7 SQEREN	Modulation Word Sequence Error Interrupt Enable The SQEREN bit enables the SQER flag to generate an interrupt request.

Table continues on the next page...

REACM2_CHCR*n* field descriptions (continued)

Field	Description
	0 SQER interrupt disabled 1 SQER interrupt enabled
8 RAEREN	Resource Allocation Error Interrupt Enable The RAEREN bit enables the RAER flag to generate an interrupt request. 0 RAER interrupt disabled 1 RAER interrupt enabled
9 DMAEN	Direct Memory Access Enable bit The DMAEN bit enables a DMA request by the channel when an Modulation Word sequence advance occurs. 0 Disables channel DMA request 1 Enables channel DMA request
10 CHOFF	Output Disable bit The CHOFF bit allows disabling the output pin. DOFF[2:0] field is used as disable state for the channel outputs. The output pins will set to DOFF value if CHOFF is asserted. Note that disabling the channel through CHOFF does not disable the channel operation. Only the channel outputs are forced to DOFF state. 0 Output Disable Disabled 1 Output Disable Enabled
11 SDCM	Short Detection Counting Mode The SDCM bit configures the short detector to count one or two short detection events to set the SCDF field. 0 SCDF is set if two short detection events occur in a row 1 SCDF is set if a short detection occurs
12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13–15 DOFF	Drive Off Control field The DOFF[2:0] field defines the Reaction Channel output disabled state. This condition is achieved either when CHEN= 00, or after CHEN activation, or when Output is disabled by CHOFF in the Channel Configuration register. • DOFF[0] bit defines CHn_a output pin value • DOFF[1] bit defines CHn_b output pin value • DOFF[2] bit defines CHn_c output pin value **NOTE:** It is possible to control the channel outputs directly through the software by writing to the DOFF bits. In this case the channel should be in the disabled state, CHEN=00. **NOTE:** If the DOFF value is changed just after the channel is enabled, it is not assured the new DOFF value is immediately used in the channel output.
16–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21–23 BSB	Bank Support Bits

Table continues on the next page...

REACM2_CHCR*n* field descriptions (continued)

Field	Description
	The BSB[2:0] provides control for a banked mode operation of the Reaction Module. Each bit in this field controls the channel outputs chn_c, chn_b and chn_a respectively. When asserted the channel output implements a sharing function with the corresponding output of the subsequent channel.
24–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27–31 MODULATION_ADDR	Address for Modulation Control Bank The MODULATION_ADDR field has the address of the Modulation Word in the Modulation Control Bank. This address is used as a base address for the first modulation word. The Reaction Channel can access subsequent words in the Modulation Control Bank by incrementing the Modulation Address field. Note that this field is not modified by the Reaction Channel in this process. **NOTE:** The number of subsequent words is limited to 15. Therefore the channel can handle a sequence with as many as 16 modulation words. **NOTE:** If a sequence advance is requested in the 16th modulation word, the channel returns back and accesses the first modulation word that is indicated by the address field MODULATION_ADDR on the REACM2_CHCR*n* register.

44.4.9 Channel n Status Register (REACM2_CHSR*n*)

The Reaction Module Channel Status Register provides access to the channel flags and flag clear bits. It also provides access to the current values of the channel output being driven and the Modulation Word being accessed by the channel.

Address: 0h base + 104h offset + (16d × i), where i=0d to 9d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0		MODACT	MAXL	OCDF	SCDF	TAER	SQER	RAER	CHOUT			0			
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0			0	0	0	0	0	0	0	MODULATION_POINTER

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

REACM2_CHSR*n* field descriptions

Field	Description
0–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2 MODACT	Modulation Active Flag The MODACT flag indicates that the channel is enabled and active thus executing a modulation cycle. 0 Channel is not active 1 Channel is active

Table continues on the next page...

REACM2_CHSR*n* field descriptions (continued)

Field	Description
3 MAXL	ADC Maximum Limit Detection Flag The MAXL flag indicates that the ADC result which TAG is addressing this channel achieved or passed the maximum allowed limit specified in the ADCMAX register. This flag is set when the channel is in the active state (see section Channel Modes) or in debug mode. This bit is not set in the off time of the Threshold/Hold-off modulation mode. 0 Normal operation 1 ADC Maximum Limit Detected
4 OCDF	Open Circuit Detection Flag The OCDF flag indicates that an open circuit was detected in the channel load using the PWM monitored modulation, as described in Monitored Modulation. This Flag is set only if the channel is in the active state. 0 Normal operation 1 Open Circuit Detected
5 SCDF	Short Circuit Detection Flag The SCDF flag indicates that a short circuit was detected in the channel load using the PWM monitored modulation, as described in Monitored Modulation. This flag is set only if the channels are in the active state. 0 Normal Operation 1 Short Circuit Detected
6 TAER	Timer Allocation Error The Timer Allocation Error bit indicates that the channel tried to allocate a timer counter in the Shared Timer Bank without success. This situation is an indication that the Timer resources available in the module are not sufficient to execute the required functionality. This error indication is used during software development and should not occur during normal use of the module since it may result in incorrect operation. This flag is set only if the channel is in the active state. 0 No error occurred during timer allocation. 1 Error occurred during timer allocation
7 SQER	Modulation Word Sequence Error Flag The SQER bit indicates a Modulation Sequence error occurred, meaning that the time window which defines a modulation cycle ended in a premature modulation phase. The correct modulation phase for the time window to close is when SM field in the Modulation Word indicates no advance, or SM= 00. This Flag is set only if the channel is in the active state. 0 Modulation Sequence Error did not occur 1 Modulation Sequence Error occurred
8 RAER	Resource Allocation Error Flag The RAER bit indicates that a resource allocation error occurred. The possible allocation errors are: Modulation Control Word address is out of available range (including if the MODULATION_POINTER increments to an inexistent MCW address or wraps to 0x0), Threshold Value Bank address is out of available range, Hold Timer Bank address is out of available range, Shared Timer Bank address is out of available range, Channel Input Router points to an inexistent eTPU channel, and when the Hold timer is select for both modulation and sequence advance at the same time (i.e, SM=10 and MM=01). Note that the amount of hardware resources is configuration dependent thus may vary according to module

Table continues on the next page...

