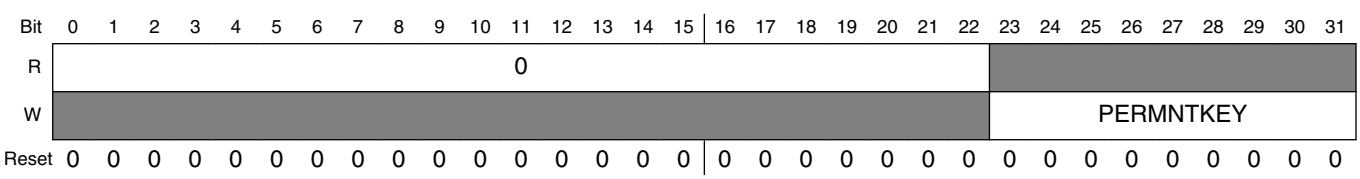
20–23 MCS1	Mode Controller State 1—Indicates the second most recent chip mode.
24 VL0	Valid 0—Indicates whether MCS0 and FS0 are valid. 0 Invalid 1 Valid
25 FS0	Fault Status 0—Indicates whether FCCU was in Fault state when FCCU captured MCS0. **NOTE:** This field might occasionally be inaccurate because the MC_ME module provides the chip modes to FCCU in synchronization with CLKSYS, but FCCU captures the chip modes in synchronization with CLKSAFE. 0 A state other than Fault state 1 Fault state
26–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28–31 MCS0	Mode Controller State 0—Indicates the most recent (current) chip mode.

78.7.24 Transient Lock (FCCU_TRANS_LOCK)

The FCCU_TRANS register is used for unlocking configuration by writing BCh. This register is available only in supervisor mode. This register is write only.

Address: 0h base + F0h offset = F0h



FCCU_TRANS_LOCK field descriptions

Field	Description
0–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23–31 TRANSKEY	Transition Unlocking Key value BCh: Configuration Unlocked Any other value:FCCU gets transiently locked again.

78.7.25 Permanent Lock (FCCU_PERMNT_LOCK)

The FCCU_PERMNT_LOCK register is used for locking configuration permanently by writing FFh. This register is available only in supervisor mode. The permanent lock can only be removed by applying a reset (not necessarily power on reset). This register is write only.

Address: 0h base + F4h offset = F4h

FCCU_PERMNT_LOCK field descriptions

Field	Description
0–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

FCCU_PERMNT_LOCK field descriptions (continued)

Field	Description
23–31 PERMNTKEY	Transition Locking Key value FFh: Configuration Locked Any other value: No Change

78.7.26 Delta T (FCCU_DELTA_T)

The FCCU_DELTA_T register is used for programming the value of delta_T constant, in microseconds.

NOTE

This register can be written only when the FCCU is in CONFIG state.

NOTE

Reserved bits should always be written as all 0's.

Address: 0h base + F8h offset = F8h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FCCU_DELTA_T field descriptions

Field	Description
0–1 Reserved	This field is reserved.
2–15 Reserved	This field is reserved.
16–17 Reserved	This field is reserved.
18–31 DELTA_T	Controls the minimum amount of time (T_min) that the EOUT fault-indication timer runs according to this equation: T_min = 250 µs + DELTA_T FCCU starts the EOUT fault-indication timer when all of the following are true: • The EOUT fault-indication timer isn't already running. • FCCU enters Fault state as the result of a fault.

Table continues on the next page...

FCCU_DELTA_T field descriptions (continued)

Field	Description

	When the EOUT fault-indication timer is already running and a new fault occurs:
	• When FCCU is in Configuration state: FCCU doesn't restart the EOUT fault-indication timer.
	• When FCCU is in Normal state or Alarm state:
	  • And Alarm state is enabled for the fault (noncritical): FCCU enters (or remains in) Alarm state but doesn't restart the EOUT fault-indication timer.
	  • And Alarm state is disabled for the fault (noncritical) or not applicable: FCCU enters Fault state and restarts the EOUT fault-indication timer.
	• When FCCU is in Fault state: FCCU restarts the EOUT fault-indication timer.
	
	FCCU stops and reinitializes the EOUT fault-indication timer when all of the following are true:
	• T_min has expired.
	• All faults that caused FCCU to enter or remain in Fault state since FCCU started the EOUT fault-indication timer have been cleared, causing FCCU to return to Normal state.
	
	The following values and meanings are for DELTA_T:
	00_0000_0000_0000: 0 µs
	00_0000_0000_0001: 1 µs
	…
	11_1111_1111_1110: 16,382 µs
	11_1111_1111_1111: 16,383 µs
	
	NOTE: The specified values for DELTA_T may vary ±2% due to the post-trimming inaccuracy of the CLKSAFE clocks.

78.7.27 IRQ Alarm Enable (FCCU_IRQ_ALARM_EN*n*)

These registers enable the corresponding IRQ alarm.

Table 78-80 shows FCCU IRQ alarm enable register channels.

Table 78-80. FCCU IRQ alarm enable register channels

Address offset	Register name	Channel range (x) (bit location [0:31])
0FCh	FCCU_IRQ_ALARM_EN0	IRQENE[31:0]
100h	FCCU_IRQ_ALARM_EN1	IRQENE[63:32]
104h	FCCU_IRQ_ALARM_EN2	IRQENE[95:64]

NOTE

These registers can be written only when the FCCU is in CONFIG state.

Address: 0h base + FCh offset + (4d × i), where i=0d to 2d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

FCCU_IRQ_ALARM_EN*n* field descriptions

Field	Description
0–31 IRQENx	IRQ alarm enable See Table 78-80 for register offset to channel number relationship. 0 Alarm is disabled for error source x. 1 Alarm is enabled for error source x.

78.7.28 NMI Enable (FCCU_NMI_EN*n*)

These registers enable the NMI.

NOTE

Do not configure the same channel for both a RESET reaction in the FCCU_NCFS_CFGn register and an NMI reaction in the FCCU_NMI_ENn register at the same time.

Table 78-88 shows FCCU NMI enable register channels.

Table 78-88. FCCU NMI enable register channels

Address offset	Register name	Channel range (x) (bit location [0:31])
10Ch	FCCU_NMI_EN0	NMIENE[31:0]
110h	FCCU_NMI_EN1	NMIENE[63:32]
114h	FCCU_NMI_EN2	NMIENE[95:64]

NOTE

These registers can be written only when the FCCU is in CONFIG state.

Address: 0h base + 10Ch offset + (4d × i), where i=0d to 2d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FCCU_NMI_EN*n* field descriptions

Field	Description
0–31 NMIENx	NMI enable See Table 78-88 for register offset to channel number relationship. 0 NMI is disabled for error (NCF) source x. 1 NMI is enabled for error (NCF) source x.

78.7.29 Fault-Output (EOUT) Signaling Enable (FCCU_EOUT_SIG_EN*n*)

Writable only when FCCU is in Configuration state. Controls whether fault-output (EOUT) signaling is enabled for the associated noncritical fault channels when FCCU is configured for Bistable fault-output mode (FCCU_CFG[FOM]).

Register	Offset	EOUTENx fields	
		Most significant (leftmost)	Least significant (rightmost)
FCCU_EOUT_SIG_EN0	11Ch	EOUTEN31	EOUTEN0
FCCU_EOUT_SIG_EN1	120h	EOUTEN63	EOUTEN32
FCCU_EOUT_SIG_EN2	124h	EOUTEN95	EOUTEN64

Address: 0h base + 11Ch offset + (4d × i), where i=0d to 2d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

FCCU_EOUT_SIG_EN*n* field descriptions

Field	Description
0–31 EOUTENx	Fault-Output (EOUT) Signaling Enable Writable only when FCCU is in Configuration state. Controls whether fault-output (EOUT) signaling is enabled for the associated noncritical fault channel (x) when FCCU is configured for Bistable fault-output mode (FCCU_CFG[FOM]). Fault-output signaling is always enabled for the associated channel, regardless of the value of this field, when FCCU is configured for any other fault-output mode. **NOTE:** To ensure that the FOSU module is aware that fault-output signaling is enabled as a reaction for the associated noncritical fault channel (so that FOSU doesn't mistakenly generate a destructive chip reset), you must set this field to enabled when FCCU is configured for any mode other than Bistable fault-output mode. For the mapping of the EOUTENx fields among registers, see the earlier table in this register description.

FCCU_EOUT_SIG_EN*n* field descriptions (continued)

Field	Description
	0 Disabled 1 Enabled

78.8 FCCU Output Supervision Unit

The FOSU provides a supervision of the primary fault notification path by analyzing FCCU behavior for correctness. It waits for any reaction of the FCCU in a fixed time window after a fault is signaled.

The intention of the FOSU is to provide a secondary fault reaction path in most cases when the FCCU fails but not to needlessly propagate a fault which is already handled by the FCCU in a full chip reset. Only a failed primary fault reaction (that is, FCCU's failure) is a reason for the secondary reaction to take over (and generate a destructive reset request).

There is a 'do nothing' input coming from the FCCU that indicates that the FCCU is programmed for no reaction for ALL FAULTS. It is a "static" input in the sense that it does not change after FCCU configuration. The FOSU masks the incoming faults with the 'do nothing' control from the FCCU, meaning that a fault is not captured by the FOSU if the 'do nothing' signal is asserted, (i.e., a disabled fault). There is no minimum pulse width requirement on the fault indication other than what is required by the technology, which is the same as that of the FCCU. FOSU does not monitor FCCU for the case of faults occurring during CONFIG state. Also, the case of a continuously incoming disabled fault being enabled later, is not monitored.

The FOSU contains a timer with a duration of FOSU_COUNT, driven by CLKSAFE. The timer is initialized and started on any captured, enabled fault. While the timer is running, any subsequent captured fault will neither restart nor reinitialize the timer. The timer is stopped when the FCCU shows any of the following reactions (the FOSU does not check whether the reaction is the configured one for the faults which occurred):

- Reset: Long or short functional reset
- IRQ: NMI or Alarm
- Error out triggered (by FCCU or by SW)

When the timer is stopped, the fault capture logic is cleared in order to ensure that the timer is not restarted due to faults still 'stuck' in the capture logic. The timer will then be restarted by the next new failure indication. When the timer expires, the FOSU's failure

indicator output is asserted after it ensures that the fault is enabled and the static "fccu program to do nothing" signal is deasserted. This is because FCCU uses settings after it exits CONFIG state, even if fault captured before the exit.

The FOSU's failure indicator output is connected to one of the MC_RGM's 'destructive' reset inputs, so its assertion will cause a reset sequence to be initiated starting at PHASE0. The FOSU module is reset with the same reset as is used by the FCCU, which is asserted on power-on, 'destructive', and external resets. When this reset is asserted, the FOSU's capture logic is cleared, its timer is kept stopped and in a non-expired state, and its failure indicator output is deasserted.

NOTE

FOSU is triggered on assertion of enabled fault. In case the triggering fault is disabled, FOSU times-out without reaction. All intermediate faults are masked (not monitored) during this timeout cycle.

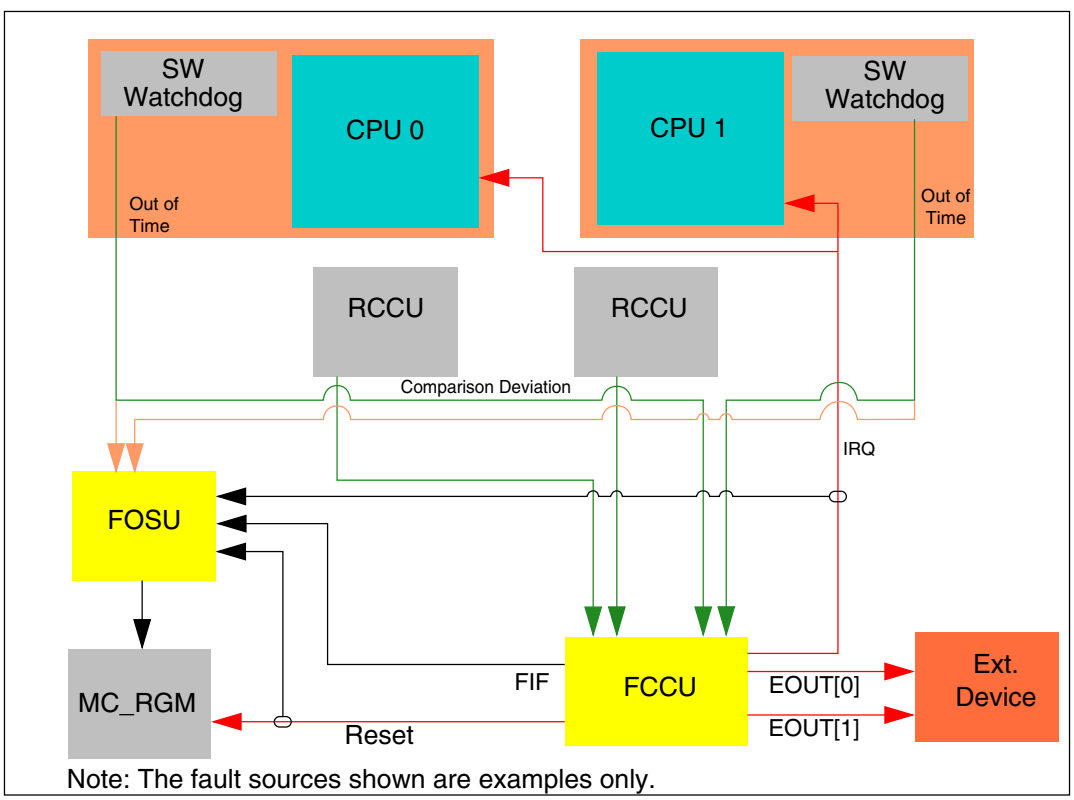

Figure 78-72. FOSU connections to the FCCU and MC_RGM

It is important to remember that there will be no FCCU reaction to a fault while the FCCU is in the CONFIG state. For this reason, the FCCU should not be kept in CONFIG for longer than the FOSU_COUNT duration. Otherwise, there is a risk that an incoming error report causing the FOSU to mistakenly see the FCCU as having failed, and then resets the MCU.

NOTE

FCCU and FOSU timeout counter settings: The FCCU counter value should always be programmed less than the FOSU counter value, FOSU_COUNT, or destructive resets may be generated by an FOSU time-out. This ensures that the FOSU reacts only when the FCCU fails to react to any particular fault.

78.9 Use cases and limitations

78.9.1 Misconfigurations

The following configurations are appropriate:

1. If at least one reaction to fault is enabled by default then the corresponding fault should also be enabled by default.
2. Enabling a fault but disabling all reactions is not a meaningful configuration from safety point of view.
3. Disable the fault and also its reactions. Applicable when a specific fault line is not of interest in a specific application scenario

   Example: FCCU goes into ALARM state due to a failure, but the IRQ is disabled for that failure.
4. If the user programs the FCCU for a higher timeout value than what is hardcoded for FOSU, then FCCU reacts later than what FOSU would be expecting and, as a result, FOSU will generate destructive reset request on its timeout.

78.9.2 Recommendations to configure FCCU

1. After a power on, 'destructive', or long external reset, where both system and FCCU are reset, the following steps could be followed to configure FCCU:
   a. Check and clear any pending fault status
   b. Verify FCCU is in NORMAL state, else repeat step(a) above
   c. Configure FCCU
2. After a short external or any 'functional' reset of the system, arising out of a reset request from FCCU or other sources, the following steps could be followed to reconfigure FCCU:
   a. If active, wait for the Error out T_min to expire

b. Check and clear fault status
c. Error pin moves to "non faulty" state, once fault status is cleared and T_min expires
d. Verify FCCU is in NORMAL state, else repeat step(a) above
e. Read and verify value in FCCU_NCF_Ex
f. Reconfigure FCCU, if necessary

Chapter 79
Self-Test Control Unit (STCU2)

79.1 STCU2 chip-specific module information

This section describes the chip-specific implementation of the STCU2 module.

79.1.1 STCU2 register reset values

The following table shows chip-specific reset values for several STCU2 registers. All other register reset values are shown in Register description.

NOTE

These are the reset values when startup self-test is not configured by DCFs. Otherwise, these will change per the DCF configurations of startup self-test.

Table 79-1. STCU2 register reset values

Register	Reset value
STCU2 Configuration Register (STCU2_CFG)	0000_0000h
STCU2 PLL Configuration Register (STCU2_PLL_CFG)	0000_0000h
STCU2 Watchdog Register Granularity (STCU2_WDG)	0000_FFFFh
STCU2 CRC Expected Status Register (STCU2_CRCE)	0000_0000h
STCU2 CRC Read Status Register (STCU2_CRCR)	FFFF_FFFFh
STCU2 Error FM Register (STCU2_ERR_FM)	0000_0000h
STCU2 LBIST Unrecoverable FM Register (STCU2_LBUFM)	0000_0000h
STCU2 MBIST Unrecoverable FM Low Register (STCU2_MBUFML)	0000_0000h
STCU2 MBIST Unrecoverable FM Medium Register (STCU2_MBUFMM)	0000_0000h
STCU2 MBIST Unrecoverable FM High Register (STCU2_MBUFMH)	0000_0000h
STCU2 LBIST Control Register (STCU2_LB_CTRLn)	0000_0000h
STCU2 LBIST PC Stop Register (STCU2_LB_PCSn)	0000_0000
STCU2 LBIST PRPG Low Register (STCU2_LB_PRPGLn)	FFFF_FFFFh

Table continues on the next page...

Table 79-1. STCU2 register reset values (continued)

Register	Reset value
STCU2 LBIST PRPG High Register (STCU2_LB_PRPGHn)	FFFF_FFFFh
STCU2 Off-Line LBIST MISR Expected Low Register (STCU2_LB_MISRELn)	FFFF_FFFFh
STCU2 Off-Line LBIST MISR Expected High Register (STCU2_LB_MISREHn)	FFFF_FFFFh
STCU2 Off-Line LBIST MISR Read Low Register (STCU2_LB_MISRRLn)	0000_0000h
STCU2 Off-Line LBIST MISR Read High Register (STCU2_LB_MISRRHn)	0000_0000h
STCU2 On-Line LBIST MISR Expected Low Register (STCU2_LB_MISRELSWn)	FFFF_FFFFh
STCU2 On-Line LBIST MISR Expected High Register (STCU2_LB_MISREHSWn)	FFFF_FFFFh
STCU2 On-Line LBIST MISR Read Low Register (STCU2_LB_MISRRLSWn)	0000_0000h
STCU2 On-Line LBIST MISR Read High Register (STCU2_LB_MISRRHSWn)	0000_0000h
STCU2 MBIST Control Register (STCU2_MB_CTRLn)	0000_0000h

79.1.2 Chip-specific STCU2 registers

Chip-specific implementation of registers are shown in the table below.

Table 79-2. Chip specific registers

79.1.5 Running Offline MBIST

To run offline MBIST on this chip you must follow the procedure below:

1. Run offline MBIST on the desired memories. If a memory fault occurs (single- or multi-bit), the corresponding bit in the Off-Line MBIST Status Register (STCU_MBSL, STCU_MBSM, or STCU_MBSH) will be set. When offline MBIST is done, a global functional reset is issued.
2. When code starts running on the CPU, check the Off-Line MBIST Status Registers (STCU_MBSL, STCU_MBSM, and STCU_MBSH) for failing BISTs. If a failed BIST execution is found, then you can choose between aborting at this point or getting more information (i.e. whether the fault occurred due to single- or multi-bit error(s)) about the failed BISTs.
3. If you choose to get more information about the failed BISTs, run online MBIST on the failed BISTs. When the online MBIST is done, you can decide on how to proceed based on this more specific information.

79.1.6 Off-line LBIST

The chip supports off-line LBIST operation for all LBIST partitions.

Summary of an off-line LBIST sequence:

1. The user stores off-line self-test parameters in a DCF record in flash memory. The self-test can include multiple LBIST partitions.
    - For off-line self-tests, LBIST execution on individual LBIST partitions occurs serially. The chip does not support LBIST execution on individual LBIST partitions in parallel.
    - An off-line LBIST can run with either the 16 MHz IRC or with PLL0 or PLL1.
    - For an off-line self-test, the STCU2 can enable and program PLL0 or PLL1 using STCU2 DCFs.
2. The user resets the chip by cycling power or asserting the RESET pin.
3. The STCU2 loads the stored off-line LBIST parameters from the DCF record via the SSCM interface.
4. The off-line LBIST executes and ends.
5. Hardware issues a functional reset. The STCU2 is not affected by this reset.

6. The user verifies the STCU2 result registers related to LBIST and FCCU channels corresponding to STCU2 faults.

79.1.7 On-line LBIST

The chip supports on-line LBIST operation on all LBIST partitions.

NOTE

When LBIST execution begins, the embedded flash memory must be in an idle state; program or erase operations must not be active.

Summary of an on-line LBIST sequence:

1. The user initiates an on-line LBIST by programming STCU2 memory-mapped registers.
   - An on-line LBIST is able to test only one partition at a time.
   - An on-line LBIST can run with the functional operating frequencies. The maximum-frequency clock for the LBIST partition is derived from PLL0 or PLL1.
   - The user can initiate a sequence of more than one on-line LBIST. Multiple on-line LBISTs can execute serially, with each self-test run on an individual partition.
2. The on-line LBIST executes and ends.
3. After the completion of the LBIST on-line self-test sequence, hardware issues a functional reset. The STCU2 is not affected by this reset.
4. The user verifies the STCU2 result registers related to LBIST and FCCU channels corresponding to STCU2 faults.

79.1.8 LBIST Partitions

The following table describes the LBIST partitions on this chip.

79.1.9 LBIST Configuration

The following table shows the configurations the user should set to run LBIST on a specific partition as well as the expected MISR and coverage values at the end of the run.

NOTE

When running LBIST the Reserved bit DCF_SELFTEST_CONFIG_IPS_1[0] has to be set to "1".

The expected MISR values in the table assume that the UTEST DCF records are not modified from the default reset values except for the above.

Table 79-6. LBIST Configuration by Partition and Expected MISR

Partition	Clock Config	PRPG seed	MISR seed	Number of Patterns	Number of Shifts	Expected MISR	Coverage
L0	1	3fffffffffff	ffffffffffffffff	2,150	63	64'h18F2A1F5FDC31B19	90%
L1	1	ffffffffffff		2,000	48	64'hac001775d8e3627d	90%
W0	1	ffffffffffffffff		2,100	55	64'h765D7C3D4A32B225	90%
W1	1	3fffffffffff		2,750	62	64'hB489FD55EED3E3B7	90%

79.1.9.1 LBIST online self-test

For LBIST online self-test, the user must program the STCU_LBRMSW[LBRMSWn] field corresponding to the LBIST partition to "1" to generate a global functional reset at the end of the test:

- LBRMSW0: corresponds to LBIST L0

- LBRMSW1: corresponds to LBIST L1
- LBRMSW2: corresponds to LBIST W0
- LBRMSW3: corresponds to LBIST W1

79.1.10 AUTOLOCK_VALUE for register write access via STCU2_SKC

Register write-access watchdog timer explains that access to STCU2 registers via the STCU2_SKC security-key mechanism times out after a number of STCU2 clock cycles equal to AUTOLOCK_VALUE. On this chip, AUTOLOCK_VALUE is 1023.

79.1.11 Wait time for writing to the online registers

When writing to the online registers, the user must wait for the expiration of the offline key. The time the user should wait is (IPS_CLK)*4096 clock periods. If the IPS_CLK is 66.5 Mhz then the user must wait (1/66.5)*4096 = 61.6 µs.

79.1.12 On-Line reset generation (only MBIST)

The On-Line execution of the MBIST does not generate any reset from STCU2 at the end of the execution. This is because the software application has to manage all the possible consequences related to the write operations performed by the MBIST execution other than preventing any read/write operation during the Self-Test execution. If necessary, the software must also restore the memory content (only for RAMs) at the end of the Self-Test execution.

79.1.13 On-Line reset generation (LBIST enabled)

The LBRMSW register should be configured to generate a global functional reset after LBIST online self-test. It is not recommended to use a dedicated reset due to random data injected by the LBIST Controller.

NOTE

If an ABORT condition is detected by STCU2 during the On-Line Self-Test execution, independently of the value of the LBRMSW register, only the related reset line is pulsed to prevent any potential dangerous system level operations.

79.2 Introduction

Self Test Control Unit (STCU2) is a comprehensive programmable hardware module that controls the self test sequence applied both during the Off-Line and/or On-Line conditions. It is able to manage by hardware the device's Logic Built-In Self Test (LBIST) and the SRAM/ROM Built-In Self Test (MBIST) blocks. The STCU2 includes the SSCM DCF bus to load the Self-test parameters (L/MBIST scheduling activity, LBIST setup, Unrecoverable/Recoverable faults management, and MISR expected values, PLL management, and so on) from flash memory during the Off-Line Self-Test phase. This interface is able only to write the configuration parameters and start the Self-Test execution once after the STCU2 global reset has been applied. The register access by software is granted by an IPS interface with the purpose to check the results of the Off-Line Self-Test but also to load/check the execution of the On-Line Self-Test.

The STCU2 includes:

- A programmable Watchdog timer (WDG) to check the Self-Test operations (both LBIST and MBIST) have been completed within the assigned time slot or the STCU2 RUN or BYPASS bits have been programmed before Watchdog time-out
- The PLL direct control during the Off-Line Self-Test sequence
- Interrupt lines enabled only during the On-Line Self-Test to simplify the software handling of Self-Test execution end
- Two sets of Result registers to collect the L/MBIST result during Off/On-Line Self-Test separately

To increase the security capability of this module, a different Security Key sequence is also required during Off/On-Line Self-Test in order to unlock the write access to the STCU2 registers. The STCU2 also implements two power-saving mechanisms to switch off:

- The global STCU2 clock after Self-Test sequence is completed
- The register ITF clock when the WDG time-out is detected after a Double Security Key sequence is applied during the application run (available only when IPS write access is enabled otherwise the clock is off).

79.3 Main features

- Double registers interface (SSCM DCF with priority over IPS)

- SSCM DCF write one time register interface
- IPS read and write (depends on SSCM enable parameters and STCU2_CFG.WRP bit) register interface
- Programmable scheduler for LBIST/MBIST execution
- LBIST sequential execution
- MBIST concurrent/sequential execution
- On-Line hardware Self-Test sequence abort capability
- On-Line software Self-Test sequence abort capability
- Programmable Internal clock prescaler to reduce Internal and MBIST/LBIST TCK clocks
- Programmable PLL direct control during Off-Line Self-test sequence
- PLL Lock signal monitoring during Off/On-Line Self Test
- L/MBIST dedicated On-Line interrupt source generation
- Programmable WDG Timer for Self-Check M/LBIST Time Execution
- Hard Coded WDG time-out to flag off-line initialization faults
- Hard Coded WDG time-out to Auto-lock STCU2 write access after Double-Key sequence
- LBIST and SRAM/ROM MBIST Off-Line status flags
- STCU2 internal errors Off-Line status flag
- LBIST and SRAM/ROM MBIST On-Line status flags
- STCU2 internal errors On-Line Status flag
- On-Line hardware abort status flag
- On-Line software abort status flag
- LBIST and SRAM/ROM MBIST Off/On-Line programmable failure severity - unrecoverable fault/recoverable fault (UF/RF)
- STCU2 internal errors Off-On/Line programmable failure severity - unrecoverable fault/recoverable fault (UF/RF)
- STCU2 errors (UF/RF) lines for FCCU signaling
- Redundant UF/RF generation logic to improve reliability

- FCCU UF/RF faults injection mechanism
- LBIST MISRE registers access to perform redundant check by software
- Self-Test Bypass capability
- Global write register's protection mechanism based on Double Security Key
- STCU2 Global Auto Power-saving when Self-Test is completed, bypass mode is selected or WDT time-out is detected
- STCU2 ITF/WDG clock wake-up mechanism when software application writes Double Security Key sequence (available when STCU2_CFG.WRP bit is active)
- STCU2 ITF/WDG Auto Power-saving when Hard Coded WDG time-out is detected after software application writes Double Security Key sequence (available when STCU2_CFG.WRP bit is active)

79.4 Block diagram

The top level diagram of the STCU2 module is given in Figure 79-1.

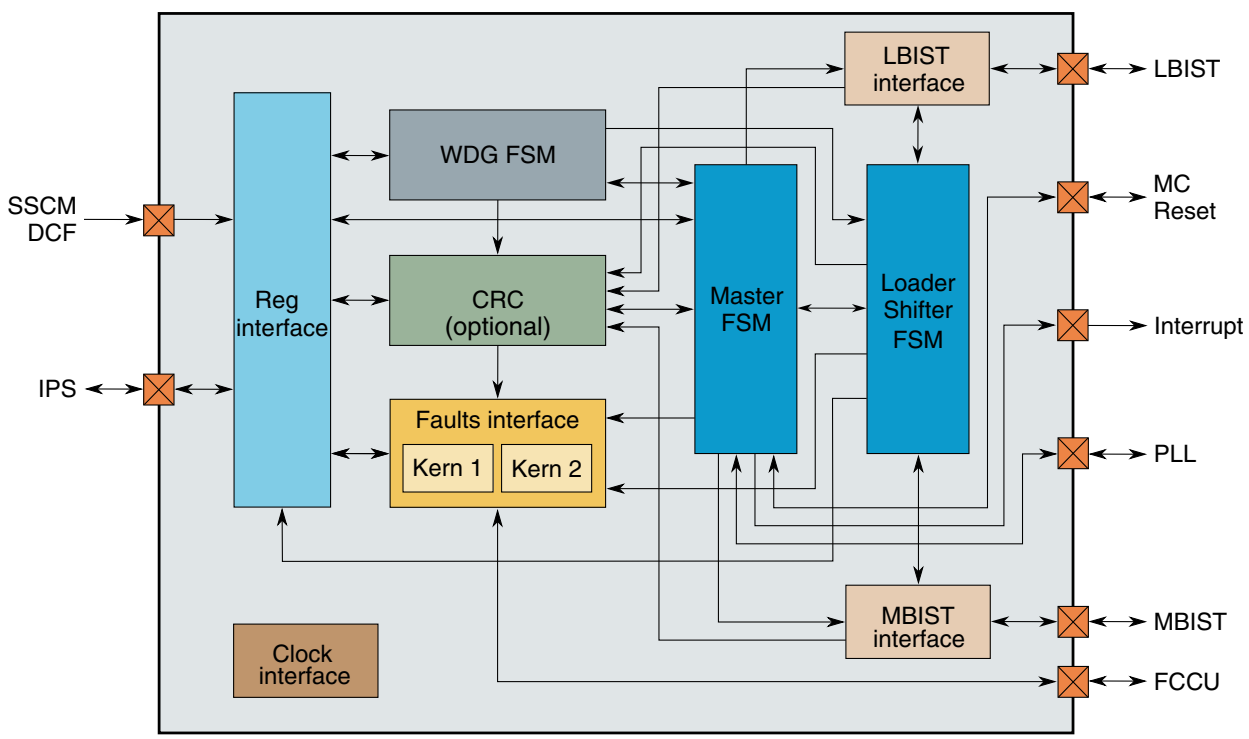

Figure 79-1. STCU2 block diagram

The STCU2 module includes the following sub-modules:

- ***Reg interface***: This module includes the registers, the security key logic, the IPS and SSCM DCF bus interface
- ***Fault interface***: This module collects the fault conditions related to L/MBIST execution and STCU2 internal failures and, depending on the UF/RF configuration of each one of them, sets the global STCU2 UF or RF flag. It also manages the UF/RF fault lines and the Set/Clear injection mechanism provided by the FCCU. To improve the intrinsic reliability of this critical logic, the generation logic is duplicated.
- ***Clock Interface***: This module manages the internal and the L/MBIST TCK clock prescaler, the internal Clock Gating Power Saving and the wake-up clock feature.
- ***WDG FSM***: This module includes two different Watchdogs. The first one is Hard Coded and is used to Auto Lock the STCU2 access forcing a reset condition on the Double Security Key registers while the second one has a double functionality. After a reset event initializes the STCU2, it is used as Hard Coded Watchdog time-out while during L/MBIST run it is used as programmable Watchdog timer to check the L/MBIST have been completed in the assigned L/MBIST time slot.
- ***STCU2 Master FSM***: This module includes the main FSM of the STCU2 used to coordinate and schedule all the operations performed during the Self-Test Sequence.
- ***STCU2 Load Shifter FSM***: This module includes the common shifter register and the related state machine used to program the L/MBIST registers and read back the data to be checked at the end of each Test operation.
- ***LBIST interface***: This module includes the interface between the device's LBIST engines and the STCU2 controllers.
- ***MBIST interface***: This module includes the interface between the MBIST controller and STCU2 controllers.

79.5 IPS bus interface

The IPS bus interface is a slave bus used for configuration purposes via CPU. The following bus read operations (contiguous byte enables) are supported:

- Word (32 bits) data read operations to any registers
- Low and high half-words (16 bits, data[31:16] or data[15:0]) data read operations to any registers

- Byte(8 bits, data[31:24] or data[23:16] or data[15:8] or data[7:0]) data read operations to any registers
- Any other operation (free byte enables or other operations) has to be avoided.

The same operations are also supported in write mode only in the following scenario:

- The Self-Test sequence parameters are loaded before Off-Line Self-test is executed
- The IPS access on a specific register is allowed by software only when the bit STCU2_CFG.WRP is cleared
- In all the other conditions the write operations are not supported and all the STCU2 registers can be only read. Only exceptions are the following read/write bits: STCU2_CFG.WRP, STCU2_ERR_STAT.UFSF and STCU2_ERR_STAT.RFSF. See related register description for additional details

The STCU2 module generates a transfer error in the following cases:

- Any write/read access to the register addresses not mapped on the peripheral but included in the address space of the peripheral
- Any write/read operation different from byte/halfword/word (free byte enables or other operations) on each register
- Any write operation on Double Security Key register applying a wrong sequence of keys (the two write operations cannot be interleaved with other access to STCU2 registers)
- Any write operation performed on a register when the Double Security keys have not been applied
- Any write operation performed on registers when the STCU2_CFG.WRP bit is set and the access is performed through software (IPS interface)
- Any write operation performed through software (IPS interface) on Read/On-Line_Write/Off-Line registers
- Any write operation performed off-line on registers in which writing operation is allowed only in the On-Line Self-Test phase when STCU2_CFG[WRP] = 1
- Any write operation performed on Read Only registers

The registers of the STCU2 module are accessible (read/write) in each access mode: user, supervisor or test.

In case there are write operations on bits marked as reserved, the transfer error is not generated.

NOTE

See the chip-specific STCU2 information for the wait time necessary to write to the online registers.

79.6 Functional description

79.6.1 FSM description

The module has three state machines that work together: Master State Machine, Loader/Shifter State Machine, and the Watchdog State Machine. Basically the Master State Machine is the core unit of the STCU2 module. It coordinates all the Self Test operations and the other State Machines. The Loader/Shifter State Machine is used to program the MBIST and the LBIST parameters and to retrieve the related results depending on the parameters stored into the STCU2 registers and under the control of the Master State Machine. The Watchdog State Machine evaluates all the schedule time for MBIST and LBIST and the time-out in case of wrong STCU2 programming.

79.6.2 Reset management

Assertion of the STCU2 reset input signal initializes the STCU2 module status, forcing the Off-Line Self-Test condition and cleaning up all the registers and state machine of the module.

The reset signals generated by the STCU2 module at the end of the Self-Test execution phase depends on the Self-Test conditions and on the content of the LBRMSW register.

79.6.2.1 Off-Line reset generation

At the end of the Off-Line Self-Test execution the STCU2 raises the global functional reset.

79.6.2.2 On-Line reset generation

See the chip-specific STCU2 information for details about On-Line reset generation.

79.6.3 Built-in self-test scheduling

The STCU2 module has been designed to be very flexible allowing to program the parallel/serial execution of the MBIST or LBIST depending on the power/timing/ coverage constraints. The limitation in the programming flexibility is described in Design implementation information.

The mechanism used to provide this flexibility is a linked list where the starting pointer is the bitfield STCU2_CFG.PTR. The first LBIST is mapped on 00h, the second on 01h, and so on. The first MBIST is mapped to the address 10h, the second to 11h and so on. The additional pointers are in the bitfield STCU2_LB_CTRL[X].PTR for LBIST[X] (where X is the selected LBIST) and STCU2_MB_CTRL[Y].PTR for MBIST (where Y is the selected MBIST) and have to be filled depending on the selected sequence of run. The additional bitfield STCU2_MB_CTRL.CSM provide the flexibility to run concurrently or sequentially the chosen set of the MBIST or to close the linked list setting the NIL pointer. For more details, see STCU2 LBIST Control Register (STCU2_LB_CTRL*n*) and STCU2 MBIST Control Register (STCU2_MB_CTRL*n*).

NOTE

Program operation should ensure that no flash write/erase operations are ongoing when online LBIST is triggered. Otherwise, a flash segment may be corrupted.

79.6.4 ABORT management

The STCU2 module provides two mechanisms to perform the On-Line Self-Test execution abort. When the abort is detected in both cases, the On-Line Self-Test operation stops running and the status of the currently running MBIST or LBIST is saved into the related registers to provide intermediate results that might be useful in case of debug or in case of concurrent run. In case of LBIST run, see Reset management, for more details about reset specific management when abort is detected.The following sections describe the differences between these two modalities.

79.6.4.1 Hardware ABORT management

The STCU2 enters the hardware abort condition as a consequence of a Functional reset which causes Self-Test execution to abort .

When hardware abort is detected the bit ABORTHW of the STCU2_ERR_STAT register is set. This flag allows the software to diagnose what has happened during the On-Line Self-Test execution run.

79.6.4.2 Software ABORT management

The STCU2 enters in the abort condition because the software set the bit RUNSW_ABORT in the STCU2_RUNSW register. In order to allow the software to understand when STCU2 has completed the abort sequence, this bit will be maintained active until the abort sequence is completed. At that time the STCU2 will clear this bit as described in STCU2 Run Software Register (STCU2_RUNSW).

When software abort is raised the bit ABORTSW of the STCU2_ERR_STAT register is set. Even if the abort condition is forced by software operation, this flag allows to diagnose what has happened during the On-Line Self-Test execution run.

79.6.5 PLL interface

The STCU2 module is able to directly control the PLL during the Off-Line Self-Test operations depending on the status of the STCU2_RUN[MBPLLEN] and STCU2_RUN[LBPLLEN].

When STCU2_RUN[RUN] is set to start the Off-Line Self-test operations, the STCU2 takes control of the PLL and changes the PLL clock configurations parameters according to the values programmed into the STCU2_PLL_CFG register.

When the STCU2_RUN[MBPLLEN] is active and the MBIST is currently selected, the STCU2 waits for the PLL lock signal. As soon as the lock happens, the STCU2 forces the clock to switch to the PLL output clock. This allows the MBIST to proceed at the PLL output frequency. At the end of the MBIST run the clock source is reverted to the original one.

Same behavior will be applied when STCU2_RUN[LBPLLEN] is active and LBIST is currently selected.

79.6.6 Interrupt interface

Interrupt sources:

- Triggered by MBIST (enabled by programming STCU2_RUNSW[MBIE] = 1)
- Triggered by LBIST (enabled by programming STCU2_RUNSW[LBIE] = 1)

As described in the STCU2 Run Software Register (STCU2_RUNSW) description, the interrupts are generated at the end of any concurrent run. This means that in case of multiple sequential run in the same session, the number of interrupts generated is equivalent to the number of the sequential session providing in such a way a fine granularity with respect to the completed run.

The LBIFLG bit and MBIFLG bit in the STCU2 Interrupt Flag Register (STCU2_INT_FLG) register flag interrupt conditions and allow the clearing of interrupt requests. Interrupt bits are cleared by writing the related flag bit to 1 to enable the next interrupt request.

79.6.7 FCCU interface

The FCCU interface is the hardware flag mechanism towards the system, to indicate the occurrence of an Unrecoverable fault and/or a Recoverable fault failure during the Self Test sequence.

To diagnose physical defects on the two fault signals, a fault injection mechanism is also provided. In this case, the FCCU interface allows the user application to check the integrity of the UF and RF connection lines between the STCU2 and the FCCU. Refer to the description of FCCU fault injection mechanism to understand how the UF/RF set/clear mechanism works.

79.6.8 Watchdogs

The STCU2 implements three different watchdogs to ensure that operations are finished in time.

79.6.8.1 Initialization watchdog timer

The STCU2 has two initialization operating modes: program the self-test sequence and run it (Safety mode) or bypass completely the self-test sequence setting the bit STCU2_CFG.BYP. In case there are faults during the initialization phase preventing the selection of one of these two operating modes, a hard-coded watchdog time-out flags the wrong behavior.

79.6.8.2 Built-in self-test watchdog timer

The LBIST and MBIST execution time has to be configured as described in STCU2 Watchdog Register Granularity (STCU2_WDG), to account for the overall execution time of the Self-Test sequence. In case the selected LBISTs or MBISTs are not yet completed during the Off-line Self-Test assigned time, the current LBISTs or MBISTs execution is interrupted and a failure is flagged into STCU2_ERR_STAT.WDTO and STCU2_MBEL/M/H or STCU2_LBE registers while in case of On-Line Self-Test into STCU2_ERR_STAT.WDTOSW and STCU2_MBELSW/MSW/HSW or STCU2_LBESW.

In case of multiple sequential run in the same On-Line/Off-Line session and the time-out happens in the middle of a sequential run, the next sequential run will be skipped and the execution ends with the current updated status of the registers reported above.

In all the cases, the STCU2 reset generation is managed in one of the modes described in Reset management.

79.6.8.3 Register write-access watchdog timer

The access on the STCU2 registers during the self-test configuration phase (both online/offline) is protected by a key mechanism to prevent any unwanted access, as described in the STCU2_SKC register description. In addition to this malicious access protection feature, there is a hardware watchdog timer that, after AUTOLOCK_VALUE STCU2 clock cycles, lock the access requiring to apply again the STCU2_SKC keys. AUTOLOCK_VALUE is given in the chip-specific STCU2 information.

NOTE

Each DCF record takes 8 STCU2 clock cycles for write completion. The maximum number of DCF records that can be executed before the watchdog timer must be refreshed is AUTOLOCK Value divided by 8. To refresh the hardware watchdog timer, the user must write key 2 into the STCU2_SKC register.

This feature is particularly useful in case STCU2_CFG[WRP] is 0 during the software self-test configuration since in this case the software application might enable the write access to the STCU2 registers.

79.6.9 SSCM interface

The SSCM interface is used to program the STCU2's configuration parameters without the CPU intervention after a reset trigger event initializes the STCU2. This bus interface has the priority over the IPS.

79.7 Register description

During Offline SELFTEST, once the STCU2 registers are configured they cannot be overridden.

During Online SELFTEST, once the STCU2 registers are configured they cannot be overridden via IPS till the selftest is complete.

The STCU2 registers are listed in this section.

STCU2 memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	STCU2 Run Register (STCU2_RUN)	32	R/W	0000_0000h	79.7.1/3378
4	STCU2 Run Software Register (STCU2_RUNSW)	32	R/W	0000_0000h	79.7.2/3379

79.7.1 STCU2 Run Register (STCU2_RUN)

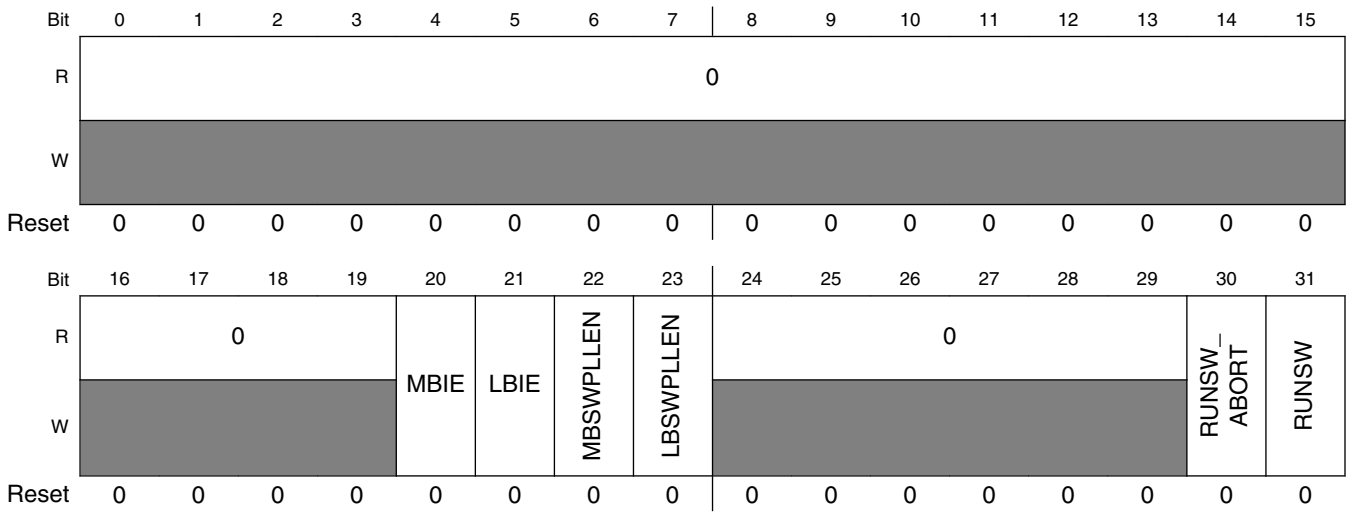
The STCU2_RUN register defines the RUN bit to start the off-line self testing procedure.

The R/W fields in this register are readable at any time. However, you can write to these fields only when Off-line Self-Test phase is still active.

Address: 0h base + 0h offset = 0h

STCU2_RUN field descriptions

Field	Description
0–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21 BYP	Bypass mode 0 Off-Line Self-Test is active. In case the RUN bit into the STCU2_RUN register is not set before the Hard-Coded WDG Time-out, the WDTO error is generated into the STCU2_ERR_STAT register. 1 Off-Line Self-Test is completely bypassed and the access to STCU2 is locked until the STCU2_SKC register is written according to the request access mode.
22 MBPLLEN	Off-Line MBIST with PLL Enabled 0 Off-Line MBIST is executed without using the on-chip PLL. 1 Off-Line MBIST is executed enabling the on-chip PLL control interface selecting the parameters defined into STCU2_PLL_CFG register.
23 LBPLLEN	Off-Line LBIST with PLL Enabled 0 Off-Line LBIST is executed without using the on-chip PLL. 1 Off-Line LBIST is executed enabling the on-chip PLL control interface selecting the parameters defined into STCU2_PLL_CFG register.
24–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 RUN	RUN: RUN The RUN bit is automatically cleared by the STCU2 when the off-line self testing procedure has been completed. 0 Idle 1 Off-Line Self testing procedure is running



79.7.2 STCU2 Run Software Register (STCU2_RUNSW)

The STCU2_RUNSW register defines the RUN bit to start the on-line self testing procedure.

The R/W fields in this register are readable at any time. However, you can write to these fields only when both of the following conditions are true:

- STCU2_CFG[WRP] = 0
- On-line Self-Test phase is active. The On-Line condition starts when the Off-Line is over. In this condition, system is alive and the SW can program the STCU2

Address: 0h base + 4h offset = 4h

STCU2_RUNSW field descriptions

Field	Description
0–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20 MBIE	MBIST Interrupt Enable 0 Interrupt is not generated at the end of the software MBIST execution phase of the selected Memories. 1 At the end of the software MBIST execution phase of the concurrent selected memories the STCU2 forces an interrupt request to notify that MBISTs of concurrent selected memories are over. In case there is a sequence of concurrent runs in the same Self-Test run, the interrupt request is generated at the end of each concurrent runs provided that the software will clear the STCU2_INT_FLG[MBIFG] bit in between.
21 LBIE	LBIST Interrupt Enable 0 Interrupt is not generated at the end of the software LBIST execution phase of the selected LBIST. 1 At the end of the software LBIST execution phase of the concurrent selected LBIST the STCU2 forces an interrupt request to notify that LBISTs of the concurrent selected partitions are over. In case there is a sequence of concurrent runs in the same Self-Test run, the interrupt request is generated at the end of each concurrent run provided that the software will clear the STCU2_INT_FLG.LBIFG bit in between.
22 MBSWPLLEN	On-Line MBIST with PLL Enabled 0 On-Line MBIST is executed without using the on-chip PLL. 1 On-Line MBIST is executed using the PLL configuration provided by software. STCU2 does not take the PLL control but monitors the PLL lock signal to check if PLL is working correctly.

Table continues on the next page...

STCU2_RUNSW field descriptions (continued)

Field	Description
23 LBSWPLLEN	On-Line LBIST with PLL Enabled 0 On-Line LBIST is executed without using the on-chip PLL. 1 On-Line LBIST is executed using the PLL configuration provided by software. STCU2 does not take the PLL control but monitors the PLL lock signal to check if PLL is working correctly.
24–29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30 RUNSW_ABORT	Software abort of the self-test currently running This bit is automatically cleared by the STCU2 when the software self-test abort sequence has been completed. 0 On-line self-test abort is not requested. 1 On-line self-test abort is requested.
31 RUNSW	RUNSW The RUNSW bit is automatically cleared by the STCU2 when the on-line self testing procedure has been completed. 0 Idle 1 On-line self testing procedure is running

79.7.3 STCU2 SK Code Register (STCU2_SKC)

The STCU2_SKC register implements the security key code mechanism needed to access in write mode to the other STCU2 registers. In order to unlock the STCU2 access after:

- The STCU2 asynchronous reset
- The end of the STCU2 run

the software (IPS bus) or the SSCM interfaces have to apply the following sequence:

- write the key1 into the STCU2_SKC register
- write the key2 into the STCU2_SKC register

Depending on the off/on-line test step, the two keys will be different. Byte write operation is not allowed since the full key has to be recognized as one unit.

It should be noted that after the Self-Test sequence has been completed or the Bypass feature has been enabled (setting the bit BYP into the STCU2_CFG), the SSCM interface is no longer available.

In case of invalid access or sequence (Key1/2 have to be applied consecutively), a transfer error on the IPS or SSCM bus is asserted depending on the selected source. The STCU2 write access is locked and to unlock the access the sequence has to be applied again.

In case the STCU2 register access lasts more cycles than the one defined into the Hard-coded WDG time-out, the STCU2 write access is locked and the WDG and Register ITF clocks are switched off. Also in this case, in order to enable again the write access to the STCU2 and the WDG and Register ITF clocks, it is required to apply again the sequence.

In case it is required to extend the STCU2 register access cycles before the Hard-coded WDG time-out expires, only the Key2 has to be applied. The effect of this write operation is to re-initialize the WDG time-out counter. In such a condition, Key1 has not to be applied otherwise a transfer error on the IPS or SSCM bus is asserted depending on the selected source. The STCU2 write access is locked and to unlock the access the sequence has to be applied again.

The STCU2_SKC register is not readable. The value 00000000h is always returned in case of read operation.

Address: 0h base + 8h offset = 8h

STCU2_SKC field descriptions

Field	Description
0–31 SKC	STCU2 security key code for off-line Test = D3FEA98Bh: Key1 to unlock the write access the STCU2 = 2C015674h: Key2 to unlock the write access the STCU2 STCU2 security key code for on-line Test = 753F924Eh: Key1 to unlock the write access the STCU2 = 8AC06DB1h: Key2 to unlock the write access the STCU2

79.7.4 STCU2 Configuration Register (STCU2_CFG)

NOTE

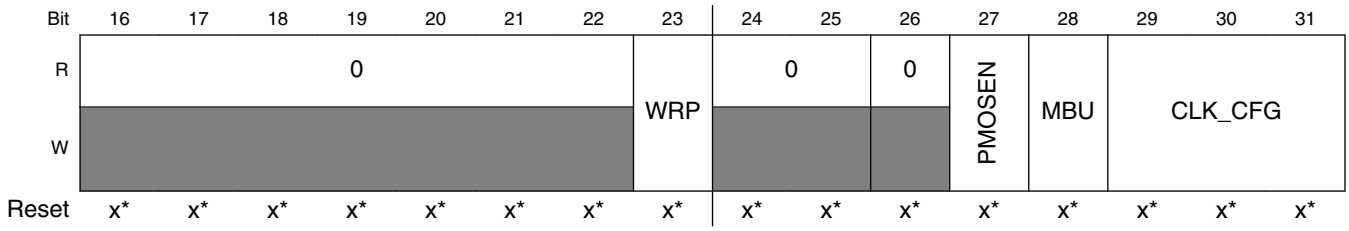
The reset value is chip-specific; see the chapter that describes how modules are configured and connected.

The STCU2_CFG register includes the global configuration of the STCU2 and can be updated both in the Off/On-Line Test steps.

The access to this register is described in the following figure. It further depends on the state of the WRP bit as follows:

- When WRP = 0: The register can be written during the on-line Self-Test case without restrictions
- When WRP = 1:
  - The only bit that can be written without any restriction is WRP.
  - In case there are software operations that write all the register's bits, a transfer error is raised only if the value of the selected byte written differs from the current status of the register. This functionality has been implemented to prevent potential compilation behavior that might invalidate this single bit clean capability.

MBIST can be run in three different test types according to how the STCU2_CFG register bits 27 and 28 are set.



The following table describes the test algorithm and coverage of the different test types.

Table 79-12. MBIST algorithm and coverage according to test type

MBIST Type	STCU2_CFG[PMOSEN]	STCU2_CFG[MBU]	MBIST Algorithm	Internal Nodes/ Circuits Additionally Covered by Test	Usecase	Test Cycle
Full Test	1	0	Test memory using all built in algorithms. Open PMOS algorithm included	Address Decoder and Bitcell as well as resistive defects in the address decoder	Used by FSL production test. Recommended to use in the field for MBIST online self-test.	About 3 to 4x more than Auto Test
Reduced Test	0	0	Test memory using all built in algorithms except the open PMOS algorithm.	Address Decoder and Bitcell	Recommended to use in the field for MBIST online self-test if the Full Test takes too long.	About 10% less than Full Test
Auto Test	x	1	A smaller set of algorithms which target latent defect mechanisms.	Latent defects such as NBTI of the PMOS transistors in the bitcells	Recommended to use for MBIST offline self-test as an optimum balance of test time vs. fault coverage.	About 3 to 4x faster than Full Test

Address: 0h base + Ch offset = Ch

- The reset value is chip-specific; see the chapter that describes how modules are configured and connected.x = Undefined at reset.

STCU2_CFG field descriptions

Field	Description
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1–7 PTR	LBIST or MBIST pointer PTR defines the logical pointer to the first LBIST or MBIST to be scheduled when the self testing procedure is enabled. PTR is the entry pointer to a linked list of BIST descriptors. If PTR = 0 then the LBIST0 is initially scheduled. You can always read this field. In the off-line Self-Test phase, you can always write to this field. In the on-line Self-Test phase, you can write to this field only when WRP = 0. 0h to (LBIST -1): pointer to LBIST 10h to (10h + MBIST -1): pointer to MBIST 7Fh: pointer to NIL. No BIST execution.
8–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23 WRP	Write Protection 0: Specific STCU2 registers can be written through IPS bus interface after Off-Line Self-Test sequence has been completed 1: Specific STCU2 registers cannot be written though IPS also after Off-Line Self-Test sequence has been completed preventing in such a way any user application write operation
24–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 PMOSEN	MBIST PMOS Test Enable When MBU is 1 then "Auto test" MBIST test type will be selected regardless of the setting of this field.. 0 When MBU is 0 then selects the "Reduced test" MBIST test type. 1 When MBU is 0 then selects the "Full test" MBIST test type.
28 MBU	MBIST MBU Test Enabled 0 Either "Full test" or "Reduced test" MBIST test type will be selected according to the PMOSEN value. 1 Selects "Auto test" MBIST test type regardless of the PMOSEN value.

Table continues on the next page...

STCU2_CFG field descriptions (continued)

Field	Description
29–31 CLK_CFG	Logic, Memory Bist and STCU2 core CLK Clock configuration CLK_CFG defines the ratio between the sys_clk and the TCK used to program both the LBIST and the MBIST and the STCU2 core clock. The punch-out mechanism is used to generate the derived clocks. The allowed configurations are the following: 000: sys_clk 001: sys_clk/2 010: sys_clk/3 ... 101: sys_clk/6 110: sys_clk/7 111: sys_clk/8 You can always read this field. In the off-line Self-Test phase, you can always write to this field. In the on-line Self-Test phase, you can write to this field only when WRP = 0.

79.7.5 STCU2 PLL Configuration Register (STCU2_PLL_CFG)

NOTE

The reset value is chip-specific; see the chapter that describes how modules are configured and connected.

The STCU2_PLL_CFG register defines the parameters used to program the PLL only when the Off-line L/MBIST are performed and STCU2_RUN[MBPLLEN] = 1 or STCU2_RUN[LBPLLEN] = 1.

In the On-line condition, these bits are not effective. It is also possible to set the PLL during active On-line mode to prevent any potential functionality issue.

The R/W fields in this register are readable at any time. However, you can write to these fields only when Off-line Self-Test phase is still active.

Address: 0h base + 10h offset = 10h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

* Notes:
- The reset value is chip-specific; see the chapter that describes how modules are configured and connected.x = Undefined at reset.

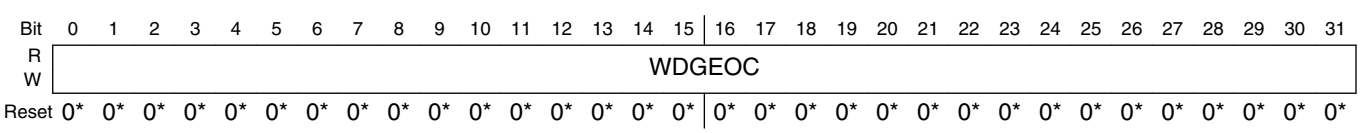
STCU2_PLL_CFG field descriptions

Field	Description
0–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2–7 PLLODF	PLL Output Division Factor The value of this field drives the Output Division factor of the PLL embedded into the device. Refer to the PLL specifications to define the exact mapping between the PLLODF value and the related PLL's Output Division factor.
8–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13–15 PLLIDF	PLL Input Division Factor The value of this field drives the Input Division factor of the PLL embedded into the device. Refer to the PLL specifications to define the exact mapping between the PLLIDF value and the related PLL's Input Division factor.
16–24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25–31 PLLLDF	PLL Loop Division Factor The value of this field drives the Loop Division factor of the PLL embedded into the device. Refer to the PLL specifications to define the exact mapping between the PLLLDF value and the related PLL's Loop Division factor.

79.7.6 STCU2 Watchdog Register Granularity (STCU2_WDG)

NOTE

The reset value is chip-specific; see the chapter that describes how modules are configured and connected.



The STCU2_WDG register defines the time budget of LBIST and MBIST execution providing a protection mechanism in case of dead-lock or end-less conditions during the Self-Test procedure. When the Off-line Self-Test sequence is not run and the BYP bit of the STCU2_CFG register is not set, the bits 15...0 defines the time-out before the bit WDTO of the STCU2_ERR register is set and the STCU2 core clock is switched off.

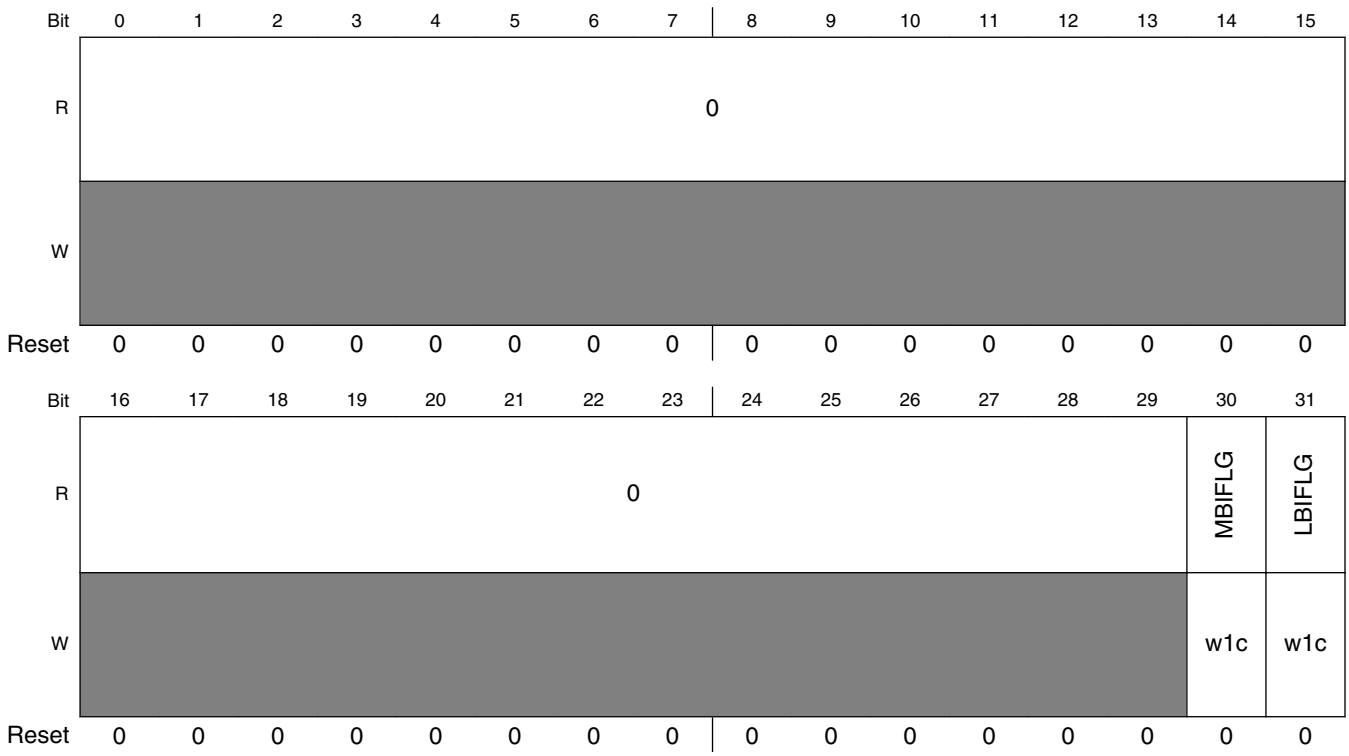
In case Off/On-line Self Test sequence is run, it defines the time-out of the execution run.