REACM2_CHSR*n* field descriptions (continued)

Field	Description
	parameterization in the SoC. This flag is intended to help on the debug of the Reaction Module during software development and can be set only if the channel is in the enabled state. **NOTE:** The condition that sets the RAER bit must be resolved prior to clear the bit, otherwise the bit can be set again. 0 No allocation error occurred 1 Allocation error occurred
9–11 CHOUT	Channel Output Monitoring bits The CHOUT[2:0] Channel Output Monitoring bits provides for the software the ability to monitor the output provided by the channel. This data is not buffered thus represents the channel output at the time the CPU read access is done. CHOUT[0] corresponds to the chn_a output, CHOUT[1] corresponds to the chn_b output and CHOUT[2] corresponds to the chn_c output pin. These bits are available independent of the channel mode or state.
12–18 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
19 MAXLC	ADC Maximum Limit Flag Clear The MAXLC clears the MAXL flag if "1" is written. This bit reads always as 0x0. If a set event occurs at the same time a flag clear is done, the set event has precedence over the clear thus the flag remains set. 0 No action 1 Clears MAXL bit
20 OCDFC	Open Circuit Detection Flag Clear The OCDFC clears the OCDF flag if "1" is written. This bit reads always as 0x0. If a set event occurs at the same time a flag clear is done, the set event has precedence over the clear thus the flag remains set. 0 No action 1 Clears OCDF bit
21 SCDFC	Short Circuit Detection Flag clear The SCDFC bit clears the SCDF flag if "1" is written. This bit is self negated thus read always as ‘0’. If a set event occurs at the same time a flag clear is done, the set event has precedence over the clear thus the flag remains set. 0 No action 1 Clears SCDF
22 TAERC	TAER Clear bit The TAERC bit clears the TAER bit if "1" is written. This bit is self-negated thus reads always as ‘0’. If a set event occurs at the same time a flag clear is done, the set event has precedence over the clear thus the flag remains set. 0 No action 1 Clears TAER
23 SQERC	Modulation Word Sequence Error Flag clear The SQERC bit clears the SQER flag in the Channel Status register. 0 SQER flag is not cleared 1 SQER flag is cleared

Table continues on the next page...

REACM2_CHSR*n* field descriptions (continued)

Field	Description
24 RAERC	Resource Allocation Error Flag clear The RAERC bit clears the RAER flag in the Channel Status register. 0 RAER flag is not cleared 1 RAER flag is cleared
25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26–31 MODULATION_ POINTER	Modulation bank address generated by the channel The MODULATION_POINTER[5:0] gives to the software the information of the current address being generated by the channel to access the Modulation Word. Note that the address increments from a base address stored in the channel, MODULATION_ADDR[5:0]. This register is not buffered thus represents the current address being generated.

44.4.10 Channel n Router Register (REACM2_CHRR*n*)

The Reaction Module Channel Router Register controls the channel connection to external timers, such as eTPU and eMIOS and ADC result data. The channels have access to any 16 timer inputs and any ADC sample tag from 0 to 15. Note that this architecture allows several Reaction Channels to point to the same timer channel or to the same ADC result.

Address: 0h base + 108h offset + (16d × i), where i=0d to 9d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0												ADCR				0												CHIR			
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

REACM2_CHRR*n* field descriptions

Field	Description
0–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12–15 ADCR	ADC result router field The ADCR[3:0] field selects which ADC result is used by the Reaction Channel for the modulation. The TAG[3:0] received along with the ADC result is used for comparison with the ADCR[3:0] field in order to define if the received result is used by the Reaction Channel.
16–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28–31 CHIR	Channel Input router field The CHIR field selects which eTPU channel is used by the Reaction Channel for the modulation.

44.4.11 Shared Timer Bank (REACM2_STBK*n*)

The Reaction Modulation Shared Timer Bank is a set of registers which define the values used by the Reaction Module Timer. The timer values are programmed by the Host CPU during the configuration of the Reaction Module. Modulation Word accessed by the Reaction Channel contains the address of a specific Timer value stored in the Shared Timer bank. By selecting a Timer value the Reaction Channel also selects and enables a counter. When this counter reaches the selected Timer value a time-out indication is generated for the Reaction Channel that initiated the counter. This event is used for example to indicate that a next Modulation Word should be used for the modulation.

Address: 0h base + 300h offset + (4d × i), where i=0d to 4d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

REACM2_STBK*n* field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 SHARED_TIMER	Timer Value The SHARED_TIMER value is one element of the Timer Register Bank. Up to 5timer values can be stored within the Timer Bank. **NOTE:** When using the shared timer for sequence advance, the counted time (considering prescaler) must be greater than 64 clock cycles.

44.4.12 Hold Timer Bank (REACM2_HOTBK*n*)

The Reaction Module Hold Timer Bank is a set of registers that defines the values used by the Reaction Channels to measure hold time on certain modulation schemes. The timer values are programmed by software and addressed by the Reaction Channel based on the data read from a Modulation Word.

Address: 0h base + 380h offset + (4d × i), where i=0d to 4d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0																				HOLD_TIM											
W

REACM2_HOTBK*n* field descriptions

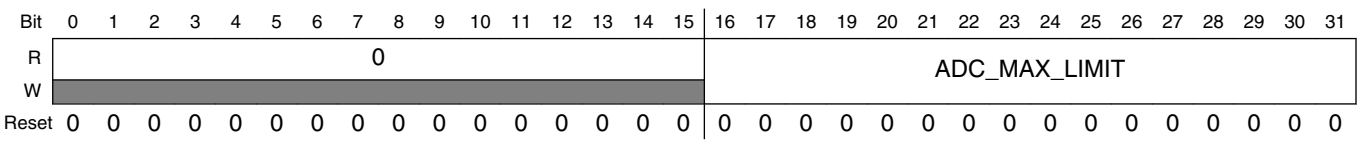
Field	Description
0–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20–31 HOLD_TIM	Hold Timer Value The HOLD_TIM value is one element of the Hold Timer Register Bank. Up to 5timer values can be stored within the Hold Timer Bank. **NOTE:** When using the hold timer for sequence advance, the counted time (considering prescaler) must greater than 64 clock cycles.

44.4.13 Threshold Bank (REACM2_THBK*n*)

The Reaction Module Threshold Bank holds the value to be used for comparison against results received from the ADC. Based on that comparison the Reaction Channel decides the Channel output value to be either HOD or LOD.

Address: 0h base + 400h offset + (4d × i), where i=0d to 31d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0																THRESHOLD_VALUE																
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0



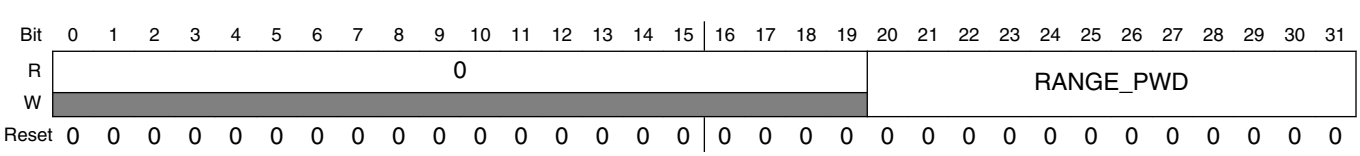
REACM2_THBK*n* field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 THRESHOLD_ VALUE	Threshold Value The THRESHOLD_VALUE unsigned value is one element of the Threshold register used for a threshold modulation. Up to 32timer values can be stored within the Threshold Bank.

44.4.14 ADC Result Maximum Limit Check (REACM2_ADCMAX)

The Reaction Module ADC Maximum Limit Check register holds the maximum expected value of the ADC result. If a value greater than or equal to ADC_MAX_LIMIT is received the MAXL bit in the corresponding Channel Status Register Error is asserted.

Address: 0h base + 600h offset = 600h



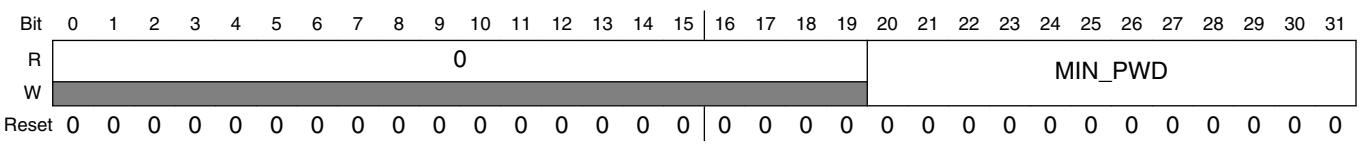
REACM2_ADCMAX field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 ADC_MAX_ LIMIT	Maximum Limit allowed for the ADC result The ADC_MAX_LIMIT[15:0] value indicates the maximum expected value for the ADC result. The MAXL bit in the corresponding channel Status register is set in case a greater or equal value is received from the ADC. If set to zero no limit checking is performed, thus MAXL bit will not be set anyway. **NOTE:** ADC results are always considered unsigned unless specific note states the contrary. Since ADC received results can be 14-bit values a two bit sign extension must be performed before any comparison is executed.

44.4.15 Modulation Range Pulse Width (REACM2_RANGE_PWD)

The Reaction Module Range PulseWidth Detection Check register provides the value used to check if the PWM pulse width generated during the modulation process is larger than a maximum pulse width specified by (MIN_PWD + RANGE_PWD). The checking is performed by the channel logic during appropriate time intervals. See section Monitored Modulation. This function is implemented by sharing the use of Reaction Channel Hold counter, thus if the Hold timer is used by the channel sequence mode, SM in the Channel Configuration register, this checking function is not active.

Address: 0h base + 680h offset = 680h



REACM2_RANGE_PWD field descriptions

Field	Description
0–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20–31 RANGE_PWD	Range Pulse Width The RANGE_PWD[11:0] field defines the maximum pulse width allowed by the channel PWM generation. The checking is performed by the channel internal Hold Timer at appropriate times in the PWM modulation process. The maximum pulse is defined as (RANGE_PWD + MIN_PWD). See “REACM2 Minimum Pulse Width Check (REACM2_MIN_PWD)" for MIN_PWD description. If RANGE_PWD = 0x00 then no maximum pulse width checking is performed. **NOTE:** The RANGE_PWD value should be calculated considering the prescaler settings used for the HOLD counter. For a programmed (RANGE_PWD + MIN_PWD) value, a pulse narrower than or equal to (RANGE_PWD + MIN_PWD + 1) does not set the OCDF flag.

44.4.16 Modulation Minimum Pulse Width (REACM2_MIN_PWD)

The Reaction Module Minimum PulseWidth Check register provides the value used to check if the pulse width generated during the PWM modulation process on the channel outputs is shorter than a minimum pulse width specified by this register. The checking is performed by using the channel internal Hold timer during appropriate times on the channel operation when this counter is not being used for the hold modulation cycle.

Address: 0h base + 6C0h offset = 6C0h

REACM2_MIN_PWD field descriptions

Field	Description
0–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20–31 MIN_PWD	Minimum Pulse Width The MIN_PWD[11:0] field defines the minimum pulse width allowed by the channel PWM generation. The checking is performed by the channel hold timer. If MIN_PWD[11:0] = 0x00 then no checking is done even for maximum pulse width or minimum pulse width. **NOTE:** The MIN_PWD value should be calculated considering the prescaler settings used for the HOLD counter. For a programmed MIN_PWD value, a pulse wider than (MIN_PWD+1) does not set the SCDF flag.