The R/W fields in this register are readable at any time. You can write to these fields when either of the following conditions is true:

- Off-line Self-Test phase is active
- On-line Self-Test phase is active and STCU2_CFG[WRP] = 0

Address: 0h base + 14h offset = 14h

* Notes:
- The reset value is chip-specific; see the chapter that describes how modules are configured and connected.



STCU2_WDG field descriptions

Field	Description
0–31 WDGEOC	Watchdog End of Count Timer This value has to be set in order to define the time budget related to the Off/On-Line Self Test execution and check that everything is correctly working within this slot of time. The allowed delay time are the following: 0000 0000h: 1 x 16 STCU2 Core clock cycles 0000 0001h: 2 x 16 STCU2 Core clock cycles 0000 0002h: 3 x 16 STCU2 Core clock cycles ... FFFF FFFDh: 4294967294 x 16 STCU2 Core clock cycles FFFF FFFEh: 4294967295 x 16 STCU2 Core clock cycles FFFF FFFFh: 4294967296 x 16 STCU2 Core clock cycles

79.7.7 STCU2 Interrupt Flag Register (STCU2_INT_FLG)

The STCU2_INT_FLG register includes an MBIST interrupt pending bit and an LBIST interrupt pending bit. Each bit is effective only during the On-Line Self-Test phase and is managed only when the related control bit in the STCU2_RUNSW register (MBIE or LBIE) is enabled.

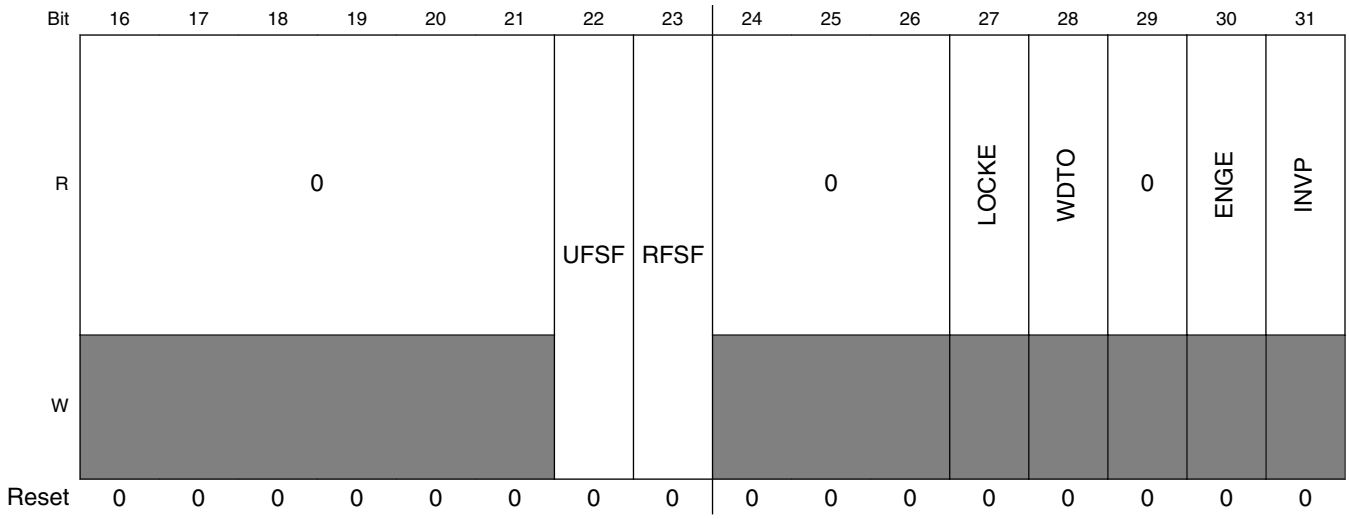
Address: 0h base + 18h offset = 18h

STCU2_INT_FLG field descriptions

Field	Description
0–29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30 MBIFLG	MBIST Interrupt Flag 0 No interrupt is pending 1 An interrupt, highlighting that the On-Line execution of the concurrent scheduled MBIST is completed, is pending. Write 1 to clear the bit.
31 LBIFLG	LBIST Interrupt Flag 0 No interrupt is pending 1 An interrupt, highlighting that the On-Line execution of the concurrent scheduled LBIST is completed, is pending. Write 1 to clear the bit.

79.7.8 STCU2 Error Register (STCU2_ERR_STAT)

The STCU2_ERR_STAT register includes the status flags related to the STCU2 internal fault conditions occurred during the configuration or the On/Off-Line self testing execution.



The UFSF and RFSF can be set/cleared using the FCCU dedicated channels.

The access to this register is described in the following figure and as follows:

- If you select the byte write capability to write only the UFSF and RFSF, then there is no restriction in writing these bits.
- If your software performs the write operations on other bits besides UFSF/RFSF, then a transfer error is generated only if the value you are writing to the other bits differs from their value currently stored in the register. This functionality has been implemented to prevent potential compilation behavior that might invalidate the UFSF/RFSF single bit set/clean capability.

Address: 0h base + 24h offset = 24h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0						ABORTHW	ABORTSW	0			LOCKESW	WDTOSW	0	ENGESW	INVPSW
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

STCU2_ERR_STAT field descriptions

Field	Description
0–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6 ABORTHW	On-line hardware abort flag You can always read this field. The content of this field is initialized to its reset value as soon as STCU2_RUNSW[RUNSW] = 1. 0 No hardware abort was requested during the On-Life Self-Test sequence 1 A hardware abort was detected during the On-Life Self-Test sequence
7 ABORTSW	On-line software abort flag You can always read this field. The content of this field is initialized to its reset value as soon as STCU2_RUNSW[RUNSW] = 1. 0 No software abort was requested during the On-Life Self-Test sequence 1 A software abort was detected during the On-Life Self-Test sequence
8–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11 LOCKESW	On-Line LOCK Error You can always read this field. The content of this field is initialized to its reset value as soon as STCU2_RUNSW[RUNSW] = 1. 0 In case PLL is enabled, it is correctly locked during the Self-Test sequence 1 When the PLL is enabled, this flag highlight that there has been an unexpected PLL unlock event during the On-Line Self-Test sequence execution. The On-Line Self-test run is stopped and the status of the current running LBISTs or MBISTs is saved into the related registers. The LOCK signal is monitored during the LBIST run when STCU2_RUNSW.LBSWPLLEN is set and/or during the MBIST run when STCU2_RUNSW[MBSWPLLEN] = 1.
12 WDTOSW	On-Line Watchdog time-out You can always read this field. The content of this field is initialized to its reset value as soon as STCU2_RUNSW[RUNSW] = 1.

Table continues on the next page...

STCU2_ERR_STAT field descriptions (continued)

Field	Description
	0 LBIST and MBIST time slot have been completed within the assigned watchdog time. 1 LBIST and MBIST time slot haven't been completed within the assigned watchdog time or there are internal mismatches among End of Execution signals. The conditions that flag the failures are the following: • MBIST BEND status flags that at least one of the selected MBIST run is not finished • lbist_done of the selected LBIST flags the LBIST run is/are not finished
13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14 ENGESW	On-Line Engine Error You can always read this field. The content of this field is initialized to its reset value as soon as STCU2_RUNSW[RUNSW] = 1. 0 Valid Engine execution 1 Invalid Engine execution. The following conditions set this bit: • STCU2 state machines (Watchdog, Master and Loader/Shifter) selects an unused code • Serial pass/fail status of the selected MBIST and the global BBAD flag are not aligned • Serial bend status of the selected MBIST and the global BEND flag are not aligned
15 INVPSW	On-Line Invalid Pointer You can always read this field. The content of this field is initialized to its reset value as soon as STCU2_RUNSW[RUNSW] = 1. 0 Valid linked pointer list 1 Invalid linked pointer list. The following conditions set this bit: • Initial LBIST or MBIST pointer is out of range • LBIST is selected when MBIST is concurrently running or vice versa • Error in the LBIST/MBIST linking (execution generates an infinite loop)
16–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22 UFSF	Unrecoverable Faults Status Flag This flag reports the global status of the UF. This field can be set or cleared using the FCCU dedicated channel, and can also be set or cleared by software. 0 No errors that trigger the Unrecoverable Faults condition 1 There are errors that trigger the Unrecoverable Faults condition
23 RFSF	Recoverable Faults Status Flag This flag reports the global status of the RF. This field can be set or cleared using the FCCU dedicated channel, and can also be set or cleared by software. 0 No errors that trigger the Recoverable Faults condition 1 There are errors that trigger the Recoverable Faults condition
24–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 LOCKE	Off-Line LOCK Error 0 The PLL is correctly locked during the Self-Test sequence 1 When the PLL is enabled, this flag highlights that there has been an unexpected PLL unlock event during the Off-Line Self-Test sequence execution. The Off-Line Self-test run is stopped and the status of the current running LBISTs or MBISTs is saved into the related registers. The LOCK signal is

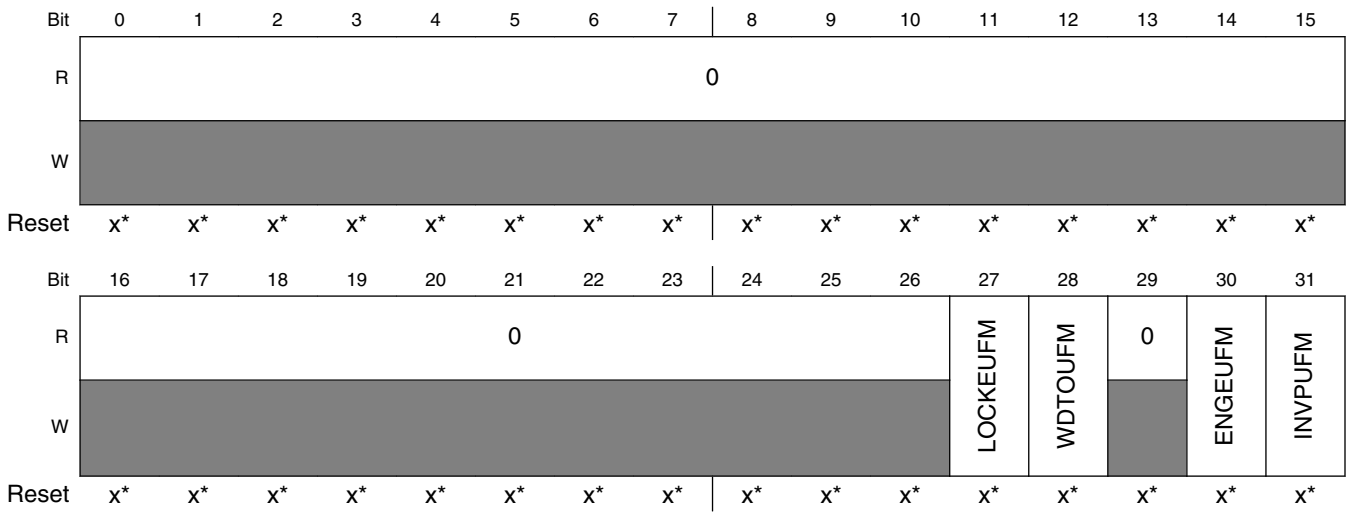
Table continues on the next page...

STCU2_ERR_STAT field descriptions (continued)

Field	Description
	monitored during the LBIST run when STCU2_RUN[LBPLLEN] = 1 and/or during the MBIST run when STCU2_RUN[MBPLLEN] = 1.
28 WDTO	Off-Line Watchdog time-out 0 LBIST and MBIST time slot have been completed within the assigned watchdog time. 1 LBIST and MBIST time slot haven't been completed within the assigned watchdog time or there are internal mismatches among End of Execution signals. The conditions that flag the failures are the following: • The STCU2_RUN[RUN] bit or the STCU2_RUN[BYP] bit is not set before the Watchdog reaches the End of Count • MBIST BEND status flags that at least one of the selected MBIST run is not finished • lbist_done of the selected LBIST flags the LBIST run is/are not finished
29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30 ENGE	Off-Line Engine Error 0 Valid Engine execution 1 Invalid Engine execution. The following conditions set this bit: • STCU2 state machines (Watchdog, Master and Loader/Shifter) selects an unused code • Serial pass/fail status of the selected MBIST and the global BBAD flag are not aligned • Serial bend status of the selected MBIST and the global BEND flag are not aligned
31 INVP	Off-Line Invalid pointer 0 Valid linked pointer list 1 Invalid linked pointer list. The following conditions set this bit: • Initial LBIST or MBIST pointer is out of range • LBIST is selected when MBIST is concurrently running or vice versa • Error in the LBIST/MBIST linking (execution generates an infinite loop)

79.7.9 STCU2 Error FM Register (STCU2_ERR_FM)

NOTE



The reset value is chip-specific; see the chapter that describes how modules are configured and connected.

The STCU2_ERR_FM register defines the fault mapping of the STCU2 faults described into the register STCU2_ERR_STAT in terms of Unrecoverable or Recoverable Fault. All sources of internal faults can be routed to UF and RF.

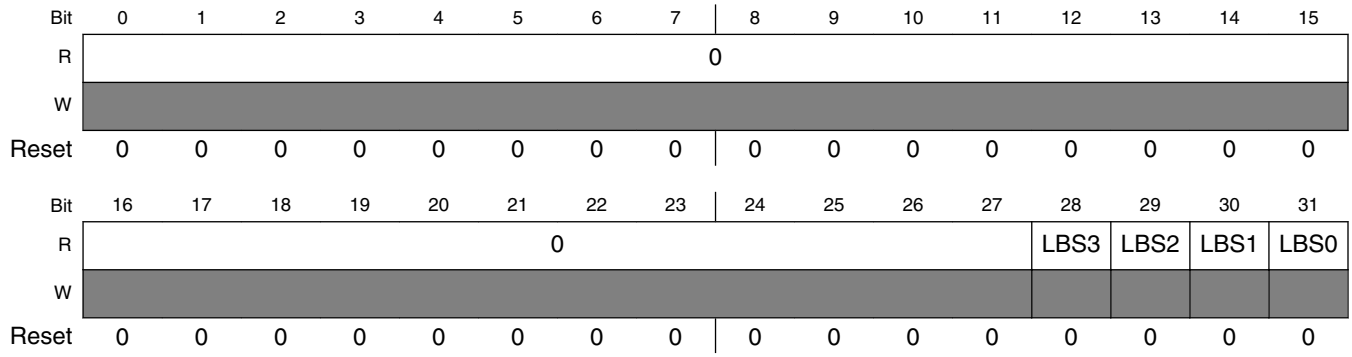
The R/W fields in this register are readable at any time. You can write to these fields when either of the following conditions is true:

- Off-line Self-Test phase is active
- On-line Self-Test phase is active and STCU2_CFG[WRP] = 0

Address: 0h base + 28h offset = 28h

* Notes:
- The reset value is chip-specific; see the chapter that describes how modules are configured and connected.x = Undefined at reset.

STCU2_ERR_FM field descriptions



Field	Description
0–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

79.7.10 STCU2 Off-Line LBIST Status Register (STCU2_LBS)

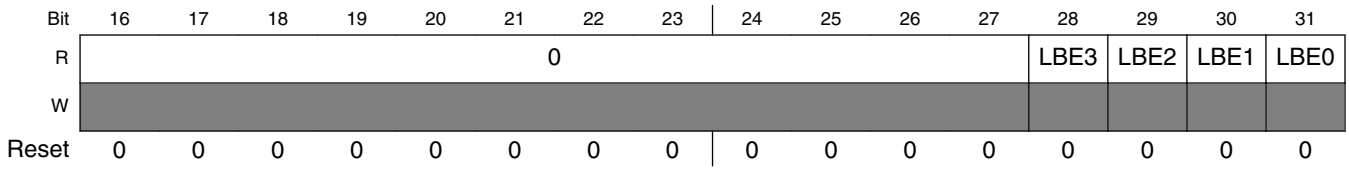
The STCU2_LBS register includes the results corresponding to the execution of the selected Off-Line LBIST.

The size of the register depends on the number of LBIST .

Address: 0h base + 2Ch offset = 2Ch

STCU2_LBS field descriptions

Field	Description
0–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28 LBS3	Off-Line status of the selected LBIST 0 Failed LBIST execution 1 Successful LBIST execution
29 LBS2	Off-Line status of the selected LBIST 0 Failed LBIST execution 1 Successful LBIST execution
30 LBS1	Off-Line status of the selected LBIST 0 Failed LBIST execution 1 Successful LBIST execution
31 LBS0	Off-Line status of the selected LBIST 0 Failed LBIST execution 1 Successful LBIST execution



79.7.11 STCU2 Off-Line LBIST End Flag Register (STCU2_LBE)

The STCU2_LBE register includes the End Flag related to the execution of the selected Off-Line LBIST.

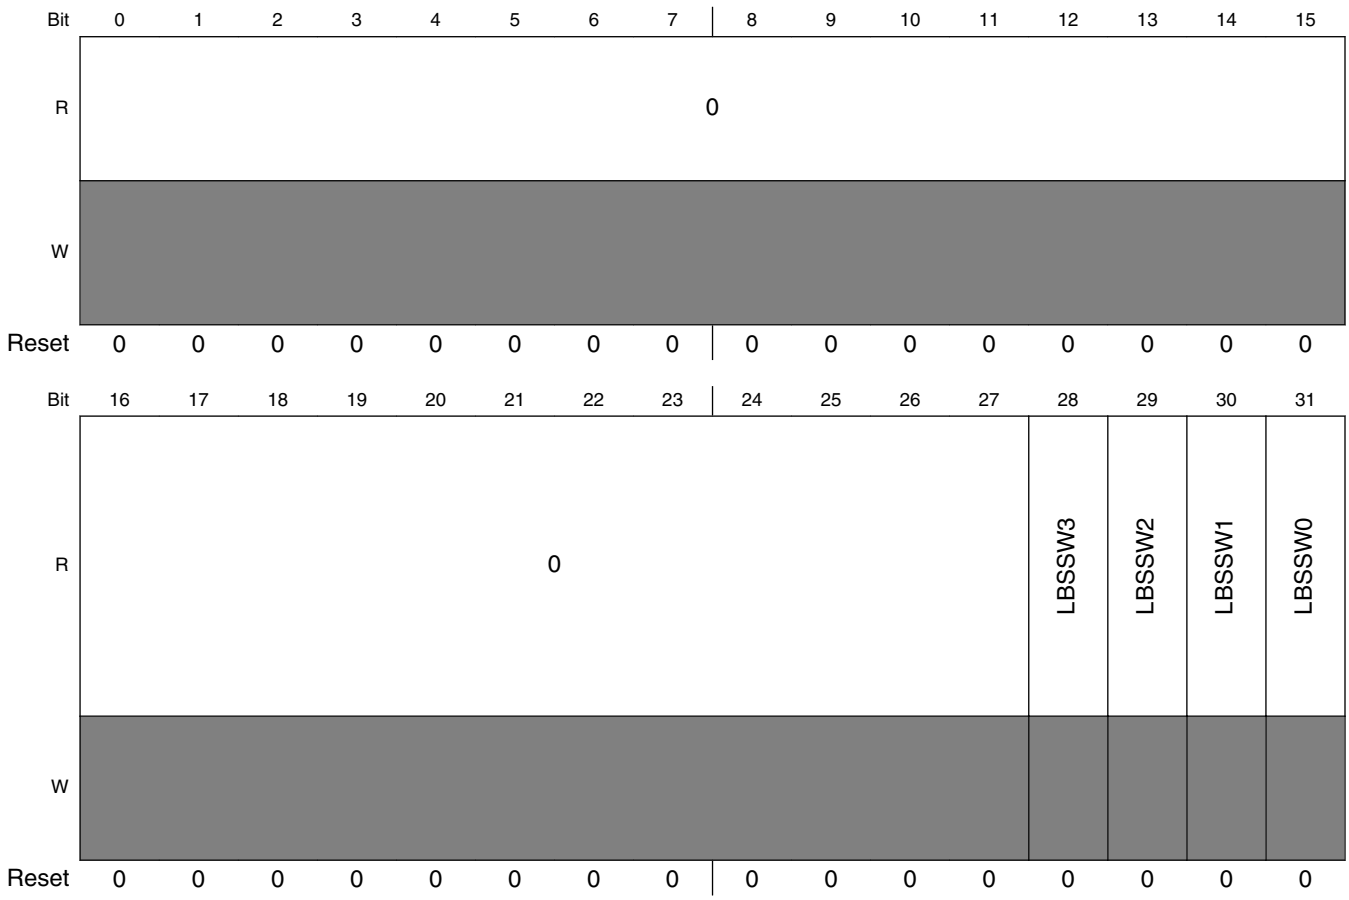
The size of the register depends on the number of LBIST .

Address: 0h base + 30h offset = 30h

STCU2_LBE field descriptions

Field	Description
0–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28 LBE3	Off-Line End status of the selected LBIST 0 LBIST execution not yet completed 1 LBIST execution finished
29 LBE2	Off-Line End status of the selected LBIST 0 LBIST execution not yet completed 1 LBIST execution finished
30 LBE1	Off-Line End status of the selected LBIST 0 LBIST execution not yet completed 1 LBIST execution finished
31 LBE0	Off-Line End status of the selected LBIST 0 LBIST execution not yet completed 1 LBIST execution finished

79.7.12 STCU2 On-Line LBIST Status Register (STCU2_LBSSW)



The STCU2_LBSSW register includes the results corresponding to the execution of the selected On-Line LBIST.

The size of the register depends on the number of LBIST .

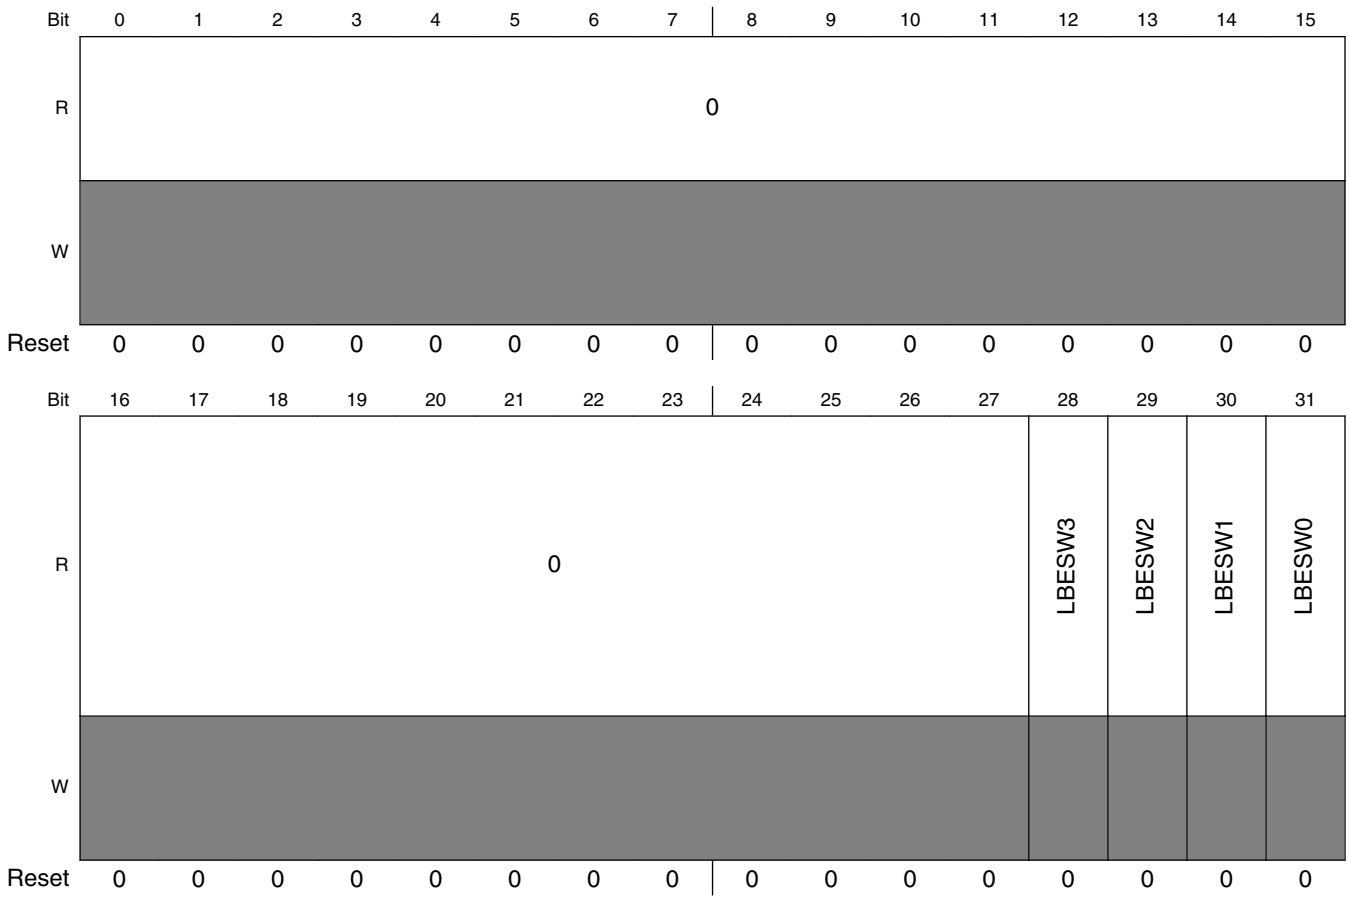
The content of this register is initialized to its reset value as soon as STCU2_RUNSW[RUNSW] = 1.

Register description

Address: 0h base + 34h offset = 34h

STCU2_LBSSW field descriptions

Field	Description
0–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28 LBSSW3	LBSSWx: On-Line status of the selected LBIST 0 Failed LBIST execution 1 Successful LBIST execution
29 LBSSW2	LBSSWx: On-Line status of the selected LBIST 0 Failed LBIST execution 1 Successful LBIST execution
30 LBSSW1	LBSSWx: On-Line status of the selected LBIST 0 Failed LBIST execution 1 Successful LBIST execution
31 LBSSW0	LBSSWx: On-Line status of the selected LBIST 0 Failed LBIST execution 1 Successful LBIST execution



79.7.13 STCU2 On-Line LBIST End Flag Register (STCU2_LBESW)

The STCU2_LBESW register includes the End Flag related to the execution of the selected On-Line LBIST.

The size of the register depends on the number of LBIST .

The content of this register is initialized to its reset value as soon as STCU2_RUNSW[RUNSW] = 1.

Address: 0h base + 38h offset = 38h

STCU2_LBESW field descriptions

Field	Description
0–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28 LBESW3	LBESWx: On-Line LBIST End status 0 LBIST execution not yet completed 1 LBIST execution finished

Table continues on the next page...

30 LBESW1	LBESWx: On-Line LBIST End status 0 LBIST execution not yet completed 1 LBIST execution finished
31 LBESW0	LBESWx: On-Line LBIST End status 0 LBIST execution not yet completed 1 LBIST execution finished

79.7.14 STCU2 On-Line LBIST Reset Management (STCU2_LBRMSW)

NOTE

The reset value is chip-specific; see the chapter that describes how modules are configured and connected.

The STCU2_LBRMSW register defines the On-Line reset mapping for each LBIST. Global or specific functional reset can be programmed depending on the On-Line Self-Test requirements and top level integration architecture.

The size of the register depends on the number of LBIST .

The R/W fields in this register are readable at any time. You can write to these fields when either of the following conditions is true:

- Off-line Self-Test phase is active
- On-line Self-Test phase is active and STCU2_CFG[WRP] = 0

Address: 0h base + 3Ch offset = 3Ch

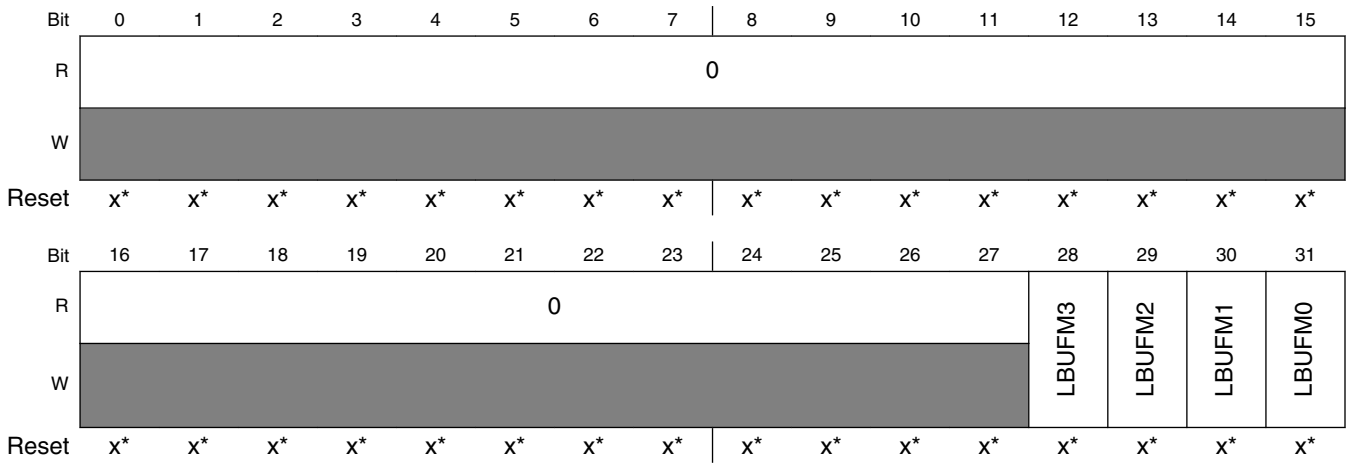
31 LBRMSW0	On-Line LBIST Reset Management **NOTE:** In case one of the selected LBIST has this bit set to '1', then only the Global functional reset will be pulsed. 0 Dedicated functional reset is pulsed at the end of LBIST run 1 Global functional reset is pulsed at the end of LBIST run

79.7.15 STCU2 LBIST Unrecoverable FM Register (STCU2_LBUFM)

NOTE

The reset value is chip-specific; see the chapter that describes how modules are configured and connected.



The STCU2_LBUFM register defines the fault mapping of each LBIST in terms of Unrecoverable or Recoverable Fault.

The size of the register depends on the number of LBIST .

The R/W fields in this register are readable at any time. You can write to these fields when either of the following conditions is true:

- Off-line Self-Test phase is active
- On-line Self-Test phase is active and STCU2_CFG[WRP] = 0

Address: 0h base + 40h offset = 40h

* Notes:
- The reset value is chip-specific; see the chapter that describes how modules are configured and connected.x = Undefined at reset.

STCU2_LBUFM field descriptions

79.7.16 STCU2 Off-Line MBIST Status Low Register (STCU2_MBSL)

The STCU2_MBSL register includes the results corresponding to the execution of the selected Off-Line MBIST in the range NMCUT = 0-31.

The size of the register depends on the number of BISTed RAMs/ROMs .

Address: 0h base + 44h offset = 44h

STCU2_MBSL field descriptions

Field	Description
0 MBS31	Off-Line status (NMCUT range = 0 to 31) of the selected MBIST **NOTE:** This bit is meaningful when the related bit of the STCU2_MBEL register reports the MBIST is finished. 0 Failed NMCUT BIST execution 1 No Fault detected during the NMCUT BIST execution
1 MBS30	Off-Line status (NMCUT range = 0 to 31) of the selected MBIST **NOTE:** This bit is meaningful when the related bit of the STCU2_MBEL register reports the MBIST is finished. 0 Failed NMCUT BIST execution 1 No Fault detected during the NMCUT BIST execution
2 MBS29	Off-Line status (NMCUT range = 0 to 31) of the selected MBIST **NOTE:** This bit is meaningful when the related bit of the STCU2_MBEL register reports the MBIST is finished.

Table continues on the next page...

STCU2_MBSL field descriptions (continued)

Field	Description
	0 Failed NMCUT BIST execution 1 No Fault detected during the NMCUT BIST execution
3 MBS28	Off-Line status (NMCUT range = 0 to 31) of the selected MBIST **NOTE:** This bit is meaningful when the related bit of the STCU2_MBEL register reports the MBIST is finished. 0 Failed NMCUT BIST execution 1 No Fault detected during the NMCUT BIST execution

79.7.23 STCU2 On-Line MBIST Status Medium Register (STCU2_MBSMSW)

The STCU2_MBSMSW register includes the results corresponding to the execution of the selected On-Line MBIST in the range NMCUT = 32..63.

The size of the register depends on the number of BISTed RAMs/ROMs.

The content of this register is initialized to its reset value as soon as STCU2_RUNSW[RUNSW] = 1.

Address: 0h base + 60h offset = 60h

79.7.30 STCU2 MBIST Unrecoverable FM High Register (STCU2_MBUFMH)

NOTE

The reset value is chip-specific; see the chapter that describes how modules are configured and connected.

The STCU2_MBUFMH register defines the fault mapping, in terms of Unrecoverable or Recoverable fault, of the MBIST in the range NMCUT = 64-95.

The size of the register depends on the number of BISTed RAMs/ROMs.

The R/W fields in this register are readable at any time. You can write to these fields when either of the following conditions is true:

- Off-line Self-Test phase is active
- On-line Self-Test phase is active and STCU2_CFG[WRP] = 0

Address: 0h base + 7Ch offset = 7Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

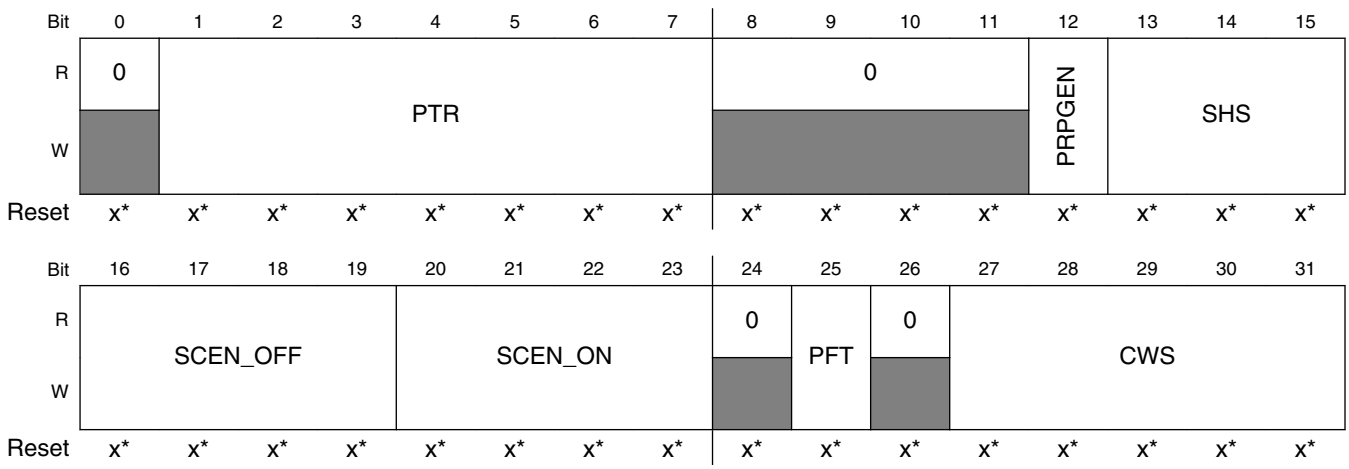
* Notes:
- The reset value is chip-specific; see the chapter that describes how modules are configured and connected.x = Undefined at reset.

STCU2_MBUFMH field descriptions

Field	Description
0–31 Reserved	This field is reserved.

79.7.31 STCU2 LBIST Control Register (STCU2_LB_CTRL*n*)

NOTE



The reset value is chip-specific; see the chapter that describes how modules are configured and connected.

The STCU2_LB_CTRL register defines the control setting of each LBIST controller.

The R/W fields in this register are readable at any time. You can write to these fields when either of the following conditions is true:

- Off-line Self-Test phase is active
- On-line Self-Test phase is active and STCU2_CFG[WRP] = 0

Address: 0h base + 100h offset + (64d × i), where i=0d to 3d

* Notes:
- The reset value is chip-specific; see the chapter that describes how modules are configured and connected.x = Undefined at reset.

STCU2_LB_CTRL*n* field descriptions

Field	Description
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1–7 PTR	Next LBIST pointer PTR defines the logical pointer to the next LBIST. In case of NIL pointer the CSM bit has to be set Sequential (0) to define this is the end of the list. The self testing procedure is stopped when the current LBIST has been completed. LBIST POINTERS 0000b - pointer to LBIST partition 0 0001b - pointer to LBIST partition 1 0010b - pointer to LBIST partition 2 0011b - pointer to LBIST partition 3 ... 0x7F - pointer to NIL, end of LBIST execution Values not defined in this list will result in an error being set in the STCU2_ERR register.
8–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

STCU2_LB_CTRL*n* field descriptions (continued)

Field	Description
12 PRPGEN	Enable PRPG Loading 0 Default LBIST value of the PRPG is used during LBIST run 1 LBIST PRPG value is initialized with the STCU2_LB_PRPGL/H
13–15 SHS	Shift speed SHS defines the shift speed 000 Shift at full rate of STCU2 core clock 001 Shift at 1/2 rate of STCU2 core clock 010 Shift at 1/3 rate of STCU2 core clock 011 Shift at 1/4 rate of STCU2 core clock 100 Shift at 1/5 rate of STCU2 core clock 101 Shift at 1/6 rate of STCU2 core clock 110 Shift at 1/7 rate of STCU2 core clock 111 Shift at 1/8 rate of STCU2 core clock
16–19 SCEN_OFF	Scan enable OFF SCEN_OFF defines the number of clock cycles OFF following the falling transition on the SCEN **NOTE:** Scen_off must be programmed to a value >=1 0000 0 delay cycles 0001 1 delay cycle 0010 2 delay cycles 0011 3 delay cycles 0100 4 delay cycles 0101 5 delay cycles 0110 6 delay cycles 0111 7 delay cycles 1000 8 delay cycles 1001 9 delay cycles 1010 10 delay cycles 1011 11 delay cycles 1100 12 delay cycles 1101 13 delay cycles 1110 14 delay cycles 1111 15 delay cycles
20–23 SCEN_ON	Scan enable ON SCEN_ON defines the number of clock cycles OFF following the rising transition on the SCEN **NOTE:** Scen_on delay register value must be programmed to a value >=1> 0000 0 delay cycles 0001 1 delay cycle 0010 2 delay cycles 0011 3 delay cycles 0100 4 delay cycles 0101 5 delay cycles 0110 6 delay cycles

Table continues on the next page...

STCU2_LB_CTRL*n* field descriptions (continued)

Field	Description
	0111 7 delay cycles 1000 8 delay cycles 1001 9 delay cycles 1010 10 delay cycles 1011 11 delay cycles 1100 12 delay cycles 1101 13 delay cycles 1110 14 delay cycles 1111 15 delay cycles
24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25 PFT	Past Flush Test The LBIST controller, by default, applies 32 Flush Test patterns. This bit allows to skip/apply the Flush test pattern sequence.
26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27–31 CWS	Capture window size CWS defines the capture window size. 00000: Illegal 00001: Controller waits 1 shift cycle for capture to finish. 00010: Controller waits 2 shift cycles for capture to finish. 00011: Controller waits 3 shift cycles for capture to finish. ... 11110: Controller waits 30 shift cycles for capture to finish. 11111: Controller waits 31 shift cycles for capture to finish.

79.7.32 STCU2 LBIST PC Stop Register (STCU2_LB_PCS*n*)

NOTE

The reset value is chip-specific; see the chapter that describes how modules are configured and connected.

The STCU2_LB_PCS register defines the pattern counter stop of each LBIST controller.

The R/W fields in this register are readable at any time. You can write to these fields when either of the following conditions is true:

- Off-line Self-Test phase is active
- On-line Self-Test phase is active and STCU2_CFG[WRP] = 0

Address: 0h base + 104h offset + (64d × i), where i=0d to 3d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

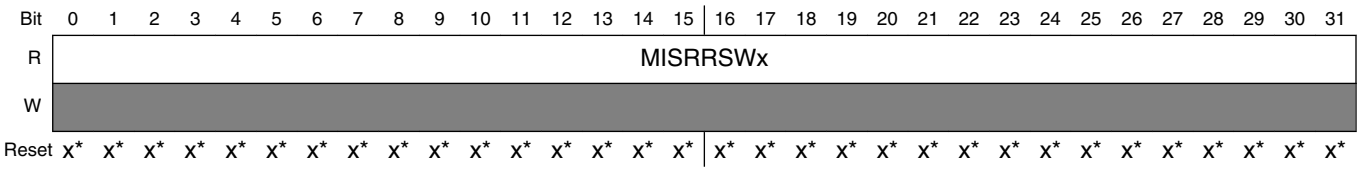
STCU2_LB_MISRRLSW*n* field descriptions

Field	Description
0–31 MISRRSWx	On-Line MISR Read Low Bin This field is equivalent to the Low Bits (31-0) of the MISR obtained at the end of the Off-Line LBIST execution.

79.7.42 STCU2 On-Line LBIST MISR Read High Register (STCU2_LB_MISRRHSW*n*)

NOTE



The reset value is chip-specific; see the chapter that describes how modules are configured and connected.

The STCU2_LB_MISRRHSW register report the MSB part (63-32) of the MISR obtained at the end of each On-Line LBIST controller execution.

The size of the register depends on the number of MISR bits of the related LBIST.

The content of this register is initialized to its reset value as soon as STCU2_RUNSW[RUNSW] = 1.

Address: 0h base + 12Ch offset + (64d × i), where i=0d to 3d

* Notes:
- The reset value is chip-specific; see the chapter that describes how modules are configured and connected.x = Undefined at reset.

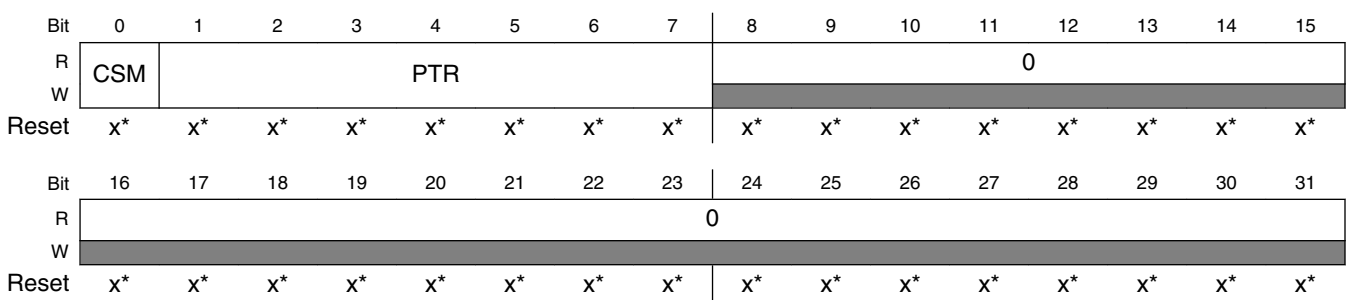
STCU2_LB_MISRRHSW*n* field descriptions

Field	Description
0–31 MISRRSWx	On-Line MISR Read High Bits This field is equivalent to the Low Bits (63-32) of the MISR obtained at the end of the Off-Line LBIST execution.

79.7.43 STCU2 MBIST Control Register (STCU2_MB_CTRL*n*)

NOTE

The reset value is chip-specific; see the chapter that describes how modules are configured and connected.



The STCU2_MB_CTRL register defines the control setting of MBIST controller.

The R/W fields in this register are readable at any time. You can write to these fields when either of the following conditions is true:

- Off-line Self-Test phase is active
- On-line Self-Test phase is active and STCU2_CFG[WRP] = 0

The offset of this register is a function of NMCUT .

Address: 0h base + 600h offset + (4d × i), where i=0d to 46d

* Notes:

- The reset value is chip-specific; see the chapter that describes how modules are configured and connected.x = Undefined at reset.

STCU2_MB_CTRL*n* field descriptions

Field	Description
0 CSM	Concurrent/sequential mode 0 Sequential mode 1 Concurrent mode
1–7 PTR	Next LBIST or MBIST pointer PTR defines the logical pointer to the next LBIST or MBIST to be scheduled. The next MBIST is scheduled concurrently to the current one if the CSM bit is set to 1; otherwise it is scheduled sequentially to the completion of the current MBIST execution. In case of NIL pointer the CSM bit must be set Sequential (0) to define this is the end of the list. The self-testing procedure is stopped when the current MBIST has been completed. 0h to (LBIST -1): pointer to LBIST 10h to (10h + MBIST -1b): pointer to MBIST 7Fh: pointer to NIL. No BIST execution. others: invalid pointer => an error is set into the STCU2_ERR register.
8–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

79.8 Use cases and limitations

The STCU2 module is designed to give high flexibility during the on/off-line test. In the following are reported the programming operations that have to be performed to correctly use the functionality of this module considering the three typical usage cases:

- the Off-line Self Test Sequence after a reset trigger event
- the bypass mode of the Self Test Sequence after a reset trigger event
- the On-line Self-test Sequence

79.8.1 Offline self-test sequence

This is the typical mode of using the STCU2 module after reset trigger event is applied to STCU2. The SSCM DCF bus is used to retrieve the STCU2 schedule and L/MBIST execution parameters stored into the NVM memory.The target is to cover the amount of physical defects in the digital logic and in the System RAMs/ROMs according to the System specifications. The sequence is the following:

- Unlock the Off-Line STCU2 access writing the Key1/Key2 sequence into the STCU2_SKC register
- Program the LBIST fault reaction conditions (UF/RF) setting the STCU2_LBUFM register

- Program the MBIST fault reaction conditions (UF/RF) setting, depending on the number of memories, the STCU2_MBUFML/M/H registers
- Program the STCU2 internal fault reaction conditions (UF/RF) setting the STCU2_ERR_FM register
- Program the STCU2_LB_CTRL, STCU2_LB_PCS, STCU2_MISREL/H registers of each LBIST to be executed. Optionally, also the STCU2_LB_PRPGL/H can be programmed in order to load a specific seed.
- Program the STCU2_MB_CTRL registers of each NMCUT to be executed
- Program the STCU2_WDG register to define the time budget assigned for the L/MBIST execution
- Program the STCU2_CFG register to define: the core and LBIST/MBIST TCK clock prescaling factor setting the CLK_CFG bits, the PMOSEN or MBU in order to define the algorithm to be used during MBIST run, and finally set the pointer to the first LBIST/NMCUT to be executed
- In case the PLL usage has been enabled, program the STCU2_PLL_CFG value in order to set the required system frequency
- Program the RUN bit into the STCU2_RUN register to enable the Off-Line Self-Test execution and the L/MBPLLEN bits to enable the PLL during L/MBIST execution according to STCU2_PLL_CFG register content
- Start the Off-Line Self-Test and, depending on PLL management and L/MBIST execution order, when PLL LOCK is high.
- Wait the WDGEOC run time execution specified into the STCU2_WDG register.
- The STCU2 switchs off the core clock at the end of the Self-Test run and releases the PLL control in case this feature has been enabled.
- The STCU2 resets the STCU2_RUN[RUN] bit and the device exits from boot sequence. In case there are failures, the STCU2 flags these failures toward the FCCU.
- The software application reads the STCU2_LBS flag register to check the failed LBIST when UF or RF conditions is/are detected.
- The software application reads the STCU2_LBE flag register to check the LBIST still on-going when UF or RF is/are detected.
- The software application reads the STCU2_MBSL/M/H flag registers, depending on the number of memories, to check the failed RAMs/ROMs Memory BIST when UF or RF is/are detected.
- The software application reads the STCU2_MBEL/M/H flag registers, depending on the number of memories, to check if the RAMs/ROMs Memory BIST is still on-going when UF or RF is/are detected.

- The software application reads the bits INV, ENGE, WDTO, LOCKE of the STCU2_ERR_STAT register to check whether there has been an internal STCU2 engine/parameters failure when UF or RF is/are detected.
- The software application reads for each device's LBIST, the STCU2_LBMISREL/H and STCU2_LBIST_MISRRL/H registers to check the coherence with the STCU2_LBS bits.

NOTE

The software application reads operations on the STCU2 and LBIST MISR registers after off-line self test execution has been successfully performed are just an additional reliability layer added to improve the already implemented Auto Self-Test feature included into STCU2.

79.8.2 Online self-test sequence

This is the typical mode of using the STCU2 module during the application run. The IPS interface is used to program the STCU2 registers and to schedule the L/MBIST execution. Since the On-Line L/MBIST operations clean-up the content of the related Digital Logic (LBIST) or RAM (MBIST) the activation of this mode has to be done carefully. The suggested sequence is the following:

- Unlock the On-Line STCU2 access writing the Key1/Key2 sequence into the STCU2_SKC register
- Check and/or clean-up the bit WRP into the STCU2_CFG register to open the IPS access on the STCU2 On-Line Self-Test registers
- The LBIST, MBIST and STCU2 internal fault reaction should have been already programmed during the Off-Line Self-Test sequence and so they should not be programmed again. However, in case they have not been programmed or there is the need of changing them for any reason, they can be overwritten setting respectively the registers: STCU2_LBUFM, STCU2_MBUFML/M/H and STCU2_ERR_FM.
- Program the Reset management during on-Line LBIST execution setting the STCU2_LBRMSW register
- The STCU2_LB_CTRL, STCU2_LB_PCS should have been already programmed during Off-Line Self-test sequence and so they should not be programmed again. However, in case they have not been programmed or there is the need of changing

them for any reason, they can be overwritten. The registers STCU2_LB_MISRELSW/HSW have to be programmed according to the expected signature.

- Overwrite/Program the STCU2_MB_CTRL registers of each NMCUT to be executed
- Overwrite/Program the STCU2_WDG register to define the time budget assigned for the L/MBIST execution
- Overwrite/Program the STCU2_CFG register in order to define: the core and L/MBIST TCK clock prescaling factor setting the CLK_CFG bits, the PMOSEN or MBU in order to define the algorithm to be used during MBIST run, and finally set the pointer to the first LBIST/NMCUT to be executed.
- Program the RUNSW bit into the STCU2_RUNSW register to enable the On-Line Self-Test execution; the L/MBSWPLLEN bits to enable the PLL lock signal monitor during L/MBIST execution and the L/MBIE to enable the related Interrupt requests.
- Start the On-Line Self-Test and depending on PLL management and L/MBIST execution order, also when PLL LOCK is high.
- Wait the WDGEOC run time execution specified into the STCU2_WDG register
- In case the L/MBIE have been enabled, an interrupt is generated at the end of all the L/MBIST execution. The software application has to manage these interrupt signals and clean-up the related flag (L/MBIFLG) into the STCU2_INT_FLG register.
- The STCU2 switch-off the core clock at the end of the Self-Test run
- The functional reset activated is managed by the STCU2_LBRMSW.
- In case, at least one of the selected LBIST enables the Global functional reset, the STCU2 requests a functional reset which restarts the system while, when all the selected LBIST enables its own dedicated functional reset, only these local reset lines are applied and only the related LBIST partitions are cleaned-up.
- The STCU2 resets the STCU2_RUNSW[RUNSW] bit. In both the reset cases and in case of fault/s, the STCU2 flags the failure toward the FCCU.
- The software application reads the STCU2_LBSSW flag register to check the failed LBIST when UF or RF conditions is/are detected
- The software application reads the STCU2_LBESW flag register to check if the LBIST is still on-going when UF or RF is/are detected

- The software application reads the STCU2_MBSLSW/MSW/HSW flag registers, depending on the number of memories, to check the failed RAMs/ROMs Memory BIST when UF or RF is/are detected
- The software application reads the STCU2_MBELSW/MSW/HSW flag registers, depending on the number of memories, to check if the RAMs/ROMs Memory BIST is still on-going when UF or RF is/are detected
- The software application reads the bit INVPSW, ENGESW, WDTOSW, LOCKESW of the STCU2_ERR_STAT register to check whether there has been an internal STCU2 engine/parameters failure when UF or RF is/are detected
- The software application reads for each device's LBIST, the STCU2_LBMISRELSW/HSW and STCU2_LBIST_MISRRLSW/HSW registers to check the coherence with the STCU2_LBS bits

NOTE

The software application read operations on the STCU2 and LBIST MISR registers after on-line self-test execution has been successfully performed are just an additional reliability layer to be added to improve the already implemented Auto Self-Test feature included in the STCU2.

NOTE

Flash memory must be in the idle state when BIST execution is started. Program and erase functionality must not be enabled when entering BIST execution.

79.8.3 Bypass USER Mode

In this case, the USER application parameters stored in FLASH and read by SSCM are written in order to skip the Self-Test procedure after a reset trigger event is applied. It might be useful in case the device is not configured for applications requiring improved reliability. The sequence is the following:

1. Unlock the STCU2 access writing the Off-Line Key1/Key2 sequence into the STCU2_SKC register
2. Set the BYP bit in the STCU2_RUN register

After BYP bit is set, the core clock is switched off, the Self-Test sequence is not applied and the system can wake up and start the user application.

79.8.4 Design implementation information

The following list reports the limitations related to the current implementation:

- Every NMCUT BIST can be run once during the online or offline self-test procedure.
- It is not possible to run LBIST and MBIST concurrently.
- Because software has full control of the system while applications are running during the online self-test, STCU2 is not allowed to take control of the PLL but can just monitor the lock signal to flag wrong unlock events.

CAUTION

Do not execute an LBIST on more than one partition at a time.

Chapter 80
Register Protection (REG_PROT)

80.1 Register protection (REG_PROT) chip-specific module information

Some modules on this device include a built-in register protection mechanism that can be used to override the normal write permissions associated with individual registers in the module. This mechanism is software-controlled and can be dynamically reconfigured at runtime or made effective until device reset.

Table 80-1. Modules with protected registers

Topic	Related module
SIUL2 registers	SIUL2
CMU registers	CMU_0 (pll), CMU_1 (fxbar), CMU_2 (sxbar), CMU_3 (aips) and CMU_4 (per)
PMC registers	PMC
PLLDIG registers	PLLDIG
XOSC registers	XOSC
MEMU registers	MEMU
MC_ME registers	MC_ME
MC_CGM registers	MC_CGM
MC_RGM registers	MC_RGM
SSCM registers	SSCM
JTAGM registers	JTAGM

The protected registers are listed in subsequent sections.

80.1.1 SIUL2 protected registers

Table 80-2. Protected SIUL2 registers

Register	Register size (bits)	Offset from module base address	Protected size (bits)
DIRER0	32	18h	32

80.2 Overview

The Register Protection (REG_PROT) module offers a mechanism to protect defined memory-mapped address locations in a module under protection from being written. The address locations that can be protected are module-specific.

The protection module is located between the module under protection and the peripheral bridge (PBRIDGE/AIPS-Lite). This is shown in the following figure.

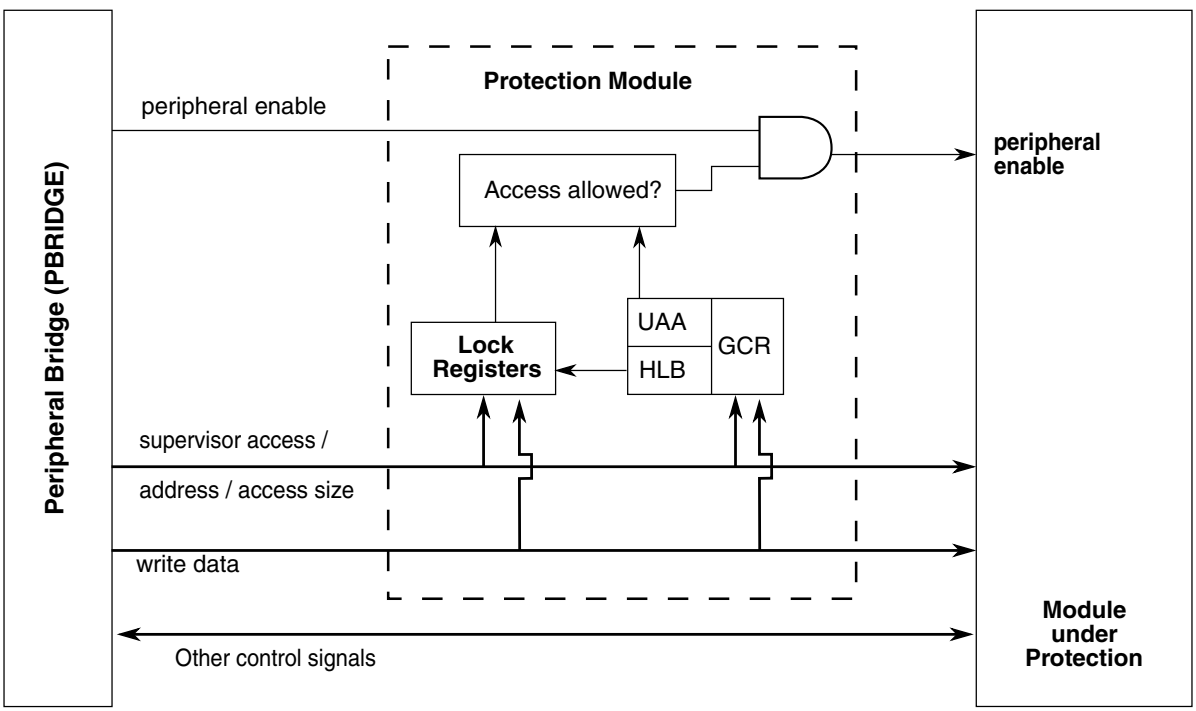

Figure 80-1. REG_PROT Block Diagram

80.3 Features

Register Protection includes these distinctive features:

- Restrict write accesses for the module under protection to supervisor mode only
- Lock registers for first 6 KB of memory-mapped address space
- Write to address mirror automatically sets corresponding lock bit
- Once configured lock bits can be protected from changes

80.4 Modes of operation

The Register Protection module is operable when the module under protection is operable.

80.5 External signal description

There are no external signals.

80.6 Memory map and register definition

This section provides a detailed description of the memory map of a module with register protection. The original 16 KB module memory space is divided into five areas as shown in the following figure.

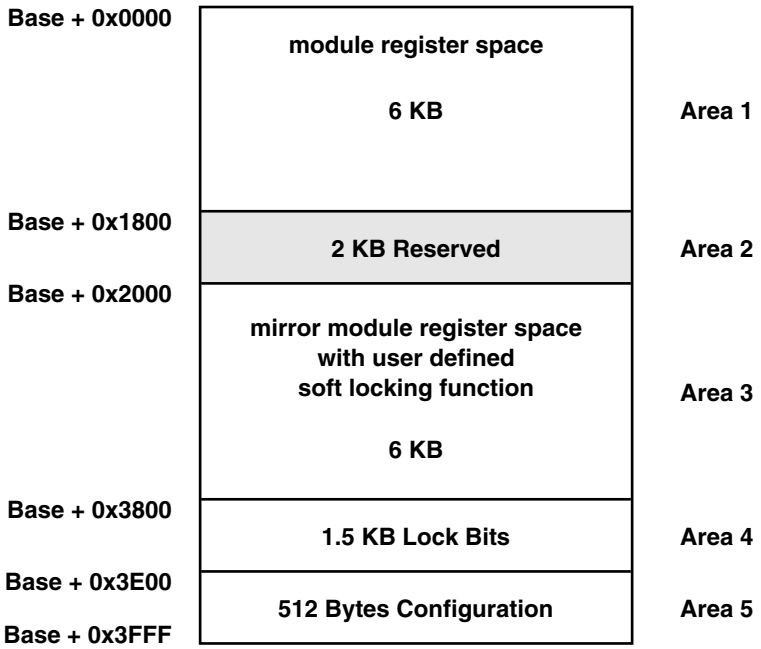

Figure 80-2. REG_PROT Memory Diagram

- Area 1 is 6 KB and holds the normal functional module registers and is transparent for all read/write operations.
- Area 2 is 2 KB starting at offset 0x1800 is a reserved area, which shall not be accessed.
- Area 3 is 6 KB, starting at offset 0x2000 and is a mirror of area 1. A read/write access to an offset 0x2000+X will read/write the register at offset X. However a write access to offset 0x2000+X will additionally set the optional Soft Lock Bits for this offset X in the same cycle as the register at offset X is written. This provides for an automatic write and lock operation. Not all registers in area 1 need to have protection defined by associated Soft Lock Bits. For unprotected registers at offset Y, accesses to offset 0x2000+Y will be identical to accesses at offset Y.
- Area 4 is 1.5 KB and holds the Soft Lock Bits, one bit per byte in area 1. The four Soft Lock Bits associated with one module register word are arranged at byte boundaries in the memory map. The Soft Lock Bit registers can be directly written using a bit mask.
- Area 5 is 512 bytes large and holds the configuration bits of the protection mode. There is one configuration hard lock bit per module that prevents all further modifications to the Soft Lock Bits and can only be cleared by a system reset once set. The other bits, if set, will allow user access to the protected module.

If any locked byte is accessed with a write transaction, a transfer error will be issued to the system and the write transaction will not be executed. This is true even if not all accessed bytes are locked.

Accessing unimplemented 32-bit registers in Areas 4 and 5 will result in a transfer error.

80.6.1 Memory map

Following is the memory map for a module which is protected via a REG_PROT module.

Table 80-13. Generic Protected Module Memory Map

Offset	Use
0x0000	Module Register 0 (MR0)
0x0001	Module Register 1 (MR1)
0x0002	Module Register 2 (MR2)
0x0003 - 0x17FF	Module Register 3 (MR3) - Module Register 6143(MR6143)
0x1800 - 0x1FFF	Reserved
0x2000	Module Register 0 (MR0) + Set Soft Lock Bit 0 (LMR0)
0x2001	Module Register 1 (MR1) + Set Soft Lock Bit 1 (LMR1)
0x2002 - 0x37FF	Module Register 2 (MR2) + Set Soft Lock Bit 2 (LMR2) - Module Register 6143 (MR6143) + Set Soft Lock Bit 6143 (LMR6143)
0x3800	Soft Lock Bit Register 0 (SLBR0): Soft Lock Bits 0-3
0x3801	Soft Lock Bit Register 1 (SLBR1): Soft Lock Bits 4-7
0x3802 - 0x3DFF	Soft Lock Bit Register 2 (SLBR2): Soft Lock Bits 8-11 -Soft Lock Bit Register 1535 (SLBR1535): Soft Lock Bits 6140-6143
0x3E00 - 0x3FFB	Reserved
0x3FFC	Global Configuration Register (GCR)

Note

Reserved registers in area #1 will be handled as specified in the protected module's documentation.

80.6.2 Register descriptions

This section describes in address order all the REG_PROT registers. Each description includes a standard register diagram with an associated figure number. Details of register bit and field function follow the register diagrams, in bit order.

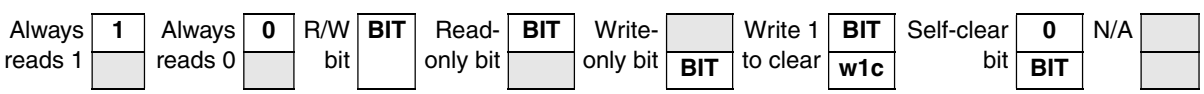

Figure 80-3. Register description

80.6.2.1 Module Registers (MR0-6143)

This is the lower 6 KB module memory space which holds all the functional registers of the module that is protected by the REG_PROT module.

80.6.2.2 Module register and set soft lock bit (LMR0-6143)

This is memory area #3 that provides mirrored access to the MR0-6143 registers with the side effect of setting Soft Lock Bits in case of a write access to a MR that is defined as protectable by the locking mechanism. Each MR is protectable by one associated bit in a SLBRn.SLBm, according to the mapping described in the Soft Lock Bit Register section.

80.7 Memory map and registers

REG_PROT memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
3800	Soft Lock Bit Register n (REG_PROT_SLBRn)	8	R/W	00h	80.7.1/3463
3FFC	Global Configuration Register (REG_PROT_GCR)	32	R/W	0000_0000h	80.7.2/3465

80.7.1 Soft Lock Bit Register *n* (REG_PROT_SLBRn)

The Soft Lock Bit Registers hold the Soft Lock Bits for the protected registers in memory area #1, which is the normal register address space of the protected module. Each SLB register has a four Soft Lock Bits (SLB0-SLB3), each of which controls write access to a byte in memory area #1. Each Soft Lock Bit also has a corresponding Write Enable bit in the same register that controls whether the Soft Lock Bit can be written. The following table shows the mapping between the Soft Lock Bits to the bytes in memory area #1.

Table 80-16. Soft Lock Bits vs. Protected Address

Soft Lock Bit	Protected address
SLBR0.SLB0	MR0
SLBR0.SLB1	MR1
SLBR0.SLB2	MR2
SLBR0.SLB3	MR3
SLBR1.SLB0	MR4
SLBR1.SLB1	MR5
SLBR1.SLB2	MR6

Table continues on the next page...

Table 80-16. Soft Lock Bits vs. Protected Address (continued)

Soft Lock Bit	Protected address
SLBR1.SLB3	MR7
SLBR2.SLB0	MR8
...	...

NOTE

- As many as 1536 Soft Lock Bit Registers (SLBRn) may be implemented, depending on the number of protected module register bytes.
- Access in User Mode is read-only; in Supervisor Mode access is read/write.

Address: 0h base + 3800h offset = 3800h

Bit	0	1	2	3	4	5	6	7
Read	0	0	0	0	SLB0	SLB1	SLB2	SLB3

REG_PROT_GCR field descriptions (continued)

Field	Description
	NOTE: Access in User Mode is read-only; in Supervisor Mode access is read/write. 1 All SLB bits are write protected and can not be modified. 0 All SLB bits are accessible and can be modified.
1–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8 UAA	User Access Allowed. 1 The registers in the module under protection can be accessed in the mode defined for the module registers without any additional restrictions. 0 The registers in the module under protection can only be written in supervisor mode. All write accesses in non-supervisor mode are not executed and a transfer error is issued. This access restriction is in addition to any access restrictions imposed by the protected IP module.
9–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

80.8 Functional description

The following sections describe the functional characteristics of the Register Protection module.

80.8.1 General

This module provides a generic register (address) write-protection mechanism. The protection size can be:

- 32-bit (address == multiples of 4)
- 16-bit (address == multiples of 2)
- 8-bit (address == multiples of 1)

Which addresses are protected and the protection size depends on the SoC and/or module.

For all addresses (peripheral registers) that are protected there are SLBRn.SLBm bits that specify whether the address is locked. When an address is locked it can only be read but not written in any mode (supervisor/normal). If an address is unprotected the corresponding SLBRn.SLBm bit is always 0b0 no matter what software is writing to.

80.8.2 Change lock settings

To change the setting whether an address is locked or unlocked the corresponding SLBRn.SLBm bit needs to be changed. This can be done using the following methods:

- Modify the SLBRn.SLBm directly by writing to area #4
- Set the SLBRn.SLBm bit(s) by writing to the mirror module space (area #3)

Both methods are explained in the following sections.

80.8.2.1 Change lock settings directly via Area #4

In memory area #4 the lock bits are located. They can be modified by writing to them. Each SLBRn.SLBm bit has a mask bit SLBRn.WEm which protects it from being modified. This masking makes clear-modify-write operations unnecessary.

The following figure shows two modification examples. In the left example there is a write access to the SLBRn register specifying a mask value which allows modification of all SLBRn.SLBm bits. The example on the right specifies a mask which only allows modification of the bits SLBRn.SLB[3:1].

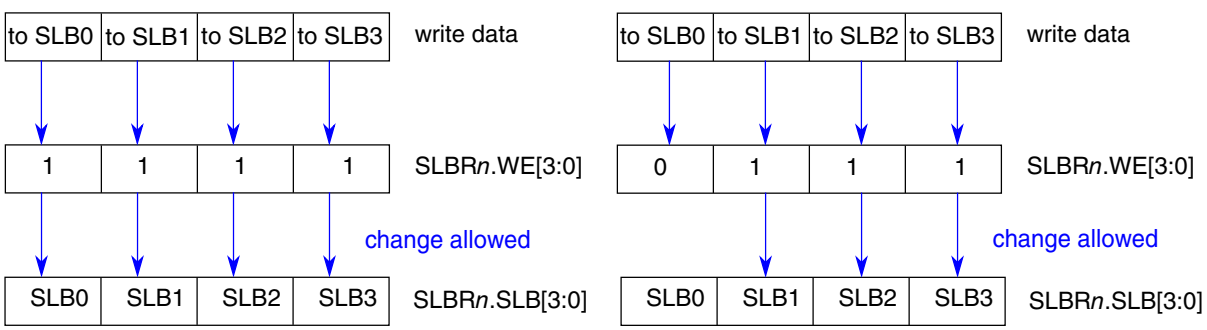

Figure 80-6. Change lock settings directly via Area #4

The previous figure shows four registers that can be protected 8-bit wise. The following figures show registers with 16- and 32-bit protection respectively:

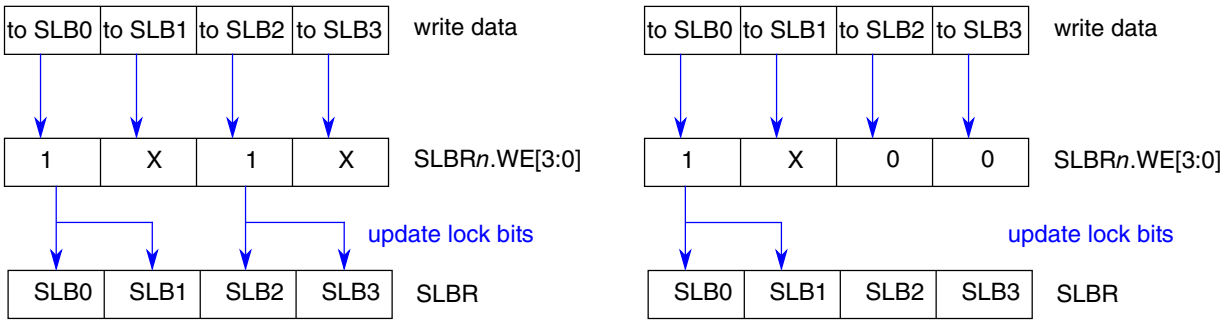

Figure 80-7. Change lock settings for 16-bit protected addresses

On the right side of the previous figure it is shown that the data written to SLBRn.SLB[0] is automatically written to SLBRn.SLB[1] also. This is done as the address reflected by SLBRn.SLB[0] is protected 16-bit wise. Note that in this case the write enable SLBRn.WE[0] must be set while SLBRn.WE[1] does not matter. As the enable bits SLBRn.WE[3:2] are cleared the lock bits SLBRn.SLB[3:2] remain unchanged.

In the example on the left side of the previous figure the data written to SLBRn.SLB[0] is mirrored to SLBRn.SLB[1] and the data written to SLBRn.SLB[2] is mirrored to SLBRn.SLB[3] as for both registers the write enables are set.

The next figure shows a 32-bit wise protected register. When SLBRn.WE[0] is set the data written to SLBRn.SLB[0] is automatically written to SLBRn.SLB[3:1] also. Otherwise SLBRn.SLB[3:0] remains unchanged.

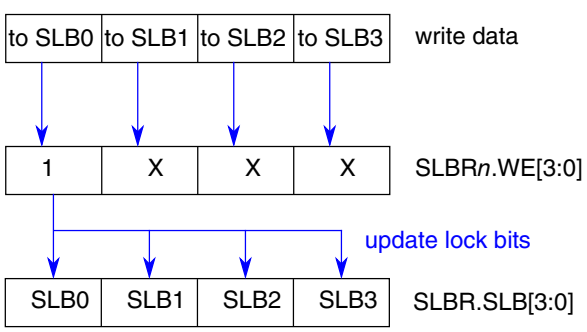

Figure 80-8. Change lock settings for 32-bit protected addresses

The following figure shows a mixed protection size configuration:

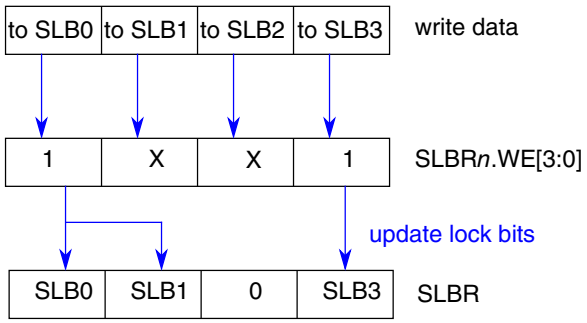

Figure 80-9. Change lock settings for mixed protection

The data written to SLBRn.SLB[0] is mirrored to SLBRn.SLB[1] as the corresponding register is 16-bit protected. The data written to SLBRn.SLB[2] is blocked as the corresponding register is unprotected. The data written to SLBRn.SLB[3] is written to SLBRn.SLB[3].

80.8.2.2 Enable locking via mirror module space (Area #3)

It is possible to enable locking for a register after writing to it. To do so the mirrored module address space must be used. For example:

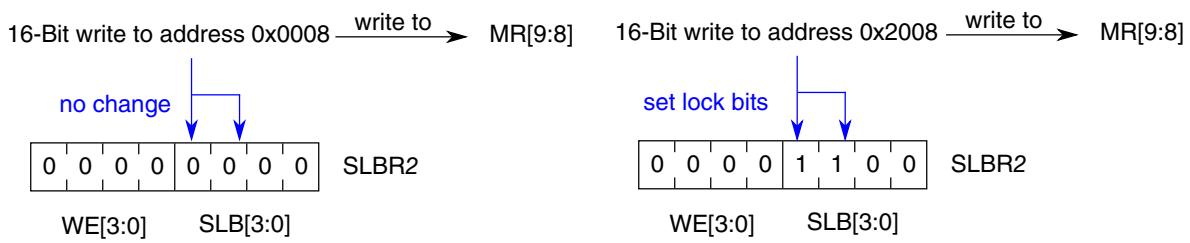

Figure 80-10. Enable Locking Via Mirror Module Space (Area #3)

When writing to address 0x0008 the registers MR9 and MR8 in the protected module are updated. The corresponding lock bits remain unchanged (see the left part of Figure 80-7).

When writing to address 0x2008 the registers MR9 and MR8 in the protected module are updated. The corresponding lock bits SLBR2.SLB[1:0] are set while the lock bits SLBR2.SLB[3:2] remain unchanged (right part of Figure 80-7).

The following figure shows an example where some addresses are protected and some are not:

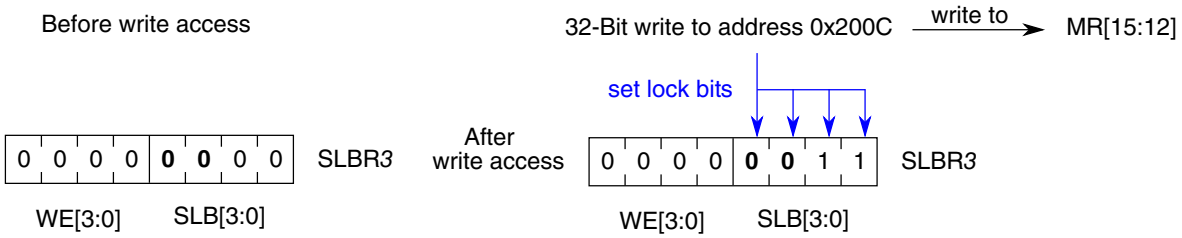

Figure 80-11. Enable locking for protected and unprotected addresses

In the previous figure addresses 0x0C and 0x0D are unprotected. Therefore their corresponding lock bits SLBR3.SLB[1:0] are always 0b0 (shown in bold). When doing a 32-bit write access to address 0x200C only lock bits SLBR3.SLB[3:2] are set while bits SLBR3.SLB[1:0] stay 0b0.

Note

Lock bits can only be set via writes to the mirror module space. Reads from the mirror module space will not change the lock bits.

80.8.2.3 Write protection for locking bits

Changing the locking bits through any of the procedures mentioned in Change lock settings directly via Area #4 and Enable locking via mirror module space (Area #3) is only possible as long as the bit GCR.HLB is cleared. Once this bit is set the locking bits can no longer be modified until there is a system reset.

80.8.3 Access errors

The protection module generates transfer errors under several circumstances. For the area definition refer to Figure 80-2

1. If accessing area #1 or area #3, the protection module will pass on any access error from the underlying Module under Protection.
2. If user mode is not allowed, user writes to all areas will assert a transfer error and the writes will be blocked.
3. If accessing the reserved area #2, a transfer error will be asserted.
4. If accessing unimplemented 32-bit registers in area #4 and area #5 a transfer error will be asserted.
5. If writing to a register in area #1 and area #3 with Soft Lock Bit set for any of the affected bytes a transfer error is asserted and the write will be blocked. Also the complete write operation to non-protected bytes in this word is ignored.

6. If writing to a Soft Lock Register in area #4 with the Hard Lock Bit being set a transfer error is asserted.
7. Any write operation in any access mode to area #3 while Hard Lock Bit GCR.HLB is set

Chapter 81
Security

81.1 Overview

The MCP574xR has a comprehensive set of customer-configurable security features designed to protect code and data from unauthorized access.

The security level for any MCP574xR microcontroller is dependent on a variety of factors, including configuration, level of maturity within the microcontroller's life cycle, and customer software design. This chapter gives an overview of available security features and how they interact.

81.1.1 Security Concepts

Table 81-1 shows the security concepts included in MCP574xR and their corresponding HW implementation. Most of these concepts are valid throughout the whole family. See Table 81-2 for a detailed description about what is available for each device of the MCP574xR.

Table 81-1. Security Concepts

Concepts	Description	HW Implementation
Secure system configuration	All the critical security-related data, which are transferred during the reset phase to their respective clients, are protected vs. manipulation	UTEST DCF Records parsed by SSCM See chapter Secure System Configuration
External access protection	Protection vs. access to the internal resources from an external tool	Debug access protection, Censorship, BAF Serial Boot See chapter External access protection
Flash memory protection	Protection vs. Flash memory access and modification	Censorship, PASS module, TDM module, Flash Sealing, See chapter Flash Memory Protection
End of life protection	Protection vs. the testing of the unit once it has been working in field	BAF execution See chapter End of Life Protection

81.1.2 Security Feature

Table 81-2. Security Features

Feature	MCP574xR
Device Life cycle	YES
BAF	YES
Censorship	YES
PASS Module	YES
TDM Module	YES
Flash Sealing	YES

81.2 Secure System Configuration

This section describes the secure system configurations.

81.2.1 Overview

The whole Security Architecture is based on a set of configuration data, which are permanently stored during both FSL Production and Customer Production/Development stages. The MCP574xR devices implements a set of security concepts aimed to guarantee:

- that the programmed data can not be modified (re-programmed)
- that the value of the data being read can not be altered
- that some secret data can not be read by the device CPUs

81.2.2 Security-related configuration

The security architecture and functionality is based on a set of information stored in the protected area of the Flash memory. Below is a list of security related content of the UTEST memory map:

- Device Life Cycle (UTest fixed locations)
- Passwords (UTest fixed locations)

- Censorship (DCF records)
- Block assignment versus TDM erase counter (DCF records)
- Sealing (UTest fixed locations)
- OTP assignment (UTest fixed locations)
- Block assignment versus PASS module password groups (DCF records)
- Security watchdog configuration (SW-DCF records)

Following sections explain how these data are protected versus reading and re-programming.

81.2.3 Device Configuration Format (DCF) records

Most device configuration data for MCP574xR microcontrollers is stored in a format referred to a DCF (Device Configuration Format) record. DCF is part of a mechanism developed to handle settings of device parameters via data stored in OTP Flash memory. Starting at a location in UTest flash memory block, the user stores a series of DCF records during configuration/test activities. The SSCM processes these records during the system reset sequence before the CPU leaves reset. See the DCF Records chapter for a detailed discussion of DCF records.

81.2.4 Security-related data protection

This section describes security-related data protection.

81.2.4.1 Permanent alteration (re-programming)

In order to avoid a malicious permanent alteration of the programmed security configuration data, the UTest and BAF Flash blocks are protected by a set of layers, as described into chapter Flash Memory Protection.

In addition, some of the DCF related to the security are qualified as "write-once", which means that even in case the same be programmed a second time, only the very first programmed value is considered to be valid. This prevents the possibility to alter some permanent DCF configuration.

81.2.4.2 Data alteration upon reading

In order to avoid a malicious alteration of value read from the programmed security configuration, the following protections are used:

- Data is read during the reset phase, when no CPU is enabled, and transferred directly to the intended system clients. This prevents any possibility to alter the data value through SW intervention
- The reading is done under the supervision of voltage, clock, and temperature monitors, which will trigger reset in case the operating conditions are manipulated. This prevents the possibility to corrupt the data being read, by altering the external operating conditions
- ECC engine is applied over the data being read and a reset will be triggered in case of 2 bit failure. This acts as an additional guardian, to prevent the system clients to use altered data
- In case the same DCF is found twice the DCF client may run some check on the read data, in order to allow or not a change of the data to be stored into the client. This acts as a further check to verify that the data being read is consistent.

81.2.4.3 Secret data read protection

In addition to the read and write protection described in the previous two sections, some of the security configuration data shall also be protected versus any type of reading done after the reset phase. Following data shall be protected:

- PASS Module passwords
- JTAG password
- Test Mode Disable Override Passcode

The MCP574xR implements two mechanism to guarantee the protection of those data vs. reading:

- the data is read by a dedicated peripheral under protected conditions, particularly

  - the passwords are read run-time by the peripheral in charge of running the password compare check, with a direct access to the Flash memory, i.e., without using the system data bus
- out the reset phase and depending on the Life Cycle value - see Table 1, the location where the data is stored is blocked versus any reading request coming from the system masters,

Furthermore, two additional mechanisms are available, aimed to protect the access to parts of the Flash memory in case any block of the Flash memory contains data intended to be secret. The mechanisms are:

- the Sealing - see End of Life Protection
- the PASS region read protection - see Block Read Protection

81.2.4.4 PASS Module passwords

The PASS module passwords are programmed by the customer in UTest Flash block locations, which are protected by the mechanism shown in Table 81-2.

81.2.4.5 JTAG password

The JTAG passwords is programmed by the customer in UTest Flash block locations, which are protected by the mechanism shown in Table 81-2. See Debug access protection.

81.3 External access protection

This section describes external access protection.

81.3.1 Overview

The MCP574xR includes several ports to access the device from the external, in order to guarantee the test and development. This chapter describes the concepts implemented in order to protect the external port access.

81.3.2 Debug access protection

This section describes the debug access protection.

81.3.2.1 JTAG TAP controller architecture

The device CPUs embeds a Nexus protocol engine, which makes it possible to control the CPU itself, to trace the read and write bus transactions, and to directly read and write the system memories. The Nexus protocol features are activated by the JTAG TAP controller hardware state machine, which evolves based on the signals forced at the JTAG interface. The JTAG interface is unique. On the other side, the system embeds multiple TAP controller state machines, each one dedicated to a specific resource (e.g. CPU). It is possible, via specific JTAG commands, to route the JTAG commands to each different TAP controllers in order to control the various system resources. The next sections show how the route to the various TAP controller is protected.

81.3.2.2 JTAG TAP controller protection scheme

The mechanism implemented to block the access to a TAP controller is keeping it under reset. As shown in Figure 81-1, when debug interfaces are enabled the JTAGC module is active, allowing access to the IDCODE register, censorship password register, and JDC registers. All other Auxiliary TAP/Nexus clients are held in reset.From security point of view, the system TAP controllers are grouped into:

- JTAG access to all the system TAP controllers (hereafter called Main TAP controller for sake of simplicity)

The external tool connection to the Main TAP controller is protected by a set of conditions:

- Censorship
- JTAG Password
- PASS Debug Lock

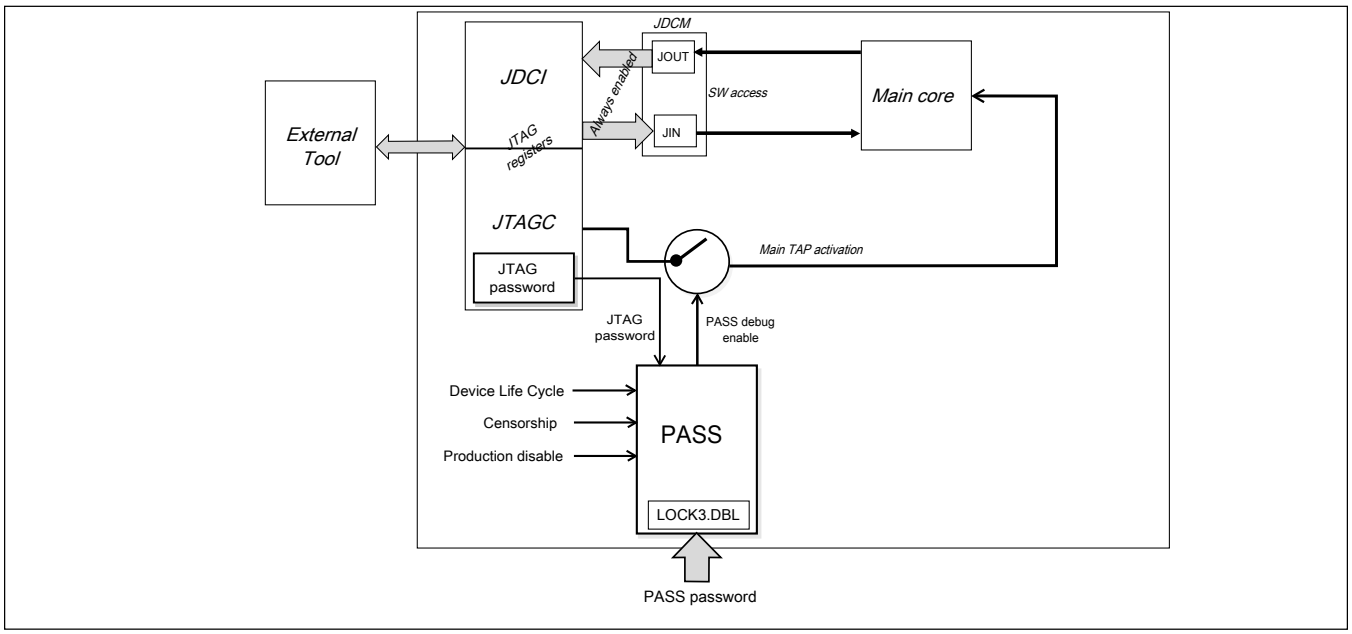

Figure 81-1. JTAG protection architecture

81.3.2.3 Debug protection truth tables

shows the truth tables that regulates the MainTAP Controller debug activation. The PASS module drives an output signal, which is used to enable the Debug TAP Controllers. The PASS Debug Enable output signal depends on the following inputs:

- Censorship
- Debug lock bit
- JTAG password

The censorship works in conjunction with the PASS DBL lock bit. The censorship information is a DCF record loaded during boot and has priority on temporary unprotection. In this way, the debugger can be configured as locked/unlocked multiple times as there are no restrictions on setting and clearing the censorship status in corresponding DCF, apart from the available space for DCF records. The DBL bit protection is used to lock or unlock the debug access once the censorship is activated. The DBL bit can be changed via software, but the writing of the bit can be conditioned by the PASS module password matching (see the PASS chapter for more information). The debug interface is disabled according to the censorship control word settings. The main debug interface can be temporarily re-enabled by the Main cores, following dedicated procedures or exchanging correct passwords.

The JTAG password is used to bypass the DBL bit status. The value sent via JTAG is compared with the password stored inside the Flash.

See Table 82-1.

81.3.2.4 External Tool Authentication protocol

An external tool may be required to authenticate itself with a Challenge/Response protocol before the Debug interface is enabled. This protocol can be implemented in software by any of the MCU CPU.

The Challenge/Response protocol requires that a communication channel between the external tool, requesting the access, and the internal device CPUs exist, independently from the debug interface enable status. For this purpose, a Debug/Host communication interface is implemented to allow Main CPUs to communicate with the external tool. Two 32-bit registers are provided in the Debug/Host communication interface, called JDC (JTAG Data Communication). These registers are always active and allow the requested communication between CPUs and external tool:

- JIN for Debug2HOST communication: writable by the external tool via JTAG and readable by the Main CPUs via software on peripheral bus (AIPS bus)
- JOUT for HOST2Debug communication: writable by Main CPUs via software on peripheral bus (AIPS bus) and readable by the external tool via JTAG

These two registers plus the associated control and status registers are implemented in a module called JDC. JIN register supports an interrupt generation when the debugger has written a data versus the main CPUs. JOUT register support a ready bit, set when the register is written via IPS bus and cleared when debugger reads the data.

An internal CPU can use these communication registers to implement a software authorization protocol, which can be simply a password comparison or a more complex challenge/response protocol.

81.3.3 JTAGM and Debug Over CAN

The MCP574xR embeds the JTAGM module, which makes it possible to inject JTAG commands via software or CAN messages. The JTAG control via CAN is automatically protected by the same mechanism described in chapter Debug access protection. As a results of this, in order to be able to control the TAP controller via CAN, the TAP controller shall be enabled.

81.3.4 Serial bootloader protection

The BAF code include a specific routine, called BAF bootloader (see the BAF chapter for more information), meant to upload data into the system RAM. This feature is intended to let the customer upload into the RAM some code, in order to be able to program the Flash content during their production and development phase. Usually, the BAF Bootloader is executed in case no valid application entry point is found (see the BAF chapter for more information). In order to meet the security requirements, the BAF Bootloader execution is conditioned by the Life Cycle: in case no valid application entry point is found, the BAF code reads the Life Cycle from a read-only register of the SSCM and triggers a destructive reset if the Life Cycle is In Field or OEM_PROD.

81.3.5 BAR execution protection

The BAR (Boot Assist ROM) is ROM-based code, mapped within the AIPS space, which is used during FSL production phase. The BAR code makes it possible to upload data into the system RAM by reading the data directly from a GPIO port. During FSL Production test, the boot CPU1 processor starts executing from the BAR code. After FSL Production test, the CPU1 always starts executing the BAF code. Nevertheless, after FSL Production test, it is still possible to accidentally or maliciously, jump to the BAR code. It is advisable to prevent execution of the BAR code.

The BAR ROM code hardware is designed to always generate an Illegal Peripheral Access Error when it is accessed. This is the same error that is caused by accessing a 'reserved' location in any peripheral. But by default this error is masked by a configuration bit in the SSCM. The Register bit is SSCM_ERROR[RAE]. If this bit is set to '1', any access to BAR code ROM, or any other peripheral reserved location, causes a Prefetch or Data Abort exception to the CPU. The SSCM_ERROR register can also be locked, using REG_PROT from any changes till the next reset.

It is recommended for safe and secure operation, that SSCM_ERROR[RAE] bit is set and the register is locked.

81.4 Flash Memory Protection

This section describes the flash memory protection.

81.4.1 Overview

The Flash memory protection consists of four main features:

- Protection to prevent Flash memory from being erased or programmed by unauthorized users; either malicious or accidental
- Protection to prevent Flash memory from being read by unauthorized users; mainly malicious
- Protection to ensure an authorized user has unimpeded access to programme and erase Flash memory
- Protection to prevent test features of the device from being used to maliciously change the contents of the Flash memory
- Protection for selected flash block from ever being erased; or to log any erase event

These features are described in the sections below.

81.4.2 Flash memory program and erase protection

This section describes flash memory program and erase protection.

81.4.2.1 Password Protection

The Flash memory is protected from Programme and Erase operations by 4 × 256 bit passwords. These passwords are programmed into fixed locations in UTEST flash while Life Cycle = Customer_Delivery. Once Life Cycle is advanced beyond Customer_Delivery, all read accesses to these passwords are blocked.

All the Flash memory blocks can optionally be assigned to one or more of the 4 passwords, by writing DCF Records to UTEST memory.

The passwords and assignment of flash blocks to the passwords is implemented in the PASS module. For full details, refer to the PASS module chapter.

81.4.2.2 One Time Programmable (OTP) Protection

The flash blocks can also be optionally assign as 'OTP'. A flash block assigned as OTP has two attributes

- the block can never be erased.
- a page (64 bits) in the block can only be programmed if it is already erased (0xFFFF_FFFF_FFFF_FFFF). Over programming an page already programmed is not possible

There are no backdoors or passwords to bypass these attributes in User mode; but Flash Test Mode can still erase the flash block - unless the flash block is 'sealed' For more details of flash sealing, refer to Flash Block Sealing.

Flash blocks are assigned as OTP by writing DCF Records to UTEST flash. For mode details of OTP assignment, refer to the Tamper Detect Module (TDM) chapter.

81.4.2.3 Erase Counter Protection

The flash blocks can also optionally be assigned to a mechanism that allows the logging of the number of times a flash block is erased.

This erase counter mechanism uses a log file to record each erase operation. The log file is called a 'Diary' and is maintained in flash memory that has been assigned as OTP. The user is responsible for writing to the diary. The hardware prevents erase operation until the diary has been written.

There are no backdoors or passwords to temporarily bypass the TDM diaries in User mode; but Flash Test Mode can still erase the flash block - unless the flash block is 'sealed'. For more details of flash sealing, refer to Flash Block Sealing.

The flash blocks can be assigned to a Diary using DCF Records written to UTEST flash. There are 6 completely independent Diaries. For mode detail, refer to Tamper Detect Module (TDM) chapter.

81.4.2.4 Flash Programme and Erase Implementation

The Flash memory contains a group of registers called LOCK0, LOCK1, LOCK2 & LOCK3. These registers contain a bit for each individual flash block. To programme or erase a flash block, the relevant bit in one of these registers must first be cleared. Each bit in these LOCKx registers is further qualified by 3 signals per bit from outside the flash. These signals are:

- plock - when asserted, prevents a block being programmed
- elock - when asserted, prevents a block being erased
- opplock - when asserted, prevents a block being over-programmed

These signals come from the PASS module and the TDM module as shown below. The logic is repeated for every bit in all four LOCKx registers

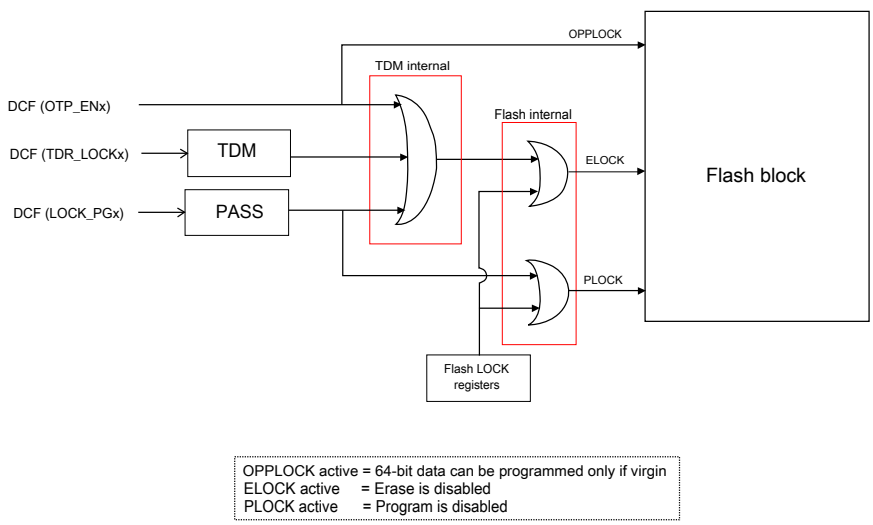

Figure 81-2. Flash Prog/Erase Protection Glue Logic Diagram

81.4.3 Block Read Protection

This section describes block read protection.

81.4.3.1 General Read Protection

The Flash blocks can optionally be configured to have all read accesses blocked in certain conditions.

There are two conditions that cause this flash block read protection:

- Lifecycle = OEM_Production or In_Field; Device is Censored; Debug Interface is Enabled.
- Life Cycle = FA; Device is censored.

The hardware monitors the enablement of the debug interface, and if Debug is enabled AND the device is Censored, the pflash controller is instructed to block read (and write) accesses from all bus masters, as configured by the PASS_LOCK3[RLx] bits.

See Table 82-2.

The purpose of this is to prevent unauthorized reading of the flash contents. The side affect of this is that if a debugger is 'Hot Attached' while the application is running, and debug is enabled, the application will probably crash because the CPUs can no longer fetch code from flash.

To prevent this crash from occurring, there are two options:

- Enable debug access while the device is held in reset. Then use the debugger to write to the PASS module LOCK3[RLx] bits to temporarily remove the read protection. Then release reset to allow the application to run
- Use one of the running CPUs to write to the PASS module LOCK3[RLx] to temporarily remove read protection before enabling debug access

The complete flash array address range is divided into the following read protection regions:

1. UTEST Flash
2. Main code flash (most of the flash)
3. Main EEPROM data

These regions can be configured independently through the PASS_LOCKn_PGm register of the PASS module.

81.4.4 Test Feature Protection

Flash Test mode is a mode of the flash memory that allows direct access to the internal operation of the flash memory read and write mechanism. Therefore flash test mode has the capability read and to disturb the data stored in the flash. As most of the security

features are either configured from flash memory or software stored in flash memory, the Flash Test mode is considered a security vulnerability. Following independent features are used to protect from Flash Test Mode attacks

- Flash block sealing is a feature that allows any flash block to be marked as 'sealed from flash test mode'. Flash sealing is described in the next section.

81.4.4.1 Flash Block Sealing

Sealing a block has no affect on normal user operation but it means that in Flash Test Mode, no test features can be used on the sealed block. Sealing is very good for preventing flash content from being read or changed in Flash Test mode, but it has the side-effect that no FA can be performed either. So care should be taken in selecting blocks to seal as this reduces the FA capability of the device.

81.4.4.1.1 Assigning Flash blocks as sealed

Within UTEST Flash are two regions called 'Test Mode Disable Block Select Group A' and 'Test Mode Disable Block Select Group B'. Each of these two regions contains 4 × 32 bit registers that contain a bit for each flash block. Flash blocks are assigned as seal by writing the relevant bit in either Group A or Group B. Note: UTEST is OTP. The smallest data size that can be written to UTEST is 8 bytes - 2 × 32bit registers. Therefore it is only possible to assign blocks in the same register pair as sealed, twice. Once for Group A and once for Group B.

81.4.4.1.2 Test Mode Override Password

The Flash block sealing mechanism also includes a password protected override called 'Test Mode Override Passcode.

This is a 32 bit password that the customer programmes into UTEST flash during module production.

If a device is returned to FSL for FA, this password can be used to unlock the sealing mechanism and allow full flash test capability on sealed blocks.

The Test Mode Override Passcode has 3 illegal values: 0x0000_0000, 0xFFFF_FFFF, 0x5555_5555. If the customer programmes the Test Mode Override Passcode in UTEST to any of these values, no sealing override is possible. Flash blocks marked as 'sealed' are permanently sealed with no override possible.

81.4.4.1.3 Sealing Truth Tables

The table below show the effect of sealing blocks.

Table 81-4. Flash Block Sealing

Block	Test Mode Disable Block Select	Flash Block Access through		
		Flash Test Mode Register Interface	Main/Alternate Register Interface	Read Bus
Test Flash	Don't care	Read and Write	No access	No access
UTest	Don't care	No access	Program operation is allowed only on nonprogrammed words. Erase is blocked. User test operations (e.g. Margin Read) are blocked	Read is allowed
BAF	Not sealed	Read and Write	Program operation is allowed only on nonprogrammed words. Erase is blocked. Program and user test operations are allowed	Read is allowed
	Sealed	No access		
Others	Not sealed	Read and Write	Program, erase, and user test operations are allowed	Read is allowed
	Sealed	No access		

81.4.5 Flash overlay mechanism restrictions

Load and Instruction-fetch accesses from any bus master to flash, can be configurably diverted to overlay RAM or system RAM.

The flash is memory mapped twice: one memory map allows overlay remap; the other doesn't.

No overlay memory region: 0x00000000 - 0x07FFFFFF

Mirrored region, that allows overlay remap: 0x08000000 - 0x0BFFFFFF

Remappable flash blocks are mapped in both memory map regions at the same address, with only different offset: 0x0800000 offset has to be applied to access flash blocks in mirrored overlay region.

OTP blocks should be used in the no-remap region.

If code is to be executed, it should be in the no-remap region.

Caches and RAMs can not be remapped anyway because the access is not through the flash controller.

81.5 End of Life Protection

This section describes End of Life protection.

81.5.1 Overview

After the module has been in the field for some time, it is possible that a defect may occur and the module is returned to the customer for further debugging and analysis. The MCP574xR includes several mechanisms that make this possible, but at the condition (under customer's choice) that the device will not be working any more in the customer application. The following sections describes each of these mechanisms.

81.5.2 BAF code in Failure Analysis

The BAF code checks at the very beginning the Life Cycle value and, in case it is acknowledged as Failure Analysis, terminates the BAF execution in an endless loop.

81.5.3 Protection of Flash Test Mode activation

Flash Test mode provides access to the hardware that controls the reading and writing of the individual flash bit cells and includes several modes for measuring and stressing the flash bit cells. For highly secure applications, this makes Flash Test Mode a security vulnerability and merits special features to protect it.

Flash Test mode is required during initial manufacture and testing of the device (Lifecycle < Customer_Delivery) and also during Failure Analysis of the device (Lifecycle = Failure_Analysis).

When Lifecycle = FSL_Production, the test mode is always available.

Chapter 82
Password and Device Security Module (PASS)

82.1 Password and Device Security Module (PASS) chip-specific module information

The PASS module is used to implement password-based read and write protection for flash blocks. Up to four levels of password protection can be implemented for each flash block.

NOTE

The registers discussed in this section are initialized via DCF records, so the reset values depend on user settings.

Each password group defined in the DCF records has a set of four LOCK*n* registers association with it—PASS_LOCK*n*_PG*n*. The bits of these registers are associated with specific flash blocks. The mapping is shown in the attached Flash Block Assignment spreadsheet.

NOTE

Password Challenge passwords and JTAG passwords that are all 0's or all 1's are invalid.

The following table shows the the Debug Interface Access scenarios on this chip.

Table 82-1. Debug Interface Enable Truth Table

Input Conditions					Outcome
Lifecycle	**Production Disable mode**	**DCF Censorship**	**Debug Enable (LOCK3[DBL] bit)**	**JTAG Password**	**Debug Interface Enable**
Customer Delivery	Don't Care	Don't Care	Don't Care	Don't Care	Enabled
OEM Production	Don't Care	Not censored	Don't Care	Don't Care	Enabled
		Censored	Unlocked (DBL=0)	Don't Care	Enabled
			Locked (DBL=1)	Matched	Enabled
				Not Matched	Blocked

Table continues on the next page...

Table 82-1. Debug Interface Enable Truth Table (continued)

Input Conditions					Outcome
Lifecycle	**Production Disable mode**	**DCF Censorship**	**Debug Enable (LOCK3[DBL] bit)**	**JTAG Password**	**Debug Interface Enable**
In Field	Off	Not censored	Don't Care	Don't Care	Enabled
		Censored	Unlocked (DBL=0)	Don't Care	Enabled
			Locked (DBL=1)	Matched	Enabled
				Not Matched	Blocked
	On	Don't Care	Don't Care	Don't Care	Blocked

82.2 Introduction

82.2.1 Overview

The Password and device security (PASS) module shown in the following figure, receives password challenges and determines their validity. It also maintains the device security and access states.

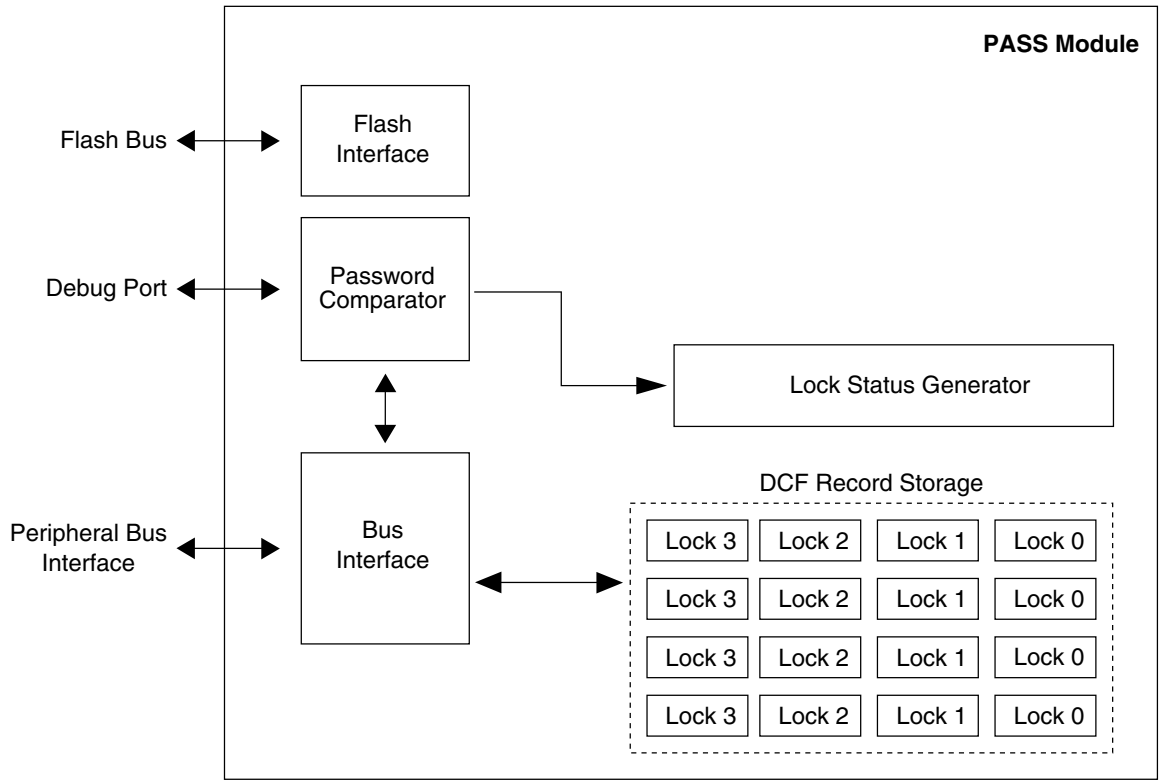

Figure 82-1. PASS module block diagram

82.2.2 Features

The PASS includes these distinctive features:

- Life Cycle status
- Password comparison
- JTAG password comparison
- Production Disable control
- Flash read, write, and erase control

82.2.3 Modes of operation

The PASS operates identically in all system modes.

82.3 External signal description

The PASS has 1 external pin that is used for Production Disable control.

82.4 Memory map and register definition

This section provides a detailed description of all memory-mapped registers and DCF clients in the PASS.

Where a DCF client is listed, the reset value of that register may automatically be pre-loaded during reset based on the data stored in DCF Records in flash UTEST region.

The following table shows the memory map for the PASS. Note that all addresses are offsets; the absolute address for registers may be calculated by adding the specified offset to the base address of the PASS. The address of the DCF client is local to the PASS module and must be qualified with the appropriate Client Select (CS[14:0]) for the PASS module, as defined in the DCF Record Section of the Reference Manual.

NOTE

Non-implemented registers generate bus aborts if enabled.

The following registers are available in the PASS. The shaded bits are reserved for future use. For future compatibility, only write ‘0’ to these bits; they always read ‘0’.

PASS memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	Life Cycle Status Register (PASS_LCSTAT)	32	R	See section	82.4.1/3494
8	Challenge Selector Register (PASS_CHSEL)	32	R/W	0000_0000h	82.4.2/3495
10	Challenge Status Register (PASS_CSTAT)	32	R	0000_0000h	82.4.3/3495
20	Challenge Input Register (PASS_CIN0)	32	W (always reads 0)	0000_0000h	82.4.4/3496
24	Challenge Input Register (PASS_CIN1)	32	W (always reads 0)	0000_0000h	82.4.4/3496
28	Challenge Input Register (PASS_CIN2)	32	W (always reads 0)	0000_0000h	82.4.4/3496
2C	Challenge Input Register (PASS_CIN3)	32	W (always reads 0)	0000_0000h	82.4.4/3496
30	Challenge Input Register (PASS_CIN4)	32	W (always reads 0)	0000_0000h	82.4.4/3496

Table continues on the next page...

PASS memory map (continued)

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
34	Challenge Input Register (PASS_CIN5)	32	W (always reads 0)	0000_0000h	82.4.4/3496
38	Challenge Input Register (PASS_CIN6)	32	W (always reads 0)	0000_0000h	82.4.4/3496

138	Password Group n - Lock 2 Status Register (PASS_LOCK2_PG3)	32	R/W	See section	82.4.7/3499
13C	Password Group n - Lock 3 Status Register (PASS_LOCK3_PG3)	32	R/W	See section	82.4.8/3501

82.4.1 Life Cycle Status Register (PASS_LCSTAT)

The Life Cycle Status Register reflects the production status and DCF Censorship client status of the device. It is possible to mature the device (move the device life cycle forward), but never to revert the life cycle to an earlier state.

The reset value of the LCSTAT register LIFE field derives from an external life cycle management module (like SSCM). It is a 3-bit life cycle. This register simply displays the life cycle input from external blocks.

Address: 0h base + 0h offset = 0h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	CNS	JUN	1	0												
W																
Reset	*	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0													LIFE		
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1

* Notes:
- CNS field: Reset value depends on the Censorship DCF client

PASS_LCSTAT field descriptions

Field	Description
0 CNS	This field indicates whether the DCF Censorship client has been written with a DCF record to 0x55AA or if the DCF Censorship client contains any other value than 0x55AA. The bit can be set (or cleared) via DCF Record in UTest Flash. **NOTE:** If no DCF record has been written to affect the value of the CNS bit, its reset value will be 1. 1 DCF Censorship Client value is anything other than 0x55AA. 0 DCF Censorship client value is 0x55AA.
1 JUN	This field indicates whether the device has been temporarily uncensored. Successful transmission of the JTAG password sets this bit to '1', otherwise it will be 0. (In life cycle FA, the JUN bit will always be 0.) Unsuccessful transmission clears this bit.
2 Reserved	This field is reserved. This read-only field is reserved and always has the value 1.
3–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29–31 LIFE	The life cycle setting is manipulated externally (SSCM). Pass displays a 3-bit input life cycle 000 Failure Analysis 001 Reserved

82.4.2 Challenge Selector Register (PASS_CHSEL)

This register determines which password group is challenged via the Challenge Input Register.

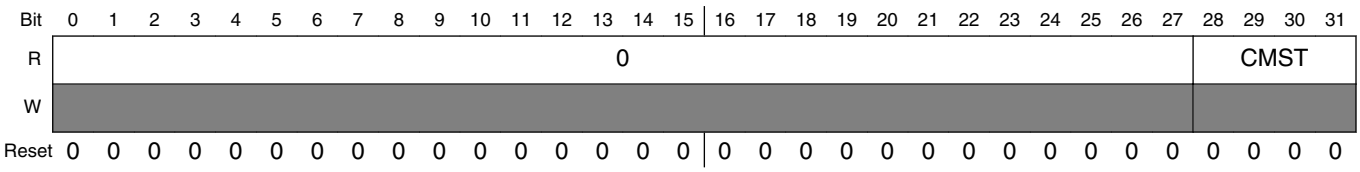
When the Master Only (MO) bit of the PASS_LOCK3_PGn register is set, only the master that unlocked access to the passgroup settings will be able to access these registers. The CMST field of the Challenge Status Register will reflect the locking master. When the Master Only (MO) bit of the PASS_LOCK3_PGn register is not set, the passgroup settings can be accessed by any master.

When a master writes this register, its ID sets the CMST field of the Challenge Status register.

Address: 0h base + 8h offset = 8h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0																														GRP	
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PASS_CHSEL field descriptions



Field	Description
0–29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30–31 GRP	Password Group to unlock 00 Password Group 0 01 Password Group 1 10 Password Group 2 11 Password Group 3

82.4.3 Challenge Status Register (PASS_CSTAT)

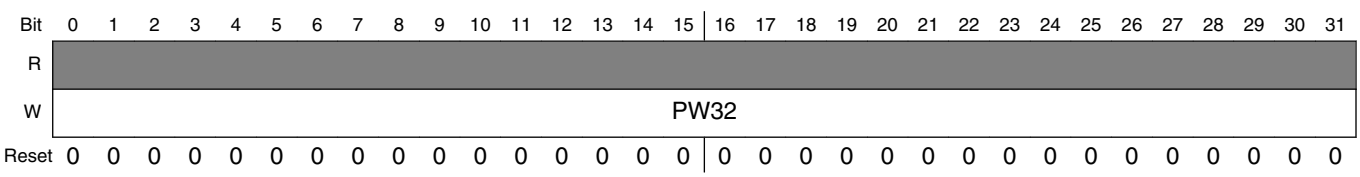
This register provides status information for the password challenge.

Only the master shown in this register can access the CINn registers - access by other masters result in a comparison fail regardless of the values written.

Address: 0h base + 10h offset = 10h

PASS_CSTAT field descriptions

Field	Description
0–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28–31 CMST	ID of the master which has last written the CHSEL register



82.4.4 Challenge Input Register (PASS_CIN*n*)

This register is used to provide the Challenge word *n* for a password group as selected by the Challenge Selector Register.

After programming the Challenge Selector Register, the password challenge needs to be written with eight 32-bit writes from CIN0 to CIN7 in that order. The most significant 32 bits of the password challenge must be written to CIN0. Once CIN7 is written, the password is compared. The write access only completes after the comparison has been executed. In case of a successful password comparison, the PASS module stores the ID of the master which has written CIN0 to CIN7 in the PASS_LOCK3_PGn register of the selected password group, as well as clears the PGL bit of that register.

All accesses to these registers need to be made by the bus master that wrote the CHSEL register previously. If another master writes any of the CIN registers before the original master has written CIN7, the comparison fails.

Address: 0h base + 20h offset + (4d × i), where i=0d to 7d

PASS_CIN*n* field descriptions

Field	Description
0–31 PW32	32 bits of the 256-bit password challenge. Only 32-bit writes may be used.

82.4.5 Password Group *n* - Lock 0 Status Register (PASS_LOCK0_PG*n*)

Each Password Group has one Lock 0 Status register. This register shows the current lock state for the Flash blocks. Each time a password group is unlocked the register becomes writable. For additional details of the LOCK bits, refer to the Flash memory description.

The LOCK bits do not come into effect before the life cycle has matured to *OEM Production* or older.

LOCK0_PG*n* register functions are as shown in this section.

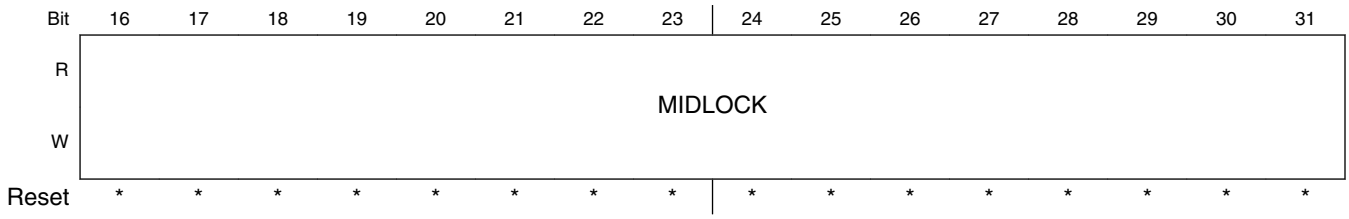
NOTE

Lock registers can only be accessed with 32-bit operations.

The initial value of the lock bits is set via DCF records stored in UTEST Flash block and copied over during functional reset. The default value before any DCF record is written is '1', indicating that a block is locked.

During the Customer Delivery life cycle, the user must program a valid password or a DCF record that writes to this register to unprotect the UTEST for each password group in order to prevent permanent and irreversible locking of Flash blocks.

Warning



Failure to program valid passwords or DCF records for all password groups before the life cycle matures to OEM Production renders the part unusable.

Once a password group is unlocked, software can set or clear any of the lock bits in the group, by writing to the registers.

The resulting lock status of a Flash block is determined by the combination of the lock bits of all password groups. If a block is locked in multiple groups, then all lock bits for the block need to be cleared before program and erase is possible. However, unless the life cycle is OEM Production or older, the Flash blocks are always unlocked, regardless of the values in the password groups.

Address: 0h base + 100h offset + (16d × i), where i=0d to 3d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	TSLOCK	ATSL	LOWLOCK													
W																
Reset	*	*	*	*	*	*	*	*	*	*	*	*	*	*	*	*

* Notes:
- MIDLOCK field: For each implemented bit of this field, if no DCF records have been written to change the lock state, the bit will reset to ‘1’.
- LOWLOCK field: For each implemented bit of this field, if no DCF records have been written to change the lock state, the bit will reset to ‘1’.
- ATSL field: If no DCF records have been written to change the ATSL bit state, the bit will reset to ‘1’.
- TSLOCK field: If no DCF records have been written to change the TS bit state, the bit will reset to ‘1’.

PASS_LOCK0_PG*n* field descriptions

Field	Description
0 TSLOCK	UTest NVM Lock. This bit is used to lock the UTest NVM block from programs (erase protection not needed since UTest NVM is OTP and not erasable).
1 ATSL	Alternate Interface UTest NVM Lock. This bit is used to lock the UTest NVM block from programs on the alternate interface (erase protection not needed since UTest NVM is OTP and not erasable).
2–15 LOWLOCK	Low Block Lock. A value of 1 in a bit of the lock register signifies that the corresponding block is locked for program and erase.
16–31 MIDLOCK	Mid Block Lock. A value of 1 in a bit of the lock register signifies that the corresponding block is locked for program and erase.

82.4.6 Password Group *n* - Lock 1 Status Register (PASS_LOCK1_PG*n*)

Each Password Group has one Lock 1 Status Register. This register shows the current lock state for the Flash blocks. Each time a password group is unlocked, the register becomes writable . For additional details of the LOCK bits, refer to the Flash description.

The LOCK bits do not come into effect before the life cycle matures to OEM Production or older.

LOCK1_PG*n* register functions are as shown in this section.

NOTE

Lock registers can only be accessed with 32-bit operations.

The initial value of the lock bits is set via DCF records stored in UTEST Flash block and copied over during functional reset . The default value before any DCF record is written is '1', which indicates a block is locked. If no DCF records have been written to change the lock state, the bits will reset to '1'.

During the Customer Delivery life cycle, the user must program a valid password or a DCF record that writes this register to unprotect the UTEST for each password group to prevent permanent and irreversible locking of Flash blocks.

CAUTION

Failure to program valid passwords or DCF records for all password groups before the life cycle matures to OEM Production renders the part unusable. However, additional DCF Records can be written to UTEST to change the initial value of this register.

Once a password group is unlocked, software can set or clear any of the lock bits in the group by writing to the registers.

The resulting lock status of a Flash block is determined by the combination of the lock bits of all password groups. If a block is locked in multiple groups, then all lock bits for the block need to be cleared before program and erase is possible. However, unless the life cycle is older than OEM Production, the Flash blocks are always unlocked, regardless of the values in the password groups.

Address: 0h base + 104h offset + (16d × i), where i=0d to 3d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

* Notes:

- HIGHLOCK field: For each implemented bit of this field, if no DCF records have been written to change the lock state, the bit will reset to ‘1’.

PASS_LOCK1_PG*n* field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 HIGHLOCK	High Block Lock. A value of 1 in a bit of the lock register signifies that the corresponding block is locked for program and erase.

82.4.7 Password Group *n* - Lock 2 Status Register (PASS_LOCK2_PG*n*)

Each Password Group has one Lock 2 Status Register. This register shows the current lock state for the Flash blocks. Each time a password group is unlocked, the register becomes writable . For additional details of the LOCK bits, refer to the Flash description.

The LOCK bits do not come into effect before the life cycle is matured to OEM Production or older.

NOTE

Lock registers can only be accessed with 32-bit operations.

LOCK2_PG*n* register functions are as shown in this section.

The initial value of the lock bits is set via DCF records stored in UTEST Flash block and copied over during functional reset. The default value before any DCF record is written is '1', which indicates a block is locked.

During the Customer Delivery life cycle, the user must program a valid password or a DCF record that writes this register to unprotect the UTEST for each password group in order to prevent permanent and irreversible locking of Flash blocks.

Warning

Failure to program valid passwords or DCF records for all password groups before the life cycle matures to OEM Production renders the part unusable. However, additional DCF Records can be written to UTEST to change the initial value of this register.

Once a password group is unlocked, software can set or clear any of the lock bits in the group, by writing to the registers.

The resulting lock status of a Flash block is determined by the combination of the lock bits of all password groups. If a block is locked in multiple groups, then all lock bits for the block need to be cleared before program and erase is possible. However, unless the life cycle is older than OEM Production, the Flash blocks are always unlocked, regardless of the values in the password groups.

Address: 0h base + 108h offset + (16d × i), where i=0d to 3d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

Reset	*	*	*	*	*	*	*	*	*	*	*	*	*	*	*	*	*	*	*	*	*	*	*	*	*	*	*	*	*	*	*	*

* Notes:

- L_256LCK field: For each implemented bit of this field, if no DCF records have been written to change the lock state, the bit resets to '1'.

PASS_LOCK2_PG*n* field descriptions

Field	Description
0–31 L_256LCK	Lower 256KByte Block Lock. A value of 1 in a bit of the lock register signifies that the corresponding block is locked for program and erase.

82.4.8 Password Group *n* - Lock 3 Status Register (PASS_LOCK3_PG*n*)

Each Password Group has one Lock 3 Status Register. This register shows the current lock state for the Flash blocks. Each time a password group is unlocked, the register becomes writable.

The LOCK bits do not come into effect before the life cycle matures to OEM Production or older.

LOCK3_PGn register functions are as shown in this section.

NOTE

Lock registers can only be accessed with 32-bit operations.