44.4.17 Modulation Control Word Bank (REACM2_MWBK*n*)

The Reaction Module Control Word Bank is a set of registers that controls the Reaction Channel Modulation scheme. These registers are programmed by software and read by the Reaction Channels. All the information required by the Reaction Channels to perform a modulation is stored in these words. All channels have access to the same words thus sharing of Modulation Words among channels is possible in this architecture.

There are 32 modulation control words in this device.

Address: 0h base + 700h offset + (4d × i), where i=0d to 31d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

REACM2_MWBK*n* field descriptions

Field	Description
0 LOOP	Loop Control Bit The LOOP Control bit indicates that the next Modulation Control Word accessed by the Reaction Channel when a Modulation Word address increment event occurs should be the one indicated by the Channel MODULATION_ADDR[5:0] register with no offset. 0 Increment to the next modulation word 1 Loop back to initial channel modulation word
1 IOSS	Initial Output State Selection The IOSS bit defines the state of the channel output pins when a modulation phase is started by the Reaction Channel. This bit is important in the Modulation Word first access. This first access occurs after the channel is enabled by CHEN bit field in the Channel Configuration register, or when the modulation phase advances, e.g. due to a timer event. This bit also defines the modulation initial behavior for some modulation modes. See Modulation Mode MM[1:0] field for more details. 0 LOD[2:0] is initially used for chn_c, chn_b and chn_a respectively 1 HOD[2:0] is initially used for chn_c, chn_b and chn_a respectively
2 DMA	DMA bit

Table continues on the next page...

REACM2_MWBK*n* field descriptions (continued)

Field	Description
3–4 MM	Modulation Mode The MM[1:0] Modulation Mode field indicates the type of the modulation that is executed by the channel while the IOSS bit determines the modulation mode initial state. The initial behavior of the modulation modes (or the threshold comparison level performed in threshold/Period modulation) is selected by the IOSS bit. 00 Modulation Type: threshold/threshold Modulation occurs between two threshold levels defined by THRESPT upper level threshold pointer and THRESPT +1 which corresponds to a lower level threshold pointer. IOSS selects the initial output state. Output ON state is defined by HOD (IOSS=1) and Output OFF state is defined by LOD (IOSS=0). 01 Modulation Type: threshold/Hold-off • IOSS="0": Modulation starts with channel outputs set to LOD for an amount of time defined by the hold timer. After that outputs are set to HOD until an upper threshold defined by THRESHPT is reached. • IOSS="1": Modulation starts with channel outputs set to HOD until an upper threshold defined by THRESHPT is reached. After that level is achieved outputs are set to LOD for an amount of time defined by the hold timer. 10 Modulation Type: Threshold/Hold-on • IOSS="0": Modulation starts with channel outputs set to LOD until a lower threshold defined by THRESHPT is reached. After that level is achieved outputs are set to HOD for an amount of time defined by the hold timer. • IOSS="1": Modulation starts with channel outputs set to HOD for an amount of time defined by the hold timer. After that outputs are set to LOD until a low threshold is reached. 11 • IOSS="0": Modulation Type: threshold-low/Period. In this modulation mode channel outputs starts in LOD and a low threshold comparison is performed. When the threshold level defined by THRESPT is achieved, the channel outputs state changes to HOD until the modulation period expires. • IOSS="1": Modulation Type: threshold-high/Period. In this modulation mode channel outputs starts in HOD and a high threshold comparison is performed. When the threshold level defined by THRESPT is achieved, the channel outputs state changes to LOD until the modulation period expires.
5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6–7 SM	Sequencer Mode The SM[1:0] field defines the event that makes the channel address the next modulation word. This event can be a timer event or a threshold level event. Note that the channel does not necessarily increments the Modulation Word address thus the same Modulation Word is executed again in the new modulation sequence. **NOTE:** For time-out event selections, it is required the related time should be greater than 64 clock cycles. 00 Current modulation word is used, no advance is performed on any event. No timer is activated by this modulation word. 01 Advance to the next modulation word when a Timer time-out event is detected. The Timer is activated when the modulation word is accessed by the channel.

Table continues on the next page...

REACM2_MWBK*n* field descriptions (continued)

Field	Description
	10 Advance to the next modulation word when a Hold Timer time-out event is detected. The Hold timer is activated when the modulation word is accessed by the channel. This is only for MM=00 (THR-THR). 11 Advance to the next modulation word when a threshold level is achieved (greater or equal). The threshold level is defined by the THRESPT pointer.
8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
9–11 HOD	High Output Drive The HOD[2:0] field defines the values driven on the chn_c, chn_b and chn_a channel output pins, respectively, when the channel is at ON state.
12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13–15 LOD	Low Output Drive The LOD[2:0] field defines the values driven on the chn_c, chn_b and chn_a channel output pins, respectively, when the channel is at OFF state.
16–17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
18–22 THRESPT	Threshold Pointer The THRESPT Threshold Pointer is the address of the Threshold Bank that holds values to be used for ADC result comparisons in the modulation process. This pointer has the resolution for a 16-bit data stored in the register described in section “REACM Threshold Bank Register (REACM_THBK)".
23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–26 STPT	Shared Timer Pointer The STPT Shared Timer Pointer field is the pointer for the Shared Timer Bank. The Shared Timer is used as timer sequencer defining the advance of Modulation Words.
27–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29–31 HDOFFTPT	Hold on/off Pointer The HDOFFPT field is the address of the Hold timer value in the Hold Timer Bank that is used in the modulation cycle. Note that there are modulation sequences that does not require hold on/off measurement such as threshold/threshold modulations.

44.5 Functional Description

The following sections describe the Reaction Module functionality.