The initial value of the lock bits is set via DCF records stored in UTEST Flash block and copied over during functional reset. The default value before any DCF record is written is '1', which indicates a block is locked.

During the Customer Delivery life cycle, the user must program a valid password or a DCF record that writes this register to unprotect the UTEST for each password group in order to prevent permanent and irreversible locking of Flash blocks.

Warning

Failure to program valid passwords or DCF records for all password groups before the life cycle matures to OEM Production renders the part unusable. However, additional DCF Records can be written to UTEST to change the initial value of this register.

Once a password group is unlocked, software can set or clear any of the lock bits in the group, by writing to the registers.

The resulting lock status of a Flash block is determined by the combination of the lock bits of all password groups. If a block is locked in multiple groups, then all lock bits for the block need to be cleared before program and erase is possible. However, unless the life cycle is older than OEM Production, the Flash blocks are always unlocked, regardless of the values in the password groups.

Once a censored device enters the Failure Analysis life cycle, read protection is active regardless whether the system is in debug mode or not. It is still possible to unlock Flash regions with the correct passwords, however. Flash Utest region controlled by LOCK3[0] is read unlocked in Failure Analysis life cycle.

NOTE

Do not toggle DBL and RLx bits with the same write command. Use one instruction to program the DBL bit and a separate instruction to toggle the RLx bits.

Address: 0h base + 10Ch offset + (16d × i), where i=0d to 3d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

* Notes:

- U_256LCK field: For each implemented bit of this field, if no DCF records have been written to change the lock state, the bit will reset to '1'.
- RL0 field: If no DCF records have been written to change the RL0 bit lock state, the bit will reset to a logic 1. This Flash block region is always readable if the life cycle is Customer Delivery or earlier. To determine if this region is readable for Life Cycle states later than Customer Delivery, consult the Flash Memory Read Protection Truth Table.
- RL1 field: If no DCF records have been written to change the RL1 bit lock state, the bit will reset to a logic 1. This Flash block region is always readable if the life cycle is Customer Delivery or earlier. To determine if this region is readable for Life Cycle states later than Customer Delivery, consult the Flash Memory Read Protection Truth Table.
- RL2 field: If no DCF records have been written to change the RL2 bit lock state, the bit will reset to a logic 1. This Flash block region is always readable if the life cycle is Customer Delivery or earlier. To determine if this region is readable for Life Cycle states later than Customer Delivery, consult the Flash Memory Read Protection Truth Table.
- MO field: If no DCF records have been written to change the MO bit lock state, the bit will reset to ‘1’.
- DBL field: If no DCF records have been written to change the DBL bit lock state, the bit will reset to ‘1’.
- PGL field: Reset value depends on life cycle. If life cycle is Customer Delivery or earlier, the value will be 0, otherwise 1.

PASS_LOCK3_PG*n* field descriptions

Field	Description
0 PGL	Password Group Lock. This bit may be set in software to lock the password group, when the device is older than Customer Delivery. Before that the value of the bit is always 0. This bit is only updatable from SW path. It cannot be updated from DCF load from Flash. This bit would be automatically locked once Flash Scanning is finished after functional reset. This bit can be cleared by writing a valid password to the Password Challenge Input Registers. 0 Password group registers are unlocked. All four registers in the Password group may be read and written without restriction. 1 Password group registers are locked. Writes to the password group registers have no effect. Read accesses work normally. (If life cycle is Customer Delivery or earlier, this bit has no effect and the registers are always unlocked.)

Table continues on the next page...

PASS_LOCK3_PG*n* field descriptions (continued)

Field	Description
1 DBL	Debug Interface Lock. The default value of this bit would be '1' if not updated from flash. At power on, this bit would be updated from DCF records in flash. This bit cannot be updated from FLASH after first functional reset. After first functional reset, it can only be updated by writing to it once the passgroup has been unlocked via the PASS Password challenge mechanism. 0 Debug interface is unlocked. Accessed to all JTAG clients is allowed 1 Debug interface is locked. Only access to JTAG password challenge register is possible. Access to all other JTAG clients is blocked
2 MO	Master Only. 0 All masters can modify the passgroup settings if PGL is cleared 1 Only the Master which unlocked the passgroup can change the passgroup settings
3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4–7 MSTR	Master Access. Only the Master with this matching master ID can change the passgroup settings. This field is loaded with the ID of the master which unlocked the passgroup once the correct password is provided.
8–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11 Reserved	This field is reserved. This read-only field is reserved and always has the value 1.
12 Reserved	This field is reserved. This read-only field is reserved and always has the value 1.
13 RL2	Region 2 is protected. The default value of this bit would be '1' if not updated from flash. At power on, this bit would be updated from records loaded in flash. This bit cannot be updated from FLASH after first functional reset. After first functional reset, It can only be updated by Test Access Port or Through PASS Password challange mechanism. 0 Region 2 is not protected. 1 Region 2 is protected.
14 RL1	Region 1 is protected. The default value of this bit would be '1' if not updated from flash. At power on, this bit would be updated from records loaded in flash. This bit cannot be updated from FLASH after first functional reset. After first functional reset, It can only be updated by Test Access Port or Through PASS Password challange mechanism. 0 Region 1 is not protected. 1 Region 1 is protected.
15 RL0	Region 0 is protected. The default value of this bit would be '1' if not updated from flash. At power on, this bit would be updated from records loaded in flash. This bit cannot be updated from FLASH after first functional reset. After first functional reset, It can only be updated by Test Access Port or Through PASS Password challange mechanism. 0 Region 0 is not protected. 1 Region 0 is protected.

Table continues on the next page...

PASS_LOCK3_PG*n* field descriptions (continued)

Field	Description
16–31 U_256LCK	Upper 256 KB Block Lock. A value of 1 in a bit of the lock register signifies that the corresponding block is locked for program and erase.

82.5 DCF clients

The following table shows the DCF clients for the PASS.

Where a DCF client is listed, the reset value of that register may automatically be pre-loaded during reset based on the data stored in DCF Records in Flash UTEST region.

The address of the DCF client is local to the PASS module and must be qualified with the appropriate Client Select (CS[14:0]) for the PASS module, as defined in the DCF Record Section of the Reference Manual or in DCF sheet attached to this document.

Table 82-36. PASS DCF clients

Offset	Register	Access	Reset Value	DCF Client Address (ADDR[14:0])	Section
Censorship

82.5.1 Censorship

Censorship is a DCF client that is *not* accessible by software. It is automatically pre-loaded during reset with data stored in DCF Record format in the Flash UTEST region.

Field	Description
16:31	Censorship If this value is 0x55AA the MCU is NOT censored If this value is anything other than 0x55AA, the MCU is censored

82.5.2 Production Disable

Production Disable is a DCF client that is not accessible by software. It is automatically pre-loaded during reset with data stored in DCF Record format in the Flash UTEST region. The Production disable DCF client defines the Debug Disable aspects of the Production Disable feature.

The DCF client implements 1 bit with a default value of ‘0’. The DCF client can only be written once and writes from subsequent DCF records are ignored.

For more information on Production disable, see Production disable

DCF Client Address: 0x00C0 Production Disable — Access: DCF Record Write Once Only

Figure 82-34. Production Disable DCF client

Table 82-37. Production Disable DCF Client field descriptions

Field	Description
0-30	This bit is reserved and always has the value 0.
31 DD	Debug disable. '0' = Debug Interface is Enabled and Disabled using Censorship, JTAG password and PASS_LOCK3[DBL] bit (see chip-specific PASS information). '1' = Debug Interface is disabled

82.5.2.1 Debug Disable (DD)

Debug Disable is an optional feature that, once the life cycle is In Field or beyond, overrides all other debug controls and disables the debug interface. The Debug Disable feature has a higher priority than Censorship, JTAG password and the PASS LOCK3[DBL] bit.

82.6 Functional description

The primary purpose of the PASS is to provide fine-grained access control to the Flash and debugger interface. It utilizes the DCF mechanism, as described in the SSCM section.

82.6.1 Censorship

Censorship is the overall control that enables and disables two independent security features: Debug Interface access and flash memory read protection.

The Debug Interface access is controlled by the CNS and LIFE bits of the LCSTAT register according to the Debug Interface Access truth table. The flash memory read protection is also controlled by the CNS and LIFE bits of the LCSTAT register according to the Flash memory read protection truth table.

The CNS bit is set or cleared by executing a DCF record that writes to the Censorship DCF client (See Censorship). The LIFE bits of the LCSTAT register are controlled by the SSCM using user programmed values from specific locations in the UTEST flash.

82.6.2 Debug Interface Access

The debug interface is fully enabled in Customer Delivery life cycle. But from OEM Production life cycle, it can be blocked using censorship and unlocked by either entering a 256 bits password via JTAG or by software clearing the DBL bit the PASS_LOCK3 registers (See Password Group *n* - Lock 3 Status Register (PASS_LOCK3_PG*n*)). Both these debug enabling options are further conditioned by life cycle and Production Disable.

The debug interface enable truth table for this chip is shown in the device specific PASS section of this chapter.

82.6.2.1 JTAG Password Challenge

To enable the Debug Interface Access, the JTAG password challenge register in the JTAGC, needs to be written by an external tool. If that password matches the JTAG password stored in UTEST flash, Debug Interface Access is enabled until the next destructive reset.

82.6.3 Flash Memory Read Protection

Flash Memory Read Protection is a security feature that can selectively make regions of the flash memory unreadable. Any attempt to read a region of flash that is read protected results in the read access terminating with a transfer error. This is consistent for all bus masters including debug bus masters.

The assertion of flash memory region read protection is controlled by Life Cycle, Censorship and whether the Debug Interface access is enabled or blocked. The Flash memory read protection truth table describes the combination of conditions that drive Flash Memory Read Protection.

The intention of the feature is to protect the contents of the flash from being read. The flash memory is readable in normal operation, allowing the application to run, but becomes read protected when a Debug tool is attached and enabled (JTAG password or LOCK3[DBL] bit).

The flash memory is also read protected when the life cycle status is Failure Analysis. This life cycle is used for a module field failure, where the device is returned for failure analysis. This protection prevents the contents of the flash memory from being read.

The flash memory is divided into a number of Regions (3 to 5 depending on the device). The assignment of the regions is defined in the device reference manual.

The memory read protection truth table for this chip is shown in the device specific PASS information.

82.6.4 Production Disable

82.6.4.1 Overview and rationale

Production Disable is an optional feature that, once enabled, allows the MCU to function completely normally without any constraints, except the Debug interface is disabled.

82.6.4.2 Enabling

The feature is enabled via the Production Disable DCF client in the PASS module. Bit 0 enables the Debug Interface Disable. See Production Disable for details.

This information can be written by adding a DCF Record to the DCF record list in Flash UTEST. The DCF Client is configured to accept only one write. Subsequent DCF records that write to this DCF client are ignored.

If no DCF Record writes to this client, the default state of this feature is disabled. If, for a particular application, there is no intention of ever using this feature, it would be good practice to add a DCF Record that writes this client to 0x0000_0000. This is not essential, but ensures the feature can not be enabled accidentally.

82.7 Initialization/application information

82.7.1 Reset

The reset state of each individual bit is shown within the Register Description section. However, many bits receive their values based on DCF records stored in the UTEST Flash memory block.

82.7.2 Setting lock bits in a password group

There is no restriction on setting and clearing lock registers in the UTEST Flash, apart from the available space for DCF records. It is possible to set and clear them multiple times.

Table 82-38. CS/ADDR Values for Lock Registers

Register	DCF Command Word
PW Group 0	
Lock0	0xxxxx[1, 1] _0100
Lock1	0xxxxx[1] _0104

Lock3	0xxxxx[1] _013C

1. Value depends on the DCF Client Select assigned to the PASS module in the device. See chip specific PASS information for the Client Select assignment

In order to set the MIDLOCK field in the Lock0 register of password group 1 to the value 0x00FF and other fields to 0, the DCF record has to be added as shown in Table 82-39.

Table 82-39. Setting some bits in the MIDLOCK field

ADDR offset	DATA	Description
0x00	0x05AA_55AF	Start Record
0x04	0x0000_0000	
0x08	0x0000_00FF	PW Group 1, Lock0
0x0C	0xxxxx[1]_0110	Set MIDLOCK to 0xFF
0x10	0xFFFF_FFFF	Non-Programmed Addresses
0x14	0xFFFF_FFFF	
…	…	

1. Life cycle is governed by external life cycle management (SSCM).

Chapter 83
Tamper Detection Module (TDM)

83.1 Tamper Detection Module (TDM) chip-specific module information

The Tamper Detection Module provides a type of flash memory write protection mechanism that forces software to write a record associated with one or more blocks in a Tamper Detection Region (TDR) before the block(s) can be erased. An additional feature is provided to enable customers to override the protection mechanism for any TDR so that no record is required to be written before a block within the TDR can be erased.

Additionally, the TDM provides a mechanism for configuring individual flash memory blocks as One Time Programmable (OTP), that is, write-once, blocks.

The following sections provide details on the TDM configuration registers and DCF clients.

NOTE

The TDM configuration registers detailed in this section are DCF clients. In general, DCF clients can only be written once —their intended values must be carefully selected beforehand.

83.1.1 TDR*n*/Lock*m* OTPEN*m* register bit map

See the attached Flash Block Assignment spreadsheet for block naming and register bit maps.

83.1.2 OTPEN0 value

On this chip OTPEN0 is factory-programmed to 0x00010000.

83.2 Overview

The Tamper Detection Module provides a type of flash memory erase protection mechanism that requires software to write a record associated with one or more blocks in a Tamper Detection Region (TDR) before the block(s) can be erased. The mechanism does not *prevent* an erase operation on any block within a TDR—it requires a record to be written before the operation can execute. Collectively, the records are referred to as a "diary". At minimum, the diary serves as an erase counter. Because the diary record content is customer-defined, the diary can also serve as a history.

Up to 6 TDRs can be defined via DCF records.

The following figure shows the block diagram of the TDM and its interface to other system components.

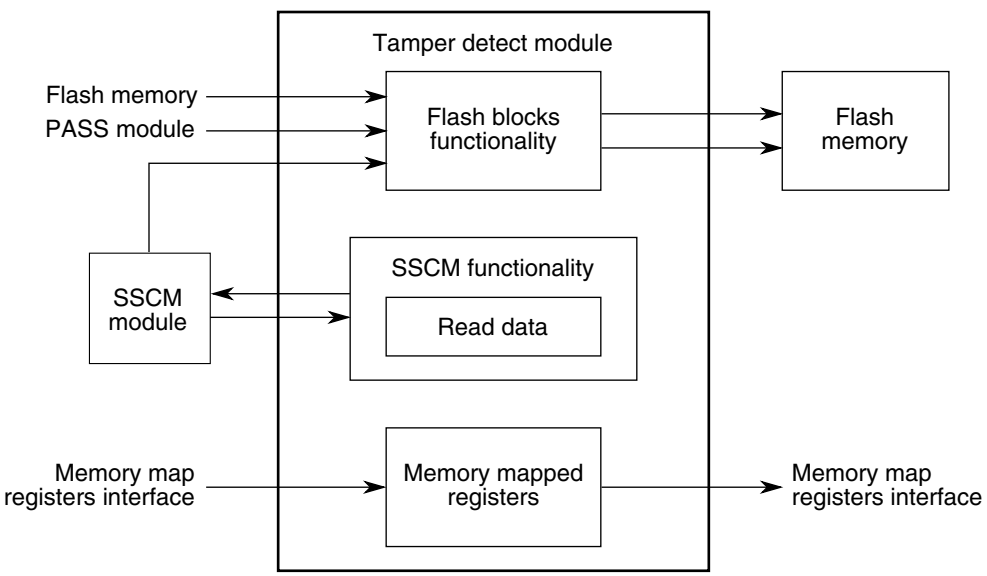

Figure 83-1. Tamper Detection Module block diagram

Security information is passed to the TDM by the SSCM module via the DCF bus. Among the data are:

- OTP (One Time Programmable) settings for each of the flash blocks
- Base address for the diary in the flash
- Block assignments for the TDRs
- Tamper region override information
- Software tamper region disable

The TDM module controls the flash blocks for erase operations and sets them as OTP.

The two flash buses are used to control the flash blocks for erase operation and set them as OTP. OTP means that flash erase of the entire block is disabled and the only words that are already erased can be programmed. Over-programming is not possible.

NOTE

The pass module provides the control for erase operation for each flash block as well as for each region of flash memory, and the PASS settings have priority over the settings of TDM.

The flash block indicates to the TDM the address of the programmed word. This address is internally decoded and provides a means to verify whether the block is part of any TDRs. The memory map registers interface provides a means to the user to read information of the TDM registers.

83.3 Features

The Tamper Detection Module supports these distinctive features:

- Erase counter (diary) for each TDR to record up to 256 write attempts on the flash blocks
  - The diary is divided into 6 parts (TDRs), each consisting of 256 64-bit records.
  - The diary block should be assigned as OTP region in flash.
  - The diary area can store any type of relevant information.
- Tamper Detection Region Block Assignment
  - Any flash block can be assigned to any TDR and be controlled.
- 32-bit Erase Lock DCF clients for each flash memory TDR defined.
- 32-bit OTP Enable DCF clients to disable the erase operation for an entire flash block
- Override TDR via DCF records[1]
  - Allows block assigned to a TDR to be unlocked for erase even if the TDR is locked for this operation.
- Memory mapped registers interface for reading via software of specific registers.

83.4 External signal description

There are no external signals driving or being driven by the TDM.

1. The Tamper Region Override DCF record is a "write one only" DCF record. If an override is applied to a TDR it is permanent and cannot be reversed.

83.5 DCF clients

TDM-related DCF records perform the following functions:

- Establish a permanent diary base address
- Define Tamper Detect Regions (TDRs) to monitor on-chip flash memory program/ erase activity
- Permanently disable one or more Tamper Regions
- Permanently disable ability for software to permanently override one or more TDRs
- Configure flash memory as One Time Programmable (OTP) on a per-block basis

The following table gives an overview on the TDM DCF clients implemented.

Table 83-1. DCF clients

DCF Client Name	Description	Strategy
Diary Base Address	Stores the base address of the tamper detection diary	write once, write 1 to 0 only
Tamper Region Override	Stores information of which TDR is to be overridden	write 0 to 1 only
Software Tamper Region Override Disable	Stores information to disable the software mechanism to override the TDR	write once, write 0 to 1 only
OTPEN[nb] (OTP Enable)	Stores information of which flash blocks is to be assigned as OTP (One Time Programmable) - nb means one register for each Lock register of the flash memory	write 0 to 1 only
TDR[n]_LOCK[m] Region Assignment	Stores information of which flash block is assigned to a TDR. • n specifies a TDR • m specifies the flash blocks as per the LOCK registers of the flash memory.	write 0 to 1 only

83.5.1 Diary Base Address (DBA) DCF client

This DCF client holds base address information of the diary. The following diagram depicts this client.

CAUTION

- This write-once DCF client can be written only one time. After one DCF record has written to this client, all subsequent writes are ignored.
- This DCF client is writable from 1 to 0 only.

DCF Client Address: 0x0000 Access: DCF write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

Table 83-2. Diary Base Address (DBA) DCF client field description

Field	Description
0–31 DBA	Diary Base Address. This field holds the base address of the diary. This information is then used to verify if the diary being programmed matches any TDR region. **NOTE:** Diary Base Address must be on a 4 KB boundary.

83.5.2 Tamper Region Override (TO) DCF client

This DCF client holds override information for each TDR. The following figure shows the diagram for this register.

CAUTION

This DCF client is writable from 0 to 1 only. Attempted writes of bits from 1 to 0 are ignored, making the override of a TDR permanent.

DCF Client Address: 0x0001 Access: DCF write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

Table 83-3. Tamper Region Override (TO) DCF client field descriptions

Field	Description	
0–25 Reserved	This field is reserved and should be written with all zeroes when programming the TOE fields.	
26–31 TOE5 to TOE0	TDR Override Enable. Each TOE*n* field, where *n* represents the TDRs, holds information of the Override Enable status for each TDR.	
	0	Normal operation. Blocks assigned to this TDR can NOT be erased until the diary is written.
	1	Diary override. The blocks assigned to this TDR can be erased WITHOUT writing to the diary.

83.5.3 Software Tamper Region Override Disable (STO_DIS) DCF client

This DCF client holds information to disable the software mechanism to override the tamper detect regions.

CAUTION

- This write-once DCF client can be written only one time. After one DCF record has written to this client, all subsequent writes are ignored.
- This DCF client is writable from 0 to 1 only.

DCF Client Address: 0x0002 Access: DCF write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

26–31 STO_DIS5 to STO_DIS0	Software TDR Override Disable TDR*n*. Each STO_DIS*n* field, where *n* represents the TDR number, holds information to disable the software mechanism to override TDR*n*.	
	0	Software tamper detect override mechanism supported
	1	Software tamper detect override mechanism disabled. Any attempt to override TDR*n* by loading a service key value in STO_KEY*n* register is ignored.

83.5.4 One Time Programmable Enable (OTPEN0) DCF client

This DCF client holds OTP information for particular blocks of flash memory. This DCF client mirrors the LOCK0 register of the flash memory. The following diagram depicts this client.

CAUTION

This DCF client is writable from 0 to 1 only. Attempted writes of bits from 1 to 0 are ignored, making the OTP assignment of a flash memory block irreversible.

DCF Client Address: 0x0008 Access: DCF write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

	0	Corresponding flash blocks are not assigned as OTP
	1	Corresponding flash blocks are assigned as OTP

83.5.8 Tamper Region Assignment DCF client (TDRn_LOCK0)

This DCF client holds the assignment information of flash memory blocks to a specific TDR. Each flash memory block can be assigned to any TDR (*n* varies from 0 to 5). This DCF client holds the assignment information for only those blocks specified in the LOCK0 register in the flash memory. For that reason, the layout of this DCF client mirrors the LOCK0 register in the flash memory. The following diagram depicts the TDRn_LOCK0 DCF client.

CAUTION

This DCF client is writable from 0 to 1 only. Attempted writes of bits from 1 to 0 are ignored, making the assignment of a flash memory block to a TDR irreversible unless the entire TDR is overridden.

DCF Client Address: 0x0014 + ((n x 4) + 0) Access: DCF write

83.5.10 Tamper Region Assignment DCF client (TDRn_LOCK2)

This DCF client holds the assignment information of flash memory blocks to a specific TDR. Each flash memory block can be assigned to any TDR (*n* varies from 0 to 5). This DCF client holds the assignment information for only those blocks specified in the LOCK2 register in the flash memory. For that reason, the layout of this DCF client mirrors the LOCK2 register in the flash memory. The following diagram depicts the TDRn_LOCK2 DCF client.

CAUTION

This DCF client is writable from 0 to 1 only. Attempted writes of bits from 1 to 0 are ignored, making the assignment of a flash memory block to a TDR irreversible unless the entire TDR is overridden.

DCF Client Address: 0x0014 + ((n x 4) + 2) Access: DCF write

	1	Corresponding flash blocks are assigned to the TDRn

83.5.11 Tamper Region Assignment DCF client (TDRn_LOCK3)

This DCF client holds the assignment information of flash memory blocks to a specific TDR. Each flash memory block can be assigned to any TDR (*n* varies from 0 to 5). This DCF client holds the assignment information for only those blocks specified in the LOCK3 register in the flash memory. For that reason, the layout of this DCF client mirrors the LOCK3 register in the flash memory. The following diagram depicts the TDRn_LOCK3 DCF client.

CAUTION

This DCF client is writable from 0 to 1 only. Attempted writes of bits from 1 to 0 are ignored, making the assignment of a flash memory block to a TDR irreversible unless the entire TDR is overridden.

DCF Client Address: 0x0014 + ((n x 4) + 3) Access: DCF write

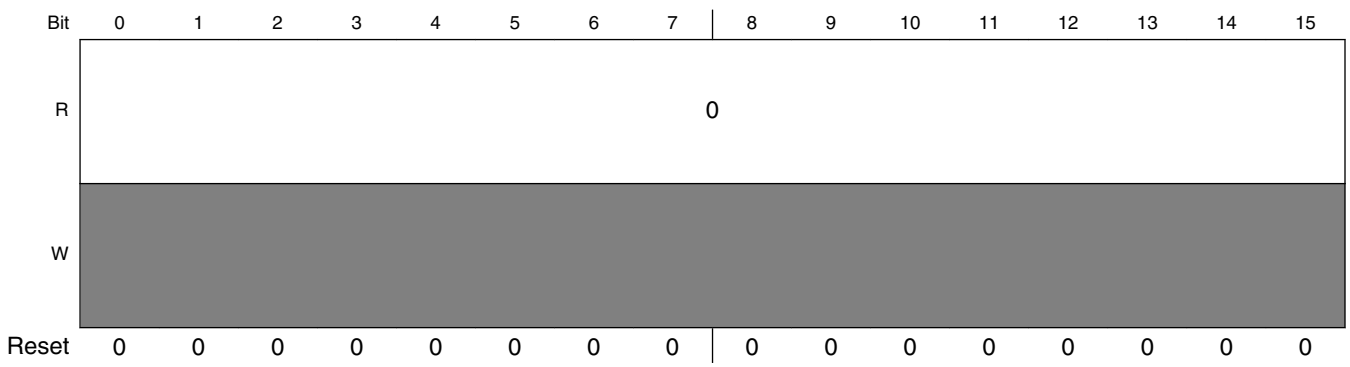
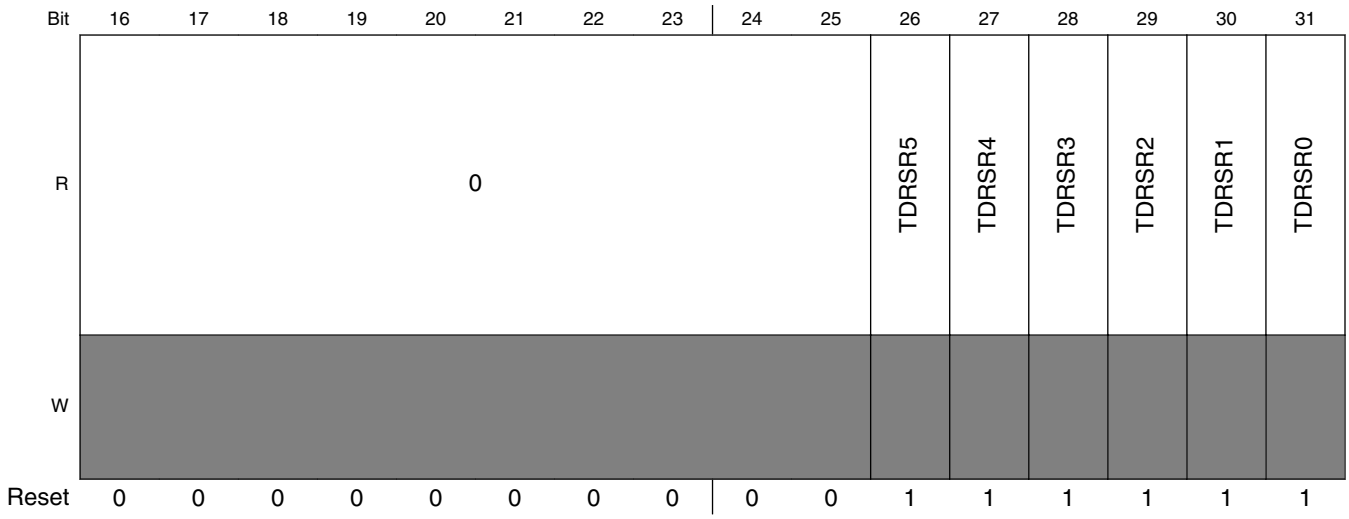
83.6.1 TDR Status Register (TDM_TDRSR)

This register contains the current status, i.e., locked or unlocked, of each tamper region, i.e., TDR.

- If a tamper region is locked, the blocks assigned to that tamper region cannot be erased.
- If a region is unlocked, the blocks within the tamper region can be erased.



The register contains a status bit for each TDR. Status is determined as follows:



1. The default status for each TDR is ‘1’, which indicates that the erase operation is disabled for all flash blocks associated with the TDR.
2. The status bit for a TDR is set to ‘0’ (indicating that the erase operation for all flash blocks associated with the TDR is enabled) if either a successful programming operation to the TDR diary region has been performed or the TDR Override bit for that TDR is set.

NOTE

- TDRSR is a read-only register and writes have no effect on it. Write operations result in a transfer error.
- If the reset value for this register is determined by a DCF record, it will be noted in the chip-specific information at the beginning of this chapter. Otherwise, the reset value is as shown.

Address: 0h base + 0h offset = 0h

TDM_TDRSR field descriptions

Field	Description
0–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26 TDRSR5	Represents the status of TDR 5 in conjunction with the Diary Override Enable status. 0 TDR is unlocked. Blocks assigned to this TDR are NOT blocked for erasing by the TDM module. This unlock state is achieved by a successful programming operation to the correct diary region or this TDR has been permanently unlocked by a DCF record that writes to the Tamper Region Override DCF register or a successful software override operation. 1 TDR is locked. Erase of blocks assigned to this TDR is not possible.
27 TDRSR4	Represents the status of TDR 4 in conjunction with the Diary Override Enable status. 0 TDR is unlocked. Blocks assigned to this TDR are NOT blocked for erasing by the TDM module. This unlock state is achieved by a successful programming operation to the correct diary region or this TDR has been permanently unlocked by a DCF record that writes to the Tamper Region Override DCF register or a successful software override operation. 1 TDR is locked. Erase of blocks assigned to this TDR is not possible.
28 TDRSR3	Represents the status of TDR 3 in conjunction with the Diary Override Enable status. 0 TDR is unlocked. Blocks assigned to this TDR are NOT blocked for erasing by the TDM module. This unlock state is achieved by a successful programming operation to the correct diary region or this TDR has been permanently unlocked by a DCF record that writes to the Tamper Region Override DCF register or a successful software override operation. 1 TDR is locked. Erase of blocks assigned to this TDR is not possible.
29 TDRSR2	Represents the status of TDR 2 in conjunction with the Diary Override Enable status. 0 TDR is unlocked. Blocks assigned to this TDR are NOT blocked for erasing by the TDM module. This unlock state is achieved by a successful programming operation to the correct diary region or this TDR has been permanently unlocked by a DCF record that writes to the Tamper Region Override DCF register or a successful software override operation. 1 TDR is locked. Erase of blocks assigned to this TDR is not possible.
30 TDRSR1	Represents the status of TDR 1 in conjunction with the Diary Override Enable status. 0 TDR is unlocked. Blocks assigned to this TDR are NOT blocked for erasing by the TDM module. This unlock state is achieved by a successful programming operation to the correct diary region or this TDR

Table continues on the next page...

TDM_TDRSR field descriptions (continued)

Field	Description
	has been permanently unlocked by a DCF record that writes to the Tamper Region Override DCF register or a successful software override operation. 1 TDR is locked. Erase of blocks assigned to this TDR is not possible.
31 TDRSR0	Represents the status of TDR 0 in conjunction with the Diary Override Enable status. 0 TDR is unlocked. Blocks assigned to this TDR are NOT blocked for erasing by the TDM module. This unlock state is achieved by a successful programming operation to the correct diary region or this TDR has been permanently unlocked by a DCF record that writes to the Tamper Region Override DCF register or a successful software override operation. 1 TDR is locked. Erase of blocks assigned to this TDR is not possible.

83.6.2 Last Flash Programmed Address Register (TDM_LFPAR)

This register holds information of the address of the last successful programming operation provided from the flash memory to the TDM. Writes to this register are ignored and will generate a transfer error.

Address: 0h base + 4h offset = 4h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

* Notes:
- The reset value of this register is set via DCF record.x = Undefined at reset.

TDM_DBA field descriptions

Field	Description
0–31 DBA	Diary Base Address. These bits represent the address of the diary location in the flash. **NOTE:** The diary base address is established via the DBA DCF record. The reset value of this register is determined by that record.

83.6.4 Software Tamper Override Key Region (TDM_STO_KEY*n*)

The STO_KEYn register holds the service key for overriding the Tamper Detect Region n, where n denotes the Tamper Detect Region number.

Caution

1. The STO_KEYn registers can only be written once.
2. The associated DCF client is writable from 0 to 1 only. Attempted writes of bits from 1 to 0 are ignored.

Address: 0h base + 10h offset + (4d × i), where i=0d to 5d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

TDM_STO_KEY*n* field descriptions

Field	Description
0–31 STO_KEY	Software Tamper Override Key Diary n. This field holds the service key value for overriding Tamper Detect Region n. By loading STO_KEYn with the correct signature of 0x55AA5A5A, Tamper Detect Region n is overridden, and the flash blocks assigned to Tamper Detect Region n are open for erase. This field has no effect when STO_DISn field of STO_DIS DCF client is set. **Caution:** The STO_KEYn registers can only be written once.

TDM_STO_KEY*n* field descriptions (continued)

Field	Description

83.7 Functional description

The primary purpose of the TDM is to provide a Tamper Detection mechanism by enabling an Erase Counter (or diary) for regions within the flash. These regions are called Tamper Detection Regions. The following sections cover the entire functionality of this module.

83.7.1 Flash erase counter and tamper detection

A flash region block or part of it is assigned for implementing the diary. The base address for the diary is defined by a DCF Record.

The diary is divided into 6 parts where each part consists of 256 × 64-bit records, to record up to 256 write attempts on the flash blocks assigned to each Tamper Detection Region. For correct operation, the diary should reside in a flash block that is assigned as OTP.

Each flash block can be assigned to any of the TDRs. Related to each TDR is a group of 4 x 32-bit internal hardware registers that are initialized by DCF records that define the tamper region. These registers mirror exactly the LOCK registers bits from the flash module.

Each TDRn_LOCK*m* register is loaded at boot time by the SSCM, which defines if the associated flash block is Locked for Erase in a particular TDR:

- ’1’ means the flash block is locked for erase
- ’0’ means the flash block is not locked for erase

Before performing an erase in one of the blocks locked for erase and associated to a TDR, a program operation has to be performed on the diary part for that TDR. As the diary should be OTP, successive writes are allowed on unprogrammed double words only. This ensure that diary records can only increase and that data recorded in the diary is not modifiable by software.

At the end of a successful double word program operation, the flash module indicates to the TDM the address of the programmed double word. TDM determines whether the programmed data was written to the correct TDR diary location and then unlocks the

blocks for erase operation for the corresponding TDR. TDM ensures that this erase operation on unlocked blocks is allowed until the completion of the erase sequence or until next desctructive reset.

NOTE

All blocks associated to a TDR where an erase operation is allowed can be erased all together.

The data programmed in the diary location is flexible, and may include count information or other important customer information.

NOTE

There is no restriction on the type or format of data that can be programmed in the diary, so software must verify whether the diary is full. If a TDR's diary area is full, the tamper detect mechanism can be disabled for that TDR by creating a Tamper Region Override (TO) DCF record with the TDR's corresponding TDR Override Enable (TOE) bit set to '1'. This allows erase operations to be performed to the TDR without any diary entry. Alternatively, if another TDR is available it can be defined to contain the same blocks to extend the diary length for that TDR.

The setting from “override tamper region lock” DCF record (Diary) has priority over the settings in the TDRn_LOCK0- 3 registers. In other words, if a TDR is unlocked for erase by the override tamper region lock, the TDR*n*_LOCK*m* bits have no effect on the TDR that has been overridden, but the tamper detection remains active for all TDRs not having the override bit set.

Moreover, if a block is locked by the PASS_LOCK*x*_PG*n* registers or by TDR*n*_LOCK*m*, the block is locked for erase.

NOTE

The settings in the Tamper Region Override Register have priority over the TDR*n*_LOCK*m* registers. The PASS module also has priority over the settings done in the TDM. For instance, if blocks in a TDR are unlocked for erase operation via TDM, but the same blocks are programmed to be locked for erase operation in PASS, the blocks end up being locked for erase operation.

83.7.2 Assigning blocks to Tamper Detect Regions (TDR)

Each TDR is defined by a group of 4 x 32-bit DCF records and clients, with each containing bits that map to specific blocks in a flash region. These mappings mirror exactly the LOCK registers bits from the flash module. Hence, the block assignment registers are named as TDR*n*_LOCK*m* where *n* is the number of a tamper region, that is, 0- 5 and *m* varies from 0-3 as flash contains four Lock registers.

In these DCF records:

- '1' means that the corresponding flash block is assigned to this TDR
- '0' means that the corresponding flash block is not assigned to this TDR (Default)

DCF clients are not visible to software. They can not be read nor written. They can only be initialized by DCF record within the UTest flash block during reset. The value of these registers can be evaluated by reading all the UTest DCF records and searching for records that correspond to these clients.

NOTE

No flash block should be assigned to more than one TDR. Each block should correspond to a single TDR. For example, if a single block is assigned to TDR0 and TDR1, then even if the Diary is programmed for both TDR0 and TDR1, this flash block will never be unlocked for erase operation.

83.7.3 Diary

The diary is a region of the flash memory where records of block erases for each TDR are stored. The format and size of the records are not fixed. The only requirements are that each diary has a maximum size of 2 KB, and the minimum size of any programming operation is 8 bytes to honor OTP restrictions. Therefore, each diary can hold a maximum of 256 64-bit entries.

A flash region block or part of it must be assigned for implementing the diary. The base address for the diary is determined by a value written in a DCF record. The diary can be placed within any flash block in flash array, and history records in it can be read by any core.

NOTE

To maintain the security of the TDR, the block where the diary is placed must be assigned as OTP within the OTP registers.

The base address of the diary is implemented using a DCF Client. The DCF client is only writable once and the default bit state is 1.

The DCF clients can not be read nor written by software. They can only be initialized by DCF record from within UTEST block during reset. The value of these registers can be evaluated by reading all the UTEST DCF records and searching for records that write these DCF clients.

83.7.4 Specifying the diary base address

The diary is a region of flash memory where records of block erases for each TDR are stored. The format and size of these records is defined by the customer. The only hardware constraints are that each diary has a maximum size of 2 KB and the minimum size of any programming operation is 8 bytes. Therefore, each diary region limits the erases of the assigned blocks to 256 erases.

The diary can be placed within any flash block in the flash array. To maintain the security of the TDR, the block where the diary is placed, must be assigned as OTP within the OTP registers, while in customer delivery or OEM production life cycle states.

The base address of the diary is implemented with a 20-bit DCF client that can be initialized by the SSCM during reset. The DCF client is writable once and the default bit state is ‘1’.

The base address register is not visible to software. It cannot be read nor written. It can only be initialized by DCF record within UTest flash during reset. The value of this register can be evaluated by reading all the UTest flash DCF Records and searching for record that writes this register.

Each TDR is assigned a 2 KB section of the diary. With 6 TDRs, 12 KB of diary space is required.

The diary base address must be at a 4 KB boundary. Therefore the least significant 12 bits of the base address must all be ‘0’.

The Base address of the diary is represented by:

Diary_Base_Address = 0bxxxx_xxxx_xxxx_xxxx_xxxx_0000_0000_0000

The base address of each TDR is shown below:

- TDR0 = Diary_Base_Address + 0b00_0000_0000_0000
- TDR1 = Diary_Base_Address + 0b00_1000_0000_0000
- TDR2 = Diary_Base_Address + 0b01_0000_0000_0000
- TDR3 = Diary_Base_Address + 0b01_1000_0000_0000
- TDR4 = Diary_Base_Address + 0b10_0000_0000_0000
- TDR5 = Diary_Base_Address + 0b10_1000_0000_0000
- End of the diary = Diary_Base_Address + 0b11_0000_0000_0000

83.7.5 TDR lock status

The status of whether a TDR is locked for erase is maintained by the TDM. This is accomplished by implementing a register with as many bits as the number of TDRs. The default state of these bits is 1, which is defined as "TDR Erase Blocked". See TDR Status Register (TDM_TDRSR) for further details about this register.

When the flash memory module has completed a programming operation, the address of the location programmed is output from the flash module. The TDM in turn compares that address to determine if it falls within the range of any TDR diary regions. If it is within any TDR, the corresponding status bit is set to 0 meaning "TDR Erase Enabled".

These status bits are all reset to 1 when the flash module signals an erase complete by asserting the PEC (Program Erase Complete) signal.

The state of the 6 status bits can be read through the TDRSR. See TDR Status Register (TDM_TDRSR). The address of the last successful programming operation provided from the flash memory to the TDM can be read through the LFPAR. See Last Flash Programmed Address Register (TDM_LFPAR).

83.7.6 TDR override

Before a block protected by a tamper detect region can be erased, a record must be written to the associated diary. Software must search through the diary to find the end of the records, where the next available diary location that can be written. After a maximum of 256 records are programmed to the diary, a TDR diary is full. Full means that at least 1 bit has been programmed to ‘0’ in each 64 bit double word within the 2 KB diary.

If software determines that a particular TDR diary is full it may override the diary to allow erasing to continue or it may choose to stop further erases and to flag an error.

Diary Override bits are implemented with a DCF client consisting of 6 bits, one for each TDR. See the device configuration information at the beginning of this chapter for TDM DCF client details.

The Diary Override bits are by default set to ‘0’; which means the diary must be written before an erase can occur. The DCF client can be written many times but the bits can only be written to ‘1’. Writes to ‘0’ are ignored. In this way, by default, all Tamper Detect Regions are active. The Tamper detect region diaries can be individually overridden by writing a DCF record that sets that corresponding bit to ‘1’. In this mode, the TDR status bit is permanently set to 0 to allow flash erase.

The application can also override the diary by loading a service key to the STO_KEY*n* program-visible register, where n denotes the tamper detect region. By loading the value 0x55AA5A5A into STO_KEYn register, the corresponding tamper detect region is overridden. This software override mechanism is disabled if the STO_DISn field of the STO_DIS DCF Client is set.

83.7.7 One time programmable (OTP)

83.7.7.1 Overview

Any flash block within the flash array can be assigned, at any time, to be OTP. Once a flash block is assigned OTP, it cannot be changed back.

OTP means that flash erase of the entire block is disabled and only 64-bit double words that are already erased (that is, flash content is 0xFFFF_FFFF_FFFF_FFFF) can be programmed. Over-programming is not possible.

Flash blocks are assigned as OTP by writing a DCF record. The block will become OTP after the next functional reset.

Appendix A
Release Notes for Revision 6

A.1 General changes

- In the OSC Digital Interface (XOSC) chapter:
  - In section "Oscillator bypass mode", changed "The power-down mode has priority over the bypass configuration for FXOSC." to "The bypass configuration is independent of the power-down mode of the oscillator." and removed the NOTE on FXOSC, as the feature is not supported.
- In the Flash memory controller chapter, removed descriptions on flash remap to flash:
  - In section Features, removed the phrase "on-chip flash memory" in the second from last bullet.
  - In section PFlash calibration remap support, removed sentence "Additionally, support is provided to reroute flash accesses to other on-chip flash memory addresses" and bullet "Addresses within any non-dedicated block of on-chip flash memory. Secure flash, UTEST flash, EEPROM, and BAF cannot be used as overlay targets" .
  - Removed section "PFlash calibration remap to flash memory".
- In the Embedded Flash Memory (c55fmc) chapter, added test mode disable seal information:
  - In section UTest NVM block, changed last sentence of first paragraph.
  - Added section Test mode disable seal.
  - Added register Test Mode Disable Password Check register (C55FMC_TMD).
  - In section Erase, updated step 3 of the erase sequence.
  - In section Array integrity self check, added note to step 2 of the array integrity sequence.
  - In section User margin read, added note to step 2 of the margin read procedure.
- In the Sigma Delta Analog-to-Digital Converter (SDADC) Digital Interface chapter:
  - Removed all descriptions referencing the external modulator feature:
    - [Addendum Rev.1] In sections "Features" and "External signal description" removed mention of external modulator feature.
    - In sections "Overview", "Functional description", "High-pass filter support", "Hardware triggering", and "Initialization information" removed mention of external modulator feature.
    - [Addendum Rev.1] Removed section "External modulator mode".
    - [Addendum Rev.1] In the MCR register changed EMSEL field to Reserved.
    - In SDADC_MCR[TRIGEN], SDADC_MCR[PDR], and SDADC_OSDR[OSD] field descriptions, removed mention of external modulator feature.
  - In the FCR register changed FOWEN field to Reserved.
- In the Analog-to-Digital Converter (ADC) chapter, removed ADC_ALTR register.
- In the Temperature Sensor (TSENS) chapter:
  - Removed section "Temperature sensor chip-specific module information" as all references to the high temperature digital output 2 signals (165°C operation) have been removed in the rest of the chapter.
- In the CAN (FlexCAN) chapter removed all references to CAN FD.
- In the Fast Ethernet Controller (FEC) chapter:
  - Added MII-Lite feature descriptions in the following sections:
    - Section Introduction
    - Section Block diagram
    - Section Features
    - Section External signal description
  - Added section 10 Mbps and 100 Mbps MII-Lite interface
- In the Boot Assist Flash (BAF) chapter, added NO_ECHO feature descriptions in the following sections:
  - Section Serial boot mode protocol
  - Section LINFlexD download protocol
  - Section FlexCAN download protocol
  - Section Download start address, VLE bit, NO_ECHO bit and code size
  - Section Protocol summary
- In the Memory Error Management Unit (MEMU) chapter: In the MEMU memory map, corrected the MEMU_PERIPH_RAM_OFLW instances to show only one instance, MEMU_PERIPH_RAM_OFLW0. In the MEMU_PERIPH_RAM_OFLWn register, corrected the "i" value in the address description.
- In the Fault Collection and Control Unit (FCCU) chapter:
  - [Addendum Rev.1] Removed section "NVM interface"
  - [Addendum Rev.1] Removed mention of "NVM" throughout the chapter, in the following sections: "Introduction", "Acronyms and abbreviations", "Main features", "EOUT interface", "Control Register (FCCU_CTRL)", "Configuration Register (FCCU_CFG)", and "CFG Timeout Register (FCCU_CFG_TO)".
- In the Password and Device Security Module (PASS) chapter:
  - In section "Flash Memory Read Protection", removed table "Flash Memory Read Protection Truth Table". The table has been moved to section Password and Device Security Module (PASS) chip-specific module information with modified description in the Censorship column and addition of the Debug Interface column.

A.2 Preface changes

- Added section Special terms.

- In section Acronyms and abbreviations :
  - "LFAST" changed to "Zipwire (LFAST/SIPI)".
  - Removed "SIPI".
  - "LINFlexD" changed to "LINFlex".
  - Added "STAC".

A.3 Introduction changes

- In section Introduction, removed "new" in first sentence.
- In section Target applications, changed "mid-end" to "mid-range" and changed "applications" to "target applications".
- In section Block diagrams :
  - Removed mention of "Dual Interrupt Controllers".
  - In figure "Peripherals allocation":
    - "DECIM" changed to "DECFILTER".
    - "SIPI" changed to "Zipwire".
    - I/O lines added to Zipwire, SIUL2, REACM, eTPU, eMIOS, IGF, and XOSC.
- In section Features summary :
  - Removed references to CAN "FD" modules.
  - In the first bullet for the Main CPUs, removed "identical".
  - In the fifth bullet for the Main CPUs, changed "Local" to "local".
  - In the bullet for the SRAM, removed the parenthetical phrase.
  - In the bullet for INTC, removed "serving two computational cores".
  - Rephrased bullet for UART.
  - Rephrased second bullet for LINFlexD instances that they are Masters "only".
  - Rephrased bullet for eTPU.
  - Added bullet for IGF.
  - Rephrased bullet for eMIOS
  - Added bullet for REACM.
- [Addendum Rev.1] In section Feature list, Table 2-1, MPC5743R column DSPI row, "3+2 MSB" changed to "4+2 MSB", and footnote "DSPI 4 and 3 are not supported" corrected to "DSPI 4 is not supported".
- In section Software debug and calibration, changed "Interprocessor bus" to "Zipwire" and changed "eTPU" to "eTPUs".

A.4 Embedded memories changes

- No substantial content changes

A.5 Signal Multiplexing and Signal Description changes

- In section System pin functions table "System pin functions":
  - Made editorial corrections to table header.
  - Added 144QFP column.
  - Corrected pin numbers for 176QFP.

A.6 Memory Map changes

- No substantial content changes

A.7 Device Configuration Format Records changes

- In section DCF record structure, Table 6-1 Parity bit description:
  - [Correction to change in Addendum Rev.1] Added "Even parity"
  - [Addendum Rev.1] Removed Note that the bit is not implemented for DCF Clients written from UTEST.
- In section DCF clients :
  - Unders subsection "DCF Client Special Strategy", modified Parity description to state even parity is expected of all DCFs which require parity evaluation.
  - In Table 6-5 :
    - [Addendum Rev.1] Corrected DCF Client Special Strategy value for "DCF_UTEST_Miscellaneous" to "SPRD, Triple voting, and PARITY".
    - Corrected DCF Client Special Strategy value for "ERROR0_PAD_SELECT" and "ERROR1_PAD_SELECT" to "SPRD, Triple voting, and PARITY".
- In DCF_UTEST_Miscellaneous DCF client :
  - [Addendum Rev.1] In stcu_CFB field description, corrected "online LBIST" with "offline LBIST".
  - Changed bit 15 (formerly "self_test_failure") to Reserved Read-only 0.
- In DCF_IVPR1 DCF client, added Note that this DCF client is put into effect only after BAF is executed and the application code starts executing, and that the value gets left-shifted by 8 bits when programmed in to the Core_1 IVPR.
- [Addendum Rev.1] In DCF_SELFTEST_CONFIG_IPS_2 DCF client, corrected System clock divider assignment to the bit fields:
  - 29 to 31: System clock divider 0
  - 26 to 28: System clock divider 1
  - 23 to 25: System clock divider 2
  - 20 to 22: System clock divider 3
- In section DCF_SELFTEST_CONFIG_IPS_3 DCF client :
  - Bits [5:7]: Removed "Aux_Mux_11_Divider_0_Division_Value" from the field name. The field name is now "Aux_Mux_10_Divider_0_Division_Value".
  - Bits [14:16]: Removed "Aux_Mux_7_Divider_0_Division_Value" and made the field Reserved Read-only 0.

A.8 e200z4d Core Complex Overview changes

- No substantial content changes

A.9 Core Description changes

- In section Local Instruction and Data Memory Overview, added a sentence each to the second and third paragraphs to clarify the "frontdoor access" and "backdoor access" references.

A.10 System Integration Unit Lite2 (SIUL2) changes

A.10.1 Chip-specific SIUL2 information changes

- No substantial content changes

A.10.2 SIUL2 module changes

- In the SIUL2_SCR0n register, changed FEC_MODE field bit 1 description from "MII" to "MII-Lite".
- In the SIUL2_MSCRn register, removed reference to "Automotive" pads in the field description and changed bit value "00" to Reserved.

A.11 Crossbar Switch (AXBS) changes

A.11.1 Chip-specific AXBS information changes

- Added section Hardware Implementation Dependent Register (HID1).

A.11.2 Crossbar switch module changes

- Master General Purpose Control Register (XBAR_MGPCR*n*) : Added note to register description re. unimplemented master ports.
- General operation : Removed phrase, ", other than the flash (if present),". Removed last paragraph that began with "If present, the flash slave port..."
- Features :
  - Replaced "64-bit data bus" with "Up to single-clock 64-bit transfer".
  - Replaced "Support for byte, 2-byte, 4-byte, 8-byte, and 32-byte burst transfers" with "Support for burst transfers of up to 16 beats of data".
- Memory Map / Register Definition :Edited introductory text and note. Added paragraph to note beginning with , "All references to the crossbar switch..."

• Removed bullet beginning with, "Operation at a 1-to-1 clock frequency..." from Features.

A.12 XBIC module changes

• Overview : Removed content which is not useful to customer.
• Features : Removed bullet beginning with "hready, hresp0, and hresp2..."
• Functional description : Section has been rewritten. Removed "XBIC H Matrix Definition" table.
• Block diagram :
  • Replaced cross references to figures with "the following diagram."
  • In XBIC system block diagram, corrected label on top green signal to "hready, hresp0, hresp2".
  • Removed figure, "XBIC block diagram".

• Changed "last transfer" to "first transfer" in XBIC_EAR register description.
• Minor editing. • XBIC Error Status Register (XBIC_ESR) : Previous errata e8310 integrated into the RM: Added note to register description. • XBIC Error Address Register (XBIC_EAR) : Previous errata e8310 integrated into the RM: Added note to register description.

A.13 Peripheral Bridge (AIPS-Lite) changes

A.13.1 Chip-specific AIPS-Lite information changes

• No substantial content changes

A.13.2 AIPS module changes

• Edited General operation.

A.14 System Memory Protection Unit (SMPU) changes

A.14.1 Chip-specific SMPU information changes

• No substantial content changes.

A.14.2 SMPU module changes

- In Figure 13-2 of Block diagram section: in upper right corner, changed "Internal peripheral bus" to "Register access"
- In Features section:
  - Removed what was the first list item: "Support for a maximum of 12 program-visible 128-bit region descriptors, accessible as four 32-bit words each. "
  - Changed first (formerly second) list item from "Each region descriptor defines an arbitrarily-sized space, aligned anywhere in memory" to "Arbitrarily sized protection regions alignable anywhere in memory."
  - Raised these list items one level in list hierarchy:
    - "Arbitrarily sized protection regions alignable anywhere in memory.
      - Region sizes can vary from a minimum of 1 byte to a maximum of 4 GB.
    - Read/write access control permissions are defined in the region descriptor.
    - Global cache-inhibit attribute indicator.
    - Hardware-assisted maintenance of the descriptor valid bit minimizes coherency issues.
    - Priority given to granting permission over denying access for overlapping region descriptors."
- In Hit determination section:
  - Replaced Boolean equation for hit determination with new sentence: "When RGD*n*_Word3[VLD] is 1, a region hit occurs when the requested address is between the start address (RGD*n*_Word0[SRTADDR]) and the end address (RGD*n*_Word1[ENDADDR]), inclusive."
  - Changed first Note from "The SMPU does not verify that ENDADDR >= SRTADDR" to "If ENDADDR < SRTADDR, no hit occurs."
- Changed title of Final evaluation and error terminations section (formerly was "Putting it all together and error terminations")

A.15 Intelligent AHB Gasket (IAHBG) changes

A.15.1 Chip-specific IAHBG information changes

- No substantial content changes

A.15.2 IAHBG module changes

- No substantial content changes

A.16 Platform Configuration Module changes

- No substantial content changes

A.17 SEMA42 module changes

- Edited two citations in Multi-core programming 101: software gates.

- Edited Introduction and removed note.
- Removed "Multi-core programming 101: software gates" section.
- Edited Features and block diagram.
- Memory map/register definition :
  - Edited introductory paragraph.
  - Changed access of Reset Gate Write (SEMA42_RSTGT_W) to W.
  - Changed access of Reset Gate Write (SEMA42_RSTGT_R) to R.
- Reset Gate Write (SEMA42_RSTGT_W) :
  - Edited register description and added note.
  - Added footnote to reset value.
  - Changed access of RSTGTN field to write only.
  - Edited description of RSTGDP field and changed access to write only.
- Reset Gate Read (SEMA42_RSTGT_R) :
  - Edited register description.
  - Changed access of RSTGTN field to read only.
  - Two most-significant bits of register:
    - Changed name to ROZ.
    - Changed field description.
    - Changed access to read only.

- Functional description : Removed references to internal signals and changed "AIPS" to "peripheral bridge".

A.18 Interrupt Controller (INTC) changes

A.18.1 Chip-specific INTC information changes

- No substantial content changes

A.18.2 INTC module changes

- In Memory map and register definition :
  - Added Figure 17-2 and surrounding text explaining write restrictions for PSR*n* and SSCIR*n*.
  - In INTC Priority Select Register (INTC_PSR*n*) and INTC Software Set/Clear Interrupt Register (INTC_SSCIR*n*), added "See Figure 17-2 for limitations on writing to this register."

A.19 Enhanced Direct Memory Access (eDMA) changes

- No substantial content changes

A.20 Direct Memory Access Multiplexer (DMACHMUX) changes

A.20.1 Chip-specific DMACHMUX information changes

- No substantial content changes

A.20.2 DMAMUX module changes

- Removed the address information of CHCFG1 register (base address + 0x01) and CHCFG8 (base address + 0x08) from the section "Enabling and configuring sources."

A.21 WKPU (non-MEDC18 SC) changes

- In the WKPU_NCR register NDSS0 field description, corrected "Set HID0[MCP_EN] to 1." to "Set HID0[EMCP] to 1."

A.22 Error Injection Module (EIM) changes

A.22.1 Chip-specific EIM information changes

- No substantial content changes

A.22.2 EIM module changes

- Memory map and register definition
  - Minor editorial changes: in each list item of first two unordered lists, capitalized first letter of first word
- Memory map and register definition
  - Edited and reorganized text in Error injection channel descriptor: function and structure

A.23 Clocking changes

- [Addendum Rev.1] In section Clock generation :
  - In figure Clock generation :
    - Added “LINCLK (System Clock Synchronous domain)” output to System Clock Selector's Divider 1.
    - Added “(System Clock Asynchronous domain)” text to the existing LINCLK output from Auxiliary Clock Selector 0's Divider 4.
  - Added NOTE: "Do not bring out the ADC clock (XOSC + PLL0) or its component (XOSC and PLL0) on the CLKOUT pad when the ADC is in use using the same clock."
- In section System clock frequency limitations, Table 22-2 :
  - Added "LINCLK (System Clock Synchronous domain)" to "SXBAR, System Ram Array".
  - Changed "LINCLK" to "LINCLK (System Clock Asynchronous domain)".
- In section Ethernet clocking, changed all instances of "MII" to "MII-Lite".
- [Addendum Rev.1] Previous errata ERR002345 integrated into the RM: Added section LINFlex clocking.

A.24 PLLDIG changes

- PLLDIG PLL1 Frequency Modulation Register (PLLDIG_PLL1FM)
  - Removed the text "the binary equivalent of" from the field descriptions of INCSTP and MODPRD.

- PLLDIG PLL0 Control Register (PLLDIG_PLL0CR)
  - Updated reset value of reserved field at location 21(Reserved), and changed the access to RO.

- Frequency modulation
  - Updated the sentence "If center modulation is selected..." to "If center modulation is used..." in the Note "The device maximum operating frequency..."

- Register PLLDIG PLL1 Divider Register (PLLDIG_PLL1DV)
  - Replaced the register description with updated content.

- PLLDIG PLL1 Frequency Modulation Register (PLLDIG_PLL1FM)
  - Updated MODSEL bitfield value descriptions for both 0 and 1.

- PLLDIG PLL1 Frequency Modulation Register (PLLDIG_PLL1FM)
  - Removed the sentence "Modulation period (PLL1FM[MODPRD]) and increment step..." from the register description.
- PLLDIG PLL1 Fractional Divide Register (PLLDIG_PLL1FD)
  - Removed the sentence "The dither disable (PLLDIG_PLL1FD[DTHDIS]) and..." from the register description.

- Frequency modulation
  - Updated figure Figure 23-14 to show correct modulation depth.

- In PLLDIG PLL1 Fractional Divide Register (PLLDIG_PLL1FD)
  - Replaced DTHDIS field with Reserved field at bit locations 14:15.

- Clock configuration
  - Updated equations f_{PLL1_PHI} and f_{pll1_VCO}.

- Minor editorial updates throughout.

A.25 CMU changes

• Main features
  • Updated second bullet to "CLKMN0_RMT monitoring with respect to CLKMT0_RMN ÷ $2^{CSR[RCDIV]}$ clock."
• In CMU Control Status Register (CMU_CSR)
  • Updated RCDIV field description.
• Added CMU_ prefix in front of register/field names that did not previously include it.
• CMU Frequency Display Register (CMU_FDR)
  • Updated register description placing items in a bullet list.
• CMU Interrupt Status Register (CMU_ISR)
  • Updated Note in register description, "All flags in the CMU_ISR are set..."
  • Updated bitfield description FHHI
  • Updated bitfield description FLLI
• Frequency meter
  • Added "[FD]" to end of CMU_FDR throughout where it was not previously included.

• CMU Interrupt Status Register (CMU_ISR)   • Updated the Note in the OLRI bitfield description, "When attempting to enter STOP mode..."
• Editorial updates.
• CMU Interrupt Status Register (CMU_ISR)   • Updated the Note in the OLRI bitfield description.
• CMU Frequency Display Register (CMU_FDR)   • Added NOTE in register description, "The CMU_FDR should be read only when CMU_CSR[SFM] = 0."

A.26 Clock Generation Module changes

• No substantial content changes

A.27 XOSC changes

• Editorial updates throughout.
• XOSC Control Register (XOSC_CTL)   • Updated XOSC_CTL[I_OSC] field access.

A.28 IRCOSC changes

• Frequency trimming calculation
  • Updated table contents replacing δF_{var_SW} with δf_{TRIM}.
  • Updated all instaces of "F" with "*f*" to represent frequency.

A.29 PRAMC module changes

- Read and write operations (formerly "Read / Write introduction" :
  - Section completely rewritten

A.30 Flash memory controller changes

A.30.1 Chip-specific PFLASH information changes

- No substantial content changes

A.30.2 Flash memory controller module changes

- [Addendum Rev.1]ECC on data flash accesses :
  - Clarification: If a non-correctable error is detected, the flash memory controller returns a value of 1555_1555h to the requesting master.