The Reaction Module is designed to allow a closed feedback loop control over the driver load currents. The load can be an injector for direct injection system or an electromagnetic actuator for robotized transmission. In both cases a solenoid is expected to be the actual load. The module architecture is based on shared resources sub-modules

that can be used by all 10 Reaction Channels. Please refer to Figure 44-4 for details about the module architecture. The Reaction Module is composed of the following internal sub-modules:

- Reaction Channel
- Modulation Control Word Bank
- Shared Timer Bank
- Hold Time Bank
- Threshold Bank
- Period Pulse Generator

The following sections describe each one of these sub-modules and their combined operation.

44.5.1 Reaction Channel

The Reaction Channel is the core of the Reaction Module. Each channel controls three output pins and it is composed of a Control FSM which receives parameters to generate a modulated waveform as well as the timer control window usually provided by eTPU. The ADC interface sub-module indicates to the channel that a new ADC result is available. If *activated* by the eTPU channel, the Reaction Channel reads the Modulation Word which provides addresses for the Threshold Value bank, Shared Timer Bank and Hold Time Bank. The date provided by the Threshold Bank is compared with the incoming ADC result. Based on that comparison the Reaction Channel state machine selects the values for the output pin registers. The modulation only occurs if *activated* by the timer control signal, which can be generated by eTPU, or can be controlled by software by writing to the SWMC, software modulation control bit, in the Channel Configuration register. The MM and SM fields in the Modulation Word provide the Modulation Mode and Sequencer Mode control respectively. The following figure describes the internal architecture of the Reaction Channel and its interconnection with other sub-modules.

NOTE

The indexes corresponding to the register bit widths in the figure below will vary depending on the chip implementation. See the register descriptions for the correct bit width in your chip.

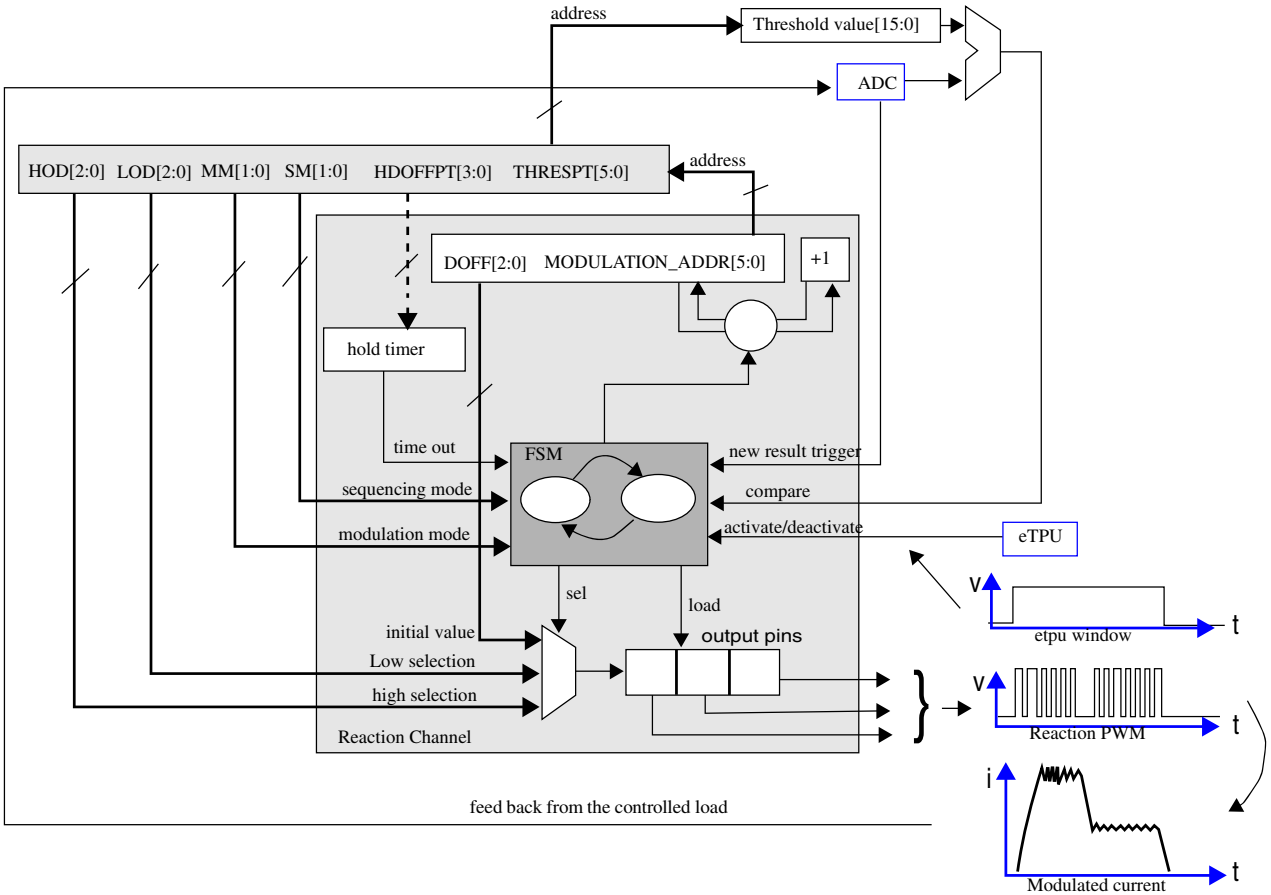

Figure 44-126. Reaction Channel Architecture Simplified Diagram

The addresses stored in the Modulation Word are pointers to timers and threshold banks. HOD and LOD provide the 3-bit field which controls the states, HIGH and LOW, respectively for the Reaction Channel output pins. The Reaction Channel FSM selects the values for the output pins as well as the load signal used to update those values. The modulation executed by the Reaction Channel is based on the feedback loop provided by the ADC results. These results are routed to one side of a comparator while the other comparator input receives the selected Threshold value from the threshold bank. The comparison result indicates for the Reaction Channel FSM if the output pin value should be defined either by HOD or by LOD. As a result a PWM is generated on the output pins. Note that since there are three independent outputs the PWM signal can be generated on any output or even on several outputs at the same time. Usually a PWM signal is generated in one of the outputs only, while the others outputs are used to control power supply switching, for example.

The preceding figure shows three waveforms at the right side of the figure. On the top there is the control signal from eTPU which defines the boundaries of the modulated waveform. In the middle there is the PWM waveform which is used to drive the power ON and OFF at the load, thus generating the third waveform which represents the current passing through the load.

NOTE

The modulation word sequence is limited to 16 words because the address value to the modulation control word bank can vary only from the configured initial value up to a maximum value given by (MODULATION_ADDR + 15).

44.5.2 Modulation Control Words Bank

The Modulation Control Word provides information about the modulation type to be performed and the addresses for several address banks. REACM2_MWBKn describes the Modulation Word register and Figure 44-127 describes the interfaces of this sub-module with some other sub-modules in the Reaction Module. The information stored in the Modulation Word are:

- Modulation control parameters for the Reaction Channel
- Threshold Value Register Bank address
- Hold time bank address
- Shared Timer bank address
- DMA support

All channels share the information stored in the Modulation Control Word Bank, which provides a size-effective implementation avoiding the duplication of information and allowing flexible implementation. The sharing of modulation control words allows several channels to execute the same modulation sequence.

The Modulation Control is designed to be used by all reaction channels as a centralized resource. However, only one channel is able to access the Modulation bank at a given time. Therefore, there is a priority in the selection of the channel that will have the access granted, but note that this condition does not occur too often since ADC results are provided for one channel at a time.

An arbiter in the Modulation Control Word bank selects one of the channels which are requesting access to a modulation word. The priority criteria is fixed and based on the channel number, considering Channel 0 the highest priority channel. The channel selected by the arbiter receives an acknowledge signal which indicates that channel was selected and therefore can access the modulation word.

Note

In order to avoid an initial delay when processing a timer window start event, the channel performs an speculative read operation of the first modulation word when it is enabled (CHEN is configured). Therefore, when the modulation cycle is triggered by the timer window start event, all needed information for the modulation is already stored inside the channel.

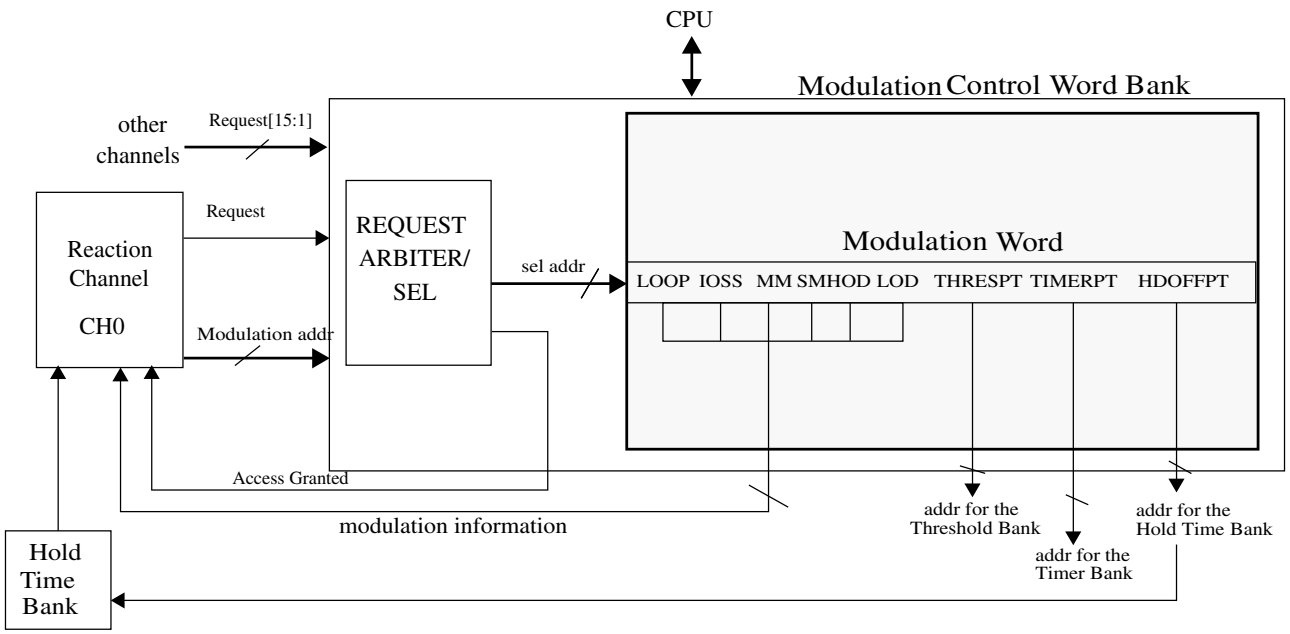

Figure 44-127. Modulation Control Word Bank Interfaces

44.5.3 Shared Timer Bank

The Shared Timer bank is an innovative concept of dynamic timer allocation. Since the number of timers can be smaller than the number of channels in the Reaction Module, there is a possibility that all timers are allocated at a certain time. This architecture is based on the low probability of such scenario since the timer allocation is a sporadic event. The timers in the Shared Timer Bank are usually in IDLE state until they are allocated by a channel. Any timer can be allocated as soon as it is in IDLE. The shared timers work in conjunction with a timer bank which stores values to be used by the timing measurement.

The Shared Timer Bank block is composed of two sub-modules:

1. Four 16-bit counters.

2. A bank with five selectable 16-bit time values.

If there is an attempt to allocate more than existing timers then an error flag TAER (see Figure 44-134) is set and no timer is allocated by the requesting channel. As a general guideline the system should be dimensioned in such a way that the timer allocation is always possible.

Note

In case of an allocation error the channel forces DOFF to its output pin preventing any damage to occur to the actuator being controlled. This state will not change until TAER bit is cleared.

During the timer allocation the channel also provides the TIMERPT pointer which selects a timing value. The value pointed by TIMERPT is loaded into one of the 4 counters which counts down until reaching zero. At this time a time-out indication is sent to the requesting channel and the timer is deallocated, moving back to IDLE state.