- Access protections :
  - Content previously located in the "Error termination" and "Flash error response operation" sections moved to this section.
- Error termination :
  - Section deleted
- Flash error response operation :
  - Section deleted
- Read cycles - buffer miss :
  - Section deleted
- Read cycles - buffer hit :
  - Section deleted

- Throughout:
  - Editorial changes

- Platform Flash Configuration Register 1 (PFLASH_PFCR1) :
  - Clarification: Following statement added to PFLASH_PFCR1[APC] field description: "For valid RWSC and APC combinations please refer to the device data sheet.
  - Following note in PFLASH_PFCR1[APC] field description reformatted into note list: "A value of '1' in the most significant bit causes the flash controller to function in retrograde/legacy mode, in which there is no pipelining between the sampling of flash read data and the presentation of the next address for flash lookup."
  - Added to note list in PFLASH_PFCR1[APC] field description: "Flash operation is not guaranteed for RWSC/APC combinations other than those specified in the data sheet."
  - Clarification: Updated portion of PFLASH_PFCR1[RWSC] field description that points to data sheet for valid values to state, "For valid RWSC and APC combinations please refer to the device data sheet. (was "The required settings are documented in the device data sheet")
  - Clarification: Following statement in PFLASH_PFCR1[RWSC] field description reformatted as item in note list for emphasis: "Higher operating frequencies require non-zero settings for this field for proper flash operation"
  - Clarification: Added to note list in PFLASH_PFCR1[RWSC] field description: "Flash operation is not guaranteed for RWSC/APC combinations other than those specified in the device data sheet"

A.31 Embedded Flash Memory (c55fmc) changes

A.31.1 Chip-specific C55FMC information changes

- No substantial content changes

A.31.2 c55fmc module changes

- Over-Program Protection 0 register (C55FMC_OPP0) :
  - Correction: Two most significant bits of the register always reset to 0 (previously shown as dependent on chip configuration)
  - Clarification: Footnote in register diagram replaced with footnotes stating that the reset value of each field (LOWOPP and MIDOPP) varies among devices
- Over-Program Protection 1 register (C55FMC_OPP1) :
  - Correction: Sixteen most significant bits of the register always reset to 0 (previously shown as varying among devices)
  - Clarification: Footnote in register diagram replaced with footnote stating that the reset value of the HIGHOPP field varies among devices
- Over-Program Protection 2 register (C55FMC_OPP2) :
  - Clarification: Footnote in register diagram replaced with footnote stating that the reset value of the A256KOPP field varies among devices
- Over-Program Protection 3 register (C55FMC_OPP3) :
  - Correction: Sixteen most significant bits of the register always reset to 0 (previously shown as varying among devices)
  - Clarification: Footnote in register diagram replaced with footnote stating that the reset value of the A256KOPP field varies among devices
  - Minor editorial fix

A.32 Decorated Storage Memory Controller (DSMC) changes

A.32.1 Chip-specific DSMC information changes

- No substantial content changes

A.32.2 DSMC module changes

- No substantial content changes

A.33 Flash Memory Programming and Configuration changes

- In section Creating the tamper detect diary, updated cross references to table "DCF Clients" in the DCF chapter.

A.34 Analog Peripheral Modules

- No substantial content changes.

A.35 Sigma Delta Analog-to-Digital Converter (SDADC) Digital Interface changes

A.35.1 Chip-specific SDADC information changes

- In section Clock source removed mention of external modulator feature.
- In section DMA/interrupt gating input from ETPU, modified description in second and third paragraphs.
- Added new section Sigma-Delta interface to eMIOS module with subsection DMA/interrupt gating input from eMIOS.

A.35.2 SDADC module changes

- Module Configuration Register (SDADC_MCR)
  - Updated the access rights to Reserved field (at bit location 13) to RW (was ROZ).
  - Updated the field description for Reserved field (at bit location 13), "This field is reserved and always has the value 0. Only the reset value shall be written to this register field."
  - Updated the access rights to Reserved field (at bit location 12) to RW (was ROZ).
  - Updated the field description for Reserved field (at bit location 12), "This field is reserved and always has the value 0. Only the reset value shall be written to this register field."

A.36 Analog-to-Digital Converter (ADC) changes

A.36.1 Analog-to-Digital Converter (ADC) chip-specific information

- [Addendum Rev.1] In SARADC channel map, Table 35-3 :
  - Added footnote to ADC0 and ADC1 channel 33 (ADC_BGREF): "This channel is functional from 4.5V to 5.5V of the corresponding reference (VDD_HV_ADR_SAR)."

A.36.2 ADC module changes

- Presampling channel enable
  - Updated formatting of table Table 35-160, added table title, and added a cross reference to the table in the preceding text.
  - Updated formatting of table Table 35-159, added table title, and added a cross reference to the table in the preceding text.
  - Added cross reference in first paragraph to the PSCR register.

- Main Configuration Register (ADC_MCR)
  - Updated the field access of Reserved field at bit location 6 (Reserved) to RW. Field description updated accordingly.

- Calibration (High Accuracy mode)
  - Updated content throughout.

- Parts of the ADC
  - Removed "TEST Interface" bidirectional i/o from Figure 35-3 .

- Calibration, BIST Control and status Register (ADC_CALBISTREG)
  - Replaced ACC_*x* fields with Reserved fields (bits 5,6,7,29,30).
  - Change access of Reserved bits 1,2.

[Addendum Rev.1] Added back ADC_MCR[TRGEN] and ADC_MCR[EDGE] fields.

- [Addendum Rev.1] Conversion time
  - Updated content of "Compare phase time (CT):" bullet.
  - Updated "Examples" excluding CALBISTREG[OPMODE] since that field is no longer implemented.

- Removed the text "CTU" throughout section "Memory Map/Register Definition".

- Crosstriggering Unit interface
  - Changed the signal name 'ctu_push' to 'ctu_EOC' in Figure 35-158.
- Conversion time
  - Changed section title from "Compare phase time" to "Conversion time".

- Features
  - Reformatted bullet "Modes of operation".
- Main Status register (ADC_MSR)
  - Replaced BCTU/CTU with BCTU, and CTU with BCTU.

• Self Test Analog Watchdog Register 4 (ADC_STAW4R)
  • Updated field description of THRH.
  • Updated field description of THRL.
• Self Test Analog Watchdog Register 5 (ADC_STAW5R)
  • Updated field description of THRH.
  • Updated field description of THRL.
• Removed section "User Defined Offset and Gain values".

• Calibration, BIST Control and status Register (ADC_CALBISTREG)
  • Added the Note "This setting is used only when the application..." to the NR_SMPL field description.
• Self Test Analog Watchdog Register 4 (ADC_STAW4R)
  • Reformatted Note in THRL field description.

• Register DMA Enable register (ADC_DMAE)   • In the DCLR bitfield value description for the case when DCLR=1, added note "When DCLR is set, ADC DMA channels should only execute read accesses on ADC_CDR*n* registers."
• Register Offset and Gain User Register (ADC_OFSGNUSR)   • Removed Note "A detailed description of the..." from register description.
• Calibration, BIST Control and status Register (ADC_CALBISTREG)   • Updated the Note in the NR_SMPL field description to "The 16 samples setting is used only when the application..."
• Editorial updates throughout.
• Added subsection Conversion time for BCTU interface to section Conversion time.

A.37 Decimation Filter (DECFILTER) changes

A.37.1 Chip-specific DECFILTER information changes

• No substantial content changes

A.37.2 DECFILTER module changes

• No substantial content changes

A.38 Temperature Sensor changes

• In Introduction and Functional Description changed number of digital outputs from 3 to 2. • In Introduction, Functional Description and Temperature threshold detection (digital output generation) changed number of high temperature thresholds from 2 to 1. • In Figure 37-1 deleted high temperature threshold 2. • Editorial changes and rephrased text in Introduction and Temperature threshold detection (digital output generation).
• "Temperature Sensor" title is changed as "Temperature Sensor (TSENS)".

A.39 Timers Overview changes

- No substantial content changes

A.40 System Timer Module (STM) changes

A.40.1 Chip-specific STM information changes

- No substantial content changes

A.40.2 STM module changes

- For reserved fields of following registers, added text to each field description: "This field is reserved."
  - STM Control Register (STM_CR)
  - STM Channel Control Register (STM_CCR*n*)
  - STM Channel Interrupt Register (STM_CIR*n*)

A.41 Software Watchdog Timer (SWT) changes

A.41.1 Chip-specific SWT information changes

- Added section SWT time-out events: configuring reset and interrupt requests.

A.41.2 SWT module changes

- In SWT Control Register (SWT_CR) changed Reserved from read-only and always zero to read/write

- In SWT Service Register (SWT_SR) description of WSC field, changed beginning of second sentence from "If the SWT_CR[KEY] bit is set" to "If the SWT_CR[SMD] field is 01b"
- In SWT Service Key Register (SWT_SK) description of SK field, changed beginning of second sentence from "If SWT_CR[KEY] is set" to "If SWT_CR[SMD] is 01b"

- In Overview changed final three sentences:
  - From: "If this servicing action does not occur before the timer expires the SWT generates an interrupt or hardware reset. The SWT can be configured to generate a reset or interrupt on an initial time-out. A reset is always generated on a second consecutive time-out."
  - To: "If this servicing action does not occur before the timer expires, the SWT generates an interrupt or hardware reset request. The SWT can be configured to generate a reset request or interrupt on an initial time-out. The SWT always generates a reset request on a second consecutive time-out."
- In SWT Control Register (SWT_CR) description of ITR field
  - Added a Note: "For a description of how this chip implements SWT reset requests resulting from SWT time-outs, see the chip-specific SWT information."
  - In descriptions of field values, changed "reset" to "reset request"
- In Time-out
  - Changed the description of a reset time-out result from "reset" to "reset request"
  - Edited and reorganized entire section

A.42 Periodic Interrupt Timer (PIT-RTI) changes

A.42.1 Chip-specific PIT information changes

- No substantial content changes

A.42.2 PIT module changes

- Previous Errata err7905 moved into documentation: In PIT_MCR register, added a note to MDIS bit field -"Always write....clock generation module."

A.43 Enhanced Modular IO Subsystem (eMIOS200) changes

A.43.1 Chip-specific eMIOS information changes

- No substantial content changes

A.43.2 eMIOS module changes

Changed the field description of eMIOS_MCR[0] to “Only write this field with the reset value.” See eMIOS200 (eMIOS)

- Removed the redundant footnote from the eMIOSx_UCDIS register.

A.44 Enhanced Time Processing Unit (eTPU) changes

A.44.1 Chip-specific eTPU2 Plus information changes

- No substantial content changes

A.44.2 eTPU module changes

- Changed the reset value of eTPU Engine 1 Time Base Configuration Register (eTPU_TBR_TBCR_ENG1) and eTPU Engine 2 Time Base Configuration Register (eTPU_TBR_TBCR_ENG2) (was 0000_0000h, is 2000_0000h).

A.45 Reaction Module 2 (REACM2) changes

A.45.1 Chip-specific REACM2 information changes

- No substantial content changes

A.45.2 REACM2 module changes

- No substantial content changes

A.46 Input Glitch Filter (IGF) changes

A.46.1 Chip-specific IGF information changes

- No substantial content changes

A.46.2 IGF module changes

- In Prescaler Register (IGF_PRESR*n*), changed description of FPRE field by adding formula to calculate rate of filter counter clock.

• In Filter types, changed "The Input Glitch Filter implements four main filter types" to "The Input Glitch Filter implements three main filter types."

A.47 Body Cross-triggering Unit (BCTU) changes

A.47.1 Chip-specific BCTU information changes

• No substantial content changes

A.47.2 BCTU module changes

• In TRG_FLAG, combined field setting descriptions into a single entry for 0 and a single entry for 1 (previously two entries for 0 and two entries for 1). Made editorial changes to the wording of these descriptions. • In SFTRG1 and SFTRG65, changed field setting for "Set software trigger" to 1 (was 0). • Editorial changes throughout.

A.48 CAN (FlexCAN) changes

A.48.1 Chip-specific FlexCAN3 information changes

• Throughout the subsections of "CAN chip-specific module information", removed all references to CAN FD.

A.48.2 FlexCAN module changes

• Minor editorial changes in register information.
• In CAN_ERRIAR register description, removed table showing RAM to memory map mapping, as the Chip-specific FlexCAN module section now shows the information for both FD-enabled and non-FD instances of the chip.

• In Module Configuration Register (CAN_MCR), added "This bit is not affected by soft reset" to the LPMACK, FRZACK, SOFTRST, and NOTRDY field descriptions. Changed sentence in description of field MDIS from "This is the only bit within this register not affected by soft reset" to "This bit is not affected by soft reset."
• In Memory Error Control Register (CAN_MECR) :
  • Revised the note in the register description.
  • Revised the ECRWRDIS field description.
• In Memory map/register definition, deleted the "FlexCAN Memory Partition for CAN FD" section.

• Removed line in FlexCAN module features about programmable clock source. • In FlexCAN memory mapping, changed reference to address offset in second paragraph. • In Table 47-6, prefixed "CAN_" to all register names.
• Changed "MCU" to "chip" throughout the chapter.

• Stop mode   • Removed the sentence "As a consequence, it will not...".
• FlexCAN module features   • Changed 64 to 96 in bullet "Flexible message buffers (MBs), totaling..."

• Memory Error Control Register (CAN_MECR)
  • Updated access of Reserved bit 12 to RW.
  • Updated access of Reserved bit 13 to RW.
  • Updated access of Reserved bit 15 to RW.
• Error Status Register (CAN_ERRSR)
  • Removed the sentence "If CAN_MECR[CEI_MSK] is..." from the field description of CEIF.

• Changed bit values for fields in Table 47-140.
• In Message buffer structure, removed note about configuring CAN FD frames.
• Changed access type and descriptions for reserved fields at bit locations 5, 9, 12, and 13 in CAN_MCR.
• In CAN_CTRL2, changed access type and descriptions for two new reserved fields at bit locations 30 and 31.
• Changed access type and description for reserved field at bit location 16 in CAN_CTRL2.
• Changed access type and description for reserved field at offset 15 in CAN_MECR. Changed description for reserved fields at offsets 12 and 13 in same register.

A.49 De-serial Serial Peripheral Interface (DSPI) changes

A.49.1 Chip-specific DSPI information changes

• No substantial content changes

A.49.2 DSPI chapter changes

• No substantial content changes

A.50 Zipwire changes

• No substantial content changes

A.51 SIPI module changes

• Updated bit field access for SIPI_ACR[ADCNT] and SIPI_ACR[Reserved] to read write.

A.52 LFAST module changes

- In Memory map and register definition, added note "Read/Write accesses to all unimplemented registers and write accesses to Read only register will return a Transfer Error.".
- Updated the register-access value of LFAST Rx ICLC Interrupt Status Register (LFAST_RIISR) register from R/W to W1C.

A.53 Fast Ethernet Controller (FEC) changes

A.53.1 Chip-specific FEC information changes

- In section FEC interface selection, table "FEC interface selection", changed "MII" to "MII-Lite". In the footnote added that full MII is not supported on this chip.

A.53.2 FEC module changes

- In Frames received with CRC error (FEC_IEEE_R_CRC), ensured that the reset value is shown as Undefined.

A.54 SENT Receiver (SRX) changes

A.54.1 Chip-specific SENT-SRX information changes

- [Addendum Rev.1] Added section SRX_GBL_CTRL[NIB_LEN_VAR_LIMIT] setting.

A.54.2 SRX/SENT module changes

- In Global Control Register (SRX_GBL_CTRL), added a note in bitfield NIB_LEN_VAR_LIMIT.
- In Global Control Register (SRX_GBL_CTRL) changed range of values from "1 to 255" to "0 to 255" in GBL_CTRL[TSPRC] field description.
- Previous errata e8082 integrated into reference manual: In Fast messages buffers added the note "In the case of a fast message overflow and continuous reading of register …".

A.55 LINFlexD changes

A.55.1 Chip-specific LINFlexD information changes

• No substantial content changes

A.55.2 LINFlexD module changes

• Updated section: Baud rate generation
• Existing note: 'The LINFlexD module in UART mode does not support communication ...' present in UART_CR register is now associated with Errata err6350.
• In section: Memory map and register description,   • In register 'LINESR' updated the bitfield description of 'OCF'
• Added section: LINFlexD Clock Tolerance
• In section Memory map and register description:, updated note 'In Master Mode, read access to IFMI register and ...'

• In section Timeout error, heading Response timeout mechanism:
  • Changed 'Nominal_time_out-Correction_factor' to 'Nominal_time_out + LINFlexD_LINTCSR[CNT]'
  • Added note 'The value of nominal_time_out ... '

• In section Memory map and register description: • Added note: "Any access to A0 location ... transfer error."

• Minor editorial updates throughout
• In section: Timeout, figure: Timeout, changed OC1 to OC2
• In section: Timeout error heading: Header timeout mechanism,
  • Updated bullet: "If the counter starts after 11 ... "
  • Updated paragraph: "The reset value of HTO ... "
• Updated note: "The LINFlexD module ..." present in UARTCR register.

• Updated section:Timer
• In section: Memory map and register description
  • Updated the access of register UARTCTO to R in table: LINFlexD memory map
  • Removed phrase 'free running' from bit LINTCSR[CNT].

A.56 Reset and Boot changes

- Added references to long external reset and made other corrections on references to phases.
  - In section *PHASE1[DEST]* Phase: temporization and monitoring setup, added that this phase can be entered from IDLE on an enabled, long external 'functional' reset event.
  - In section *PHASE1[FUNC]* Phase: temporization and monitoring setup, corrected description that this phase is "duplication of PHASE1[FUNC] after self-test" to "duplication of PHASE1[DEST] after self-test".
  - In section *PHASE2[FUNC]* Phase: flash initial configuration :
    - Corrected description that this phase is "entered on exit from PHASE2[DEST]" to "entered on exit from PHASE1[FUNC]".
    - Corrected description that the reset state machine "exits PHASE2[DEST] and enters PHASE3[DEST]" to "exits PHASE2[FUNC] and enters PHASE3[FUNC]".
    - Corrected description that this phase is "duplication of PHASE2[FUNC] after self-test" to "duplication of PHASE2[DEST] after self-test".
  - In section *PHASE3[FUNC]* Phase: device configuration monitoring, references to "shortened 'functional' reset event" modified to "shortened external 'functional' reset event" for consistency.
  - In section *IDLE[FUNC]* Phase figure "RGM state machine":
    - In the legend, clarified text description for pink and blue arrows.
    - In the legend, added new arrow named "long external 'functional' reset".
    - Added transition arrow from IDLE[FUNC] to PHASE1[DEST] for "long external 'functional' reset".
  - In section Module status during reset sequence table "Module status during reset phases":
    - Clarified text description for pink and blue arrows.
    - Added new arrow named "long external 'functional' reset".

A.57 Reset Generation Module changes

- No substantial content changes

A.58 Boot Assist Flash (BAF) changes

A.58.1 Chip-specific BAF information changes

- [Addendum Rev.1] In section Search boot header and boot options, corrected mention of "4 × 16 KB blocks" to "5 × 16 KB blocks" to match implementation.
- [Addendum Rev.1] Added section Serial boot password behavior.

A.58.2 BAF module changes

- Updated the field name in Table 57-23.
- Updated BAF NMI Event Handling.

• Editorial updates made throughout the chapter. • In section Resources, modified FCCU bullet item to refer to "SWT1 and SWT3".
• Updated Introduction. • Updated Download start address, VLE bit, NO_ECHO bit and code size.
• Added topic IVPR1_CPU1 - BAF set IVPR1 for CPU1 DCF Client. • In Table 57-13, added the row "IVPR1 for CPU1" and adjusted address range of the Reserved row.

A.59 System Status and Configuration Module (SSCM) changes

A.59.1 Chip-specific SSCM information changes

• No substantial content changes

A.59.2 SSCM module changes

• In SSCM System Status (SSCM_STATUS) register's CER field description, changed first sentence and added sentence:
  • was: "This field indicates that the SSCM has detected a configuration error during reset while loading DCF clients."
  • now: "This field indicates that the SSCM has detected a configuration error during reset while loading initial device configuration. See the chip-specific SSCM information for details about sources of the error."

• Editorial changes.
• In Memory map and register definition, added additional text ("that is, you should not..") to note regarding register accesses.
• Revised CERS-DCF Mechanism. • In CER, added cross-reference to CERS-DCF Mechanism.
• In Life Cycle, added "Life cycle sequence" figure.
• Note updated in Memory map and register definition from "SSCM does not support transfer errors in memory holes" to "SSCM does not generate transfer errors in all memory holes".
• In SSCM System Status (SSCM_STATUS), added the note "Reset value of 1 is correct in case the device is secured" in reset value of field SSCM_STATUS[5]. • In SSCM System Memory and ID Register (SSCM_MEMCONFIG), changed all instances of "JTAG ID" changed to "JTAG Part ID" • In Life Cycle, deleted the sentence "The priority of the entries is from top to bottom, so the first row that applies determines the resulting Life Cycle" and added in note the sentence "Any other combination of values will result in a system reset." • Updated Table 58-11.

A.60 Power Management changes

- In secction Supply Concept, Figure 59-2 :
  - Removed blocks LVD_FEC, LVD_JTAG, LVD_MSC_3V3, LVD_MSC_5V0 and the pads and lines connecting to them (VDD_HV_IO_MSC, VDD_HV_IO_FEC, and VDD_HV_IO_JTAG).
  - Corrected "VRC_CTL" to "VRC_CTRL".

A.61 Power Management Controller digital interface (PMC_dig) changes

A.61.1 Chip-specific PMC information changes

- In section PMC registers whose reset values can be defined by DCF clients, modified first sentence that implied that DCF control could be disabled.
- Added section PMC registers with chip-specific reset values.

A.61.2 Power Management Controller changes

- In section ADC Interface table "ADC Interface", changed the lvd_fec, lvd_msc, and lvd_jtag rows (S. No. 29, 30, 33 to 36) to Reserved.
- In the PMC_ESR_TD register:
  - Modified first sentence of the register description.
  - In the TEMP1_2, TEMP1_0, TEMP0_2, TEMP0_0 field descriptions, clarified descriptions on assertion and clearing of the bit, and removed the Notes.
- Updated PMC_REE_TD, PMC_REE, PMC_RES, and PMC_ADC_CS reset values to footnotes referring to the chip-specific information section.
- In the PMC_RES register, in the NOTE in the register description, removed sentence "If this register is programmed through DCF client…".

A.62 Power Control Unit changes

- No substantial content changes

A.63 Mode Entry Module changes

- In the MC_ME_CCTL2 register STOP0 field access to read-only.
- In section Software Considerations for Preventing the Blocking of Mode Transitions, in the sentence following "Service any pending wakeup events when transitioning to low power modes", removed "RTC", as the feature is not supported.

A.64 Calibration and Debug changes

- No substantial content changes

A.65 Core Debug Support changes

- No substantial content changes

A.66 DCI changes

- No substantial content changes

A.67 JTAGC module changes

A.68 CJTAG changes

- No substantial content changes

A.69 JDC changes

- No substantial content changes

A.70 SPU changes

• No substantial content changes

A.71 JTAGM changes

• In figures "JTAGM block diagram" and "JTAGM to DCI serial interface diagram" changed "DCI_TDO" to "TDO".
• In Memory mapped registers, added text saying that JTAGM supports only 32-bit write accesses to its registers.

A.72 DTS changes

• No substantial content changes

A.73 NAR changes

A.73.1 Chip-specific NAR information changes

• No substantial content changes

A.73.2 NAR changes

• No substantial content changes

A.74 Nexus Module changes

• No substantial content changes

A.75 NXMC changes

A.75.1 Chip-specific NXMC information changes

- No substantial content changes

A.75.2 NXMC module changes

A.76 Functional Safety changes

- No substantial content changes

A.77 CRC module changes

- In CRC_CFG*n*[SWAP], updated bit description text from "The swap operation is a bit-by-bit rotation of the content" to "The swap operation is a bit-by-bit swapping of the content".
- In CRC_CFG*n*[INV], removed the bit-description text "in case of CRC-CCITT polynomial, the inversion operation is applied on the 16 least-significant bits.".
- Updated title of Signal description section to External signal description.
- In Block diagram, updated reference to Main features section to see the number of contexts of CRC.

A.78 Memory Error Management Unit (MEMU) changes

A.78.1 Chip-specific MEMU information changes

- In section Reporting table implementation, modified description on errors that are reported to System RAM reporting tables and Peripheral RAM reporting tables.

A.78.2 MEMU changes

- In Design overview, deleted "The MEMU block has three instantiations of the basic reporting block along with a common CPU interface for the user software to access the storage block.".
- In Overview, deleted the paragraph beginning with "The Control, Error Flag, and Debug".

A.79 Fault Collection and Control Unit (FCCU) changes

A.79.1 Chip-specific FCCU information changes

- Added section FCCU fault recovery after NMI reaction explaining handling of NMI ISRs.
- In section FCCU chip-specific register reset values
  - Changed section title. Section title was previously "FCCU register availability and default values". Now the section only shows registers that are available for this chip. Also changed the lead paragraph and the table title to match.
  - In Table 78-1 :
    - [Addendum Rev.1] Removed the registers that are unimplemented on this chip.
    - Added rows for the FCCU_CFG, FCCU_CFG_TO, and FCCU_NCF_TO registers as their reset values are chip-specific.
    - Corrected mnemonics for FCCU_NCF_En registers.
    - Row for FCCU_MCS was added in Addendum Rev.1 but removed from this release, as the reset value is now described in the register section.
- In section Error signal flow diagram, Figure 78-1, added footnote to the "FCCU_EOUT_SIG_EN[0:3]: corresponding enable bit ==1?" block: "This condition must be satisfied only when FCCU is configured for Bistable fault-output mode (FCCU_CFG[FOM])."
- In section FCCU failure inputs from other modules :
  - [Addendum Rev.1] Updated NOTE to include channels 51 and 52, and clarified to mention both MBIST and LBIST.
  - In Table 78-3 :
    - Removed the entire "Fault input" column.
    - Modified "Description" for the following NCFs: 0 to 3, 6 to 8, 28 to 30, 35 to 37, 49, 50, 88, and 89.
    - [Addendum Rev.1] In NCF 25 and 26, modified "Source" and "Description".
    - In NCF 51 and 52 updated "Error Reaction Path Check" and "Description".
    - Removed rows for NCFs 65 to 68.
- [Addendum Rev.1] Added section FCCU_CFG[FCCU_SET_AFTER_RESET] explaining that the bit is not used on this chip.

A.79.2 FCCU module changes

- In Definitions, after the list of applicable reset types, added this information: *For more information on each type of reset, see the MC_RGM and reset chapters.*
- Editorial changes throughout.

- [Addendum Rev.1] In the FCCU_CFG_TO register description, added this note to the register's function description: *When the configuration watchdog timer expires, FCCU changes the value of this register to its reset value.*
- [Addendum Rev.1] In the FCCU_EINOUT register description, added this note to the description of the EOUT1 and EOUT0 fields: *When the configuration watchdog timer expires, FCCU changes the value of this field to its reset value.*
- In the FCCU_STAT register description, changed the access type of the ESTAT field from *RW* to *RO*.

• In FSM description, added the paragraph that begins with the sentence *Multiple faults can occur at the same time.*
• In FSM description, added the paragraph that begins with the phrase *After moving to FAULT state*. • In OPR, added statement about OP15.
• In the FCCU_CFG register description, in the description for the FCCU_SET_CLEAR field, changed *by writing into these fields with 00 or 10 or by going to CONFIG state* to *by writing into these fields with 00 or 10*. • In the FCCU_CFG register description, for the FCCU_SET_CLEAR field, changed the meaning of the value 01 from *Error Pin goes in Faulty state* to *Both error signals are set to low*. • In the FCCU_CFG register description, for the FCCU_SET_CLEAR field, changed the meaning of the value 11 from *write: Error Pin goes OK state (write not possible when FCCU already in the T min timer phase or if FSM enters in FAULT state by capture of a fault)* to *Both error signals are set to high (write not possible when FCCU is already in the T_min timer phase or if FCCU enters Fault state by capture of a fault)*.
• In FSM description, added two paragraphs that begin with the phrase *All pending faults that occur during CONFIG state*.
• In Main features, changed *Fault detection collection* to *Fault detection and collection*. • In Block diagram, changed the stem sentence for the table to *This table describes the FCCU submodules.*
• [Addendum Rev.1] In FCCU Output Supervision Unit, changed the first sentence of the third paragraph to *There is a 'do nothing' input coming from the FCCU that indicates that the FCCU is programmed for no reaction for ALL FAULTS*
• In Definitions, changed the descriptions of the reset types from a list to a table, clarified the description of the destructive reset, and corrected the descriptions of the long and short functional resets.
• In the FCCU_CFG register description, added this note: *If you specify a new value for any of the fields in this register that affect the EOUT signals while the EOUT fault-indication timer is running (FCCU is indicating a fault on the EOUT signals), FCCU doesn't use the new settings you specified until after the EOUT fault-indication timer expires (FCCU stops indicating a fault on the EOUT signals).*
• Changed all references to the IRCOSC and RCOSC clocks so they are in terms of CLKSAFE, which represents either CLKSAFE0 or CLKSAFE1, both of which appear on the boundary of the module. • In EOUT interface, added this sentence: *The EOUT frequency is generated by dividing the CLKSAFE frequency by a fixed factor of 2^{18}.*
• Rewrote Signals (previously titled "Pinout"). • In the FCCU_DELTA_T register description, rewrote the field description for DELTA_T.
• In Introduction, changed *when the system clock is faster than the IRC clock* to *when CLKSYS is faster than the CLKSAFE clocks*. • In Acronyms and abbreviations, removed the row for IRCOSC. • In Acronyms and abbreviations, added a row for CF. • Rewrote NMI/WKPU interface. • Revised Figure 78-8 to use signal abbreviations that match those used in NMI/WKPU interface and now described in Signals. Also changed *All NMI signals are shown active-low* to *All NMI signals shown are active-low*.
• In Figure 78-72, added the following note: *The fault sources shown are examples only.*
• In the Noncritical Fault Timeout (FCCU_NCF_TO) register description, deleted the register reset value and replaced it with a footnote to indicate that it is chip-specific. Also edited the register description for grammar and style. • In the Noncritical Fault Configuration (FCCU_NCF_CFG*n*), Noncritical Fault State Configuration (FCCU_NCFS_CFG*n*), Noncritical Fault Enable (FCCU_NCF_E*n*) and Noncritical Fault Timeout Enable (FCCU_NCF_TOE*n*) registers, deleted the register reset value and replaced it with a footnote to indicate that it is chip-specific. Deleted the following redundant note: *The reset value is chip-specific. See the chip-specific FCCU information.* Edited the registers description for grammar and style.
• In the FCCU_MCS register description, changed the reset value of the register to 0 with a footnote to indicate that the MC_ME module changes the value of the register immediately after the chip leaves RESET mode. Rewrote the rest of the register description and bits description for clarity.

• For Reserved field of Configuration (FCCU_CFG)
  • Changed the field access from read-only and always zero to read/write.
  • In field description, added text: "Always write the reset value to this field."

• In the FCCU_CFG register description, added a footnote to the diagram to indicate that the entire register reset value is chip-specific.Removed the footnote for the field that occupies bits 26–31 and changed that field's description to *Always write the reset value to this field.* Changed the access type of some reserved fields. Edited the register description for grammar, style, and clarity. • In the Memory map, changed the register access type of Noncritical Fault Timeout Enable (FCCU_NCF_TOE*n*) to *R/W*. • In the FCCU_CFG_TO register description, deleted the register reset value and replaced it with a footnote to indicate that it is chip-specific.
• In the FCCU_STAT register description, in the description of the ESTAT field, deleted this paragraph: *SW can write this bit with a different value. The new value is valid for 1 clock cycle, thereafter it returns to indicate the actual value being driven from FCCU. For example in non-faulty states, this bit reads 0 and can be set for one cycle to 1. Similarly in faulty state, this bit reads 1 and SW can write it to 0 and after one cycle the bit reads 1 again.* Edited the ESTAT description for style.
• In the FCCU_CTRL register description, rewrote the description of the DEBUG field. • In Register descriptions, replaced the two paragraphs that begin with *The FCCU generates an access error in the following cases* with a paragraph that begins with *Follow these register-access guidelines*.
• In Use cases and limitations, changed all occurrences of *Tmin* to *T_min*. • In the FCCU_DELTA_T register description, added this note to the end of the description of the DELTA_T field: *The specified values for DELTA_T may vary ±2% due to the post-trimming inaccuracy of the CLKSAFE clocks.* • In Introduction, removed this sentence from the list because it duplicates information in the description of FCCU_DELTA_T[DELTA_T] and provides the wrong maximum value for DELTA_T: *T_min = 250 µs + delta_T, with delta_T parameter being configurable by SW up to 16.67 ms*. • In STCU interface, changed *This feature is optionally programmable inside the STCU.* to *This feature is optionally programmable using MC_RGM.*

• In Introduction :
  • In the sublist for the list item *Configurable internal reactions for each NCF*, changed *No reset reaction* to *No reaction*.
  • Changed the list item *After power-on the error out pins have high impedance. FCCU goes to operational state only on software request.* to *After power on, the EOUT signals have high impedance. They show operational state only on software request.*

• In Definitions, in the list item *HW recoverable fault*:
  • Changed *until the fault cause is asserted* to *until the fault cause is deasserted*.
  • Changed *That is, if 0 on the fault signal indicates fault, then the status flags are valid until the fault line is '0'* to *That is, if logical 0 on the fault signal indicates fault, then the status flags are valid as long as the fault line stays at 0*.
  • Changed *Typically the fault signal is latched in an external module at the FCCU* to *Typically the fault signal is latched external to the FCCU in the module where the fault occurred*.

• In FSM description :
  • Edited the content for style and usage.
  • In the list item *Configuration*, changed *The configuration state is used only to modify the default configuration of the FCCU* to *Used only to modify the configuration of FCCU from its default*.
  • In the stem sentence for the second list, changed *The transition from NORMAL/ALARM state goes along with the generation of* to *The transition from Normal/Alarm to Fault state goes along with the generation of*.

• In section Block diagram, Figure 78-2 :
  • Corrected bidirectional arrow between "FAULT" and block "FAULT intf" to a unidirectional arrow from "FAULT" to "FAULT intf".
• In section FSM description in the second paragraph of the first bullet, modified sentence "The permanent configuration lock can be disabled by a reset of the FCCU".
• In section FCCU Output Supervision Unit :
  • In the third paragraph, corrected "an enabled fault" to "a disabled fault".
  • In the fourth paragraph, corrected "the FCCU does not check..." to "the FOSU does not check..."

- In EOUT interface :
  - Edited the section for style, usage, grammar, clarity, and structure, which included reordering some information and moving some information to the appropriate register descriptions.
  - Changed *Destructive reset* to *Destructive reset (including when an FOSU timeout occurs due to FCCU failing to react)*.
  - Deleted the list item *FOSU timeout reset*.
  - Changed *The FCCU provides up to two bidirectional signals (EOUT interface)* to *The FCCU provides up to two bidirectional signals (EOUT[1:0])*.
  - Changed *These signals need to be mapped to appropriate pins for external visibility* to *For information on the availability and names of these FCCU signals on the boundary of this chip, see the chip-specific FCCU information*.
  - In the list that begins with *These resets influence the state of the failure indication pins*, changed *Pin reset (RESET_b)* to *Chip pin reset (RESET_B)*.
- In the FCCU_CFG register description, edited the following field names and descriptions for clarity:
  - SM
  - PS
  - FOM
- Updated bit description of FCCU_CFG[FCCU_SET_AFTER_RESET], FCCU_CFG[RCCE1] and FCCU_CFG[RCCE0].

- Rewrote the FCCU_EOUT_SIG_EN register description for clarity.
- Added the following note to the FCCU_EOUT_SIG_EN[EOUTENx] field description: *To ensure that the FOSU module is aware that fault-output signaling is enabled as a reaction for the associated noncritical fault channel (so that FOSU doesn't mistakenly generate a destructive chip reset), you must set this field to enabled when FCCU is configured for any mode other than Bistable fault-output mode.*

- In FSM description, in the list item *Configuration*, added the following: *The locking feature only restricts the FSM movement into Configuration state. Once the user enters Configuration state and then tries to lock the configuration by writing either to TRANS_LOCK or PERMT_LOCK, the locking of configuration will be effective after FCCU moves to Normal state, it will not be effective in the current Configuration state.*

- In Definitions
  - Replaced types of reset table with two bullet lists.

- In FSM description, in the list item *Configuration*, deleted *by writing either to TRANS_LOCK or PERMT_LOCK* because these locking mechanisms are discussed elsewhere.

- In Register descriptions, in the first sentence of the second-to-last paragraph, edited text

A.80 Self-Test Control Unit (STCU2) changes

A.80.1 Chip-specific STCU2 information changes

- [Addendum Rev.1] Added sections Off-line LBIST and On-line LBIST.
- Renamed section AUTOLOCK_VALUE for register write access via STCU2_SKC (was "AUTOLOCK_VALUE") and expanded its content.
- Added section Wait time for writing to the online registers.
- Added sections On-Line reset generation (only MBIST) and On-Line reset generation (LBIST enabled).

A.80.2 STCU2 module changes

• Retitled the Built-in self-test scheduling section.
• In Watchdogs, retitled the following sections:
  • Initialization watchdog timer
  • Built-in self-test watchdog timer
  • Register write-access watchdog timer

• Edited Design implementation information for grammar and style. • In Online self-test sequence   • Updated Note "Flash memory must be in the idle..."
• [Addendum Rev.1] In Design implementation information, changed *Do not execute a* to *Do not execute LBIST*.
• In Design implementation information, corrected the grammar in the caution notice.
• In IPS bus interface, replaced the note with a reference to the chip-specific STCU2 information (which is where the correct contents now appear).
• In Reset management, replaced the subtopics pertaining to on-line reset generation with On-Line reset generation, which now states "See the chip-specific STCU2 information for details about On-Line reset generation.
• Editorial changes.
• In Register write-access watchdog timer, added "AUTOLOCK_VALUE is given in the chip-specific STCU2 information."
• In description of setting value 1 for STCU2_ERR_STAT[WDTO], changed "STCU2_CFG[BYP] bit are not set before the Watchdog reach..." to "STCU2_RUN[BYP] bit is not set before the Watchdog reaches..."
• In STCU2 Run Register (STCU2_RUN), in the BYP field description, changed "until the STCU2_SCK register" to "until the STCU2_SKC register".

• STCU2 Error Register (STCU2_ERR_STAT)
  • Updated the field description of UFSF
  • Updated the field description of RFSF

A.81 Register Protection (REG_PROT) changes

A.81.1 Chip-specific REG-PROT information changes

• No substantial content changes

A.81.2 REG_PROT module changes

• In Overview, added AIPS_LITE as an option to use the term PBRIDGE (PBRIDGE/ AIPS_LITE). • In General, modified the sentence "For all addresses that are protected …" to "For all addresses (peripheral registers) that are protected ….". • Removed topic "Initialization/application information".

A.82 Security changes

• Replaced whole chapter with more detailed descriptions on security features.

A.83 Password and Device Security Module (PASS) changes

A.83.1 Chip-specific PASS information changes

- In section Password and Device Security Module (PASS) chip-specific module information :
  - Table Table 82-1, corrected misalignment of table header.
  - Table Table 82-2 moved from section "Flash Memory Read Protection" with modified description in the Censorship column and addition of the Debug Interface column.

A.83.2 PASS module changes

- Revised Challenge Input Register (PASS_CIN*n*) description to indicate that a successful password comparison "clears the PGL bit of that register" (was "sets the PGL bit...").

- In section Features :
  - Added feature 'Flash read, write, and erase control'
- In register description of registers Password Group *n* - Lock 0 Status Register (PASS_LOCK0_PG*n*), Password Group *n* - Lock 1 Status Register (PASS_LOCK1_PG*n*), Password Group *n* - Lock 2 Status Register (PASS_LOCK2_PG*n*), and Password Group *n* - Lock 3 Status Register (PASS_LOCK3_PG*n*) :
  - Changed 'The initial value of the lock ... over during reset.' to 'The initial value of the lock ... over during functional reset.'
- In section DCF clients :
  - Added text to refer to DCF sheet attached with the Reference Manual.

- In section: Memory map and register definition, changed the width of CHSEL[GRP] to 2 (was 3), and updated bit description accordingly

- Updated topic: JTAG Password Challenge

A.84 Tamper Detection Module (TDM) changes

A.84.1 Chip-specific TDM information changes

- Added section OTPEN0 value.

A.84.2 TDM module changes

- Table 83-1 : Changed table title to "DCF clients" (was "DCF client address map").

• Editorial changes.
• Memory Map/Register Definition :
  • Changed title.
  • Removed note from beginning of the section.
• Overview : Updated and edited paragraph beginning with "Security information is passed...".
• Flash erase counter and tamper detection : Updated paragraphs beginning with:
  • "At the end of a successful double word program operation..."
  • "Moreover, if a block is locked by the PASS_LOCK*x*_PG*n* registers..."
• Overview : Changed last sentence from "The block will become OTP after the next reset." to "The block will become OTP after the next functional reset."

• TDR Status Register (TDM_TDRSR) : Removed footnotes from reset values of TDRSRn fields and changed value to 1.

Chapter 1
Emulation and Debug Device Introduction

1.1 Introduction

The emulation and debug device is a multi-die MCU that adds additional functionality specifically for ease in calibration and debug. The Emulation and debug device (ED) consists of the production die (PD) and a buddy die (BD). The BD for this chip does not implement the JTAG Master (JTAGM) functionality; disregard any references to JTAGM in the BD chapters.

1.2 Functionality

The ED is a PD packaged with a BD to provide additional capability during development. The ED is used for development, debug, and calibration of automotive powertrain controller applications. To enable these operations, the buddy device supports the following functions:

- Debug and calibration tool interface—Allows tool read/write access to buddy device resources even if main MCU supplies are removed as long as special ED debug supplies are maintained. The BD duplicates the Debug and Calibration Interface (DCI) functionality that is also available in the PD.
- High speed tool trace port (based on the IEEE-ISTO 5001-2012 Nexus Aurora standard)
- 1 MB on-chip SRAM usable as calibration overlay or trace RAM—entire SRAM contents are maintained as long as ED debug supply is maintained

1.3 Feature summary

On-chip modules available on the BD include the following features:

- 1 MB on-chip SRAM
  - Access timing matches internal PD flash accesses when used in conjunction with PD calibration remap logic
  - Includes ECC
  - Implemented as 4 × 256 KB partitions where each partition can be accessed by different masters without causing blockages to access of any other partition
- XBAR switch architecture
- XBAR slave interface
  - 64-bit data width with ECC checkbits
  - Supports "Early Write" AHB protocol (AHB-EW) for one clock trace data writes
  - Allows a PD with AHB master to support read and write to buddy device memory-mapped resources—Memory-mapped resources include buddy device SRAM and AIPS resources
- Nexus Aurora auxiliary trace port
  - 1.25 Gbit/s maximum data rate per lane
  - Four lanes supported in ED package
  - Port configurable to operate in 2- or 4-lane width
  - One lane LVDS reference clock in
  - Supports Nexus development interface (NDI) per IEEE-ISTO 5001-2003 standard, with some support for 2012 standard.
- Debug and Calibration Interface—Supports JTAG (IEEE 1149.1 and IEEE 1149.7) mode
- Independent high and low voltage supplies allow tool control of BD debug and calibration resources even when the main MCU supplies are off
- Device and board test support per Joint Test Action Group (JTAG) (IEEE 1149.1)

1.4 Block diagram

This figure shows the top-level block diagram of the emulation and debug device.

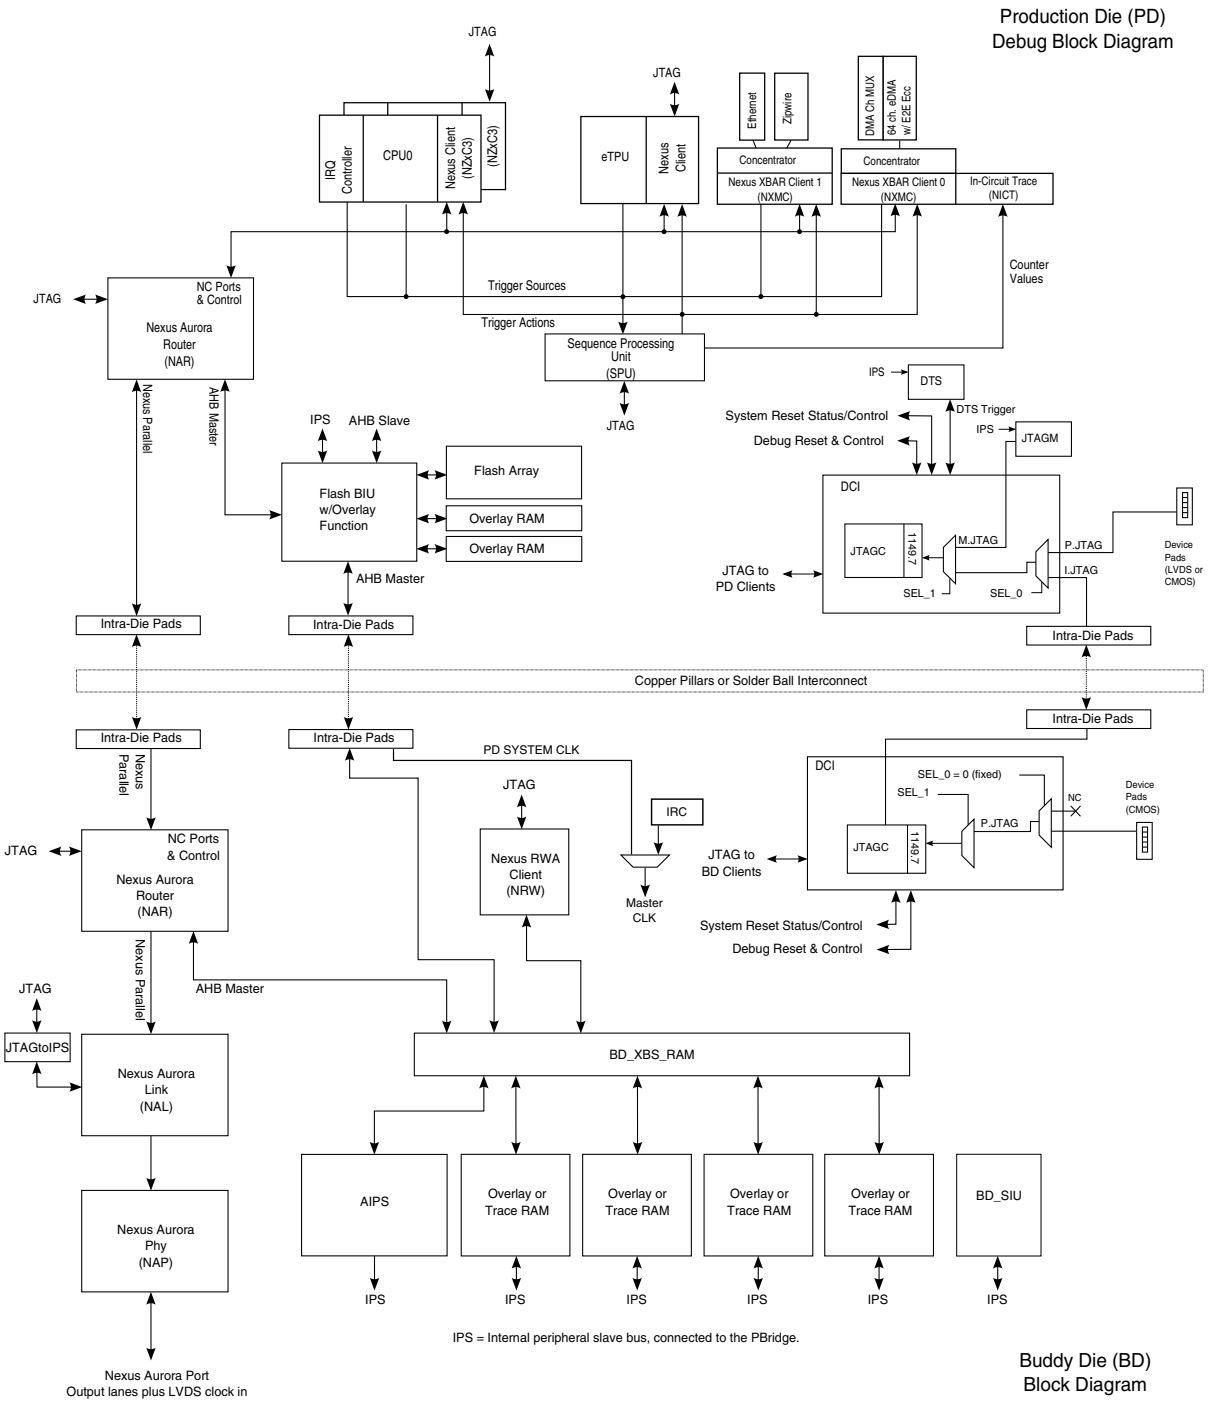

Figure 1-1. Emulation and debug device architecture

1.5 Clocking

The figure below shows the clocking structure of the BD. There is one internal clock source and four external clock sources:

- Internal RC oscillator (IRC) clock
- System clock coming from the PD (identified as BD_CLK clock in the clock generation figure of the Clocking chapter)
- JTAG clock coming from the TCK pin in the ED
- Nexus Aurora PHY clock coming from the differential LVDS pins in the ED

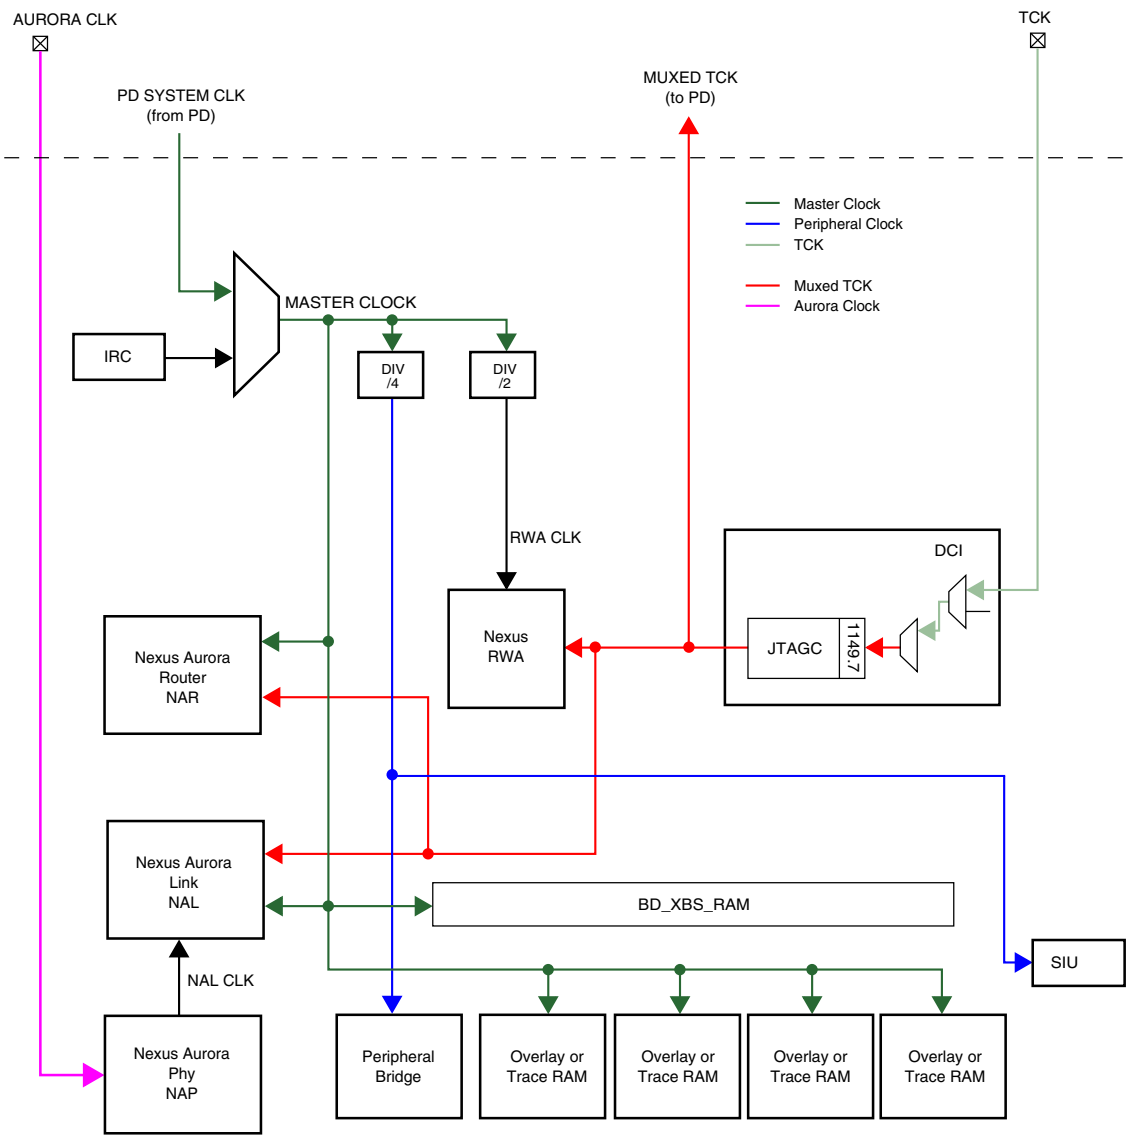

Figure 1-2. BD clock structure

The IRC is the source of the BD master clock when the PD is unpowered, or powered but still in reset state. It has a nominal frequency of 64 MHz, does not have any user accessible registers and is always enabled. It does not have any trimming capability, therefore the expected precision is on the order of ±30%.

The PD system clock is the source of the BD master clock when the PD is powered and out of reset state. When the PD PLL is engaged and locked this clock has a nominal frequency of 200 MHz, but while the PLL is not engaged the frequency is that of the PD internal RC oscillator.

The master clock directly feeds the XBAR, SRAMs and the Aurora sub-system. It is also divided down to generate the following internal clocks:

- Peripheral clock (divided by 4)—provides the clock to memory mapped registers and other low-speed logic
- Nexus RWA clock (divided by 2)—provides the clock to the Nexus Read Write Access module

The internal TCK clock (referred to as muxed clock in Figure 1-2) is used in the Nexus RWA, NAR, NAL, and it also goes to the PD to be used as the JTAG clock. (In the ED, the JTAG package pins are bonded to the BD JTAG interface; therefore, the PD receives the JTAG signals from the BD.) This clock comes from the TCK package pin, when using IEEE 1149.1 or IEEE 1149.7 access.

When the PD is unpowered, JTAG accesses can be done only by IEEE 1149.1 or IEEE 1149.7 modes accessing through the Nexus RWA module. In this mode, the TCK clock comes from the package pin and the RWA clock is a divided-by-2 version of the IRC; therefore, these clocks are asynchronous to each other. When clocks at the input of the RWA are asynchronous, there is a restriction that the RWA clock must be at least double the frequency of the JTAG clock. This means that the master clock frequency must be at least four times the JTAG clock frequency.

This table summarizes the frequency restrictions on the Nexus RWA accesses.

Table 1-1. JTAG operating frequencies

PD configuration	BD configuration	PD system clock frequency [MHz]	BD master clock frequency [MHz]	Max RWA JTAG frequency [MHz]	Notes
Unpowered or in reset state	1149.1 or 1149.7	—	44.8	11.2	Assuming 64 MHz BD IRC with 30% tolerance
Powered, out of reset, PLL not engaged, system clock at IRC frequency	1149.1 or 1149.7	15.52	15.52	3.88	Assuming 16 MHz PD IRC with 3% tolerance
Powered, out of reset, PLL engaged	1149.1 or 1149.7	200	200	27.7/50	JTAG speed is limited by TCK negedge to TDO delay (14 ns) plus external setup to TCK posedge (4 ns). Otherwise, the maximum Nexus RWA JTAG frequency is internally limited to 50 MHz.

1.6 Reset logic

There are five sources of reset that are combined to generate the reset of system portions as described in the following table:

1. BD power-on reset—asserts immediately upon assertion of BD POR, and remains asserted for 10 clock cycles after negation of POR.
2. PD reset—asserts two clock rising edges after assertion of reset signal coming from PD and remains asserted while the PD reset signal is asserted plus two clock rising edges after the PD reset signal is de-asserted (this reset source is reflected in the PD_RST bit of the BD_SIU_RSR register).
3. DCI FBD reset—asserts immediately when the FBD_RESET bit of the DCI Control Register is set, and remains asserted for one clock cycle after FBD_RESET is negated.
4. JTAG controller reset—asserts immediately when a reset request signal is received from the JTAG Controller by the execution of EXTEST, CLAMP, HIZ boundary instructions, and remains asserted for one clock cycle after the reset request is negated.
5. Nexus reset—asserts by DCI logic based on JCOMP state and JTAG source selected. DCI FBD also generates a Nexus reset.

In the following table, an 'X' indicates that the reset source generates a reset signal to the specified block. JTAG mode only indicates that those blocks are reset by the corresponding reset sources only in the case where the debug interface is running through the JTAG external pins.

Table 1-2. Reset sources and functional blocks

Blocks	BD POR	PD reset	DCI FBD reset	JTAGC reset	Nexus reset
DCI	X	—	—	—	—
Z0 Nexus RWA	X	—	X	—	X
BD XBAR	X	—	X	X	—
Overlay/Trace RAM	X	—	X	X	—
NAR	X	—	X	X	X
NAL	X	—	X	X	X
NAP	X	—	X	X	X
BD SIU	X	—	X	X	—
BD SIU GPIO registers	X	X	—	X	—

Table continues on the next page...

Table 1-2. Reset sources and functional blocks (continued)

Blocks	BD POR	PD reset	DCI FBD reset	JTAGC reset	Nexus reset
BD INIT flag	X	—	X	X	—
PD/BD interface logic	X	—	X	X	—

NOTE

The PD reset is not affected by the BD reset. The BD does not interfere with startup or shut down timing of the PD.

1.7 BD memory map

The BD memory map is contained within a 16 MB range. This entire range is accessed through the PD Flash BIU. The BD memory map is divided into two regions: overlay RAM and device registers.

The device register region allows the CPUs on the PD to access configuration registers of the peripherals in the BD, such as XBAR configuration, etc. The device register region are divided into 16 KB regions for assignment to each peripheral block.

The memory map for the BD is shown below as an absolute address relative to the PD address map. Within the BD, only a 24-bit address bus is required. The upper 8 bits of the complete 32-bit address are decoded and removed by the PD PFLASH controller.

Table 1-3. BD memory map

Start address	End address	Allocated size (KB)	Description
BD overlay RAM			
0x0C00_0000	0x0C0F_FFFF	1024	Extended overlay RAM

0x0C82_0000	0x0CFF_FFFF	8064	Reserved

Chapter 2
Buddy Device—Crossbar and RAM (BD_XBS_RAM)

2.1 Introduction

Within the buddy die (BD), there is a crossbar switch that provides the required connections between multiple bus masters and the overlay RAM. For a diagram of the Emulation device (ED) debug architecture that shows the BD blocks and crossbar, see the Emulation device introduction chapter. This section provides details on the structure of this function.

Note

Throughout this description, the term "overlay RAM" is applied to the BD memory, even though this memory can be used for *both* overlay and debug trace information.

The 64-bit BD crossbar and RAM structure consists of:

- Input registers to capture transfers (address, attributes and write data) targeted at the overlay RAM or memory-mapped peripheral space
- A 3 x 5 crossbar switch to route requests from masters to either the overlay RAM or the system bus
    - Bus masters include the BD's Nexus Aurora Router (BD-NAR), the production device's flash controller (PFLASH) and the BD's Nexus Read/Write Access Client (RWA)
    - Bus slaves include 4 equal-sized regions of the overlay RAM and a peripheral bridge (AIPS-Lite) bus controller
        - 160-bit RAM arrays (128 bits of data, 32 bits of end-to-end ECC)
        - End-to-End ECC32 address and data protection

    - ECC scheme based on 29-bit address and 32-bit data
    - Overlay RAM supports a 64-bit "early write" datapath and a 128-bit read datapath
- Output alignment logic and registers to capture read data being driven to the requesting master

The result is an efficient structure supporting concurrent references of the overlay RAM for calibration accesses from the PFLASH controller on the Production Device (PD) and debug references from the other masters. The crossbar and RAM support 200 MHz operation.

Note

Calibration reads from the PFLASH have the same timing characteristics as normal data reads from the flash array.

2.2 3 x 5 Crossbar switch and attached controllers

In the same manner as the comparable crossbar switches in the PD, the BD crossbar concurrently supports up to 3 simultaneous connections between the master and the slave ports. It implements a 64-bit "early write" datapath and a 128-bit read datapath and fully supports concurrent accesses between calibration reads and debug trace writes to different overlay RAM regions.

This crossbar implements fixed priority arbitration on a per slave port basis where the master number defines the relative priority in a reverse numeric order, that is, m0 > m1 > m2 (PFLASH > BD-NAR > Nexus RWA). Each slave port is "parked" on the last master making a request.