In case of several timer activation requests being issued at the same time, the logic in the Timer Bank will prioritize giving higher priority to the channel with lower number, thus channel zero has higher priority than the others. No flags are set in case several requests are issued simultaneously unless there are more requests than the number of available timers. In this case the TAER error flag is set in the requesting channel status register. The following figure presents a block diagram of the Timer Bank.

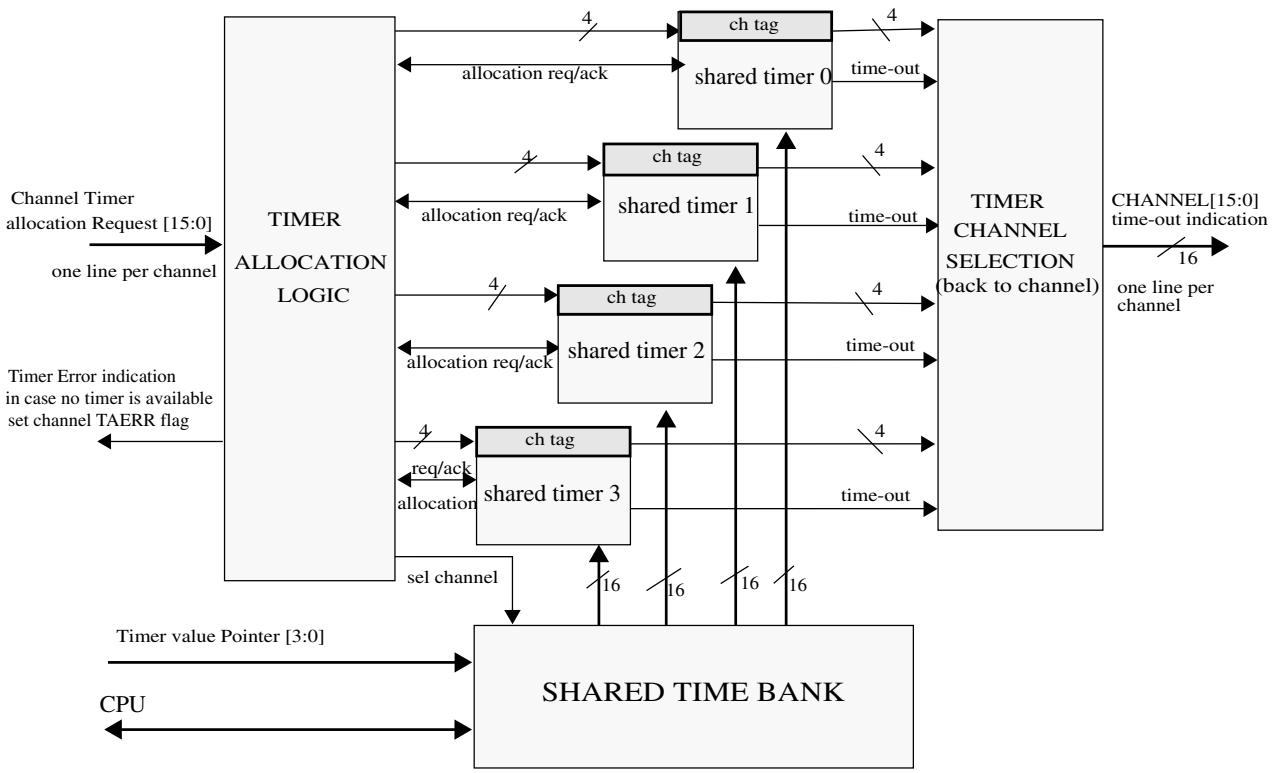

Figure 44-128. Shared Timer Bank Block Diagram with 4 Timers

44.5.4 Hold Time Bank

The Hold Time Bank stores time values that are used by the hold-on/off periods during the modulation process. This bank is shared among all channels and is addressed based on the HDOFFPT pointer in the Modulation Control Word. The following figure shows a block diagram of this bank and its interconnections.

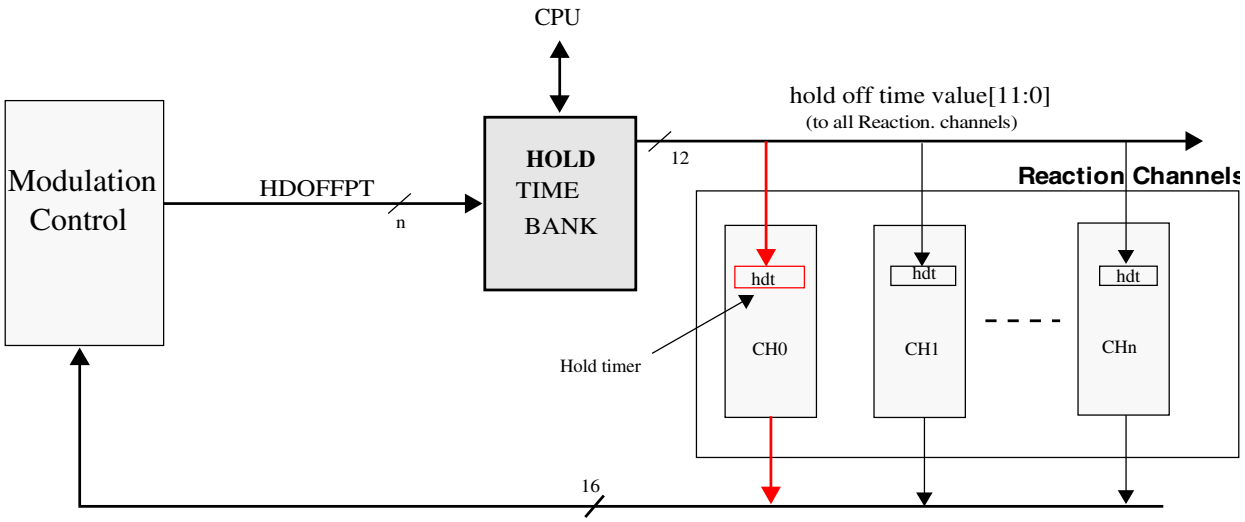

Figure 44-129. Hold Time Bank Block Diagram

The Modulation Control Word generates the address for the Hold Time bank which then generates the hold-on/off time value for the channels. The channel that addressed the Modulation Word captures the 12-bit value storing it in the channel Hold timer. In The preceding figure channel CH0 is requesting access to the Modulation Word thus receiving hold-on/off value from the Hold Time Bank. Each Reaction Channel has its own internal hold timer.