The design supports {8, 16, 32, 64}-bit SINGLE reads, {8, 16, 32, 64}-bit SINGLE writes along with 64-bit WRAP4 burst reads and writes. Two consecutive sequential 128-bit accesses of the RAM are used (only) on the WRAP4 burst read.

2.3 BD_XBS_RAM End-to-End ECC32 Checkbit/Syndrome Coding Scheme

The e2eECC scheme used in the BD overlay RAM is a simplified derivative of the algorithm used in the Production Device. The only difference is the code is based on a 32-bit data field, but the same H-matrix is used with the appropriate 32-bit data upper or lower word zeroed.

Consider the following Boolean equation definitions:

e2eECC64[7:0] = ecc_addr[7:0] ^ ecc_data_upper[7:0] ^ ecc_data_lower[7:0]

where `ecc_addr` is H-matrix evaluation of the 29-bit access address (addr[31:3]), `ecc_data_upper` is the H-matrix evaluation of the upper data word (data[63:32]) and `ecc_data_lower` is the comparable evaluation of the lower data word (data[31:0]).

For the BD RAM definition, the following (re)definitions apply:

e2eECC32_upper[7:0] = ecc_addr[7:0] ^ ecc_data_upper[7:0]

e2eECC32_lower[7:0] = ecc_addr[7:0] ^ ecc_data_lower[7:0]

As a result, the PD's H-matrix is used for the BD RAM's e2eECC32 scheme with the appropriate 32 bit data word zeroed out:

e2eECC32_upper[7:0] = ecc_addr[7:0] ^ ecc_data_upper[7:0]; data_lower[31:00] = 0

e2eECC32_lower[7:0] = ecc_addr[7:0] ^ ecc_data_lower[7:0]; data_upper[63:32] = 0

In any case, the resulting ECC32 is calculated based on the appropriate 32 data bits plus 29 address bits (the upper bits of the 32-bit address field).

The complete H-matrix for this (101, 93) code is shown in the following table. A '*' in the table indicates the corresponding data or address bit is XOR'd to form the final checkbit value on the left. For 32-bit data writes, the table sections corresponding to D[63:32] or D[31:0], together with A[31:3] are logically summed (output of each table section is XOR'd) together to the final value driven on the hwchkbit[7:0] outputs. Note that this table uses *the AHB bit numbering convention where bit[0] is the least significant bit*.

Table 2-1. e2eECC Basic H-Matrix Definition

```

Figure 2-4. C language encodeECC32_upper function description (Part 4 of 4)

As the ECC syndrome is calculated on a read operation by applying the H-matrix to the data plus the checkbits, an all zero syndrome indicates an error free operation. If the generated syndrome value is non-zero and matches one of the H-matrix values associated with the data or checkbits, it represents a single-bit error correction case and the specific bit is complemented to produce the correct data value. If the syndrome value matches one of the H-matrix values associated with the address bits, the opposite data word, or is an even weight value, or represents an unused odd weight value, a non-correctable ECC event has been detected and the appropriate error termination response is initiated.

Chapter 3
Buddy Device—System Integration Unit Lite (BD_SIUL2)

3.1 Introduction

The Buddy Device—System Integration Unit Lite2 (BD_SIUL2) provides control over the electrical pads of the buddy device (BD), as well as implementing various SoC functions that are not included in other modules.

The main functions supported by BD_SIUL2 are:

- Device identification
- Device status reporting
- Pad control and signal muxing

It should be noted that some other system level features are located in the BD DCI block including:

- Device identification available via the JTAG accessible Nexus Device ID (DID) register
- Reporting of reset status via the JTAG accessible reset status register
- Control of production device (PD) and BD reset via JTAG accessible reset control register

3.2 Device identification

The BD_SIUL2 includes a device ID register (DIDR) that identifies the BD type and version, allowing a connected tool or development/calibration software running on a connected PD to determine what debug or calibration resources are available. The DIDR uses similar formatting to the MCU ID registers (MIDR1, MIDR2) included in the SIUL2 module.

This information is made available via the BD SIU rather than via the PD because it is either not available via the PD (for example, information on BD-specific resources, such as extended overlay RAM size) or because it is useful for the tool to be able to access the information before the PD is powered up.

Information available includes:

- An ID code that can be used to uniquely identify the BD type
- A version field that is changed for every major mask revision of the BD
- A parameterized field that indicates the amount of extended overlay RAM included
    - The field coding allows indication of up to 4 MB of RAM, with resolution of 256 KB steps

It should be noted that in addition to information available in the DIDR, a connected tool can also retrieve identification information from other sources including:

- The JTAG ID returned by the buddy DCI/JTAGC module, which is different than the JTAG ID returned by a standard PD DCI/JTAGC
- The MIDR register included in the PD SIUL2 module, which includes information on the PD device type, version and package type (including identification of emulation and debug device package variants)

3.3 Device status information

This section describes the devices status information.

3.3.1 Initialization status

The BD SIU includes a flag (BD_INIT) that can be used by the connected PD or any connected debug or calibration tools to track the status of the BD.

The main expected usage mode for this bit is to allow the Boot Assist Flash (BAF) or user calibration software on the PD to determine whether the BD has lost power since it was last initialized. A typical usage sequence for BD_INIT is shown below.

- At BD power on reset (POR), BD_INIT is cleared automatically
  - BD_INIT is not cleared by external BD reset input
- A calibration tool or calibration software initializes the BD (for example, writing BD overlay RAM with calibration data and remap configuration)
- The calibration tool or calibration software sets BD_INIT
- After PD POR, the BAF executes and reads BD_INIT
  - If BD_INIT is clear, the BD overlay is assumed to be uninitialized and is not used for calibration remap
  - If BD_INIT is set, the BD overlay is assumed to be initialized and can be used for calibration remap. (Other tests to verify data integrity may be used.)

BD_INIT is cleared by BD POR, and can be set or cleared via the debug interface or writes from the PD. BD_INIT is only used to detect full power down events resulting in a subsequent POR. It does not detect brown out drops in the supply voltage.

3.3.2 PD reset status

The IPS accessible BD_SIU_RSR register shows what stage of reset processing the connected PD is in, and whether the PD is powered down or not. This is functionally different from the software accessible registers in the PD reset generation module that indicate which reset source has caused the last PD reset.

3.4 Memory mapped registers

This table gives an overview of the BD_SIUL2 registers.

BD_SIUL2 memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	Device Identification Register 1 (BD_SIUL2_DIDR1)	32	R	57BD_0000h	3.4.1/28
4	Device Identification Register 2 (BD_SIUL2_DIDR2)	32	R	0003_0100h	3.4.2/29
100	Initialization Status Register (BD_SIUL2_ISR)	32	R/W	0000_0000h	3.4.3/30
104	Reset Status Register (BD_SIUL2_RSR)	32	R	0000_0000h	3.4.4/31

3.4.1 Device Identification Register 1 (BD_SIUL2_DIDR1)

The BD_SIUL2_DIDR1 contains the part number and mask number.

Address: 0h base + 0h offset = 0h

12–15 RAM_SIZE	RAM Size. Read-only, indicates the amount of overlay RAM available in the device, with resolution of 256K byte steps 0000 0.25M byte 0001 0.5M byte 0010 0.75M byte 0011 1M byte 0100 1.25M byte 0101 1.5M byte 0110 1.75M byte 0111 2M byte 1000 2.25M byte 1001 2.5M byte 1010 2.75M byte 1011 3M byte 1100 3.25M byte 1101 3.5M byte 1110 3.75M byte 1111 4M byte
16–23 PARTNUM	Device Part Number. Read-only, mask programmed complement to the part number of the device. For the BD 1M byte part with part number 57BD1, BD_SIUL2_DIDR1.PARTNUM=57BD, and BD_SIUL2_DIDR2.PARTNUM=1. 01 1 (BD1M) 02 2 (BD2M)
24–31 Reserved	This field is reserved.

3.4.3 Initialization Status Register (BD_SIUL2_ISR)

The BD_SIUL2_ISR contains a flag that can be used by the PD or any connected debug or calibration tool to track the status of the BD. This register is reset by POR.

The main expected use case for this flag is to allow software on the PD to determine whether the BD has lost power since it was last initialized. A typical sequence is:

- At power on reset (POR), the flag is cleared automatically (not affected by software reset)
- A calibration tool or PD calibration software initializes the BD (for example, writing BD overlay RAM with calibration data and remap configuration)
- The calibration tool or PD calibration software sets the BD_INIT flag
- After PD POR, the PD boot software executes and reads BD_INIT
- If BD_INIT is clear, BD overlay is assumed to be uninitialized and is not used for calibration remap
- If BD_INIT is set, BD overlay is assumed to be initialized and can be used for calibration remap (other tests to verify data integrity may be used)

BD_INIT is cleared by BD POR, and can be set or cleared via writes from the PD or from the Nexus RWA.

Address: 0h base + 100h offset = 100h

BD_SIUL2_RSR field descriptions

Field	Description
0–28 Reserved	This field is reserved.
29 PD_RST	PD Reset Flag. Read-only, indicates if PD has finished the reset sequence. 0 PD reset sequence not completed 1 PD reset sequence completed
30 PD_TRIM	PD Trim Flag. Read-only, indicates if PD has finished trimming phase during the reset sequence. 0 PD trimming phase not completed 1 PD trimming phase completed
31 PD_POR	PD POR Flag. Read-only, indicates whether PD is powered down or not. 0 PD is powered down or power on reset has not completed 1 PD is powered and power on reset has completed

Chapter 4
Buddy Device—Debug and Calibration Interface (DCI)

4.1 Introduction

The Debug and Calibration Interface (DCI) module provides debug and calibration features for the MCU. It includes a standard IEEE 1149.1/1149.7 compatible JTAG interface which is used to connect with an external JTAG tool using a low frequency clock interface.

It also features a software based debug mode which can be controlled by the MCU without using an external tool. Additionally, the DCI provides features for debug control using break-points and synchronous restart of the cores. This chapter describes the DCI features in the Emulation and Debug Device (ED) that includes features in the Production device (PD) as well as features in the Buddy device (BD). There are two DCIs on the ED which are designated PD DCI and BD DCI.

4.1.1 Features

The DCI features are the following:

- Debug mode enable control for connected tool or software
- Dual DCI system for multi-device clients
- IEEE 1149.1 and IEEE 1149.7 controllers
- Debug break and cross-triggering control
- Synchronous restart control for CPU(s) when exiting debug mode
- Tool hot plug capability

- Security access control
- Debug reset control

4.1.2 Overview

The DCI can take the following different inputs for its JTAG signals:

- P.JTAG—JTAG signals coming from the Buddy device JTAG pads. This is the standard 5-pin JTAG interface and is the default operating mode.
- M.JTAG—JTAG signals generated by JTAGM module using software debug mode.
    - In software debug mode, there is no tool, and debug software running on the MCU generates the JTAG packets and writes them to JTAGM using special debug registers in the JTAGM module.
- I.JTAG— JTAG signals interconnecting the two DCI implementations in the ED coming from the intra-die pads.

By default the DCI operates in standard 5-pin JTAG mode (IEEE 1149.1). It can be configured in 3-pin reduced pin JTAG mode (IEEE 1149.7) after starting from standard 5-pin JTAG mode.

When reduced pin JTAG mode (IEEE 1149.7) is configured TMSC pin is configured in bidirectional mode during operation.

The DCI also provides a centralized break control for system IPs and cores, which can be controlled by an external tool as well as the internal debug peripherals such as timers/ SPU, etc. The DCI also provides the Event Out ($\overline{\text{EVTO}}$) signals to the debug tool in case of the occurrence of any internal debug event.

This figure shows the DCI block diagram.

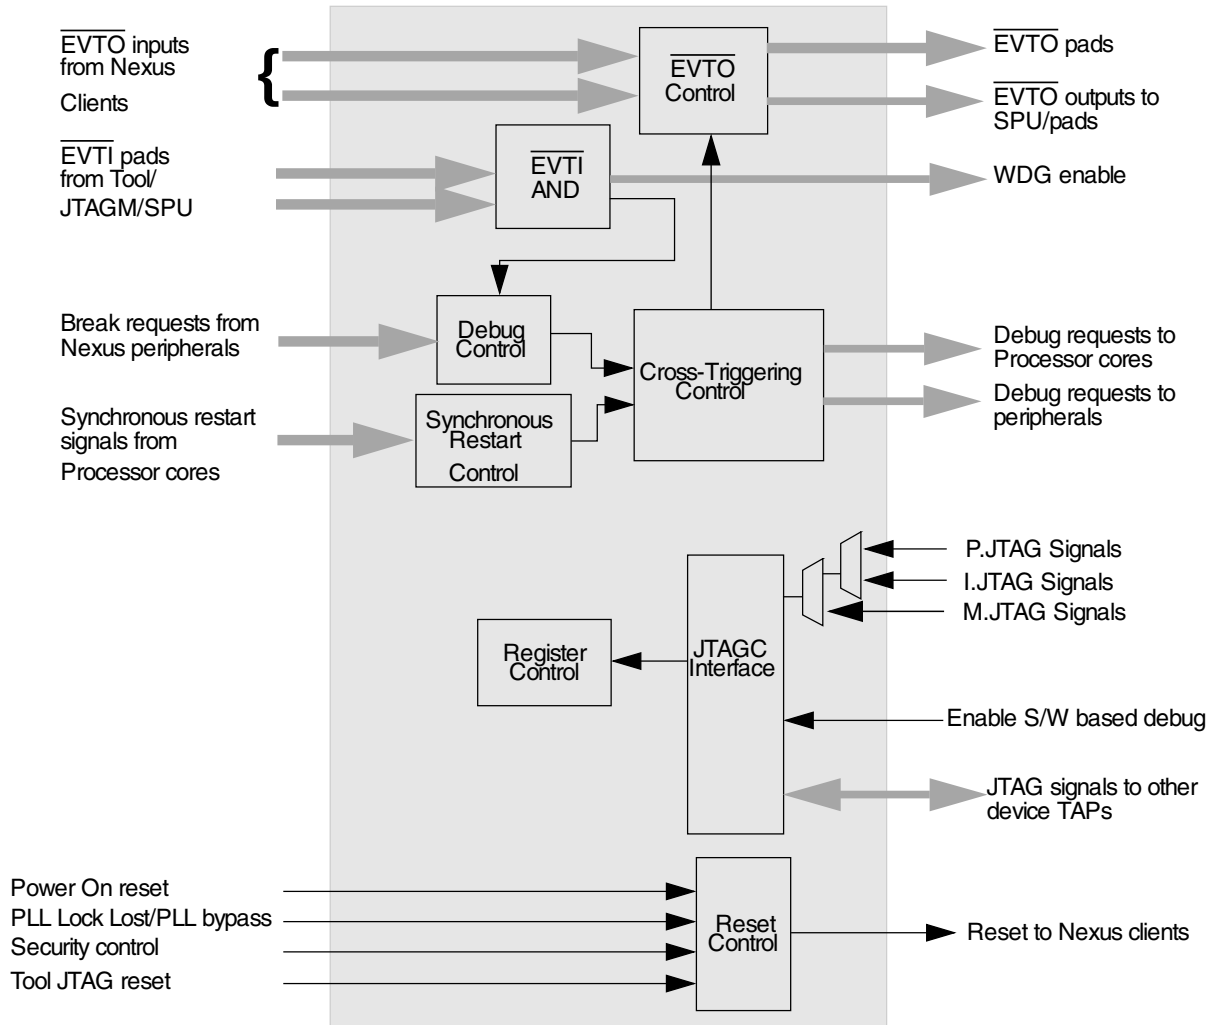

Figure 4-1. DCI block diagram

When the DCI is used in an ED package (PD and the BD together) its configuration is shown as in the following figure. In the ED package, a debug tool is connected to the BD pins and connects to the PD with the I.JTAG interface which are routed using inter-die pads.

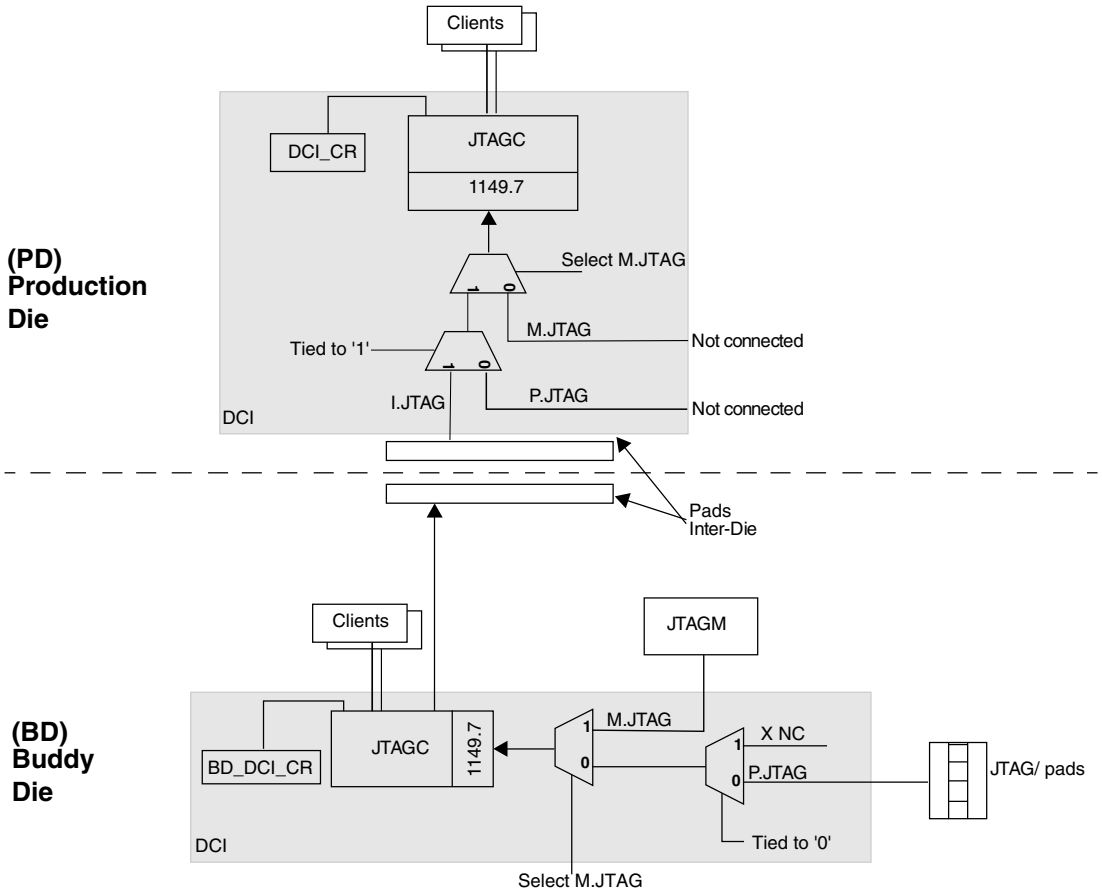

Figure 4-2. DCI in an emulation configuration

4.1.3 Operating modes

Selection between various JTAG sources is done using a JTAGM register bit, JTAGM_MCR[DTM]. The JTAGM bit, JTAGM_MCR[DTM], is programmable via memory-mapped registers. JTAGM is selected as a JTAG source when JTAGM_MCR[DTM] is set.

This table shows a summary of the configuration options.

Table 4-1. DCI JTAG source selection

JTAGM_MCR[DTM]	DCI Source	JCOMP
0	P.JTAG (Standard JTAG)	Asserted
1	M.JTAG (Software)	Negated

The reset signal to the DCI block consists of the following:

- Power-on reset, Low/High voltage detection on IO/Core supplies
- JCOMP reset

The DCI puts the JTAGC TAP in reset when either power-on/low-voltage-detect reset is asserted or JCOMP is negated. In the ED, the BD DCI is reset with BD POR/Low voltage detection on BD_VDD.

The M.JTAG provides an alternate interface to the debug logic.

When no debug tool is connected, device power-on reset puts the DCI in standard 5-pin JTAG mode. This configures the TDO pin in output mode with the reset value (1'b0). There is no change in port values if no debug tool is connected.

This table contains the operating mode descriptions.

Table 4-2. DCI operating modes

Mode	Description
DCI_JTAG	JTAG mode. This is the default state after power-on reset. In this mode the DCI is in JTAG mode (controlled with P.JTAG or I.JTAG) and is controlled by an external JTAG tool.
DCI_SW_DBG	Software Debug State. This state is achieved when no tool is present and software sets the JTAGM_MCR[DTM] bit. The DCI is then controlled using M.JTAG signals.

4.1.3.1 Software enabled debug and calibration mode

Apart from the JTAG sources, such as a JTAG-based tool, it is possible to generate JTAG sequences through software programming.

To support a software debug session via a CAN or SPI link, the software can enable debug and calibration mode via an memory-mapped register. It is done first by setting a control bit in the JTAGM (JTAGM_MCR[DTM]). For more details, refer to the JTAGM documentation. When enabled, the DCI is configured to receive M.JTAG signals which are driven by JTAGM registers accessible through software. Software can control all DCI features like any other JTAG source.

After a system reset, the JTAGM_MCR[DTM] bit is reset and the JCOMP pad is pulled-low, thus keeping the DCI in the reset state. Therefore, software is required to first change to a non-secured mode. Then it can program the JTAGM_MCR[DTM] bit, to select M.JTAG as the source inside the DCI, and then set the JTAGM_MCR[jtagm_JCOMP] bit present in the JTAGM, which takes all debug modules out of reset.

When MCR[jtagm_JCOMP] is programmed to 0, the JTAGC block reset is asserted, thus putting the debug and calibration logic in reset state. This bit is used during software based debug to initialize the debug and calibration logic.

Software based debug is not possible when a tool is connected. The presence of the tool is determined using the rising edge of the JCOMP pad to set an internal flag which, when set, disables the selection of JTAGM as a JTAG source.

NOTE

It is recommended to utilize either hardware based debug (JTAG) or software based debug. If only one of the debug method is used, all three connection methods (connect and reset target, connect and break application, connect and keep application running) are supported.

4.1.3.2 Nexus reset control

The JCOMP input that is used as the primary reset signal for the DCI is also used by the DCI to generate a single-bit reset signal for other Nexus blocks. It is used to reset all debug functions without affecting any system level functions. The DCI provides the reset signal for all Nexus blocks, with the PD DCI providing the reset signal to all PD debug blocks, and the BD DCI providing the reset signal for all BD debug blocks. This reset is controlled using the following signals:

- Power-on reset/Low voltage detect (applicable to both PD and BD)
- JCOMP (applicable to both PD and BD)
- SoC Debug_Enable signal (applicable to PD only)
- System PLL is out of lock state and not bypassed (applicable to PD only)

Asserting power-on reset, negating JCOMP, or negating the Debug_Enable signal, results in asynchronous entry into reset state. Following negation of power-on reset, the BD Nexus reset signal remains asserted until the JCOMP signal is asserted. Any subsequent loss of PLL lock does not generate a Nexus reset. This reset signal is unaffected by other sources of reset.

If Debug_Enable is de-asserted by the SoC security modules (PASS), then the DCI holds the debug and trace logic in reset. The Debug_Enable signal is generated by security logic after functional or destructive reset based on the device censored mode, the PASS_LOCK3[DBL] control, and the device life cycle. If the Debug_Enable signal is asserted by the security logic, it is possible to trace through functional resets

The following table shows how the Nexus reset is asserted/negated based on various signals.

Table 4-3. Nexus Reset Truth Table

POR	JCOMP	Debug_Enable	PLL lock	Nexus reset
Assert	X	X	X	Assert
X	Negate	X	X	Assert
X	X	Disable	X	Assert
X	X	X	Unlocked	Assert
Negate	Assert	Enable	Locked	Negate

4.1.3.3 System watchdog control

The BD DCI does not include the Software Watchdog Timer (SWT) disable feature.

4.1.3.4 Reset control

The BD DCI includes control bits to allow a connected tool to force a reset of the connected device. The description is as follows:

- Force BD Reset—This reset is generated by programming DCI_CR[FBD_RESET] bit. When set it forces reset. This bit has to be reset by the tool to negate the reset signal.

These reset signals are directly connected to the respective DCI_CR bits. The DCI does not reset the DCI_CR bits after generation of the respective reset signals. The tool must specifically reset the appropriate DCI_CR bits to remove the reset signals. These reset control bits can be set/reset through JTAG programming, and only reset through JCOMP assertion or Power-on-reset.

4.2 External signal description

The JTAGC module used inside DCI module defines the interface with external signals. It consists of five signals (TMS/TDI/TDO/TCK/JCOMP) that connect to off chip development tools and allow access to test support functions. For more details for JTAG signals, refer to JTAGC documentation.

4.3 Register description

The PD DCI module contains two registers, DCI_CR and DCI_PINCR, which are present inside the JTAGC module. The BD DCI only contains the DCI_CR and does not contain the DCI_PINCR. These registers are only controlled using the JTAGC TAP and no memory-mapped registers are present.

4.3.1 DCI control register (BD_DCI_CR)

The BD_DCI_CR is a 32-bit data register. This register is programmed using JTAG shift with the corresponding enable instruction described in the JTAGC chapter. The following table shows the format of the BD_DCI_CR.

NOTE

The BD version of this register is refered to as DCI_CR in the other sections of this chapter.

In an ED which has both PD and BD instances of the DCI, all bits must be programmed on the BD DCI instance. The only bits of this register that do not follow this rule are EVTI1_PAD_EN and EVTI0_PAD_EN, which must be programmed in both DCI instances.

	31	30	29	28	27	26	25	24
R W	Reserved							
Reset	1	1	1	1	1	1	1	1

	23	22	21	20	19	18	17	16
R W	Reserved							
Reset	1	1	1	1	1	1	1	1

	15	14	13	12	11	10	9	8
R W	Reserved					Reserved	Reserved	
Reset	1	1	1	1	1	0	0	0

	7	6	5	4	3	2	1	0
R W	FBD_RESET	Reserved	EVTI_1_PAD_EN	EVTI_0_PAD_EN	Reserved		Reserved	Reserved
Reset	0	0	0	0	0	0	0	0

The BD_DCI_CR is described in this table.

Table 4-4. BD_DCI_CR field descriptions

Field	Description	
7 FBD_RESET	Force Reset	
	0	Do not force Reset
	1	Force Reset
5 EVTI1_PAD_EN[1]	$\overline{\text{EVTI}}$[1] feature enable	
	0	$\overline{\text{EVTI}}$[1] disabled (default)
	1	$\overline{\text{EVTI}}$[1] enabled
4 EVTI0_PAD_EN[1]	$\overline{\text{EVTI}}$[0] feature enable	
	0	$\overline{\text{EVTI}}$[0] disabled (default)
	1	$\overline{\text{EVTI}}$[0] enabled

1. In an ED that has both PD and BD, EVTI1_PAD_EN and EVTI0_PAD_EN must be programmed in both BD and PD instances of the DCI in order to allow events generated on the BD to pass through the BD DCI and reach the PD DCI.

4.3.2 DCI EVTx pin multiplexing control register (DCI_PINCR)

The DCI_PINCR is a 32-bit data register. This register is programmed using JTAG shift with the corresponding enable instruction described in the JTAGC chapter. For a description of the DCI_PINCR functionality, see the Calibration and Debug configuration chapter which describes how the modules are configured.

Chapter 5
Buddy Device—JTAG Controller (JTAGC)

5.1 Introduction

The JTAGC block provides the means to test chip functionality and connectivity while remaining transparent to system logic when not in test mode. Testing is performed via a boundary scan technique, as defined in the IEEE 1149.1-2001 standard. All data input to and output from the JTAGC block is communicated in serial format.

5.1.1 Block diagram

The following is a simplified block diagram of the JTAG Controller (JTAGC) block. Refer to the chip-specific configuration information as well as Register description for more information about the JTAGC registers.

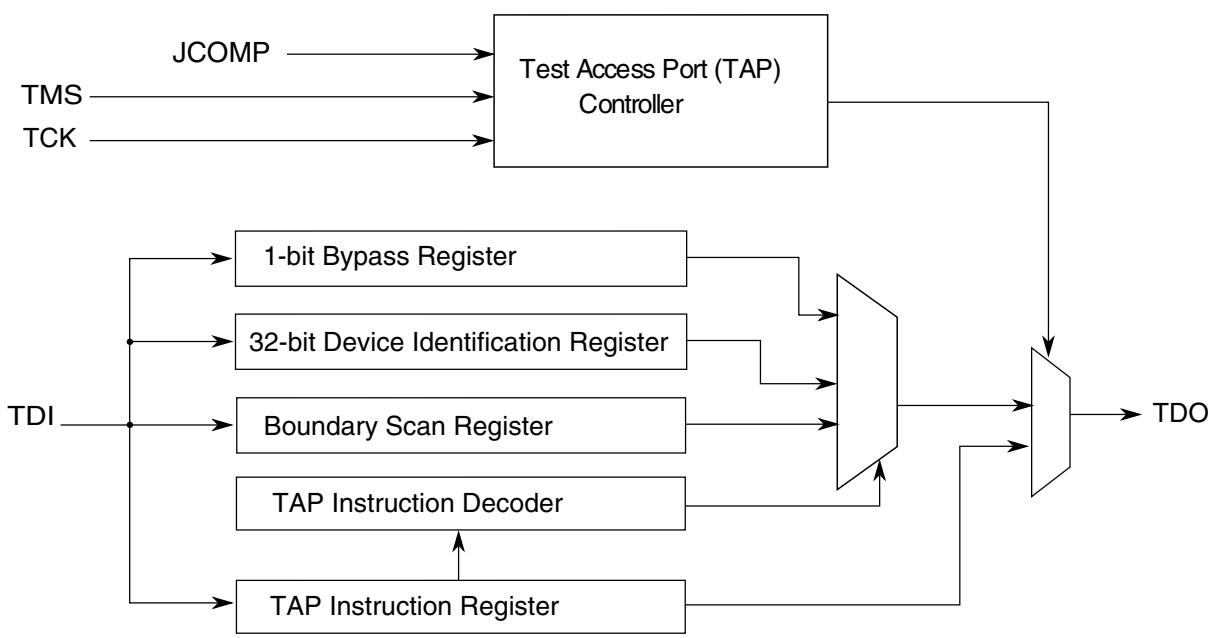

Figure 5-1. JTAG (IEEE 1149.1) block diagram

5.1.2 Features

The JTAGC block is compliant with the IEEE 1149.1-2001 standard, and supports the following features:

- IEEE 1149.1-2001 Test Access Port (TAP) interface
  - 4 pins (TDI, TMS, TCK, and TDO)
- JCOMP input that provides reset control
- Instruction register that supports several IEEE 1149.1-2001 defined instructions as well as several public and private device-specific instructions. Refer to Table 5-4 for a list of supported instructions.
- Sharing of the TAP with other TAP controllers via ACCESS_AUX_x instructions
- JTAG_PASSWORD register
- Bypass register, boundary scan register, data registers, and device identification register.
- TAP controller state machine that controls the operation of the data registers, instruction register and associated circuitry.

5.1.3 Modes of operation

The JTAGC block uses JCOMP and a power-on reset indication as its primary reset signals. Several IEEE 1149.1-2001 defined test modes are supported, as well as a bypass mode.

5.1.3.1 Reset

The JTAGC block is placed in reset when either power-on reset is asserted, JCOMP is negated, or the TMS input is held high for enough consecutive rising edges of TCK to sequence the TAP controller state machine into the Test-Logic-Reset state. Holding TMS high for five consecutive rising edges of TCK guarantees entry into the Test-Logic-Reset state regardless of the current TAP controller state. Asserting power-on reset or setting JCOMP to a value other than the value required to enable the JTAGC block results in asynchronous entry into the reset state. While in reset, the following actions occur:

- The TAP controller is forced into the Test-Logic-Reset state, thereby disabling the test logic and allowing normal operation of the on-chip system logic to continue unhindered
- The instruction register is loaded with the IDCODE instruction

5.1.3.2 IEEE 1149.1-2001 defined test modes

The JTAGC block supports several IEEE 1149.1-2001 defined test modes. A test mode is selected by loading the appropriate instruction into the instruction register while the JTAGC is enabled. Supported test instructions include EXTEST, HIGHZ, CLAMP, SAMPLE and SAMPLE/PRELOAD. Each instruction defines the set of data register(s) that may operate and interact with the on-chip system logic while the instruction is current. Only one test data register path is enabled to shift data between TDI and TDO for each instruction.

The boundary scan register is enabled for serial access between TDI and TDO when the EXTEST, SAMPLE or SAMPLE/PRELOAD instructions are active. The single-bit bypass register shift stage is enabled for serial access between TDI and TDO when the BYPASS, HIGHZ, CLAMP or reserved instructions are active. The functionality of each test mode is explained in more detail in JTAGC block instructions.

5.1.3.3 Bypass mode

When no test operation is required, the BYPASS instruction can be loaded to place the JTAGC block into bypass mode. While in bypass mode, the single-bit bypass shift register is used to provide a minimum-length serial path to shift data between TDI and TDO.

5.2 External signal description

The JTAGC consists of a set of signals that connect to off chip development tools and allow access to test support functions. The JTAGC signals are outlined in the following table and described in the following sections.

Table 5-1. JTAG signal properties

Name	I/O	Function	Reset State	Pull
TCK	Input	Test Clock	—	Down

Table continues on the next page...

Table 5-1. JTAG signal properties (continued)

Name	I/O	Function	Reset State	Pull
TDI	Input	Test Data In	—	Up
TDO	Output	Test Data Out	High Z[1]	—
TMS	Input	Test Mode Select	—	Up
JCOMP	Input	JTAG Compliancy	—	Down

1. TDO output buffer enable is negated when the JTAGC is not in the Shift-IR or Shift-DR states. A weak pull may be implemented at the TDO pad for use when JTAGC is inactive.

5.2.1 TCK—Test clock input

Test Clock Input (TCK) is an input pin used to synchronize the test logic and control register access through the TAP.

5.2.2 TDI—Test data input

Test Data Input (TDI) is an input pin that receives serial test instructions and data. TDI is sampled on the rising edge of TCK.

5.2.3 TDO—Test data output

Test Data Output (TDO) is an output pin that transmits serial output for test instructions and data. TDO is three-stateable and is actively driven only in the Shift-IR and Shift-DR states of the TAP controller state machine, which is described in TAP controller state machine.

5.2.4 TMS—Test mode select

Test Mode Select (TMS) is an input pin used to sequence the IEEE 1149.1-2001 test control state machine. TMS is sampled on the rising edge of TCK.

5.2.5 JCOMP—JTAG compliancy

The JCOMP signal provides IEEE 1149.1-2001 compatibility and provides the ability to share the TAP. The JTAGC TAP controller is enabled when JCOMP is set to the JTAGC enable encoding, otherwise the JTAGC TAP controller remains in reset.

5.3 Register description

This section provides a detailed description of the JTAGC block registers accessible through the TAP interface, including data registers and the instruction register. Individual bit-level descriptions and reset states of each register are included. These registers are not memory-mapped and can only be accessed through the TAP.

5.3.1 Instruction register

The JTAGC block uses a 6-bit instruction register as shown in the following figure. The instruction register allows instructions to be loaded into the block to select the test to be performed or the test data register to be accessed or both. Instructions are shifted in through TDI while the TAP controller is in the Shift-IR state, and latched on the falling edge of TCK in the Update-IR state. The latched instruction value can only be changed in the Update-IR and Test-Logic-Reset TAP controller states. Synchronous entry into the Test-Logic-Reset state results in the IDCODE instruction being loaded on the falling edge of TCK. Asynchronous entry into the Test-Logic-Reset state results in asynchronous loading of the IDCODE instruction. During the Capture-IR TAP controller state, the instruction shift register is loaded with the value 000001b, making this value the register's read value when the TAP controller is sequenced into the Shift-IR state.

	5	4	3	2	1	0
R	0	0	0	0	0	1
W	Instruction Code					
Reset:	0	0	0	0	0	1

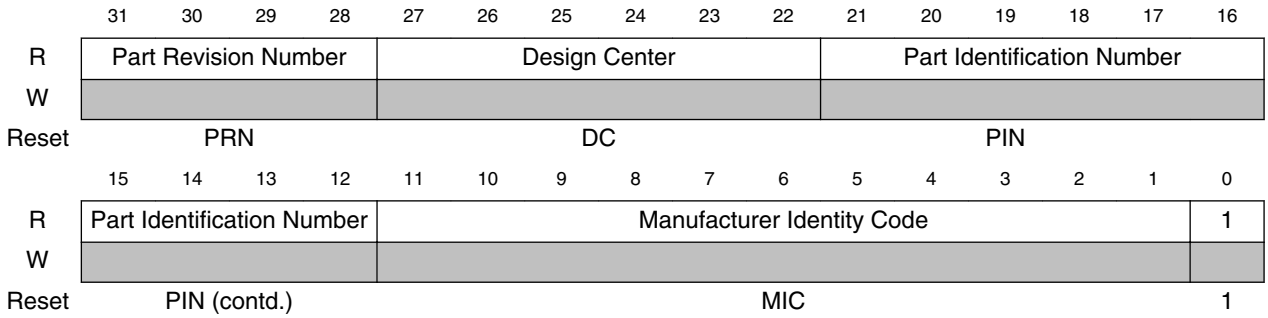

Figure 5-2. Instruction register

5.3.2 Bypass register

The bypass register is a single-bit shift register path selected for serial data transfer between TDI and TDO when the BYPASS, CLAMP, HIGHZ or reserve instructions are active. After entry into the Capture-DR state, the single-bit shift register is set to a logic 0. Therefore, the first bit shifted out after selecting the bypass register is always a logic 0.

5.3.3 Device identification register

The device identification (JTAG ID) register, shown in the following figure, allows the revision number, part number, manufacturer, and design center responsible for the design of the part to be determined through the TAP. The device identification register is selected for serial data transfer between TDI and TDO when the IDCODE instruction is active. Entry into the Capture-DR state while the device identification register is selected loads the IDCODE into the shift register to be shifted out on TDO in the Shift-DR state. No action occurs in the Update-DR state.

The following table describes the device identification register functions.

Table 5-2. Device identification register field descriptions

Field	Description
PRN	Part Revision Number. Contains the revision number of the part. Value is 0x0.
DC	Design Center. Indicates the design center. Value is 0x2B.
PIN	Part Identification Number. Contains the part number of the device. 0x381.
MIC	Manufacturer Identity Code. Contains the reduced Joint Electron Device Engineering Council (JEDEC) ID. Value is 0x00E.
IDCODE ID	IDCODE Register ID. Identifies this register as the device identification register and not the bypass register. Always set to 1.

5.3.4 JTAG_PASSWORD register

The JTAG_PASSWORD register is a 256-bit shift register path from TDI to TDO selected when the ENABLE_JTAG_PASSWORD instruction is active. The default reset value of the JTAG_PASSWORD register is 256'b0. The JTAG_PASSWORD register transfers its value to a parallel hold register on the rising edge of TCK when the TAP controller state machine is in the Update-DR state. Once the ENABLE_JTAG_PASSWORD instruction is executed, the register value remains valid until a JTAG reset occurs. The operation of this register is described in the security documentation.

	255	...	2	1	0
R	JTAG_PASSWORD				
W					
Reset:	*[1]	*	*	*	*

1. The reset value of JTAG_PASSWORD is 256 'b0.

The following table describes the JTAG_PASSWORD register functions.

Table 5-3. JTAG_PASSWORD register field descriptions

Field	Description
JTAG_PASSWORD	JTAG Password. The JTAG_PASSWORD bits are used to provide the JTAG password for security.

5.3.5 Boundary scan register

The boundary scan register is connected between TDI and TDO when the EXTEST, SAMPLE or SAMPLE/PRELOAD instructions are active. It is used to capture input pin data, force fixed values on output pins, and select a logic value and direction for bidirectional pins. Each bit of the boundary scan register represents a separate boundary scan register cell, as described in the IEEE 1149.1-2001 standard and discussed in Boundary scan. The size of the boundary scan register and bit ordering is device-dependent and can be found in the device BSDL file.

The BD boundary scan chain includes registers connected to all PD/BD interface signals at the BD side. These registers are controlled by the EXTEST, SAMPLE or SAMPLE/PRELOAD instructions applied to the BD JTAG controller. Similarly, the PD boundary scan chain also contains registers connected to the interface signals at the PD side, which are controlled by instructions applied to the PD JTAG controller.

5.4 Functional description

This section explains the JTAGC functional description.

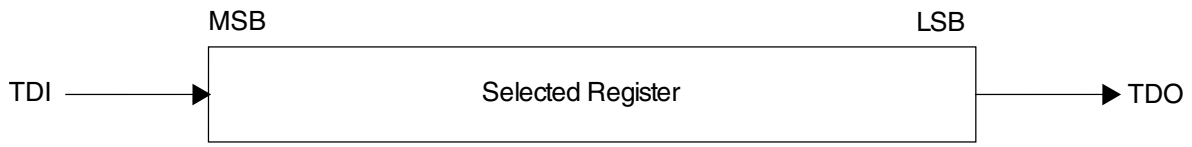
5.4.1 JTAGC reset configuration

While in reset, the TAP controller is forced into the Test-Logic-Reset state, thus disabling the test logic and allowing normal operation of the on-chip system logic. In addition, the instruction register is loaded with the IDCODE instruction.

5.4.2 IEEE 1149.1-2001 (JTAG) Test Access Port

The JTAGC block uses the IEEE 1149.1-2001 TAP for accessing registers. This port can be shared with other TAP controllers on the MCU. Ownership of the port is determined by the value of the currently loaded instruction. For more detail on TAP sharing via JTAGC instructions refer to ACCESS_AUX_x instructions.

Data is shifted between TDI and TDO though the selected register starting with the least significant bit, as illustrated in the following figure. This applies for the instruction register, test data registers, and the bypass register.



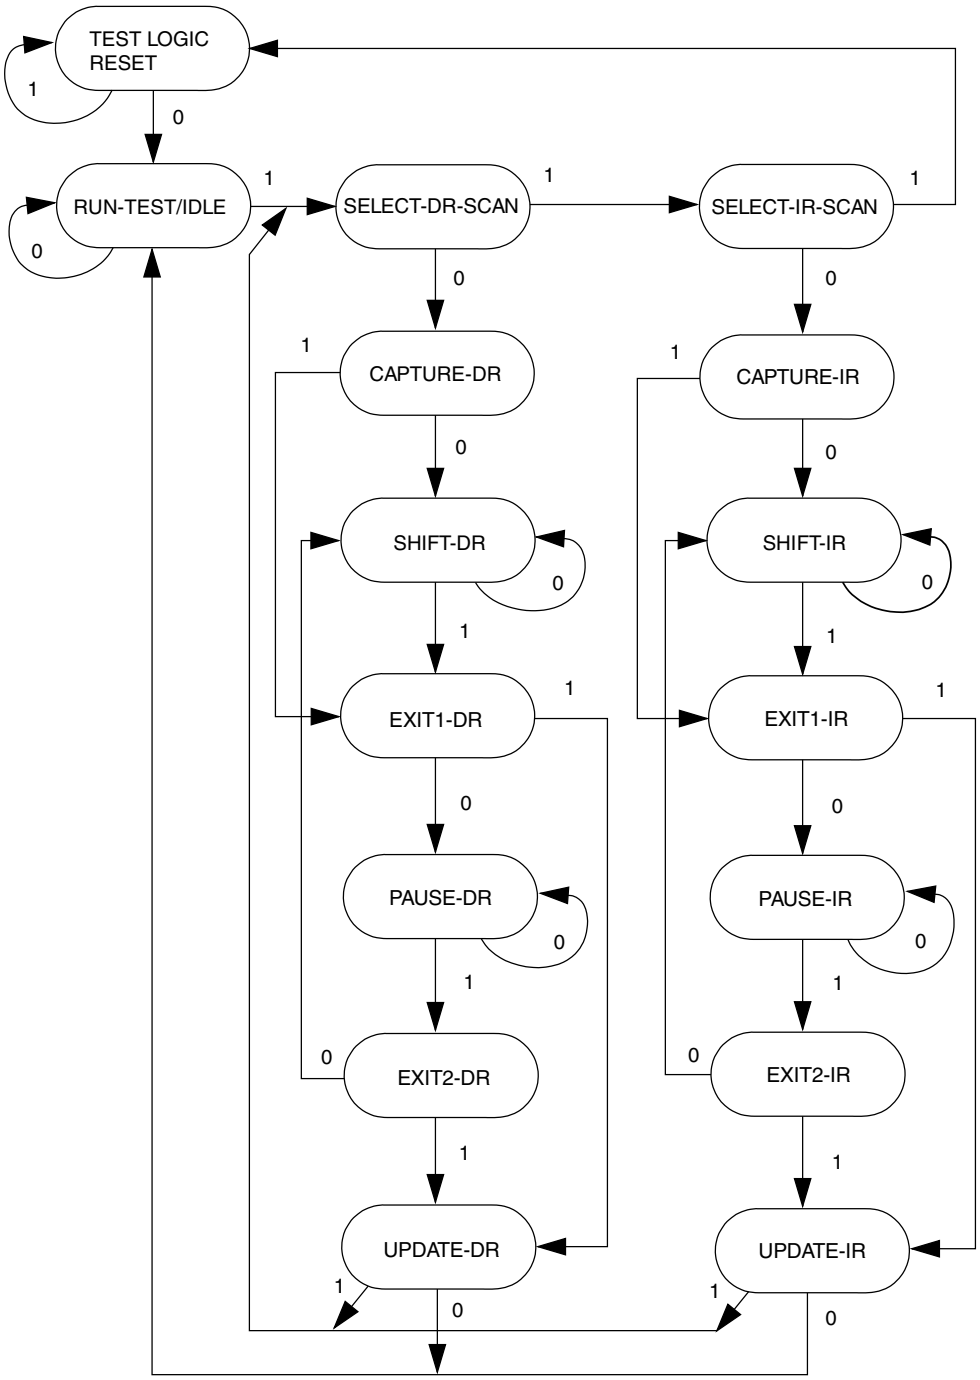


Figure 5-3. Shifting data through a register

5.4.3 TAP controller state machine

The TAP controller is a synchronous state machine that interprets the sequence of logical values on the TMS pin. The following figure shows the machine's states. The value shown next to each state is the value of the TMS signal sampled on the rising edge of the TCK signal. As the following figure shows, holding TMS at logic 1 while clocking TCK through a sufficient number of rising edges also causes the state machine to enter the Test-Logic-Reset state.

The value shown adjacent to each state transition in this figure represents the value of TMS at the time of a rising edge of TCK.

Figure 5-4. IEEE 1149.1-2001 TAP controller finite state machine

5.4.3.1 Enabling the TAP controller

The JTAGC TAP controller is enabled by setting JCOMP to a logic 1 value.

5.4.3.2 Selecting an IEEE 1149.1-2001 register

Access to the JTAGC data registers is achieved by loading the instruction register with any of the JTAGC block instructions while the JTAGC is enabled. Instructions are shifted in via the Select-IR-Scan path and loaded in the Update-IR state. At this point, all data register access is performed via the Select-DR-Scan path.

The Select-DR-Scan path is used to read or write the register data by shifting in the data (LSB first) during the Shift-DR state. When reading a register, the register value is loaded into the IEEE 1149.1-2001 shifter during the Capture-DR state. When writing a register, the value is loaded from the IEEE 1149.1-2001 shifter to the register during the Update-DR state. When reading a register, there is no requirement to shift out the entire register contents. Shifting may be terminated once the required number of bits have been acquired.

5.4.4 JTAGC block instructions

The JTAGC block implements the IEEE 1149.1-2001 defined instructions listed in the following table. This section gives an overview of each instruction; refer to the IEEE 1149.1-2001 standard for more details. All undefined opcodes are reserved.

Table 5-4. General 6-bit JTAG instructions

Instruction	Code[5:0]	Instruction Summary
IDCODE	000001	Selects device identification register for shift
SAMPLE/PRELOAD	000010	Selects boundary scan register for shifting, sampling, and preloading without disturbing functional operation
SAMPLE	000011	Selects boundary scan register for shifting and sampling without disturbing functional operation
EXTEST	000100	Selects boundary scan register and applies preloaded values to output pins. **NOTE:** Execution of this instruction asserts functional reset.
Factory debug reserved	000101	Intended for factory debug only
Factory debug reserved	000110	Intended for factory debug only
ENABLE_JTAG_PASSWORD	000111	Selects JTAG_PASSWORD register
HIGHZ	001001	Selects bypass register and three-states all output pins. **NOTE:** Execution of this instruction asserts functional reset.
Factory debug reserved	001010	Intended for factory debug only
CLAMP	001100	Selects bypass register and applies preloaded values to output pins. **NOTE:** Execution of this instruction asserts functional reset.

Table continues on the next page...

Table 5-4. General 6-bit JTAG instructions (continued)

Instruction	Code[5:0]	Instruction Summary
ENABLE_DCI_CR	001110	Enables access to DCI CR register
Reserved	001111	Reserved
BYPASS	111111	Selects bypass register for data operations
Reserved[1]	All other opcodes	Decoded to select bypass register
ACCESS_AUX_x	100000-111110	Grants one of the auxiliary TAP controllers ownership of the TAP

1. The manufacturer reserves the right to change the decoding of reserved instruction codes in the future

The ACCESS_AUX instructions are described in the chip configuration debug information.

5.4.4.1 IDCODE instruction

IDCODE selects the 32-bit device identification register as the shift path between TDI and TDO. This instruction allows interrogation of the MCU to determine its version number and other part identification data. IDCODE is the instruction placed into the instruction register when the JTAGC block is reset.

5.4.4.2 SAMPLE/PRELOAD instruction

The SAMPLE/PRELOAD instruction has two functions:

- The SAMPLE portion of the instruction obtains a sample of the system data and control signals present at the MCU input pins and just before the boundary scan register cells at the output pins. This sampling occurs on the rising edge of TCK in the Capture-DR state when the SAMPLE/PRELOAD instruction is active. The sampled data is viewed by shifting it through the boundary scan register to the TDO output during the Shift-DR state. Both the data capture and the shift operation are transparent to system operation.
- The PRELOAD portion of the instruction initializes the boundary scan register cells before selecting the EXTEST or CLAMP instructions to perform boundary scan tests. This is achieved by shifting in initialization data to the boundary scan register during the Shift-DR state. The initialization data is transferred to the parallel outputs of the boundary scan register cells on the falling edge of TCK in the Update-DR state. The data is applied to the external output pins by the EXTEST or CLAMP instruction. System operation is not affected.

5.4.4.3 SAMPLE instruction

The SAMPLE instruction obtains a sample of the system data and control signals present at the MCU input pins and just before the boundary scan register cells at the output pins. This sampling occurs on the rising edge of TCK in the Capture-DR state when the SAMPLE instruction is active. The sampled data is viewed by shifting it through the boundary scan register to the TDO output during the Shift-DR state. There is no defined action in the Update-DR state. Both the data capture and the shift operation are transparent to system operation.

5.4.4.4 EXTEST External test instruction

EXTEST selects the boundary scan register as the shift path between TDI and TDO. It allows testing of off-chip circuitry and board-level interconnections by driving preloaded data contained in the boundary scan register onto the system output pins. Typically, the preloaded data is loaded into the boundary scan register using the SAMPLE/PRELOAD instruction before the selection of EXTEST. EXTEST asserts the internal system reset for the MCU to force a predictable internal state while performing external boundary scan operations.

5.4.4.5 ENABLE_JTAG_PASSWORD instruction

The ENABLE_JTAG_PASSWORD instruction selects the JTAG_PASSWORD register for connection as the shift path between TDI and TDO.

5.4.4.6 HIGHZ instruction

HIGHZ selects the bypass register as the shift path between TDI and TDO. While HIGHZ is active all output drivers are placed in an inactive drive state (e.g., high impedance). HIGHZ also asserts the internal system reset for the MCU to force a predictable internal state.

5.4.4.7 CLAMP instruction

CLAMP allows the state of signals driven from MCU pins to be determined from the boundary scan register while the bypass register is selected as the serial path between TDI and TDO. CLAMP enhances test efficiency by reducing the overall shift path to a

single bit (the bypass register) while conducting an EXTEST type of instruction through the boundary scan register. CLAMP also asserts the internal system reset for the MCU to force a predictable internal state.

5.4.4.8 ACCESS_AUX_x instructions

The JTAGC is configurable to allow other TAP controllers on the device to share the port with it. This is done by providing ACCESS_AUX_x instructions for each of these TAP controllers. When this instruction is loaded, control of the JTAG pins are transferred to the selected TAP controller. Any data input via TDI and TMS is passed to the selected TAP controller, and any TDO output from the selected TAP controller is sent back to the JTAGC to be output on the pins. The JTAGC regains control of the JTAG port during the UPDATE-DR state if the PAUSE-DR state was entered. Auxiliary TAP controllers are held in RUN-TEST/IDLE while they are inactive. Instructions not used to access an auxiliary TAP controller on a device are treated like the BYPASS instruction.

5.4.4.9 BYPASS instruction

BYPASS selects the bypass register, creating a single-bit shift register path between TDI and TDO. BYPASS enhances test efficiency by reducing the overall shift path when no test operation of the MCU is required. This allows more rapid movement of test data to and from other components on a board that are required to perform test functions. While the BYPASS instruction is active the system logic operates normally.

5.4.5 Boundary scan

The boundary scan technique allows signals at component boundaries to be controlled and observed through the shift-register stage associated with each pad. Each stage is part of a larger boundary scan register cell, and cells for each pad are interconnected serially to form a shift-register chain around the border of the design. The boundary scan register consists of this shift-register chain, and is connected between TDI and TDO when the EXTEST, SAMPLE, or SAMPLE/PRELOAD instructions are loaded. The shift-register chain contains a serial input and serial output, as well as clock and control signals.

PD and the BD have their own separate boundary scan chains, each one controlled by the respective JTAG controller. Besides the package I/O pins, these chains also encompasses the interface signals between BD and PD. Testing of the interface can be done by applying EXTEST, SAMPLE or SAMPLE/PRELOAD instructions to both PD and BD JTAG.

5.5 Initialization/Application information

The test logic is a static logic design, and TCK can be stopped in either a high or low state without loss of data. However, the system clock is not synchronized to TCK internally. Any mixed operation using both the test logic and the system functional logic requires external synchronization.

To initialize the JTAGC block and enable access to registers, the following sequence is required:

1. Set the JCOMP signal to the JTAGC enable value, thereby enabling the JTAGC TAP controller.
2. Load the appropriate instruction for the test or action to be performed.

Chapter 6
Buddy Device—Nexus Aurora Router (NAR)

6.1 Introduction

On the device, there are multiple blocks that require development interface support. The blocks that are Nexus-compliant (based on the IEEE-ISTO 5001 standard) are expected to interface with the development tool through a dedicated high-bandwidth debug port. The Nexus Aurora Router (NAR) controls the usage of the output port in a manner that allows all the individual development interface blocks to share the port, and appear to the development tool to be a single block.

Top-level architecture is shown in the following figure. Multiple clients send messages by sharing the high-bandwidth port through the NAR. For a list of the specific clients that are connected to the NAR, see the Calibration and Debug configuration chapter which describes how the modules are configured. The Nexus Aurora Link (NAL) takes the 32-bit Nexus message beats from the NAR and processes them in Aurora-ready data octets for the Nexus Aurora Phy (NAP) block, which interfaces directly with the high-bandwidth port. The Aurora output port of NAR can be fed as a client to another NAR.

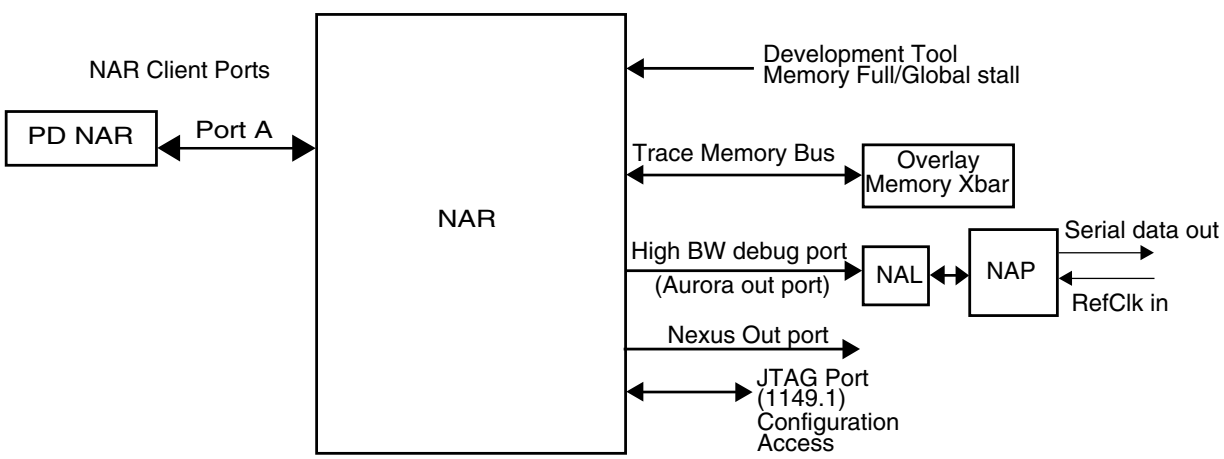

Figure 6-1. NAR top level block diagram

The trace memory bus port provides added flexibility to the channel trace data to memory on the Nexus Aurora crossbar. The Nexus Out port provides additional flexibility to the channel trace data to memory on the Nexus recipient. Setup and configuration of the NAR is performed by accessing the configuration registers via a JTAG (1149.1) port.

Each Nexus client has a dedicated receive queue to allow seamless switching between sources at Nexus message boundaries. Incoming Nexus data is parsed into the receive queues so that end-of-message can be determined. Messages are then transferred into the main queue. An arbitration block determines the order in which clients are serviced, using an optional client request level bus to prioritize the data (lacking request level data, a simple round-robin algorithm is used). The NAR has two output ports: the high bandwidth debug port (Aurora out) and the trace memory bus. If both output ports are enabled at the same time, the main queue is logically partitioned inside NAR. These two partitions of the main queue are supported for better throughput each having 50% size. The two NAR output ports can be in operation simultaneously, with the output arbitration block splitting out messages by type or by source. Data going through the Aurora out port or the Trace port goes through an additional translation block to put the data in the correct format. The actual Aurora formatting is done in the NAL. Additional blocks for message generation and timestamp generation are described in more detail in the following sections.

The Buddy Device (BD) NAR supports the following client interface:

- Aurora type interface with clock domain transfer at the same frequency

6.2 Overview

The NAR serves as an arbiter for the high-bandwidth debug port (HBDP). The NAR pulls Nexus messages from multiple clients, queues the data, and forwards it (based on the user-controlled configuration) to the high-speed Aurora Out port and/or the Trace port. The trace memory bus controller allows the NAR to transmit data via the normal system interface. NAR control and configuration registers are accessed via JTAG (IEEE 1149.1) port.

6.3 Features

The NAR supports the following features:

- Connects 1 client(s) with dedicated receive queue(s). Clients can transmit data as long as there is space in its associated receive queue, but only the active port receive queue empties into the main queue.
- Aurora output data format for dedicated high-bandwidth serial transmission
- Aurora output format support at client interface
- Trace Memory port (64-bit address and data) can be used to write Nexus messages directly to external overlay memory. Block transfer mode provides highest-bandwidth option.
- Nexus out port for direct connection to pins (low-speed applications) or to another Nexus port controller
- Configurable Start Address and Range Selection for Trace Memory port write operation provides flexibility to choose Overlay memory Section and range to store Trace data.
- Both output ports may operate simultaneously. Filtering logic sorts messages to determine destination port.
- Partitionable main queue makes it possible to simultaneously service multiple output ports. It can also be used to devote more bandwidth to high-priority message-types or split trace stream between on-chip memory and trace port.
- Re-allocatable receive queues allow queue-space of an inactive client to be reassigned to an active client
- Stall detection and handling allows NAR to continue when a client stops sending data in the middle of a message
- Programmable Global stall signal on debug tool indication of memory overflow
- Event generation on External Trace Memory (overlay) programmable full
- Suppress mode can be used to shut down message delivery and relieve back-pressure to clients without turning off Nexus messaging in the clients.

6.4 Register definition

The NAR configuration registers provide configuration and control for all NAR operations. They are accessible through the JTAG (IEEE 1149.1) port. Addressing (within the local NAR address space) for the NAR registers is shown in the following table. If the NAR clock is turned off, the NAR registers cannot be accessed.

Table 6-1. NAR registers

Register name	Read/Write	JTAG index (NAR relative)
NAR_CR—NAR Control Register	R/W	0
NAR_ST—NAR Status Register	R	1
NAR_SFR—Source Filter Register	R/W	2
NAR_TFR—Type Filter Register	R/W	3
NAR_TBALO—Trace memory port base address, low	R/W	4
NAR_TBAHI—Trace memory port base address, high	R/W	5
NAR_TCR—Trace Memory bus control register	R/W	6
NAR_STCR—Suppress Trigger Control Registers 1–4	R/W	7 (Trigger 1) 8 (Trigger 2) 9 (Trigger 3) A (Trigger 4)
NAR_CSSR–Client Suppress Status Register	R	B
NAR_CDR—Client Disable Register	R/W	C
NAR_NAPCR—Nexus Aurora Phy Control Register	R/W	D
NAR_AHFPAR—Trace memory fill level and partition configuration	R/W	E

6.4.1 NAR control register (NAR_CR)

The NAR control register provides all the main control and enable bits for the NAR and its output ports. The following table shows the format of the NAR_CR.

Register index: 0

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	NEN	NCD	TEN	TRS	TSG		SED	SRD	TBW	AQP		0	0	0	0	0
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	WPE			0	0	MSP		0	ALT		0	AFA	0	FSD	PUS	NSR
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The NAR_CR is described in the following table.

Table 6-2. NAR_CR field descriptions

Field	Description	
31	NAR Enable.	
NEN	0	NAR is disabled unless HBDP is independently enabled. See Disabled for more information.
	1	NAR is enabled.
30	NAR Communication Disable.	
NCD	0	NAR monitors clients for activity
	1	NAR communication with clients is disabled
29	Timestamp Enable.	
TEN	0	Timestamp packet is not included in messages
	1	Timestamp packet is included in messages from all client including NAR generated messages
28	Timestamp Reset.	
TRS	0 to 1 transition: reset timestamp counter in NAR	
27–26	Timestamp Granularity (Mode).	
TSG	**Note:** Some clients may only support timestamps on every message.	
	00	Add timestamp to every message
	01	Add timestamp to every 4th message
	10	Add timestamp to every 16th message
	11	Add timestamp to every 32nd message
25	Stall Error Disable.	
SED	0	NAR injects dummy complete message when active client stalls
	1	NAR does not inject dummy complete message
24	Stall Recovery Disable.	
SRD	0	Stalled receive queue resumes operation when its client comes back on line
	1	Stall error recovery is disabled
23	Tracebuffer Wrap.	
TBW	0	NAR does not capture new data when main queue is full
	1	NAR begins overwriting main queue from the beginning upon queue overflow
22–21	Alternate Queue Partition.	
AQP	00	Queue partitioning is disabled
	01	Reserved
	10	1/2 of queue is dedicated to alternate partition
	11	Reserved
20	Reserved and must be written with 0	
19–16	Reserved and must be written with 0s	
15–13	Watchpoint Enable	
WPE	000	NAR watchpoint messaging is disabled
	xx1	NAR generates a watchpoint message upon a sync event
	x1x	NAR generates a watchpoint message upon a trace memory bus or tracebuffer block full/wrap event
	1xx	NAR generates a watchpoint message upon a suppress-mode event
12	Reserved	

Table continues on the next page...

Table 6-2. NAR_CR field descriptions (continued)

Field	Description	
11	Reserved. This bit must be written with 0.	
10–9 MSP	Message Select Port. Defines which port is the target for message type/source filtering. Only active in two-port applications.	
	00	No message select port. 0–1 port is active.
	01	HBDP is the MSP
	10	Trace memory bus is the MSP
	11	Nexus is the MSP
8	Reserved	
7–6 ALT	Alternate Port. Defines which port is the target for non-filtered messages; main port in single-port applications.	
	00	No alternate port. Running in trace-buffer mode.
	01	HBDP is the ALT
	10	Trace memory bus is the ALT
	11	Nexus is the ALT
5	Reserved	
4 AFA	Automatic Flush Accumulators.	
	0	Output queue accumulators do not flush stranded beats
	1	Accumulators automatically flush stranded beats
3	Reserved. This bit must be written with 0.	
2 FSD	Frame Serial Data.	
	0	Framing disabled. Data is streamed through the Aurora out port.
	1	Framing enabled. Start/End frame symbol inserted between every 256 Aurora words.
1 PUS	Power-Up Suppressed.	
	0	NAR powers up active
	1	NAR powers up in global suppressed mode
0 NSR	NAR Soft Reset.	
	1	Resets all configuration registers and sets queue address pointers to the top of their respective queues. Also resets itself after a single-cycle delay. (This does not affect other blocks)

6.4.2 NAR status register (NAR_ST)

The NAR_ST register provides information on NAR activity and queue status, as well as HBDP status and errors. It is a read-only register. The following table shows the format of the NAR_ST.

Register index: 1

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	NEN	NUM			NCE				MPF	MLV		APF	ALV		0	0
W																

Table continues on the next page...

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	HPR	HPE	MPE	MOV	0	TOV	QWA									
W		w1c	w1c	w1c		w1c										
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

The NAR_ST register is described in the following table.

Table 6-3. NAR_ST field descriptions

Field	Description	
31 NEN	NAR Enabled.	
	0	NAR is disabled and inactive
	1	NAR is enabled with clocks on
30–28 NUM	NAR Mode.	
	000	NAR is in disabled mode
	001	NAR is in global suppressed mode
	010	NAR is in communication-disabled mode
	011	NAR is in tracebuffer mode
	100	NAR is in active transmit mode
	101	Reserved
	110	Reserved
	111	NAR is in run-control mode
27–24 NCE	NAR Config Error. See Table 6-18 for coding	
23 MPF	MSP Partition Full.	
	0	MSP partition not full
	1	MSP partition full
22–21 MLV	MSP Partition Queue Level. This field is available only when both output ports are enabled i.e. the main queue is partitioned.	
	00	0% < queue level < 25%
	01	25% < queue level < 50%
	10	50% < queue level < 75%
	11	75% < queue level <100%
20 APF	ALT Partition Full.	
	0	ALT partition not full
	1	ALT partition full
19–18 ALV	ALT Partition Queue Level.	
	00	0% < queue level < 25%
	01	25% < queue level < 50%
	10	50% < queue level < 75%
	11	75% < queue level <100%

Table continues on the next page...

Table 6-3. NAR_ST field descriptions (continued)

Field	Description	
17–16	Reserved	
15 HPR	HBDP Ready.	
	0	HBDP (Aurora Out port) is not ready
	1	HBDP is ready and accepts data for transmission
14 HPE	HBDP Error.	
	0	No HBDP error
	1	Error condition exists on HBDP
13 MPE	Trace memory bus Error.	
	0	No Trace memory bus error
	1	Error condition detected on trace transaction
12 MOV	Trace memory bus block overflow.	
	0	No Trace memory bus overflow
	1	Targeted external memory block is full. Trace memory bus writes are halted (or wrapped).
11	Reserved	
10 TOV	Tracebuffer Overflow.	
	0	No tracebuffer overflow
	1	The tracebuffer has overflowed/wrapped at least once
9–0 QWA	Queue Write Address. Current value of the output queue write pointer of ALT partition (last valid write + 1)	

6.4.3 Message filtering registers

The two output ports (HBDP and trace memory bus) are independently controllable. In the BD NAR, two ports can be active simultaneously. When multiple ports are active, user-programmable filters are determine which port receives a message, based on the message source or type. Filters apply to the designated Message Select Port (MSP), and are used to select messages for that port. All other messages go to the other (alternate) port. If multiple ports are used, an MSP must be designated; otherwise a configuration error results. See Output arbitration, for details on how the NAR arbitrates between multiple output ports. These registers should only be set in the BD NAR because partitioning is not supported in the PD NAR.

6.4.3.1 Source filter register (NAR_SFR)

The MSP can be configured to accept or exclude messages from up to four sources. The sources which are to be filtered are programmed in the source filter register (NAR_SFR) as shown in the following table. This register should only be set in the BD NAR because partitioning is not supported in the PD NAR.

Register index: 2

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	SFI	FE0	SF0				0	0	0	FE1	SF1				0	0
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0	FE2	SF2				0	0	0	FE3	SF3				0	ACC
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The NAR_SFR is described in the following table. The source trace IDs, that are compared to the source filter fields (SFn), are device specific. For a list of the clients that are connected to the NAR and their corresponding Nexus source trace IDs, see the Calibration and Debug configuration chapter which describes how the modules are configured.

Table 6-4. NAR_SFR field descriptions

Field	Description
31 SFI	Source Filter Invert. 0 Match if message source equals any of the enabled filters 1 Match if message source equals none of the enabled filters
30 FE0	Enable Filter 0. 0 Filter 0 disabled. SF0 ignored 1 Filter 0 enabled and contained in SF0
29–26 SF0	Source Filter 0. The message source trace ID is compared with this field. See Output arbitration for an example.
25–23	Reserved.
22 FE1	Enable Filter 1. 0 Filter 1 disabled. SF1 ignored 1 Filter 1 enabled and contained in SF1
21–18 SF1	Source Filter 1. The message source trace ID is compared with this field. See Output arbitration for an example.
17–15	Reserved

Table continues on the next page...

Table 6-4. NAR_SFR field descriptions (continued)

Field	Description
14 FE2	Enable Filter 2. 0 Filter 2 disabled. SF2 ignored 1 Filter 2 enabled and contained in SF2
13–10 SF2	Source Filter 2. The message source trace ID is compared with this field. See Output arbitration for an example.
9–7	Reserved
6 FE3	Enable Filter 3. 0 Filter 3 disabled. SF3 ignored 1 Filter 3 enabled and contained in SF3
5–2 SF3	Source Filter 3. The message source trace ID is compared with this field. See Output arbitration for an example.
1	Reserved
0 ACC	OR source and type filters. 0 Match if source AND type filters match 1 Match if source OR type filters match

6.4.3.2 Message type filter register (NAR_TFR)

The MSP can be configured to accept or exclude messages of up to four types, as encoded in the message TCODE field. The TCODEs which are to be filtered are programmed in the message type filter register (NAR_TFR) as shown in the following table. This register should only be set in the BD NAR because partitioning is not supported in the PD NAR.

Register index: 3

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	TFI	FE0	TF0						0	FE1	TF1					
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R	0	FE2	TF2						0	FE3	TF3					
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The NAR_TFR is described in the following table.

Table 6-5. NAR_TFR field descriptions

Field	Description
31 TFI	Type Filter Invert. 0 Match if message TCODE equals any of the enabled filters 1 Match if message TCODE equals none of the enabled filters
30 FE0	Enable Filter 0. 0 Filter 0 disabled. TF0 ignored 1 Filter 0 enabled and contained in TF0
29–24 TF0	Type Filter 0. The message TCODE is compared with this field. See Output arbitration for an example.
23	Reserved
22 FE1	Enable Filter 1. 0 Filter 1 disabled. TF1 ignored 1 Filter 1 enabled and contained in TF1
21–16 TF1	Type Filter 1. The message TCODE is compared with this field. See Output arbitration for an example.
15	Reserved
16 FE2	Enable Filter 2. 0 Filter 2 disabled. TF2 ignored 1 Filter 2 enabled and contained in TF2
13–8 TF2	Type Filter 2. The message TCODE is compared with this field. See Output arbitration for an example.
7	Reserved
6 FE3	Enable Filter 3. 0 Filter 3 disabled. TF3 ignored 1 Filter 3 enabled and contained in TF3
5–0 SF3	Type Filter 3. The message TCODE is compared with this field. See Output arbitration for an example.

6.4.4 Trace memory bus configuration registers

The trace memory bus can be used to transfer debug messages out to a dedicated block of external memory space. The trace memory bus configuration registers are used to specify the location and size of the external debug space.

6.4.4.1 Trace memory bus base address registers (NAR_TBALO and NAR_TBAHI)

The trace memory bus base address registers determine where Nexus data sent out through the trace memory bus goes. The NAR sends out blocks of data on the trace memory bus, writing to an address block defined by the specified base address. Data can transmitted either on an as-available, word-wide basis, or in larger blocks. In block transfer mode, the size of the data block is determined by the BTM field of the Control Register; the default is 64 bytes. Even if block transfer mode is not used, the 5, 6, 7, or 8 (depending on the BTS field in NAR_TCR register) LSBs of the base address are not accessible. This forces the debug memory space to be aligned to a block boundary.

When read, the address registers return the current address, allowing the user to monitor the progress of a trace memory transfer. The following tables show the format of the trace memory base address registers (NAR_TBALO and NAR_TBAHI). For a description of the allowed address for these registers, see the Calibration and Debug configuration chapter which describes how the modules are configured.

Register index: 5

The NAR_TBALO and NAR_TBAHI registers are described in the following tables.

Table 6-6. NAR_TBAHI field descriptions

Field	Description
31–0 TBAHI	Trace Debug Memory Base Address on AHB-EW port, upper part. For 32-bit address applications this field is all zeros.

Table 6-7. NAR_TBALO field descriptions

Field	Description
31–10 TBALO	Trace Debug Memory Base Address on AHB-EW port, lower part
9 ADRLO[9]	Base Address LSB for BTS = 11 (384-byte block)
8 ADRLO[8]	Base Address LSB for BTS = 10 (256-byte block)
7 ADRLO[7]	Base Address LSB for BTS = 01 (128-byte block)
6 ADRLO[6]	Base Address LSB for BTS = 00 (64-byte block)
5–0	Reserved

6.4.4.2 Trace memory bus control register (NAR_TCR)

The trace memory bus control register is used to control the attributes of the trace memory bus port, such as block transfer size and message priority. Since the trace memory bus transfers are expected to go to a static block of external memory, a maximum transfer size must be specified to prevent the NAR from overwriting memory it is not authorized to access. This is done via the MXFR max transfer size register field. The memory allocation is specified in units of the trace memory bus block transfer size (64, 128, 256, or 384 bytes), so the actual size of the reserved memory block depends on the BTS setting. The following table shows the format of the NAR_TCR.

Register index: 6

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	BTM	BTS		BTH		0	0	0	TBW	MXFR						
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	MXFR															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The NAR_TCR is described in the following table.

Table 6-8. NAR_TCR field description

Field	Description	
31	Block Transfer Mode.	
BTM	0	Data for the Trace Memory bus port is transmitted one word at a time, upon first availability
	1	Data to the Trace Memory bus port is bundled into blocks before transmitting
30–29	Block Transfer Size.	
BTS	00	Block transfer size = 64 bytes
	01	Block transfer size = 128 bytes
	10	Block transfer size = 256 bytes
	11	Block transfer size = 384 bytes
28–27	Block Transfer Threshold.	
BTH	00	Full threshold. Number of entries in partition must equal block transfer size before block transfer starts
	01	Begin transfer when block is 25% full
	10	Begin transfer when block is 50% full
	11	Begin transfer when block is 75% full
26–24	Reserved. These bits must be written with 0.	
23	Trace Memory Bus Block Wrap.	
TBW	0	NAR stops writing to the Trace Memory bus debug memory space once Max Size has been reached
	1	NAR overwrites Trace Memory bus debug memory from the beginning upon Trace Memory bus block overflow.
22–0	Trace Memory Bus Max Transfer Size.	
MXFR	Total size of the dedicated debug memory space, in Trace Memory bus data transfer blocks.	

6.4.5 Suppress mode triggers registers (NAR_STCR)

Four suppress mode triggers are provided for precise control of the NAR suppress mode feature described in Suppress mode. The suppress mode triggers are only available on the PD NAR and do not apply to the BD NAR. The registers are present in the BD NAR, but input suppress triggers are not connected. Each trigger can be programmed to suppress or wake clients individually or the entire NAR. All receive queues can be suppressed on the occurrence of a selected trigger, or the full NAR can be brought out of suppress mode upon the occurrence of the appropriate trigger. A trigger can also be programmed to toggle one or more clients between the suppressed and active states. Each Suppress Trigger Control Register, shown in the following table, is associated with one of the triggers, and are used to determine the action taken, if any, upon the assertion of that trigger. The suppress triggers are connected to the Sequence Processing Unit (SPU) action unit.

Register index: 7-A

Table continues on the next page...

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

The NAR_STCR are described in the following table. The set of clients connected to the NAR is device specific. For a list of the clients that are connected to the NAR and their corresponding NAR client index for the local suppress trigger, see the Calibration and Debug configuration chapter which describes how the modules are configured.

Table 6-9. NAR_STCR field descriptions

Field	Description	
31 GST	Global Suppress Trigger.	
	0	The associated trigger cannot cause NAR to enter global suppress mode
	1	The associated trigger is enabled for global suppress mode
29–16	Reserved	
15–0 LST	Local Suppress Trigger.	
	0000000000000000	The associated trigger is disabled for local suppress mode for all clients
	xxxxxxxxxxxxxxx1	Trigger is enabled for Client 1 local suppress
	xxxxxxxxxxxxxx1x	Trigger is enabled for Client 2 local suppress
	xxxxxxxxxxxxx1xx	Trigger is enabled for Client 3 local suppress
	xxxxxxxxxxxx1xxx	Trigger is enabled for Client 4 local suppress
	xxxxxxxxxxx1xxxx	Trigger is enabled for Client 5 local suppress
	xxxxxxxxxx1xxxxx	Trigger is enabled for Client 6 local suppress
	xxxxxxxxx1xxxxxx	Trigger is enabled for Client 7 local suppress
	xxxxxxxx1xxxxxxx	Trigger is enabled for Client 8 local suppress
	xxxxxxx1xxxxxxxx	Trigger is enabled for Client 9 local suppress
	xxxxxx1xxxxxxxxx	Trigger is enabled for Client 10 local suppress
	xxxxx1xxxxxxxxxx	Trigger is enabled for Client 11 local suppress
	xxxx1xxxxxxxxxxx	Trigger is enabled for Client 12 local suppress
	xxx1xxxxxxxxxxxx	Trigger is enabled for Client 13 local suppress
	xx1xxxxxxxxxxxxx	Trigger is enabled for Client 14 local suppress
	x1xxxxxxxxxxxxxx	Trigger is enabled for Client 15 local suppress
	1xxxxxxxxxxxxxxx	Trigger is enabled for Client 16 local suppress
	All other options	Reserved

6.4.6 Client suppress status register (NAR_CSSR)

Clients can be individually suppressed, leaving the rest of the NAR unaffected. When enabled for local suppress, assertion of one of the suppress triggers causes one or more client receive queues to stop queueing messages. A subsequent pulse of the same trigger causes the client(s) to awaken. Local suppress mode is enabled by setting the appropriate bit in one of the NAR_STCRs. An additional status register, Client Suppress Status (NAR_CSSR), shown in the following table, can then be read to determine which clients are suppressed, and which are active.

Register index: B

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	LSS																0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
W

	x1xxxxxxxxxxxxxx	Client 15 is suppressed
	1xxxxxxxxxxxxxxx	Client 16 is suppressed
	All other options	Reserved
15–0	Reserved	

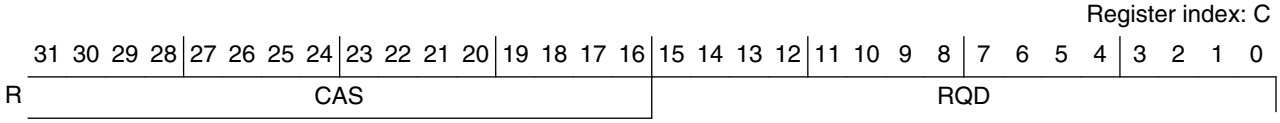
6.4.7 Receive queue client disable register (NAR_CDR)

Disabling a client reallocates its receive queue to the next active client, allowing that memory space to be put to use. The Client Disable Register, shown in the following table, allows the user to individually disable or enable clients as needed. The status bits also inform the user when the client has new data available.

Note

Even though the BD NAR is described as only having one client, there is actually a second dummy client, client 2. To re-allocate the dummy RX queue to client 1 (the PD NAR), set the BD NAR client 2 RQD bit.

Register index: C



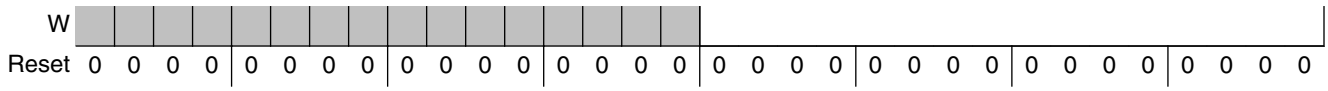


Table continues on the next page...

The NAR_CDR is described in the following table. The set of clients connected to the NAR is device specific. For a list of the clients that are connected to the NAR and their corresponding NAR client index for the client activity status and receive queue disable, see the Calibration and Debug configuration chapter which describes how the modules are configured.

Table 6-11. NAR_CDR field descriptions

Field	Description	
31–16	Client Activity Status.	
CAS	xxxxxxxxxxxxxxx1	Client 1 is active with new data
	xxxxxxxxxxxxxx1x	Client 2 is active with new data
	xxxxxxxxxxxxx1xx	Client 3 is active with new data
	xxxxxxxxxxxx1xxx	Client 4 is active with new data
	xxxxxxxxxxx1xxxx	Client 5 is active with new data
	xxxxxxxxxx1xxxxx	Client 6 is active with new data
	xxxxxxxxx1xxxxxx	Client 7 is active with new data
	xxxxxxxx1xxxxxxx	Client 8 is active with new data
	xxxxxxx1xxxxxxxx	Client 9 is active with new data
	xxxxxx1xxxxxxxxx	Client 10 is active with new data
	xxxxx1xxxxxxxxxx	Client 11 is active with new data
	xxxx1xxxxxxxxxxx	Client 12 is active with new data
	xxx1xxxxxxxxxxxx	Client 13 is active with new data
	xx1xxxxxxxxxxxxx	Client 14 is active with new data
	x1xxxxxxxxxxxxxx	Client 15 is active with new data
	1xxxxxxxxxxxxxxx	Client 16 is active with new data
	All other options	Reserved

Table continues on the next page...

Table 6-11. NAR_CDR field descriptions (continued)

Field	Description	
15–0	Receive Queue Disable.	
RQD	xxxxxxxxxxxxxxx1	Disable receive queue for Client 1
	xxxxxxxxxxxxxx1x	Disable receive queue for Client 2
	xxxxxxxxxxxxx1xx	Disable receive queue for Client 3
	xxxxxxxxxxxx1xxx	Disable receive queue for Client 4
	xxxxxxxxxxx1xxxx	Disable receive queue for Client 5
	xxxxxxxxxx1xxxxx	Disable receive queue for Client 6

	xxxxxx1xxxxxxxxx	Disable receive queue for Client 10
	xxxxx1xxxxxxxxxx	Disable receive queue for Client 11
	xxxx1xxxxxxxxxxx	Disable receive queue for Client 12
	xxx1xxxxxxxxxxxx	Disable receive queue for Client 13
	xx1xxxxxxxxxxxxx	Disable receive queue for Client 14
	x1xxxxxxxxxxxxxx	Disable receive queue for Client 15
	1xxxxxxxxxxxxxxx	Disable receive queue for Client 16
	All other options	Reserved

6.4.8 Nexus Aurora Phy control register (NAR_NAPCR)

The Nexus Aurora Phy control register provides configuration control to number of HBDP lanes of Nexus Aurora Phy and LVDS pad control signals. The following table shows the format of the NAR_NAPCR.

Register index: D

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0	0	0	0	0	0	0	0	0	0	0	0	NUM_LANE			
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0	0		0	LVDS_TXOPT				LVDS_RX_TERM_EN	LVDS_BIAS_PRG	LVDS_RXOPT					
W																
Reset	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0

The NAR_NAPCR is described in the following table.

Table 6-12. NAR_NAPCR field descriptions

Field	Description
19–16 NUM_LANE	TX Lane Configuration. Number of enabled TX lanes. This field is device specific. For a description of this field see the Calibration and Debug configuration chapter which describes how the modules are configured.
11–8 LVDS_TXOPT	This is an internal characterization field.
7 LVDS_RX_TERM_EN	This is an internal characterization field.
6 LVDS_BIAS_PRG	This is an internal characterization field.
5–0 LVDS_RXOPT	This is an internal characterization field.

6.4.9 Trace Memory fill level and partition configuration register (NAR_AHFPAR)

This register provides the configuration to set the fill level marker for debug trace memory, connected at the trace memory bus, to generate the partial full event indication and the partition related configuration for main queue (internal central queue). The following table shows the format of the NAR_AHFPAR.

Register index: E

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0	0	0	0	0	0	0	GSE	0	0	0	GLOBAL_STALL_COUNT				
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0				

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0	0	0	0	AHB6 5kEN	AHB0 1kEN	PART_CFG		AHB_65K_Marker				AHB_01K_Marker			
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The NAR_AHFPAR is described in the following table.

Table 6-13. NAR_AHFPAR field description

FIELD	Description
31-25	Reserved and must be written with 0s

Table continues on the next page...

Table 6-13. NAR_AHFPAR field description (continued)

FIELD	Description
24 GSE	Global Stall Enable. Setting this bit enables the NAR to act on dci_evti[1] event to generate a global stall
23-21	Reserved and must be written with 0s
20-16 GLOBAL_STALL_COUNT	Global Stall Count. Value at this field determines how many cycles, in the NAR's operating clock, the global stall remains asserted on a dci_evti event. This is a five bit field so the maximum value is 31 cycles. See Global (Development tool client) stall control
15-12	Reserved and must be written with 0s
11 AHB65kEN	Enable 65K Marker Event
10 AHB01kEN	Enable 1K Marker Event
9-8 PART_CFG	Partition Configuration. 00 No partition 01 Reserved 10 50% partition (in two partition two configuration case) 11 Reserved
7–4 AHB_65K_Marker	Value at this field is used to compare a 4-bit slice of internal Trace Memory address bus which works at boundary of 65K. A match with this value generates an event to SPU to indicate the fill status of External Overlay Trace memory. See Overlay and internal trace memory full status generation **Note:** This is used in BD as it has memory ranges from 65K to 983K
3–0 AHB_01K_Marker	Value at this field is used to compare a 4-bit slice of internal Trace Memory address bus which works at boundary of 1K. A match with this value generates an event to SPU to indicate the fill status of External Overlay Trace memory. See Overlay and internal trace memory full status generation **Note:** This is used in PD as it has memory ranges from 1K to 15K

6.5 Functional description

High-level descriptions of the operation of the NAR and its main functional blocks are given in the following sections.

6.5.1 Reset/Startup

Assertion of global reset causes the NAR operation to immediately cease. All queues and configuration registers are reset. Upon exiting reset, the Nexus Port Controller (NPC) block inside the NAR is disabled. Holding TMS high for five consecutive rising edges of TCK puts TAP controller into the Test-Logic-Reset state regardless of the current state.

This applies reset to only TAP controller and JTAG related logic. Applying soft reset through the NAR_CR resets the entire NAR including the TAP controller and configuration registers.

The typical startup procedure for running a trace through the NPC is as follows:

1. Reset the block
2. Upon exiting reset, the Aurora Phy configuration is determined by sampling the configuration pin values from the Nexus Aurora Phy (NAP). If the NAP is enabled, then the NAR is enabled. The Aurora communication is started only when the NAP is ready to accept data. (If any debug lanes are enabled, the Aurora Link begins training at this time.)
3. Debugger/external user sets the NAR enable (NEN) bit in the NAR_CR and configures the NAR. The configuration includes setting up message selection/ filtering when two output ports are enabled, enabling timestamp and so on.
4. User programs additional device level debug facilities, such as event-processing, performance-monitoring, and so on.
5. User sets up trace filtering.
6. Enable Nexus transmission in clients.

To enable NAR operation, either the Aurora Link must be enabled at reset, or the user must set the NEN bit in the NAR control register.

Note

The HBDP may already be active by the time the NAR comes up. The NAR only tries to initialize the HBDP if it is currently inactive.

The NAR can be enabled to begin immediate operation, or to start in suppress mode, see Suppress mode. Once the NAR and desired ports are enabled, the user should wait until the NAR-ready and HBDP port-ready status bits are set in the NAR status register before beginning Nexus messaging in the clients.

6.5.2 Operation modes

The NAR operating mode is determined by the state of the main control signals: reset and Phy enable. In its enabled state, operation is controlled by its configuration registers. A truth table for all the NAR states is given in the following table.

Table 6-14. NAR operational modes truth table

Reset	NAR enable	NAR comm disable	Global suppress	HBDP enable	ALT partition	MSP partition	Mode
0	x	x	x	x	x	x	RESET
1	0	x	x	0	x	x	Disabled
1	1	1	x	0	x	x	Trace-Disable
1	x	1	x	1	x	x	Trace-Disable
1	0	x	x	1	x	x	Trace-Disable
1	1	0	1	x	x	x	Suppressed
1	1	0	0	x	Trace Memory bus	x	NAR Transmit
1	1	0	0	1	AUR	x	NAR Transmit
1	1	0	0	1	Trace Memory bus	AUR	NAR Transmit
1	1	0	0	1	AUR	Trace Memory bus	NAR Transmit

There can be overlap between modes as modes are not mutually exclusive.

6.5.2.1 Reset

During reset all internal resources and queues are reset and all output ports are disabled. All inputs are ignored. Upon exiting reset mode, the NAR is in a fully disabled state.

6.5.2.2 Disabled

In the disabled state, all message traffic is ignored, and all output ports are disabled. The NAR is disabled if and only if the NAR enable bit of the NAR control register is not set and the Aurora Link is inactive.

6.5.2.3 Suppressed

The suppressed state differs from the disabled state in that the NAR is on. The NAR pulls out any messages that come up at the clients, keeping the Message Start-End Out (MSEO) bits (so that it can keep track of message boundaries) and discarding the rest.

In the suppressed state, the NAR is waiting for a trigger to begin normal operation. Once that trigger is received, the NAR begins queueing messages that started after the trigger arrived. Incomplete messages that were in transit to the NAR when the trigger arrived are discarded. The NAR can be put into suppressed mode by enabling one of the global suppress states.

6.5.2.4 Trace disable

In trace disable mode, the NAR is powered up but all client-trace is disabled, and no messages are pulled. This mode is also useful for port initialization (to prevent any activity from occurring before the outputs are ready) or for debug/trace-buffer mode, to ensure that, during data retrieval, the NARs queues are stable.

The NAR goes into trace disable (communication-disable) mode when the NAR-enable and NAR communication-disable bits are set or when the HBDP channel is active while the NAR-enable bit is not set.

6.5.2.5 NAR transmit

This is the standard operational mode of the NAR when it is transferring Nexus messages from multiple clients to one or two enabled output port(s). The NAR performs four main operations as described in the following table on the incoming messages before transmitting to one of the output ports.

Table 6-15. NAR transmit operations

Operation	Description
Data reception	NAR accepts data from each client based on the status of the client receive queue status. The maximum data rate is 8 × 32-bit data words (where 8 is the number of Nexus message beats in a full entry and 32 is the number of bits in the Nexus word) per cycle per client. MSEO bits of incoming data are monitored to identify end-of-message boundaries.
Input Arbitration	Active receive queue unloads into main queue(s), 8 × 32 bits per cycle (where 8 is the number of Nexus message beats in a full entry and 32 is the number of bits in the Nexus word). If end-of-message detected, new active receive queue is determined based on client request level or round-robin algorithm.
Output Arbitration	If multiple output ports are enabled, route messages from top of queue to appropriate output port based on message type or source. If split queue is used, outputs can run simultaneously, with each sub-queue communicating directly with a port.
Translation	Data going out the Aurora or trace memory bus ports must be translated into the correct format prior to transmission.

Enabling the NAR and one or more output ports without setting the communication-disable bit puts the NAR into transmit mode.

6.5.3 Data reception and arbitration

The BD NAR supports 1 client (although a second dummy client is used to increase the RX buffer size for client 1). Each client has a dedicated input port on the NAR and communicates with its associated input port via a dedicated data bus. A data transmission must consist of an integer number of 32-bit Nexus words (32-bit word is called a beat). The number of beats varies from client to client. The number of beats (Bn) for each client are described in the Calibration and Debug configuration chapter which describes how the modules are configured.

There is one type of client supported at NAR client interface. One Nexus word consists of 30 Message Data Out (MDO) bits plus two Message Start/End Out (MSEO) control bits.

When new data is available in the core, it is transferred over to the asynchronous gasket in the internal NAR clock domain. The gasket then asserts enough data valids to fill internal receive queue, using a receive queue available signal to track available space in the associated queue, under the assumption that the receive queue available signal is initialized with the size of the queue. If the internal arbiter consumes any of its queued entries, it responds with a data accept signal, which increments the receive queue available signal and allows the gasket to send the next piece of data. Under certain circumstances, like receive queue reallocation, it is possible for the internal arbiter to send out surplus data accept signals such that the receive queue available signal can become larger than the size of the queue. If the receive queues are sized correctly, when NAR is actively servicing a particular client, then asserted data accept signals allow the client to continually stream data until the NAR switches to a new client. The data tracking at the gasket assures that it never sends more data than the receive queue can accept and inactive queues are always full and ready for when they are switched to.

The client gaskets must always be in sync with the internal logic of NAR in terms of the number of available entries in each receive queue. For this reason, the internal NPC and its client gaskets need to be reset by the same signal. Any soft-reset of the NAR (via the SRESET configuration bit) is communicated to all gaskets and used to reset every thing inside it.

Each input port has a dedicated receive queue with a minimum of two entries, where an entry is wide enough to store an entire Bn × 32 data word (where 32 is the number of bits in the Nexus word or the beat). The receive queue can be made larger to allow the NAR to continue transmitting during switches from one client to another in a pipelined environment. Every cycle, if there is space in a particular receive queue, it latches in one full AUX word from its client. Because the client may be running at a much higher frequency than the NAR, several cycles worth of Nexus messages are contained in a single transaction, as shown in the following figure for a 3-beat per word transaction.

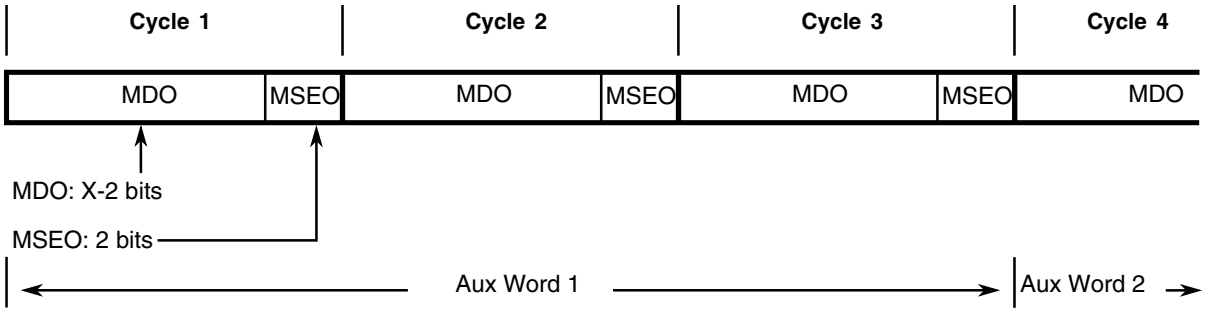

Figure 6-2. AUX bus parsing

Each AUX word consists of Bn cycles of Nexus data, along with an optional request-level sideband signal consisting of a priority field (bit 0) and a weight field (bits 1 and 2). Request level priority indicates to the NAR the clients queue status, allowing it to give preferential treatment to clients that are closer to queue overflow. Clients with a set priority bit are always chosen ahead of clients without the bit. For this reason, priority should be used sparingly, only when a client is in danger of overflowing. Request-level weighting also gives a client preferential treatment, but without entirely shutting out the other clients. Normally, the NAR attempts to switch to a new client every time it sees an end-of-message boundary.

As the AUX word is pulled into the receive queue, the MSEO bits are monitored to determine the current Nexus state of the data flow; since Nexus is a variable-length protocol, messages can end in any cycle. If the start message or end message state is detected on any data beat, the beat is marked as containing an end-of-message boundary.

Any received beat which is in the idle state, indicating null data content, is discarded (see the IEEE-ISTO 5001-2003 standard for details of the Nexus protocol). At the same time, if two outputs are enabled, then the source and TCODE fields are extracted from each new message and compared with the user-programmed filters. Messages that generate a match are tagged with an MSP bit, which allows the NAR to route it to the correct port.

Every cycle, the NAR transfers 8 beats of data from the receive queues into the main output queue. Only one port (the active port) is allowed to empty into the main queue at a time: the active port unloads its receive queue into the main queue until the end of the current Nexus message is detected. At that point, a new active port is selected based on the latest request level received at each port. In the case where multiple ports have the same request level (or when request level is not used), then the active port is rotated amongst those ports. If the end of message occurs in the middle of an AUX word, then all the beats up to the end of message are transferred from the old active port, while the rest of the beats come from the new active port. For example, if the message ended at beat two of a three-beat AUX word, then the first two beats into the main queue would come from the original active port, while the last beat would come from the new active port.

6.5.4 Suppress mode

The suppress mode feature enables the user to quickly turn Nexus messaging through the NAR on or off, based on the four dedicated suppress-mode triggers. Suppress mode is only supported in the PD NAR, it is not supported in the BD NAR. A suppress can either be global, meaning messaging is turned off for all clients, or local, which only applies to selected clients. In suppress mode, the NAR pulls messages from the suppressed client(s), but does not queue or deliver them. After extracting the MSEO bits to keep track of message boundaries, the rest of the message is discarded. This allows the NAR to better keep up with fast-running Nexus clients without having to turn off messaging in the client.

Typically, a client would be suppressed during less interesting periods, and would be awakened when some preset condition is detected. This is communicated to the NAR via the one of the suppress triggers, which can be sourced by a client or an external Event Processing block. When an enter suppress trigger is received, the NAR output queue finishes servicing the current active ports until the end of the message. If the end of the message occurs in a middle beat of a Nexus word, then the remainder of the word is padded with null messages. Once the last message has been loaded into the output queue, the receive queues are all emptied. New messages are pulled from clients as they appear, go through their respective receive queues and then are discarded. In this way, the NAR can naturally monitor the MSEO bits and keep track of each client's Nexus state. In suppress mode, the output ports remain active until the output queue is emptied, meaning there is a delay between the assertion of the suppress trigger and the end of messaging.

When the NAR is in suppress mode and receives a wake-up trigger, it continues discarding any partial messages still in the receive queues. Any message that begins after the trigger is queued normally, insuring that only complete messages are sent to the output queue.

Global suppress mode applies to all clients. Any of the suppress triggers can be programmed to cause the NAR to toggle between suppressed and awake by setting the GST bit of the associated Suppress Trigger Control Register (NAR_STCR). Additionally, the NAR starts up in global suppress mode if the PUS bit of the Control Register is set when the NAR is enabled. All clients are then suppressed until a wake-up trigger is received. If the PUS bit is set without enabling any of the triggers for global suppress, a configuration error results and the NAR powers up in active mode.

Clients can go also into local suppress mode without putting the entire NAR to sleep. Each NAR_STCR has a 16-bit LST field. Setting one or more of these bits causes the trigger assigned to that NAR_STCR to toggle the associated clients between suppressed and awake. All other clients are unaffected. Thus, suppress trigger one can be assigned to

one set of clients, while suppress trigger two can be assigned to another set of clients, and different parts of the device can be ignored at different times, all based on different, programmable events. Global suppress always has higher priority than local suppress. That is, if the NAR is in global-suppressed mode, any local suppress wake-up triggers are ignored. Also, if some clients are in local suppress when a global suppress trigger hits, then all go into suppress mode; however, upon the subsequent global wake-up, the clients that were previously in local suppress remain so.

6.5.5 Stall detection

Since the NAR can only switch between clients on an end-of-message boundary, every message that goes into the NAR must complete. If a client happens to die or stall in the middle of transmitting a message, this uncompleted message could cause the NAR to stall, at a time when other clients might still be able to deliver useful information. To prevent this from occurring, the NAR monitors each client for a stall condition, which is defined as occurring when data is not valid in the middle of a Nexus message for a set number of cycles.

When a stall condition is detected, the NAR can do one thing. If the client stalls, then the NAR must complete the current stalled message to continue operating. This scenario is termed a stall error. On a stall error, the NAR injects a dummy message beat into the message stream after the last valid beat of data received from the stalled client. The dummy message is a single beat injected at the output of the receive queue into the main queue. The MSEO bits of the data payload are set to 2b11 regardless of the previous Nexus state. This forces the dummy message into the End Message state. When the NAR injects a dummy message, it also generates an error message to notify the user what has happened.

Injecting a dummy message is an intrusive act, which alters the data stream from the client. If a stalled client is thought likely to recover cleanly, it might be advisable to suppress stall errors to prevent the data stream from being corrupted. This can be done by setting the SED bit of the configuration register, which carries the risk of a truly dead client causing the NAR to hang. Otherwise, the default operation is for the NAR to inject the dummy message and then monitor the client for signs of recovery. If the client does come back online, the NAR attempts to wait until it sees an end-of-message boundary before capturing new data. At best, if the client recovers smoothly, only the interrupted message is lost; if the client does not recover smoothly, it might not be possible for the client and NAR to get back in sync in terms of their Nexus states, which would lead to nothing but garbled data coming out. For this reason, it is also possible to prevent the

NAR from trying to recover from a stall error, by setting the SRD bit of the NAR_CR. If the SRD bit is set, a stalled client is not allowed to recover until the SRD bit is unset or the NAR is reset.

6.5.6 Output arbitration

The NAR allows two output ports to be active at the same time. This feature is only available on the BD NAR. Typically, this feature is only useful if one of the ports is used to service messages of a specific type and/or messages from a particular client, while the other port supports all the rest of the message traffic. For example, the NAR could be set up to send in-circuit trace (ICT) traffic out the HBDP and to reserve the trace memory bus port for all other Nexus messages.

If two output ports are enabled, one of them must be designated as the Message Select Port (MSP). The MSP is the destination for those messages that satisfy a set of user-defined requirements as to the source and type of message. All other traffic is sent to the other enabled port. Even though the NAR supports three outputs (HBDP, Nexus, and trace memory bus) only two can be used at the same time. Ports are enabled by setting the port enable bits in the BD NAR_CR. The MSP is designated by setting bits [10–9] and ALT is designated by setting bits [7–6]. Once the MSP has been specified, other bits in the NAR_CR, along with the Source Filter Register (NAR_SFR) and Type Filter Register (NAR_TFR), are used to determine which messages go to the MSP and which do not. These facilities can be used to build a logical expression that can filter messages based on up to four types and/or four sources.

The NAR_SFR can be programmed with up to four source codes, while the NAR_TFR can hold up to four message-type codes. Each filter also includes an enable bit to turn it on or off. A source match occurs if a messages source code matches one of the source filters or (if the SFI bit is set) if it does not match any of the source filters. Similarly, a type match occurs if a messages type code matches one of the type filters or (if the TFI bit is set) if it does not match any of the type filters. Finally, the ACC bit of the NAR_SFR determines when both source and type filters are used, whether the two are ANDed together (ACC = 0) or ORed together (ACC = 1). For example, to send ICT messages out the HBDP and all other traffic to the trace memory bus port:

- Set ALT = 10 in the NAR_CR—sets trace memory bus port as the alternate port
- Set MSP = 01 in the NAR_CR—sets HBDP as the message select port
- Set FE0 = 1 & TF0 = 100010 (0x22) in the NAR_TFR—enables type filter 0 to match ICT messages

To send everything but data trace from source 13 to the trace memory bus port, while all other traffic goes to the HBDP:

- Set ALT = 01 in the NAR_CR—sets HBDP as the alternate port
- Set MSP = 10 in the NAR_CR—sets trace memory bus port as the message select port
- Set TFI = 1—inverts type-filter logic
- Set FE0 = 1 & TF0 = 000101 (0x05) in the NAR_TFR to select data trace of size 8 bits
- Set FE1 = 1 & TF1 = 000110 (0x06) in the NAR_TFR to select data trace of size 16 bits
- Set FE2 = 1 & TF2 = 001101 (0x0d) in the NAR_TFR to select data trace of size 32 bits
- Set FE3 = 1 & TF3 = 001110 (0x0e) in the NAR_TFR to select data trace size of 64 bits
- Set FE0 = 1 & SF0 = 001101 (0x0d) in the NAR_SFR to select source trace ID = 13
- Set ACC = 0 in NAR_SFR so the final filter is ~(data_trace) AND (source = 13)HBDP

Data is written into the output queue at a maximum rate of one entry per cycle. If the current messages source and type pass the filters, then the message is marked for the MSP. When the entry is later pulled from the queue, it is then sent to the MSP. Unmarked entries are sent to the alternate port. Message destination must be recalculated on every end-of-message boundary, using the fixed-width SRC and TYPE fields at the beginning of each Nexus message.

6.5.7 Queue partitioning

It is possible to partition the queue into two sections, one that supports the MSP, and the other that supports the alternate port as shown in Figure 6-3. Messages are routed, based on the MSP bit field, to either the MSP queue partition or the alternate queue partition. This allows both ports to be active simultaneously, since messages can be taken directly from both partitions. Each partition uses an accumulator to store a full central queue width beats of data before writing into memory, since on any given cycle the full Nexus word out of receiver arbitration may be split between the two partitions. Queue partitioning is enabled by setting the AQP bits of the NAR_CR.

The main advantage of using a partitioned queue is that it can improve data throughput and performance when multiple ports are active. It allows the trace memory bus port to utilize block transfer mode, which also improves performance. The only drawback is that queue utilization efficiency can be negatively impacted.

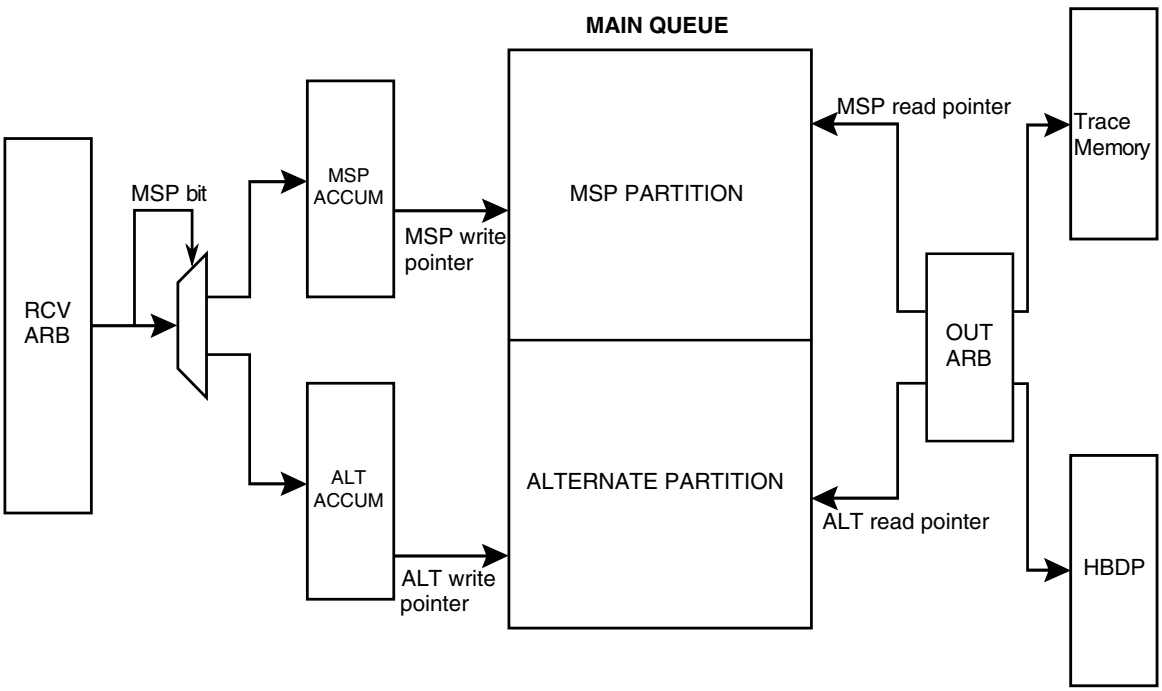

Figure 6-3. Queue partitioning

6.5.8 Message translation and formatting

The NAR performs the formatting on Nexus messages before sending them to an output port. The exact translation performed depends on the destination port.

6.5.8.1 Aurora format

Nexus messages are pre-translated before sending to the HBDP using the Aurora protocol. The NAR output is a stream of 16 × 4-bit words (where 4 is the width of the NAR Aurora out port) that are further encoded by an external Aurora block before being sent for transmission on the Aurora (HBDP) port.

Entries from the output queue are chopped into chunks of 4 × 16-bit words. The amount of data that can be transmitted per Aurora cycle depends on the number of lanes available in the HBDP (transmitted HBDP word = 16 × number of lanes).

6.5.8.2 Trace memory bus format

The trace memory bus works on AHB-EW protocol. Data destined for the trace memory bus port is split back out into 32-bit beats (Nexus word). Depending on the relative sizes of the beat and the width of the trace memory bus port, one or more Nexus words are packed into a trace memory bus data word, with any remaining bits padded to 0.

For example, if the size of the beat = 32 and the width of the trace memory bus = 64, then each trace memory bus data packet contains two beats of Nexus data. Since the data is stored in a regular format (MSEO bits in same place at every location), this makes data interpretation straightforward, regardless of where the trace memory bus port is sending the data. The trace memory bus translation block performs the necessary accumulation and resizing in the likely case where the trace memory bus width does not equal the queue entry size.

6.5.8.3 Nexus format

If the Nexus port is used, entries are sent directly out of the queue with no translation or resizing. The Nexus output, Nexus input, and queue are all the same width.

The Nexus port also includes an EVTO output. This allows EVTO signaling functionality to be maintained in systems with multiple NARs. EVTO can also be used as a trigger by an external event processing block, to allow events such as client halt to occur based on NAR events such as tracebuffer overflow. Currently, the only event that can cause an EVTO assertion is an HBDP hard error/reset, since data is almost certainly lost when the HBDP link goes down, the NAR needs to communicate that back to the clients so that they can generate sync messages.

Many Nexus message types use address/data compression, wherein the compressed data is generated by XORing the current data with the previous data sent. This type of compression can only work if there is no data lost; if data is lost, the client must start over by sending a new sync message which contains the full uncompressed address or data.

6.5.9 Aurora interface

The external Nexus Aurora Link (NAL) contains all of the link-layer, PCS, and control logic for the HBDP channel. The Aurora data is transmitted from the NAR to the NAL for sending to the HBDP. Typically, the NAL powers up coming out of reset, but it can

also be enabled by the NAR by turning on the NAR with the HBDP enabled. The reverse is true as well. If the NAL is active while the NAR is disabled, then the NAR powers up to communication-disabled mode.

Data flow between the NAR and the NAL uses a simple, synchronous interface. If the NAL is active, it indicates this by a ready signal from the NAL. If Aurora is configured as output it is indicated by a signal from the NAR.

The Aurora interface can either be operated in framing or streaming mode. Streaming mode provides the highest performance and lowest communication overhead through the link. Whereas framing mode provides greater robustness and improved error-handling at the receive side of the link. When framing mode is enabled, the NAR encapsulates the Aurora data in frames consisting of 256 Aurora chunks; that is, after every 256 Aurora transmissions, the NAR asserts end of frame and start of frame to mark the end of the last frame and the beginning of the next frame. In either mode, the NAR always asserts a start-of-frame when beginning transmission, and an end-of-frame when its output queue empties, to notify the channel partner of the end of valid data.

6.5.10 Trace memory bus output port usage

The NAR can communicate directly to external memory by sending Nexus data out onto the trace memory bus port, using the AHB-EW (Early Write) protocol. This provides a convenient, secondary area for data in applications or in situations where the HBDP is not available. The trace memory bus access are generated internally by trace memory bus controller.

Because in many systems it is desirable to have the trace memory bus interface run at a divided clock rate relative to the main platform clock, the trace memory bus port operates off of a separate AHB clock. This clock is assumed to be free-running (i.e. unaffected by NAR-enable and the status of the Aurora Link), synchronous to the platform clock used by the rest of the NAR, and either running at the same rate as the platform clock or an integer divide of that rate.

The trace memory bus interface protocol is a slightly modified version of AMBA AHB specification. The write data comes in the address phase instead of data phase and it is termed as Early Write (EW). When NAR uses the trace memory bus port as a destination for Nexus data, it performs a series of writes to a predefined block of memory space.

This memory space is specified through the trace memory bus base address and trace memory bus max transfer configuration registers. The size of the block is set by the max transaction count (MXFR field in NAR_TCR) times the size of a transaction (trace memory bus-width, 64-byte, 128-byte, 256-byte, or 384-byte, depending on block transfer mode and block transfer size). For example, if:

- Base address = 0x0D00_0000 (i.e. TBAHI = 0x0, TBALO = 0x0D00_0000)
- NAR_TCR[BTM] = 1 (Block-transfer mode enabled)
- NAR_TCR[BTS] = 00 (Block-transfer size = 64-byte)
- NAR_TCR[MXFR] = 0x100 (max transaction count)

then the total block size would be 0x100 × 0x40 = 0x4000 bytes. The dedicated debug address range would then be 0x0D00_0000 – 0x0D00_3FFF.

The NAR can either write to the debug space one (trace memory bus-width) word at a time, or for improved performance, it can use a block transfer. If the BTM bit of the trace memory bus Control Register (NAR_TCR) is set, then the NAR uses block transactions to send data through the trace memory bus port, where the size of the block is determined by the setting of the BTS field of the NAR_TCR.

In block transfer mode, the NAR waits until the main queue partition dedicated to the trace memory bus port reaches a specified threshold point, determined by the BTH field of the NAR_TCR, before initiating a block transfer. The default threshold is the size of the block transfer. That is, a block transfer does not start until there is enough data in the associated partition to fill the block. But it might be desirable, for bandwidth reasons or because the associated partition is smaller than the block transfer size, to begin the transfer sooner. Hence, based on BTH, a transfer can begin when the partition is at 25%, 50%, or 75% of the block transfer size. This capability should be used with caution. If the Nexus client does not generate enough new data during the transfer to fill the block, then a block transfer error results.

The NAR generates Nexus trace write transactions for the trace memory bus port using the address from the base address register for the first transaction and then incrementing through the memory space. Once the programmed max number of transactions have been sent, the NAR sets the trace memory bus overflow status bit and, if desired, asserts the NAR event-out. At this point, the NAR can either shut down the trace memory bus port for trace, or, if the TBW bit of the NAR_TCR is set, reset the address to the beginning of the debug space and continue sending trace data. This allows the debugger to view the most recent data, in cases where the buffer overflows.

When TBW bit of NAR_TCR is not set then NAR shuts down the trace memory bus port. To restart the trace memory write again from trace memory base address, the user should write either the NPC trace memory bus base address (TBALO/TBAHI) or the transaction count (MXFR). The user does not have to actually change the value, but can write the same target base address again. The NAR sees any write to one of these registers as a reconfiguration of the trace memory bus port, and resets its internal address pointer to the base address along with clearing the target-space-full flag.

6.5.11 Internal message generation

Generally, the NAR simply conveys Nexus messages from client to port, and does not generate messages of its own. There are, however, certain situations when the NAR needs to communicate directly with the debugger. Internally generated messages are added to the queue the same as external messages. If the queue is partitioned, then internal messages are always channeled to whichever partition is dedicated to the HBDP.

The NAR generates the following message types:

- Device_ID—The first message transmitted when the NAR comes up. It consists of a 6-bit TCODE (TCODE = 1) and the 32-bit device ID. The first beat of the message is always an IDLE (MSEO = 2b11, MDO = all 0s) to allow the debugger Nexus state machine to correctly initialize (by moving to end message or idle state). Device_ID is also generated if the queue is repartitioned (by changing either the ALT or MSP setting in the NAR_CR) while it is not empty. This serves the dual purpose of insuring that the user always gets at least one device_ID message and providing a message boundary in the case where there might have been corruption due to the lost data.
- Watchpoint—The NAR generates its own watchpoint match message under the circumstances shown in Table 6-19.
- NAR_Error (TCODE = 8)—If an error condition is detected inside the NAR, it generates its own error message. An NAR_Error message consists of the 6-bit TCODE, the 6-bit NAR source ID, and a 32-bit data field which corresponds to the NAR status register. An NAR error can be triggered by:
  - HBDP error
  - Illegal configuration
  - Stall Error
  - Trace memory bus read/write access error

This table describes the NAR message formats.

Table 6-16. NAR message formats

Message name	Min packet size (bits)	Max packet size (bits)	Packet type	Packet name	Packet description
Device ID	6	6	fixed	TCODE	TCODE value = 1
	32	32	fixed	DID	DID register value
	0	24	variable	TSTAMP	Optional, globally synchronized timestamp
Error Message[1]	6	6	fixed	TCODE	TCODE value = 8
	6	6	fixed	SRC [2]	NAR source ID
	4	4	fixed	ETYPE	See Table 6-17
	12	12	fixed	ECODE	See Table 6-18
	0	24	variable	TSTAMP	Optional, globally synchronized timestamp
Watchpoint Hit Message[3]	6	6	fixed	TCODE	TCODE value = 15
	6	6	fixed	SRC [2]	NAR source ID
	6	6	fixed	WPHIT	See Table 6-19
	0	24	variable	TSTAMP	Optional, globally synchronized timestamp

1. The Error message conforms to the IEEE-ISTO 5001-2012 standard.
2. Tools should treat the NAR SRC field as a 4-bit SRC field and a 2-bit unused field. The extra 2-bit field (the two most significant bits of the 6-bit TCODE) is always 0b00. This operation is not compliant to the IEEE-ISTO 5001 Nexus standard.
3. The Watchpoint Hit message does not conform to the IEEE-ISTO 5001-2012 standard, it conforms to the IEEE-ISTO 5001-2003 standard. The WPHIT should be a variable length packet, but is implemented as a fixed length packet. In most cases, tools will not see a difference, however, a difference will be seen if a timestamp field is appended to the message.

6.5.11.1 Error conditions

NAR errors can occur upon events such as illegal memory accesses, block-transfer overloads, communication errors, or when the NAR is configured incorrectly. If the configuration registers are programmed incorrectly, it is possible to put the NAR into an illegal state. The NARs response varies depending on the error. For a minor error, the NAR reverts to a default mode and continues operation, while major errors result in complete shutdown.

In either case, a Nexus error message is sent to the Aurora out port, if its enabled, otherwise to the trace memory bus port. The Nexus error message contains both ETYPE and ECODE fields:

- ETYPE is used to denote the basic type of error that has occurred
- ECODE carries specific additional information about the error

All NAR error types are defined in the following table.

Table 6-17. NAR error types

ETYPE	Description	Classification	NAR action	Comment
0000 (h'0)	Receive queue overrun	Minor	Dropped message	If a client sends a data word that the NAR cannot accept (due to a full receive queue), the new data word is dropped.
0001 (h'1)	Internal message contention	Minor	Dropped message	Internal errors/watchpoints occurred faster than NAR could generate messages for them, causing lower-priority message(s) to be dropped. The type of message dropped is conveyed in the ECODE field, see Table 6-18.
0011 (h'3)	Trace memory bus port read/ write access error	Minor	Access fails	Unable to send an Aurora-to-trace memory bus request. Typical causes would be writes larger than the data buffer or sending in a new request before the previous one completes.[1]
0101 (h'5)	Invalid NRR	Minor	Access fails	Tried to access an un-implemented NRR.
1001 (h'9)	Config error	Major	See Table 6-18	The specific configuration error is conveyed in bits 0–3 of the ECODE field (Table 6-18), as well as the NCE field of Status Register.
1100 (h'C)	HBDP error	Minor	N/A	A hard error is automatically reset the Aurora Link and causes it to re-initialize. Although the Link is down, the error message is queued and released as soon as the Link comes back up.
1101 (h'D)	Receive Queue Overrun	Minor	Drop message	If a client sends a data word that the NPC cannot accept (due to a full receive queue), the new data word will be dropped2.
1110 (h'E)	Block transfer error	Minor	Dummy fill	If the Trace memory bus port becomes data-starved during a block transfer, it fills the rest of the block with IDLE messages.
1111 (h'F)	Stall error	Minor	—	—

1. In the case where a request was successfully translated to a Trace memory bus transaction which itself returned an error, that is conveyed in the STATUS field of the Nexus Target Response message subsequently returned to the debugger.

Typically, the ECODE field is used to communicate which type of message was dropped in queue overflow or message contention situation, but for the NAR it is also used to denote the type of configuration error that occurred. If a configuration error is detected, the NAR generates a Config Error Nexus message and transmits it, with the actual type of error encoded in the four MSBs of ECODE, as well as the NCE field of the Status Register. The ECODE field encodings are listed in the following table.

Table 6-18. Configuration error codes

ECODE	ETYPE	Description	NAR action	Comment
0000xxxxxxx1	0001	Watchpoint message dropped	N/A	Occurs with internal message overflow error.
0000xxxxxx1x	0001	Data trace message dropped	N/A	Occurs with internal message overflow error; MMA response message was dropped.

Table continues on the next page...

Table 6-18. Configuration error codes (continued)

ECODE	ETYPE	Description	NAR action	Comment
00001xxxxxxx	0001	Response message dropped	N/A	Occurs with internal message overflow error; target response (memory access or NRR) message was dropped.
0000xxx1xxxx	0001	Status message dropped	N/A	Occurs with internal message overflow error.
000100000000	1001	Config error: multiply defined port	Communication disable mode	Both MSP and ALT were assigned to the same port. NPC waits until the configuration is fixed before proceeding.
001000000000	1001	Config error: no ALT defined	Tracebuffer	An MSP was defined without defining the ALT. The NPC reverts to tracebuffer mode.
001100000000	1001	Config error: cannot enable port	Communication disable mode	User has attempted to enable a port that does not exist in this implementation of the NPC.
010000000000	1001	Config error: cannot support message filtering	Message filtering and/or queue partitioning disabled	User has attempted to enable message filtering or queue partitioning with only one output enabled. Filtering/partitioning is turned off.
100100000000	1001	Config error: no wakeup trigger	Power up in active mode	Occurs if none of the defined clients in the system can cause a wakeup (PUS is set in NAR_CR, but no NAR_STCRs have WUT set).

6.5.11.2 Watchpoint messages

The NAR generates its own watchpoint match message under the circumstances shown in the following table. The value of the Watchpoint Hit field of the Watchpoint Message is also shown in this table.

Table 6-19. Watchpoint hit values

WPHIT	Description	Comment
b010000	Entering Suppress Mode	If (local or global) suppress mode is enabled and the appropriate trigger is received, the NAR generates a watchpoint message. The type of event (in this case, a suppress event) is encoded in the WPHIT field of the watchpoint message (see the Nexus standard, sec. 5.3.21).
b100000	Client Sync	If sync messaging is enabled, the NAR generates a sync watchpoint message whenever a client sync event occurs.
b000100	Trace Memory bus Block Overflow (TBO)	If the trace memory bus block is filled, causing it to either disable trace memory bus data trace or wrap back to the beginning of the dedicated debug memory block and if trace memory bus overflow messaging is enabled, then an TBO message is generated.
b001000	Tracebuffer Wrap	If the NAR is being used in tracebuffer mode with the wrap-around feature, then a watchpoint message is generated every time the tracebuffer wraps back to address 0. This would be useful in informing the user that the buffer had wrapped and that older data had been overwritten.

6.5.12 Timestamp function

The NAR and its clients may transmit timestamps to allow precise ordering of events. Synchronous or asynchronous clients use the NAR timer value broadcasted over a bus to ensure that all timestamps are in sync as shown in the following figure. The NAR uses enable signal to centrally control the enabling of time stamping, which informs the clients to start adding the timestamp field to their message traffic.

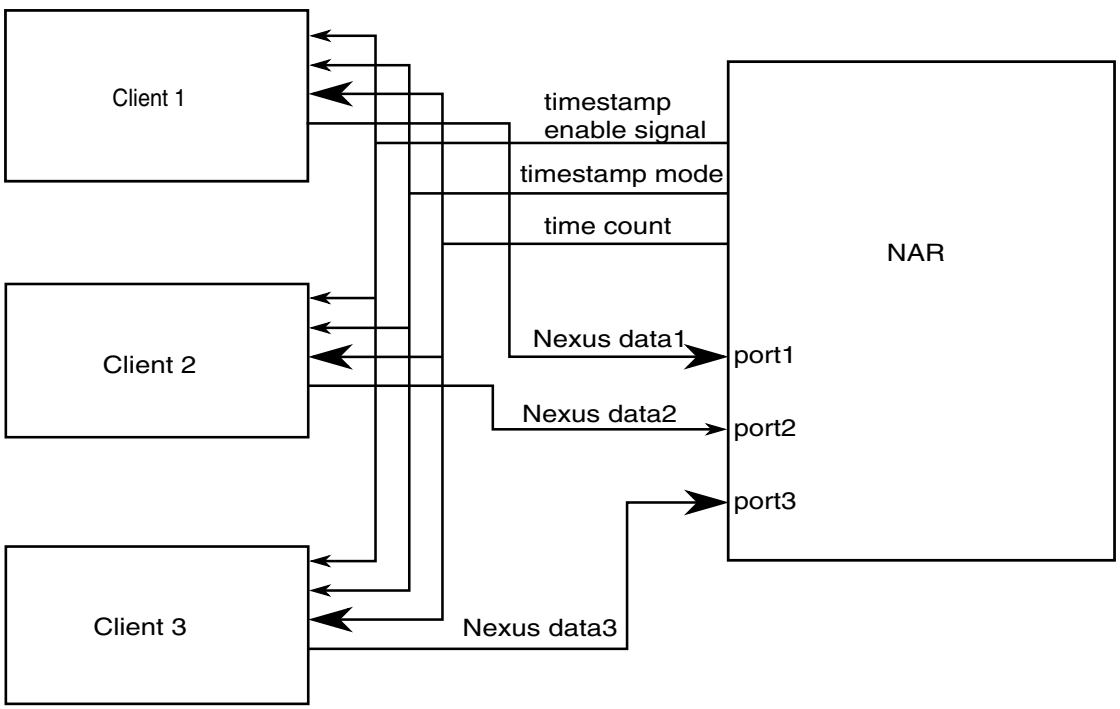

Figure 6-4. Timestamp architecture

Timestamping is enabled by setting the TEN bit of the NAR_CR. This causes the NAR to assert the time stamp enable signal to clients. Typically, the user would also set the TRS bit at this time to reset the NAR Time stamp counter. Internally the NAR has a 30-bit counter external to the NPC block. This 30-bit counter is broadcast to all clients after encoding its value in Gray code. This minimizes the error in synchronization by the clients. The NPC uses an additional internal 24-bit counter to send the timestamp inside its messages. The client converts the gray coded timestamp to binary to append to the Nexus messages.

The timestamp mode, a 2-bit field, is broadcasted to all client which tells the granularity of sending time stamps into message. This is controlled by the TSG bits of the NAR_CR.

Asynchronous clients, those on a separate clock domain from the NAR, synchronize the enable, mode, and timestamp value in their domain. The error introduced by this is assumed to be within tolerable range by application.

A timestamp counter reset can be forced by causing a 0 to 1 transition in the TRS bits of the NAR_CR. The NAR deasserts the enable signal to clients while the reset occurs, and then the counter is restarted (assuming the TEN bit is set). Data throughput can be increased (at the loss of timestamp granularity) by controlling the TSG bits of the NAR_CR. Rather than adding a timestamp to every message, clients can be told to only stamp every 4th, 16th, or 32nd message, easing the bandwidth requirements on the output ports.

The timestamp block maintains the timestamp counter for NAR. It is the central time source for all synchronous/asynchronous clients.

6.5.13 Global (Development tool client) stall control

The external development tool has finite memory. To prevent data loss when this memory is full, the tool gives an event to the device. The DCI block processes this and forwards to NAR block. The dci_evti[1] carries this information. NAR detects the falling edge of dci_evti[1] and loads a counter with a configurable value programmed in GLOBAL_STALL_COUNT field of NAR_AHFPAR. This counter starts decrementing immediately, reaches to zero and stops. During the running period of the counter the Global Stall signal remains asserted thus indicating to stall the message interface to the NAL by that many cycles. The GLOBAL_STALL_COUNT field is five bits so client can be stalled up to 31 cycles.

6.5.14 Overlay and internal trace memory full status generation

In certain events, such as main memory (internal trace memory) full or external overlay trace memory full, it is required to control the clients to stop sending data, to avoid any loss of messages from the clients.

The NAR provides three outputs (triggers) to indicate three different situations as described below:

- Internal trace memory (the main queue) is full
- External debug memory on trace memory bus is full
- External debug memory on trace memory bus is full up to a programmable watermark set by the configuration register

The last two triggers are used by SPU to generate stall and suppress triggers. Typically the stall request should be generated whenever space in the external memory connected to trace memory bus has been exhausted. The NAR starts writing from the first location (wrap) as specified in trace memory bus address register in this condition if overwrite trace memory bus debug memory (TBW bit) is set in the NAR_TCR.

The user should configure the partial full watermark register such that it can give around 90% full indication of external debug memory on the trace memory bus. The emulator tool memory full indication is typically generated from the DCI block which actually communicates with the tool.

For example, the following steps can be used to generate event at around 90% fill level for trace memory connected in AHB-EW and to set the watermark in the configuration register.

- From the configuration, the programmer knows the following:
  - AHB start (base) address—Base address = 0x0D00_0000 (i.e.TBAHI = 0x0, TBALO = 0x0D00_0000
  - Block transfer size—NAR_TCR[BTM] = 1 (Block-transfer mode enabled)
  - Max transfer count—NAR_TCR[MXFR] = 0xC0 (maximum transaction count)
- Thus, the total block size is (0xC0 × 0x40) = 0x3000 bytes. The dedicated debug address range is then 0x0D00_0000 – 0x0D00_2FFF.
- To generate an event at nearly 90% fill level of the trace memory at 1 KB boundary, the value to be programmed in the register NAR_AHFPAR[3:0] is calculated as:
  - Number of 1K blocks in 0x3000 bytes = (3000 right shift by 10 bits) = C = 12
  - So the value to be programmed should be 11 as 90% of 12 is almost 11.
- NAR_AHFPAR[3:0] = (NAR_TBALO[13:10] + 0xB) = (0x7+0xB) 0x2 (upper bits truncated due to width) and enable this with NAR_AHFPAR[10] = 1.

This assumes that NAR starts writing from base address and stops at maximum address and no reading is done in overlay memory trace data area during this operation. Whenever the address bus bits [13:10] match with this value, the partial event is generated (toggled).

Similarly for 65 KB boundary matching NAR_AHFPAR[7:4] needs to be programmed and the corresponding enable bit needs to be set.

6.5.15 Configuration/debug interface JTAG

The configuration and status registers of the NAR are accessed through the standard IEEE 1149.1 JTAG interface. The JTAG frequency (TCK) must be 1/2 of the NAR operating clock. The access mechanism through JTAG is described in this section.

The NAR block uses the IEEE 1149.1-2001 TAP for accessing registers. TAP signals include TCK, TDI, TMS, and TDO. The NAR implements a TAP controller state machine that transitions based on the state of the IEEE 1149.1-2001 16-state state machine. It also implements Nexus controller state machine as defined by the IEEE-ISTO 5001-2001 standard.

The instructions implemented by the NAR TAP controller are listed in Table 6-20. Each unimplemented instruction acts like the BYPASS instruction. The size of the NAR instruction register is 4 bits.

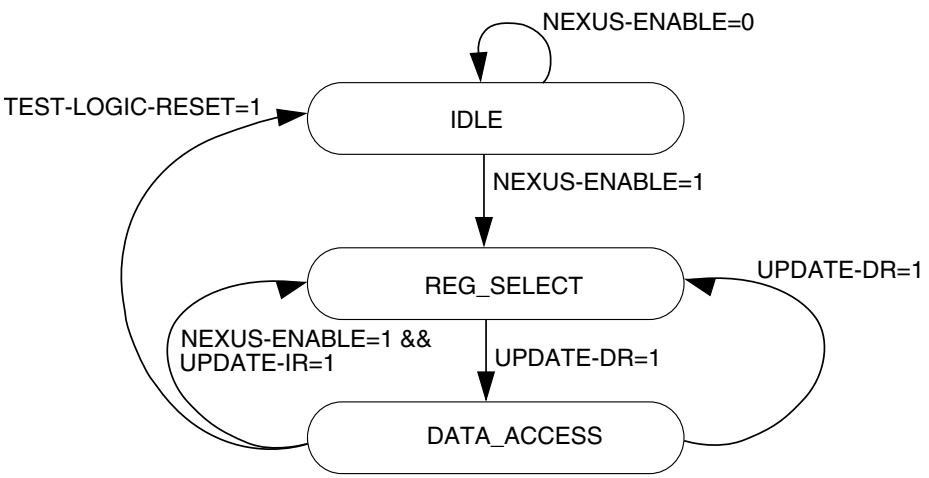

Figure 6-5. Nexus controller state machine

Table 6-20. Implemented instructions

Instruction Name	Private/ Public	Opcode	Description
NEXUS_ENABLE	Public	0x0	Activate Nexus controller state machine to read and write NAR registers.
BYPASS	Private	0x0F	NAR BYPASS instruction. Also the value loaded into the NAR IR upon exit of reset.

Data is shifted between TDI and TDO starting with the least significant bit as illustrated in the following figure. This applies for the instruction register and all Nexus tool-mapped registers.

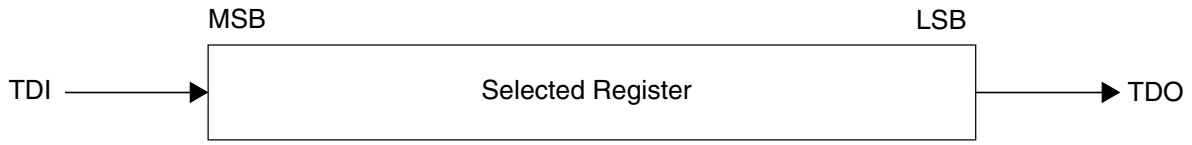

Figure 6-6. Shifting data into register

6.5.15.1 Enabling the NAR TAP controller

Assertion of the power-on reset signal resets the NAR TAP controller. When not in power-on reset the NAR TAP controller is enabled by driving JCOMP with the NAR enable value and exiting the Test-Logic-Reset state. Loading the NEXUS-ENABLE instruction then grants access to Nexus debug.

6.5.15.2 Loading NEXUS-ENABLE instruction

Access to the NAR registers is enabled when the TAP controller instruction register is loaded with the NEXUS-ENABLE instruction. This instruction is shifted in via the SELECT-IR-SCAN path and loaded in the UPDATE-IR state. At this point, the Nexus controller state machine, shown in Figure 6-5, transitions to the REG_SELECT state. The Nexus controller has three states: idle, register select, and data access. The following table illustrates the IEEE 1149.1 sequence to load the NEXUS-ENABLE instruction.

Table 6-21. Loading NEXUS-ENABLE instruction

Clock	TMS	IEEE 1149.1 state	Nexus state	Description
0	0	RUN-TEST/IDLE	IDLE	IEEE 1149.1-2001 TAP controller in idle state
1	1	SELECT-DR-SCAN	IDLE	Transitional state
2	1	SELECT-IR-SCAN	IDLE	Transitional state
3	0	CAPTURE-IR	IDLE	Internal shifter loaded with current instruction
4	0	SHIFT-IR	IDLE	TDO becomes active, and the IEEE 1149.1-2001 shifter is ready. Shift in all but the last bit of the NEXUS-ENABLE instruction.
5 TCKS				
12	1	EXIT1-IR	IDLE	Last bit of instruction shifted in
13	1	UPDATE-IR	IDLE	NEXUS-ENABLE loaded into instruction register
14	0	RUN-TEST/IDLE	REG_SELECT	Ready to be read/write Nexus registers

6.5.15.3 Selecting a JTAG register to create a bus (memory or peripheral) access

When the NEXUS-ENABLE instruction is decoded by the TAP controller, the input port allows the development tool access to all NAR registers. Each register has a 7-bit address index.

All register access is performed via the SELECT-DR-SCAN path. The Nexus controller defaults to the REG_SELECT state when enabled. Accessing a register requires two passes through the SELECT-DR-SCAN path: one pass to select the register and the second pass to read/write the register.

The first pass through the SELECT-DR-SCAN path is used to enter an 8-bit Nexus command consisting of a read/write control bit in the LSB followed by a 7-bit register address index, as illustrated in the following figure. The read/write control bit is set to 1 for writes and 0 for reads. The index for registers are shown in Table 6-1.

Table 6-22. Nexus command format for register selection

MSB	LSB
7-bit register index	R/W

The second pass through the SELECT-DR-SCAN path is used to read or write the register data by shifting in the data (LSB first) during the SHIFT-DR state.When reading a register, the register value is loaded into the IEEE 1149.1-2001 shifter during the CAPTURE-DR state.When writing a register, the value is loaded from the IEEE 1149.1-2001 shifter to the register during the UPDATE-DR state. When reading a register, there is no requirement to shift out the entire register contents. Shifting may be terminated once the required number of bits have been acquired.

The following table illustrates a sequence which writes a 32-bit value to a register.

Table 6-23. Writing a 32-bit value to a register

Clock	TMS	IEEE 1149.1 State	Nexus State	Description
0	0	RUN-TEST/IDLE	REG_SELECT	IEEE 1149.1-2001 TAP controller in idle state
1	1	SELECT-DR-SCAN	REG_SELECT	First pass through SELECT-DR-SCAN path
2	0	CAPTURE-DR	REG_SELECT	Internal shifter loaded with current value of controller command input.
3	0	SHIFT-DR	REG_SELECT	TDO becomes active, and write bit and 4 bits of register index shifted in.
7 TCKs				
11	1	EXIT1-DR	REG_SELECT	Last bit of register index shifted into TDI
12	1	UPDATE-DR	REG_SELECT	Controller decodes and selects register
13	1	SELECT-DR-SCAN	DATA_ACCESS	Second pass through SELECT-DR-SCAN path
14	0	CAPTURE-DR	DATA_ACCESS	Internal shifter loaded with current value of register

Table continues on the next page...

Table 6-23. Writing a 32-bit value to a register (continued)

Clock	TMS	IEEE 1149.1 State	Nexus State	Description
15	0	SHIFT-DR	DATA_ACCESS	TDO becomes active, and outputs current value of register while new value is shifted in through TDI
31 TCKs				
47	1	EXIT1-DR	DATA_ACCESS	Last bit of current value shifted out TDO. Last bit of new value shifted in TDI.
48	1	UPDATE-DR	DATA_ACCESS	Value written to register
49	0	RUN-TEST/IDLE	REG_SELECT	Controller returned to idle state. It could also return to SELECT-DR-SCAN to write another register.

6.5.16 Trace memory bus controller

The purpose of the trace memory bus is to transfer trace data from main queue to external overlay memory. This port works on a modified AHB protocol that supports early write. It has AHB interface signals as defined in AMBA specification (Rev 2.0). In addition, there are side-band signals for added functionality.

Key features of the module include:

- AHB-EW Interface
  - Early Write (for higher BW in special module)
  - 32-bit address bus width
  - 64-bit data bus width
  - Transfer Types
  - IDLE, NONSEQ, SEQ
  - Single Transfers
  - Burst Transfers
  - Configurable support for INCR
  - Configurable support for INCR4, INCR8, INCR16, WRAP4
  - Response Type
  - OKAY, ERROR
  - Transfer Size
  - Byte, Half Word, Word, Double-Word

- Protection Control
- Cacheable/ Non Cacheable Access Control
- User/Privilege Access

- Endianess Support
  - Configurable Little Endian/Big Endian support on AMBA-AHB interface
- Pipeline Support
  - Total of two transactions (One plus one ongoing)

6.5.16.1 Operation

The trace memory bus controller allows all read/write operations to be cut through. The controller has a pipeline depth of two. While the data phase of one transaction is ongoing, it can accept one more read/write request from the internal bus master and initiate the address phase on the AHB interface during the last data cycle of the ongoing transaction.

6.5.16.2 Write operation

When the trace memory bus initiator asserts a request for a write operation, it can find the acknowledge signal parked asserted if the controller is ready to accept the transaction. If the pipeline is full or in case of an ongoing read transaction, the controller inserts wait states by keeping the acknowledge low. The trace memory bus controller initiates the address phase on AHB interface once it accepts the transaction by asserting the acknowledge on the trace memory bus interface. The write data from the trace memory bus initiator is accepted by the gasket by asserting the acknowledge only on completion of address phase at AHB interface, which is signified by receiving the ready signal asserted. Simultaneously, the data is sent to the data bus. Once the requisite number of bytes have been accepted from the trace memory bus initiator, the gasket generates end of data and transfer according to the Trace memory bus protocol.

The AHB protocol supports data transactions of byte, half-word, word and double-word (when both trace memory bus and AHB data bus width is 64 bits). A write transaction from the trace memory bus initiator take place as single/multiple transactions on the AHB side.

6.5.16.3 Read operation

When the trace memory bus initiator asserts a request signal to request for a read operation, it can find the acknowledge signal parked asserted if the gasket is ready to accept the transaction. If the pipeline is full, the controller inserts wait states by keeping the acknowledge low. The trace memory bus controller initiates the address phase on AHB-EW interface once it accepts the transaction by asserting the acknowledge on trace memory bus interface. The controller reads the data from the bus when the ready signal is sensed asserted. The data is transferred on the trace memory bus data bus with the data acknowledge asserted. The gasket asserts end of data and transfer at the end of transaction as per trace memory bus protocol.

The AHB protocol supports data transactions of byte, word, half-word and double-word (when both trace memory bus and AHB data bus width is 64-bits). A read transaction from trace memory bus initiator takes place as single/multiple transaction on the AHB interface before the read data is merged and sent on the trace memory bus read data bus.

In case of variable data bus width on trace memory bus and AHB interface (32-bit data bus on one interface and 64-bit data bus on the other interface), a maximum of 64 bits is read on each beat.

6.5.17 Aurora client controller

This block converts the Aurora client protocol from the PD NAR into an internal client protocol that is accepted by the NPC block. The Nexus beat size must be same at both interfaces. The relation between the Aurora client data width and the NPC client interface data width must be maintained as described here.

The Aurora data width is defined as the Aurora width × 16 bits, where 16 bits comprise one Aurora word. The Nexus client data width is defined as Bn × 32, where 32 = MDO bits + 2 MSEO bits and Bn is the number of beats.

Thus:

Aurora data width = the Nexus client data

Aurora width × 16 = Bn × 32

Aurora width = 2 × Bn

This block works in a similar way to the legacy client controller block except for the interface level control. The Aurora client has the information about the FIFO size. It sends as many data as the FIFO size then waits for the data accept signal from this block.

The controller gives the data accept only when a read occurs and sends data to the NPC interface. The FIFO act as a storage and serves the purpose of clock domain transfer as well.

6.6 Application information

The base application for the NAR is collecting and collating Nexus trace data. Programming examples for how to set up the NAR for trace are given in Output arbitration.

Example flow of NAR configuration for different cases.

Configuration with Two output port enabled

1. For Two port enabled one port must be Message Select (MSP) and other Alternate (ALT); Trace Memory and Aurora ports with multiple clients

   Selection of MSP port depends on user choice. One option could be based on the requirement of Filtering. If Messages from some known sources with some specific type (if any) is required to be sent to a particular port then select user can select that port as MSP. All other messages will go to the Alternate port. The filter can be used as inverted manner where unmatched messages will go to MSP. (Please see section “Output arbitration” for details)
   - Configure the Source Filter register (NAR_SFR), To enable proper filtering of messages based on Message source going to MSP or ALT port
   - Configure the Type Filter register (NAR_TFR), To enable proper filtering of messages based on Message Type going to MSP or ALT port
   - Configure Trace Memory port attributes : (This step is not required if Trace memory port is not used)
     - Start Address (base address) in NAR_TBALO & NAR_TBAHI register
     - Transfer mode, Block size, Threshold in %, Wrapping enable and Total size of memory
   - Configure Client disable register NAR_CDR (disable clients which are not required)
   - Configure NPC suppress trigger registers NAR_STCR[x] (x=0-3) (suppress the clients for which data is not to be forwarded at output) (Difference between suppressing and disabling is that suppressing can be done dynamically during NAR operation but disabling can’t be done this way which may leads to system hang)
   - Configure the Event generation register (NAR_AHFPAR) for programmable fill level event generation
   - Configure the NAR control register for other controls and Enable NAR

- Set the MSP as Nexus Out and ALT as Trace memory
- Set AQP for partitioning the Main Queue for ALT and MSP ports
- Set time stamp controls
- Enable NAR to start operation
- Configuration for Single Output port with single partition in NAR central Message Queue

2. Only Trace Memory port is enabled with multiple client
   - Configure Trace Memory port attributes : (This step is not required if Trace memory port is not used)
     - Start Address (base address) in NAR_TBALO & NAR_TBAHI register
     - Transfer mode, Block size, Threshold in %, Wrapping enable and Total size of memory
   - Configure Client disable register NAR_CDR (disable clients which are not required)
   - Configure the Event generation register (NAR_AHFPAR) for programmable fill level event generation
   - Configure the NAR control register for other controls and Enable NAR
     - Set the Trace Memory port as ALT port (Alternate port is only the main port in single out port application)
     - Set AQP for disabling partitioning
     - Set time stamp controls
     - Set watch point controls
     - Enable NAR to start operation

Chapter 7
Buddy Device—Nexus Aurora Link (NAL)

7.1 Introduction

The Aurora Protocol is used to send debug information over a high-speed serial link out of the device. The Nexus Aurora Link (NAL) consists of all the logic on the MCU needed to implement the connection up to the physical-layer SerDes and transceivers; it includes Aurora control and data multiplexing, data-encoding and striping, and the Physical Coding Sublayer (PCS) portion of the protocol. The following figure details the NAL block diagram. The number of lanes, n, is 4.

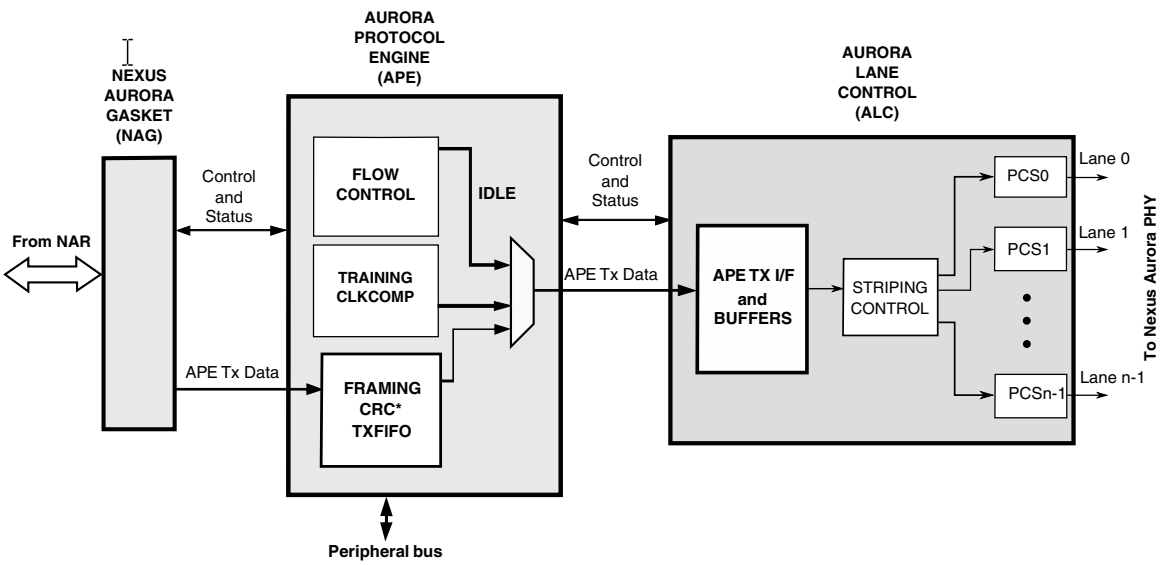

Figure 7-1. NAL block diagram

Debug data in the Nexus format from multiple clients is collected by the Nexus Aurora Router (NAR) ; messages are then packetized and sent across an asynchronous clock boundary-crossing gasket to the Aurora Protocol Engine, which performs all the logical layer functions and flow control; data from the protocol engine is sent on to the Aurora Lane Control (ALC) block, which performs data-striping and sizing, based on the number of lanes selected for debug; it also performs the PCS functions of the link. The PCS

drives the Nexus Aurora Physical (NAP) interface. The NAP, in conjunction with the NAL, supports one-way simplex high-speed serial communication with an external debugger.

The NAL is composed of three main blocks: the NAR/Aurora Gasket, the Aurora Protocol Engine, and Aurora Lane Control. The table below lists NAL functionality by block and lists the high level features for the Nexus Aurora PHY.

Table 7-1. NAL and NAP feature summary

Sub-Component	Feature
NAR Aurora Gasket (NAG)	• Transmit FIFO to buffer data as it crosses the NAR/NAL clock-domain boundary and Transmit FIFO space available indication to NAR. The NAR uses Transmit FIFO space available indication(s) to determine if data can be sent to the NAL. • Platform to Domain clock domain crossing. The NAR is on the core clock domain while the NAP is on a domain sourced from the external PHY clock input signals.
Aurora Protocol Engine (APE)	• Link training • Per the Aurora Protocol specification, clock-compensation, and data framing • Cyclic Redundancy Check (CRC) generator
Aurora Link Control (ALC)	• Striping of data stream from the Aurora core across all available lanes in two-byte chunks • PCS functionality for NAL
Nexus Aurora PHY (NAP)	• Physical transmission of serial data to device pins • External clock source for SerDes clock domain

7.2 Transmit operation

During transmit operation, the NAR collects debug data from Nexus clients over a 32-bit interface: 30 bits are used for MDO and 2 bits are used for MSEO information. The NAR places MDO data into a payload (maximum payload size depends on the number of lanes, each lane has a maximum of 7424 symbols before terminating the payload) and adds the following:

- 16-bit start symbol
- 16-bit end symbol
- 16-bit CRC if enabled before end of previous symbol

Each payload is transferred from the NAR to the NAR/NAL gasket, through the Aurora Protocol Engine, the Aurora Lane Control and finally out to the device SerDes/LVDS pins through the NAP.

After each end symbol packet transfer, the NAL adds a clock compensation sequence needed for downstream SerDes devices to remain synchronized to the MCU.

NOTE

Symbol counting for clock compensation starts just prior to the verification symbols; therefore, training symbols are excluded when counting.

7.3 Nexus Aurora formatting

The Aurora physical interface is the transport mechanism for Nexus messages. The Nexus messages are formatted by the Aurora formatter and striped into Aurora lanes. The Nexus messages themselves encapsulated into a virtual Nexus port that consists of a 30-bit Message Data Output (MDO) port and a 2-bit Message Start/End Output (MSEO) signal. The MSEO portion of the port is the two least significant bits (LSB) of the 32-bit Aurora message. The rest of the 32-bit Aurora frame consists of 30 MDO bits that are added LSB first.

7.4 Static training

The NAL supports static training. The NAL performs Static training by using programmable timers to determine how long to stay in each stage of the training process. In static training, there is no communication between the channel partners to exchange training status; rather the NAL sends the align/bond/verify sequence to its partner for a set amount of time sufficient for the receive partner to complete the training stage.

Note

Prior to initialization, the NAL must be reset to its POR state; to do this, assert the block reset. See the RST bit field description in the NAL General Control Register (NAL_GCR).

The following steps enable static training:

1. Program the counters in the NAL_TCR and set the STE bit
2. Set the RST bit

This resets the channel and start the training routine. The time spent in each stage can range from 16 to 3072 cycles; once a counter times out, a counter time-out signal is asserted to the Aurora Protocol Engine (APE) to prompt it to move to the next stage. Additionally, it is possible to hold the training procedure in any of the stages indefinitely, by setting one of the three hold bits (AHD/BHD/VHD). When set, these bits cause the

channel to sit in Align/Bond/Verify until unset, allowing a user to interactively step through the training procedure by monitoring the status at the debugger side and then stepping the device side to the next stage.

During the Aurora training sequence, the NAL generates a specific set of character sequences per the Aurora protocol specification which are to be transmitted simultaneously on all lanes.

7.5 Clock compensation considerations

The Aurora Protocol Specification describes clock compensation as a means for the link to compensate for clock rate differences between the transmitter and receiver. The spec requires that a clock compensation be inserted at a minimum every 10000 symbol pairs; this should allow the link to accomodate up to a 200 ppm difference in clock rates.

Due to the fact that the NAL is restricted to only inserting clock-compensation sequences after an end-of-frame, it may not be possible to always meet the Aurora spec requirement. However, there are ways to control the framing of data through the link and insure that satisfactory performance is maintained. There are two types of scenarios that can prevent an adequate number of clock compensation sequences from being generated: the sparse data case and the unframed data case. In the sparse data case, there are long periods of time when no data is flowing through the link; no data means no frames. In the unframed case, there is plenty of data, but this data is not framed, and so again, clock-compensation never gets a chance to make it out.

The unframed case is simplest to address. The NAR can either operate in framed or unframed mode. In unframed mode, an end-of-frame is only injected when the NAR runs out of data (as soon as new data is collected, it is sent out accompanied with a start-of-frame; if the NAR is configured in this mode, the clock-compensation spec can easily be violated. However, in framed mode, an end-of-frame/start-of-frame pair is injected after every 256 data transmissions. Here, each frame consists of 256 x AW symbol pairs. Inside the APE, a clock-compensation counter keeps track of how much data has been transmitted to the ALC since the last clock-compensation sequence; once the counter hits 7424, clock-compensation will be sent on the next end-of-frame.

On the other hand, even if the NAR is in framing mode, there is little that can be done if the NAR has no data to send. In the sparse data scenario, the NAL could end up transmitting idles for an undetermined number of cycles while waiting for the NAR to provide new data. However, a user can get around this problem by insuring that the NAR always has at least some minimal amount of data to send. There are several ways to do this:

- If full-duplex infrastructure is available, then the simplest thing to do is for the debugger to monitor the TX data stream from the NAL for long idle periods. If the link has been idle for longer than some minimal amount of time (say 8000 symbol pairs), then the debugger could send in a read request through the aurora-in RX port -- a quick NRR read of the dev_id register would be ideal for this purpose. The NAR would then return the requested data, accompanied by a start-of-frame/end-of-frame pair, which the NAL could then tag with clock-compensation. See the NAR block guide for more details on aurora-in NRR access.
- If full-duplex is not available, then the debugger could still force the NAR to send the dev_id message by going through the JTAG/SAP port and setting the NAR SRESET bit. Reinitializing the NAR puts it back into its startup state, wherein it will invariably send device ID before doing anything else. The only drawbacks to this approach are its long latency (going through JTAG) and the fact that NAR must be correctly reconfigured after every SRESET.
- Another approach is to use periodic watchpoints to insure that the data stream never falls completely silent for more than some predefined count. Most nexus clients, including the NAR itself, can generate a watchpoint sync message based on an external or internal trigger. By hooking one of these triggers up to a counter (a performance-monitor, event-processing unit debug counter can be used for this purpose), we can insure that, even if there is no other trace data traffic, there will at least be periodic watchpoint messages which can be used to trigger clock compensation. The drawback here is that it requires devoting one of the debug counters for clock compensation, but this may not always be a problem: one of the proposed methods of correlating nexus timestamps from different asynchronous domains is to use the same sort of periodic sync trigger to force all asynchornous clients to send a stamped watchpoint message at (roughly) the same time. This asynchronous sync trigger can also be used for clock compensation.

7.6 Programmable registers

The Nexus Aurora Link (NAL) module provides a Nexus parallel to Aurora formatting for the MCU trace information. These registers are not memory-mapped and can only be accessed via the JTAG interface.

Table 7-2. NAL memory map

Offset	Register name	Width (in bits)	Access	Reset value
0h	NAL General Status Register (NAL_GSR)	32	R	0008_0000h
8h	NAL General Control Register (NAL_GCR)	32	R/W	0000_0000h
Ch	NAL Training Control Register (NAL_TCR)	32	R/W	0000_0000h

7.6.1 Nexus Aurora Link General Status Register (NAL_GSR)

The NAL_GSR is a read only register that describes the status of the NAL.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0												TXONLY	0

Table 7-4. NAL_GCR field descriptions

Field	Description
31 RST	Reset the Aurora Channel. 0 to 1 transition resets the channel and begins the training sequence. 0 normal operation 1 transition from 0 to 1 resets channel and starts training sequence
30 ALCPD	ALC/NAL Power Down. Gate off clocks to the NAL blocks (ALC and APE). 0 NAL is enabled with all clocks running provided other mechanisms of powerdown (such as alc_num_lanes) are not in effect. 1 NAL is powered down and inactive.
29–18 Reserved	Reserved This read-only bitfield is reserved and always has the value zero.
17 FCM	Flow Control Mode. 0 Completion Mode 1 Immediate Mode
16-15 Reserved	Reserved and must be written with zero.
14 PCRST	Protocol Converter Reset. Resets the ALC when asserted.
13 Reserved	Reserved This read-only bit is reserved and always has the value zero.

Table continues on the next page...

Table 7-4. NAL_GCR field descriptions (continued)

Field	Description
12–10 SLD	Symbol Lock Delay. 000 Allow 3 characters to accumulate in elastic buffer before starting to read 001 Allow 4 characters to accumulate in elastic buffer before starting to read 010 Allow 5 characters to accumulate in elastic buffer before starting to read 011 Allow 6 characters to accumulate in elastic buffer before starting to read 100 Allow 7 characters to accumulate in elastic buffer before starting to read 101 Allow 8 characters to accumulate in elastic buffer before starting to read 110 Allow 9 characters to accumulate in elastic buffer before starting to read 111 Allow 10 characters to accumulate in elastic buffer before starting to read
9 Reserved	Reserved This read-only bit is reserved and always has the value zero.
8 BOOE	Bond Offset Override Enable. 0 ALC channel bond attempts to determine channel bond offset. 1 ALC uses user override setting for channel bond offset.
7–4 BOOD	Bond offset override data. Only valid when BOOE is set. 0000/1000 use 0-cycle offset 0001 use -7 cycle offset 0010 use -6 cycle offset 0011 use -5 cycle offset 0100 use -4 cycle offset 0101 use -3 cycle offset 0110 use -2 cycle offset 0111 use -1 cycle offset 1001 use +1 cycle offset 1010 use +2 cycle offset 1011 use +3 cycle offset 1100 use +4 cycle offset 1101 use +5 cycle offset 1110 use +6 cycle offset 1111 use +7 cycle offset
3 CRCEB	CRC Enable. 0 CRC generation and checking is disabled for TX and RX data. 1 CRC is inserted for TX frames and CRC is checked for RX paths.
2 CCOEN	Clock Compensation Override Enable. This is a debug feature which allows the duration between clock compensation sequences to be reduced to 1280 cycles. 0 Clock compensation counter times out at 7424 cycles 1 Clock compensation counter times out at 1280 cycles

Table continues on the next page...

Table 7-4. NAL_GCR field descriptions (continued)

Field	Description
1–0 Reserved	Reserved This read-only bitfield is reserved and always has the value zero.

7.6.3 NAL Training Control Register (NAL_TCR)

The NAL_TCR supports static training as described in Static training.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Chapter 8
Buddy Device—Nexus Aurora PHY (NAP)

8.1 Introduction

The Nexus Aurora PHY (NAP), in conjunction with the Nexus Aurora Link (NAL), supports one-way simplex high-speed serial communication with an external debugger. Configuration settings in the Nexus Aurora Router (NAR) Nexus Aurora Phy control register (NAR_NAPCR) specify the NAP and NAL lane configuration. The NAL performs all logical layer functions, flow control, data-striping and sizing based on the number of data lanes available for use, and physical coding sublayer functions on the data being sent to the NAP for transmission. The NAP receives 8b/10b encoded data from the NAL then serializes and transmits this data through a given PHY lane's Low Voltage Differential Signaling (LVDS) buffers to an external debugger.

Each NAP lane consists of a data symbol character accumulator which registers the 10-bit character for that lane from the NAL on the rising edge of the NAL clock. Next, a serializer takes the 10-bit character and serializes it into the individual data bits that are then transmitted at the PHY clock rate via the LVDS output drivers to the external debugger receive channel.

Note

The NAL performs static link training for an attached debugger's PHY. The NAP is not directly aware of the link training operation, since it merely transmits the data presented to it by the NAL.

On the receive side of the external debugger, it is the responsibility of the external debugger to perform elastic buffering, symbol detection, symbol locking (called Lane Alignment in Aurora terminology), 10b/8b decoding, decode and disparity error tracking in the received data stream.

The following figure shows a high level block diagram of the High Speed Nexus Interface and the NAP.

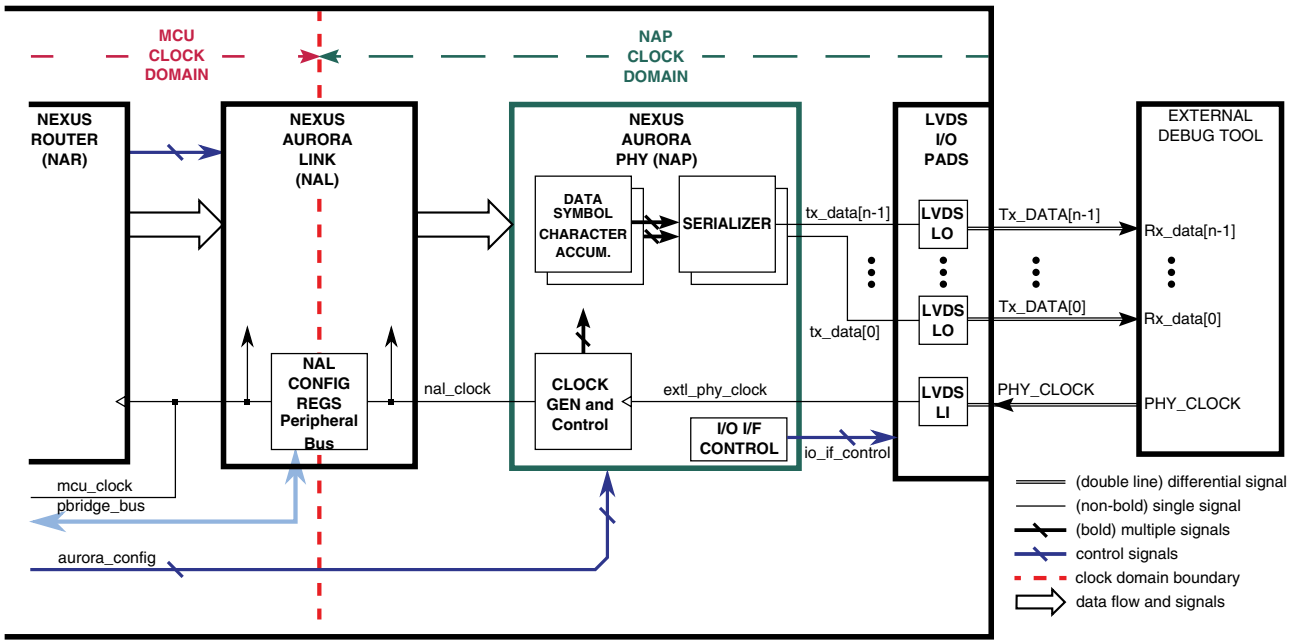

Figure 8-1. High speed Nexus interface block diagram

8.1.1 Features

The features of the NAP are as follows:

- Xilinx Aurora Protocol Specification V2.x compliant
- 1Gb/s per channel trace data payload bandwidth with 1.25 GHz clock
- Simplex mode with static (timer-based) channel training

8.1.2 Modes of operation

The operating mode of the NAP is determined by the device control signals. The functional configuration is determined by the NAR_NAPCR setting; functional operation is enabled by the NAR.

8.1.2.1 Reset

During Nexus Reset all internal NAP resources are reset, all output ports are disabled, and all inputs are ignored. Since there is no device clock domain logic in the NAP itself, the NAP is unaffected by device system reset. Depending on the NAP configuration settings, the NAP may activate upon exiting Nexus Reset if any Aurora lanes are enabled during this reset mode, else it remains disabled and inactive.

8.1.2.2 Link training

Before beginning trace output mode operation, the Aurora Link must go through a training process conducted by the NAL to ensure that an external debugger can correctly reconstruct the transmitted data stream. Training proceeds once the link powers up, and must complete successfully before data transmission can occur.

The NAL initializes and trains the Aurora Link in a simplex configuration using a timer based static-training method. The initialization and training sequence described in Aurora Protocol Specification progresses from one step to the next via the use of programmable timers contained in the NAL. A timer is programmed for each stage of training and as each timer expires, the training sequence proceeds to the next stage until complete. The NAP is not directly aware of the link training operation, since it merely transmits the data presented to it by the NAL.

8.1.2.3 Transmit

During Nexus trace output operation, it is the responsibility of the NAR to push data into the Aurora Link at a sufficiently high rate to ensure that the link does not become data-starved. The NAL and NAP support up to 4 transmit lanes. The Aurora encapsulated data is modified by the NAL to ensure the appropriate number of symbols are transmitted through the NAP.

8.2 External signal description

The external signals of the NAP are listed in the following table. Each of the NAP signals consists of a positive and negative differential pair.

Table 8-1. NAP signals

Signal Name	Direction	Description
PHY_CLOCK (CLKP/CLKN)	Input	NAP clock input from external debug tool

Table continues on the next page...

Table 8-1. NAP signals (continued)

Signal Name	Direction	Description
TX Data0 (TX0P/TX0N)	Output	NAP Tx data for lane 0
TX Data1 (TX1P/TX1N)	Output	NAP Tx data for lane 1
TX Data2 (TX2P/TX2N)	Output	NAP Tx data for lane 2
TX Data3 (TX3P/TX3N)	Output	NAP Tx data for lane 3

8.3 Memory map and register definition

There are no control, configuration or status registers within the NAP. All control, configuration and status options for number of lanes and LVDS pads are handled in the NAR_NAPCR which is described in the NAR Chapter.

8.4 Functional description

High-level descriptions of the operation of the NAP and its main functional blocks are given in the following sections.

8.4.1 Data symbol character accumulator

The data symbol character accumulator portion of the NAP for each lane is made up of a symbol character register whose inputs are connected to the 10-bit NAL character bus. The data symbol character accumulator essentially registers a 10-bit character for that lane simultaneous with the rising edge of the NAL clock and presents the 10-bit quantity to the serializer at the appropriate times.

8.4.2 Serializer

The serializer portion of the NAP for each lane takes the data captured by that lane's Data Symbol Character Accumulator and demuxes the data to provide a single serial stream of symbol data to be output by the LVDS LO buffer for that lane at the PHY clock rate.

The following figure shows a high level timing diagram that demonstrates the operation of the serializer for a NAP lane, where S0–S9 represents a 10-bit symbol, S10–S19 represent the next symbol, and so on.

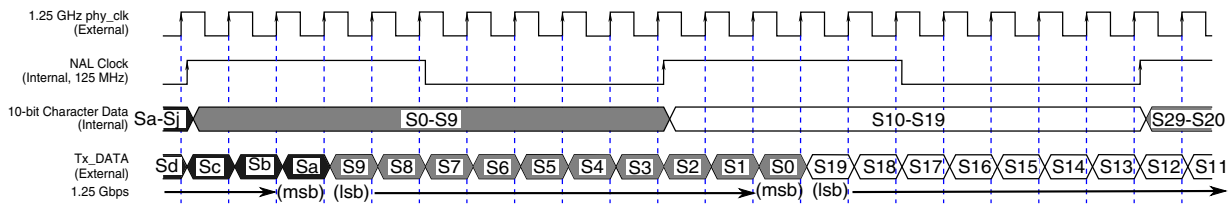

Figure 8-2. Serializer timing diagram

8.4.3 Clock generation and control

The Clock Generation and Control block is responsible for generating the necessary clocks and state signals needed by the rest of the NAP. The Data Symbol Character Accumulators and serializers are the main consumers of the signals generated by the Clock Generation and Control block.

8.5 Initialization information

The NAP does not require initialization other than the Nexus Reset and programming of the NAR_NAPCR to configure the number of lanes and LVDS pads.

Chapter 9
Buddy Device—Nexus Read Write Access (RWA)

9.1 Introduction

The Nexus Read Write Access (RWA) module allows an external tool connected to the Emulation and Debug Device (ED) to read or write the Buddy Die calibration and trace memory via the JTAG interface. All accesses are setup and initiated by the Read/Write Access Control/Status Register (RWCS), as well as the Read/Write Access Address (RWA) and Read/Write Access Data Registers (RWD). The RWA module supports single as well as block reads and writes.

The RWA module is enabled by loading a single instruction (ACCESS_AUX_RWA_BD = 0x23) into the JTAG Instruction Register (IR). After the RWA module has been enabled, access to the RWA registers is enabled by loading an instruction (CORE_ENABLE) into the JTAG IR, as described in Nexus register access via JTAG. The RWA module is disabled when the JTAG state machine initially reaches the Test-Logic-Reset state from any other state. The RWA module is also disabled if a Power-on-Reset (POR) event occurs. When disabled, the RWA module registers are not available for (32-bit or less) reads or writes.

9.2 Register definition

This table details the register map for the RWA module.

Table 9-1. RWA register map

Register	Nexus access opcode	Read/ write	Read address	Write address
Read/Write Access Control/Status (RWCS)	0x7	R/W	0x0E	0x0F
Read/Write Access Address (RWA)	0x9	R/W	0x12	0x13
Read/Write Access Data (RWD)	0xA	R/W	0x14	0x15

9.2.1 Read/write access control/status (RWCS)

The Read/write access control/status register provides control and status for the RWA module as shown in this table.

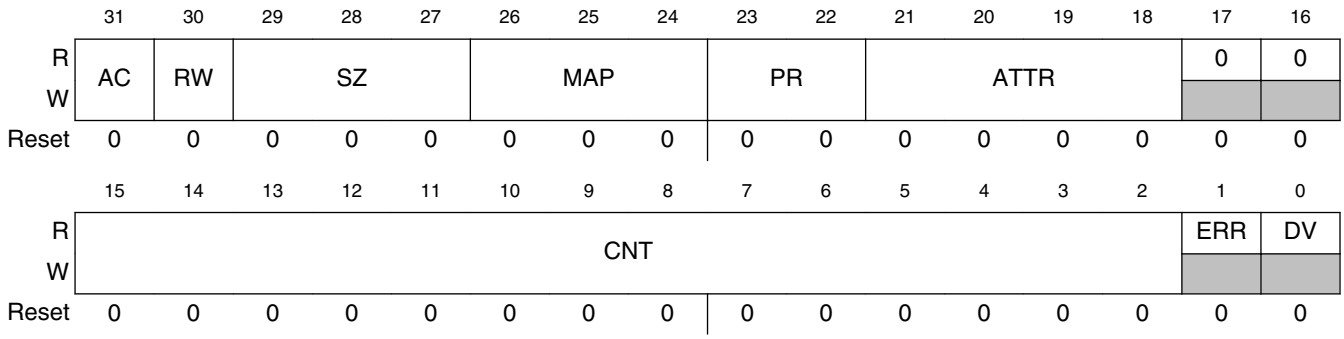

Table 9-2. RWCS fields

Field	Description	
31 AC	Access Control.	
	0	End access/ Access has completed
	1	Start access
30 RW	Read/Write Select.	
	0	Read access
	1	Write access
29:27 SZ	Word Size.	
	000	8-bit (byte)
	001	16-bit (half-word)
	010	32-bit (word)
	011	Reserved (default to word)
	100	Reserved (default to word)
	101	Reserved (default to word)
	110	Reserved (default to word)
	111	Reserved (default to word)
26:24 MAP	MAP Select.	
	000	Primary memory map
	001	Reserved
	010	Reserved
	011	Reserved
	100	Reserved
	101	Reserved
	110	Reserved
	111	Reserved

Table continues on the next page...

Table 9-2. RWCS fields (continued)

Field	Description	
23:22 PR	Read/Write Access Priority.	
	00	Reserved (default to highest priority)
	01	Reserved (default to highest priority)
	10	Reserved (default to highest priority)
	11	Highest access priority
21:18 ATTR	Access Attributes. RWA accesses are run as privileged data non-cacheable accesses by default, and drive the p_d_hprot[5:0] bus access attributes to 6'b000011 accordingly. This field is provided to allow a portion of these default values to be modified when performing read or write accesses using the RWA as shown in Table 9-4. hprot[1] must be set to one.	
	0xxx	Reserved
	1xxx	Reserved
	x0xx	p_d_hprot[4] driven to 0 for accesses
	x1xx	p_d_hprot[4] driven to 1 for accesses
	xx0x	p_d_hprot[3] driven to 0 for accesses
	xx1x	p_d_hprot[3] driven to 1 for accesses
	xxx0	p_d_hprot[2] driven to 0 for accesses
	xxx1	p_d_hprot[2] driven to 1 for accesses
17:16	Reserved for future functionality.	
15:2 CNT	Access Control Count. Number of accesses of word size SZ.	
1 ERR	Read/Write Access Error (see Table 9-3).	
0 DV	Read/Write Access Data Valid (see Table 9-3).	

Table 9-3. Read/Write access status bit encoding

Read action	Write action	ERR	DV
Read access has not completed	Write access completed without error	0	0
Read access error has occurred	Write access error has occurred	1	0
Read access completed without error	Write access has not completed	0	1
Not allowed	Not allowed	1	1

Table 9-4. Protection encoding

p_hprot[4]	p_hprot[3]	p_hprot[2]	Transfer type
0	0	0	Cache-inhibited
0	0	1	Guarded, not cache-inhibited
0	1	0	Reserved
0	1	1	Reserved

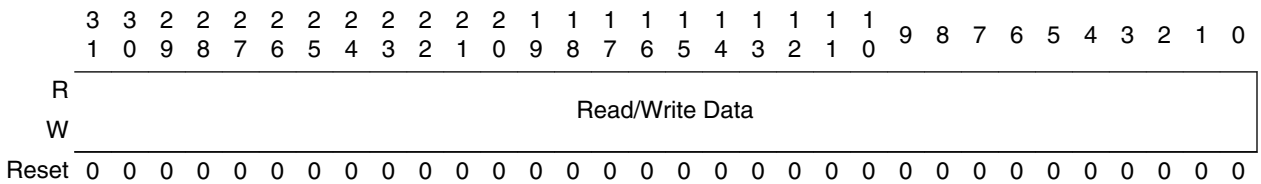

Table continues on the next page...

Table 9-4. Protection encoding (continued)

p_hprot[4]	p_hprot[3]	p_hprot[2]	Transfer type
1	0	0	Reserved
1	0	1	Reserved
1	1	0	Cachable, writethrough
1	1	1	Cachable, writeback

9.2.2 Read/write access data (RWD)

The Read/write access data register (RWD) provides the data to/from memory when initiating a read or a write access.

Read/write accesses to the memory require that the debug firmware properly retrieve/ place the data in the RWD. This table shows the proper placement of data into the RWD.

Table 9-5. RWD data placement for transfers

Transfer size and byte offset	RWA(2:0)	RWCS[SZ]	RWD[1]			
			31:24	23:16	15:8	7:0
Byte	x x x	0 0 0	—	—	—	X
Half	x x 0	0 0 1	—	—	X	X
Word	x 0 0	0 1 0	X	X	X	X

1. X indicates byte lanes with valid data; — indicated bytes lanes with unused data.

This table shows the mapping of RWD bytes to byte lanes of the read and write data buses.

Table 9-6. RWD byte lane mapping

Transfer size and byte offset	RWA(2:0)	RWD[1]			
		31:24	23:16	15:8	7:0
Byte @000	0 0 0	—	—	—	XBAR[7:0]
Byte @001	0 0 1	—	—	—	XBAR[15:8]
Byte @010	0 1 0	—	—	—	XBAR[23:16]

Table continues on the next page...

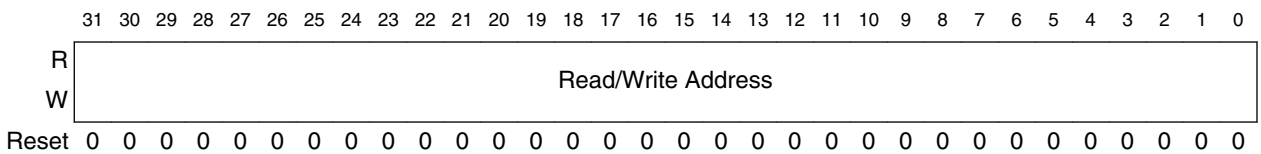

Table 9-6. RWD byte lane mapping (continued)

Transfer size and byte offset	RWA(2:0)	RWD[1]			
		31:24	23:16	15:8	7:0
Byte @011	0 1 1	—	—	—	XBAR[31:24]
Byte @100	1 0 0	—	—	—	XBAR[39:32]
Byte @101	1 0 1	—	—	—	XBAR[47:40]
Byte @110	1 1 0	—	—	—	XBAR[55:48]
Byte @111	1 1 1	—	—	-	XBAR[63:56]
Half @000	0 0 0	—	—	XBAR[15:8]	XBAR[7:0]
Half @010	0 1 0	—-	—	XBAR[31:24]	XBAR[23:16]
Half @100	1 0 0	—-	—	XBAR[47:40]	XBAR[39:32]
Half @110	1 1 0	—	—	XBAR[63:56]	XBAR[55:48]
Word @000	0 0 0	XBAR[31:24]	XBAR[23:16]	XBAR[15:8]	XBAR[7:0]
Word @100	1 0 0	XBAR[63:56]	XBAR[55:48]	XBAR[47:40]	XBAR[39:32]

1. — indicates byte lanes that contain unused data

9.2.3 Read/write access address (RWA)

The Read/write access address register provides the address to be accessed when initiating a read or a write access.

9.3 Nexus register access via JTAG

After the RWA module has been enabled, access to the RWA registers is enabled by loading an instruction (CORE_ENABLE = 0x7C) into the JTAG Instruction Register (IR). Once the CORE_ENABLE instruction has been loaded, the JTAG port allows tool/target communications with all Nexus registers according to the map in Table 9-1.

Reading or writing of a RWA module register then requires two passes through the Data-Scan (DR) path of the JTAG state machine.

1. The first pass through the DR selects the RWA module register to be accessed by providing an index and the direction (read/write) as shown in Table 9-1. This is achieved by loading an 8-bit value into the JTAG data register (DR).

This register has the following format:

(7bits)	(1 bit)
Nexus access opcode	R/W

Table 9-7. JTAG DR field description for Nexus register access

Field	Description	
Nexus Register Index	Selected from values in Table 9-1	
Read/Write (R/W)	0	Read
	1	Write

2. The second pass through the DR then shifts the data in or out of the JTAG port, LSB first.
   a. During a read access, data is latched from the selected Nexus register when the JTAG state machine passes through the Capture-DR state.
   b. During a write access, data is latched into the selected Nexus register when the JTAG state machine passes through the Update-DR state.

9.4 Memory access examples

The following subsections describe the steps which are required to access memory.

9.4.1 Single write access

1. Initialize the RWA register through the JTAG. Configure as follows:
   - Write Address = 32h'xxxxxxxx (write address)
2. Initialize the RWCS register through the JTAG. Configure the bits as follows:
   - Access Control (AC) = 1b'1 (to indicate start access)
   - Map Select (MAP) = 3b'000 (primary memory map)
   - Access Priority (PR) = 2b'00 (lowest priority)
   - Read/Write (RW) = 1b'1 (write access)

- Word Size (SZ) = 3b'0xx (32-bit, 16-bit, 8-bit)
- Access Count (CNT) = 14h'0000 or 14h'0001(single access)

Note

Access Count (CNT) of 14'h0000 or 14'h0001 performs a single access.

3. Initialize the RWD register through the JTAG. Configure as follows:
   - Write Data = 32h'xxxxxxxx (write data)
4. The RWA module then transfers the data value from the data buffer RWD register to the memory mapped address in the RWA register. When the access has completed without error (ERR = 1'b0), the RWA clears the DV bit in the RWCS register. This indicates that the device is ready for the next access.

9.4.2 Block write access

1. For a block write access, follow Steps 1, 2, and 3 outlined in Single write access to initialize the registers, but using a value greater than one (14'h0001) for the CNT field in the RWCS register.
2. The RWA module then transfers the first data value from the RWD register to the memory mapped address in the RWA register. When the transfer has completed without error (ERR=1'b0), the address from the RWA register is incremented to the next word size (specified in the SZ field) and the number from the CNT field is decremented. The RWA module then indicates it is ready for the next access.
3. Repeat Step 3 in Single write access until the internal CNT value is zero (0). When this occurs, the DV bit within the RWCS is cleared to indicate the end of the block write access.

Note

The actual RWA register value as well as the CNT field within the RWCS are not changed when executing a block write access. The original values can be read by the external development tool at any time.

9.4.3 Single read access

1. Initialize the RWA register through the JTAG. Configure as follows:
   - Read Address = 32h'xxxxxxxx (read address)
2. Initialize the RWCS register through the JTAG. Configure the bits as follows:
   - Access Control (AC) = 1b'1 (to indicate start access)
   - Map Select (MAP) = 3b'000 (primary memory map)
   - Access Priority (PR) = 2b'00 (lowest priority)
   - Read/Write (RW) = 1b'0 (read access)
   - Word Size (SZ) = 3b'0xx (32-bit, 16-bit, 8-bit)
   - Access Count (CNT) = 14h'0000 or 14h'0001(single access)

Note

Access Count (CNT) of 14'h0000 or 14'h0001 performs a single access.

3. The RWA module then transfers the data to the RWD register. When the transfer is completed without error (ERR = 1'b0), the RWA module sets the DV bit in the RWCS register. This indicates that the RWA module is ready for the next access.
4. The data can then be read from the RWD register through the JTAG.

9.4.4 Block read access

1. For a block read access, follow Steps 1 and 2 outlined in Single read access to initialize the registers, but using a value greater than one (14'h0001) for the CNT field in the RWCS register.
2. The RWA module then transfers the data to the RWD register. When the transfer has completed without error (ERR = 1'b0), the address from the RWA register is incremented to the next word size (specified in the SZ field) and the number from the CNT field is decremented. The RWA module then indicates that the device is ready for the next access.
3. The data can then be read from the RWD register through JTAG.

4. Repeat Steps 3 and 4 in Single read access until the CNT value is zero (0). When this occurs, the DV bit within the RWCS register is set to indicate the end of the block read access.

Note

The data values must be shifted out 32-bits at a time LSB first. The actual RWA value as well as the CNT field within the RWCS register are not changed when executing a block read access. The original values can be read by the external development tool at any time.

Appendix A
Release Notes for Revision 6

A.1 General changes

- No general changes.

A.2 Emulation and Debug Device Intro changes

- In section Block diagram, figure Figure 1-1 :
  - Around the middle, added IRC clock.
  - On the lower left, corrected "Aurora Port Output lanes plus LVDS dock In" to "Nexus Aurora Port Output lanes plus LVDS clock in".
  - On the middle right, corrected "(LVDS or CMOS)" to "(CMOS)".

A.3 Buddy Device—Crossbar and RAM changes

- No substantial content changes

A.4 Buddy Device SIUL changes

- No substantial content changes

A.5 DCI changes

- No substantial content changes

A.6 JTAGC module changes

- No substantial content changes

A.7 NAR changes

- No substantial content changes

A.8 NAL changes

- No substantial content changes

A.9 Nexus Aurora Phy changes

- No substantial content changes

A.10 RWA changes

- No substantial content changes