44.5.5 Threshold Bank and Comparator

The Threshold Bank and Comparator contains the threshold levels to be compared against the ADC results. This sub-module also performs the comparison between the ADC result and the selected threshold value.

The Threshold bank can be programmed with up-to 32 threshold values.

An ADC result received from the on-chip ADC is connected to the ADC router and then to the comparator (see the following figure). This result stays at the comparator input until the Reaction Channel and Modulation Control Word selects the address of the Threshold value. The THRESPT field in the Modulation Control Word sub-module is used as the address for the Threshold Bank. Note that if Threshold-Threshold modulation mode is used two comparisons need to be executed with two different Threshold values. After the first comparison is made the THRESPT pointer is incremented and a new comparison is done:

- First comparison: COMP = ADC_DATA >= THRESHOLD_VALUE[THRESPT]
- Second comparison: COMP = ADC_DATA >= THRESHOLD_VALUE[THRESPT +1]

The COMP, comparison result, is routed to the channel selected by the received TAG. Once receiving the comparison result the channel takes the appropriate actions in order to executed the modulation mode as defined by the Modulation Control Word.

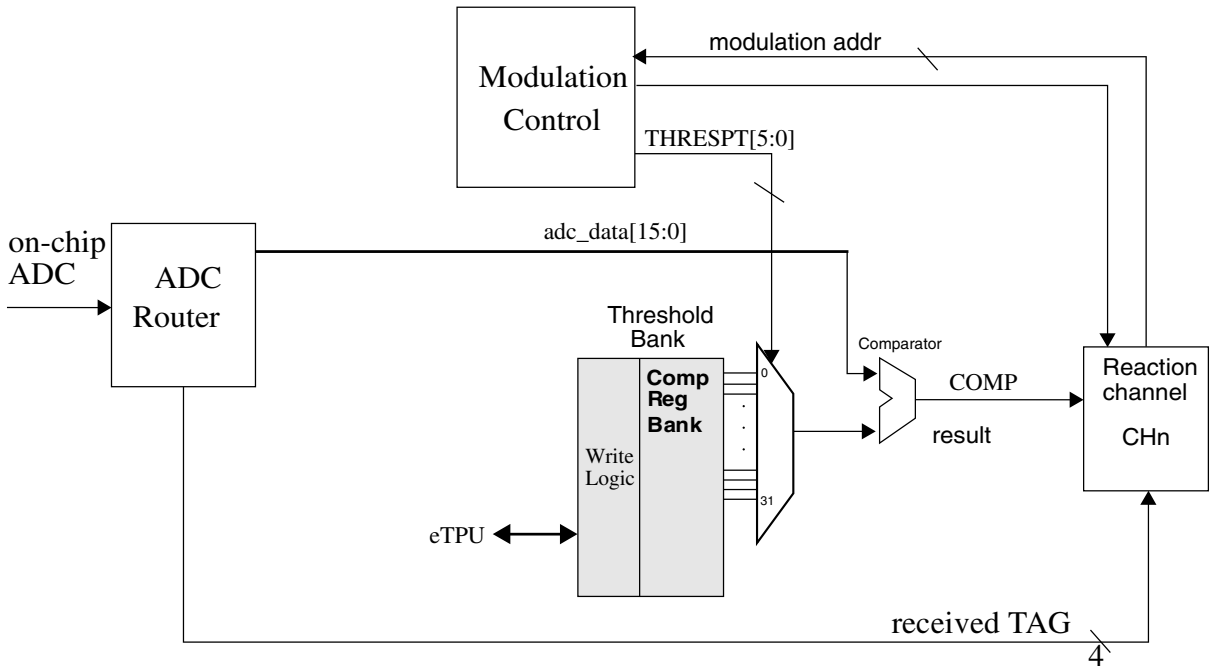

Figure 44-130. Threshold Bank and Comparator Block Diagram

44.5.6 ADC Interface

The ADC Interface connects to the BCTU module through a Parallel Side Port (PSI). Please refer to the BCTU chapter for more information about this interface. The BCTU sends conversion results to the Reaction Module which are received by the ADC Interface sub-module. The ADC Interface is capable of distinguishing between ADC results, Time stamps and *Prefill* information from BCTU. Only ADC results with no *Prefill* are considered by the Reaction Module as valid ADC samples. The TAG value received with the conversion result indicates which channel the result is addressed to. The ADC interface is also responsible to indicate for the selected Reaction Channel that a new ADC result is available. It is also possible to access the ADC Interface input buffer through the REACM_SINR register.

44.5.6.1 Input Buffer Overrun

The OVR flag indicates than an input buffer overrun occurred. This buffer is normally written by the ADC interface (PSI) but can be written also by the CPU using the REACM_SINR register.

The ADC Interface data (ADC_TAG and ADC_RESULT) should not be updated until all Reaction Channels (with ADCR = ADC_TAG) process the received data. The OVR flag is set in the case of an overrun condition occurs, indicating that at least one ADC data was lost (the input data that caused the overrun is lost).

The following situations can generate an input overrun:

- Two consecutive sample data are received from CPU.
- ADC and CPU sending sample data at the same time (asynchronous events).
- Input buffer is holding a sample data that is being processed by some channel and a new sample is received from CPU (normal mode of operation)

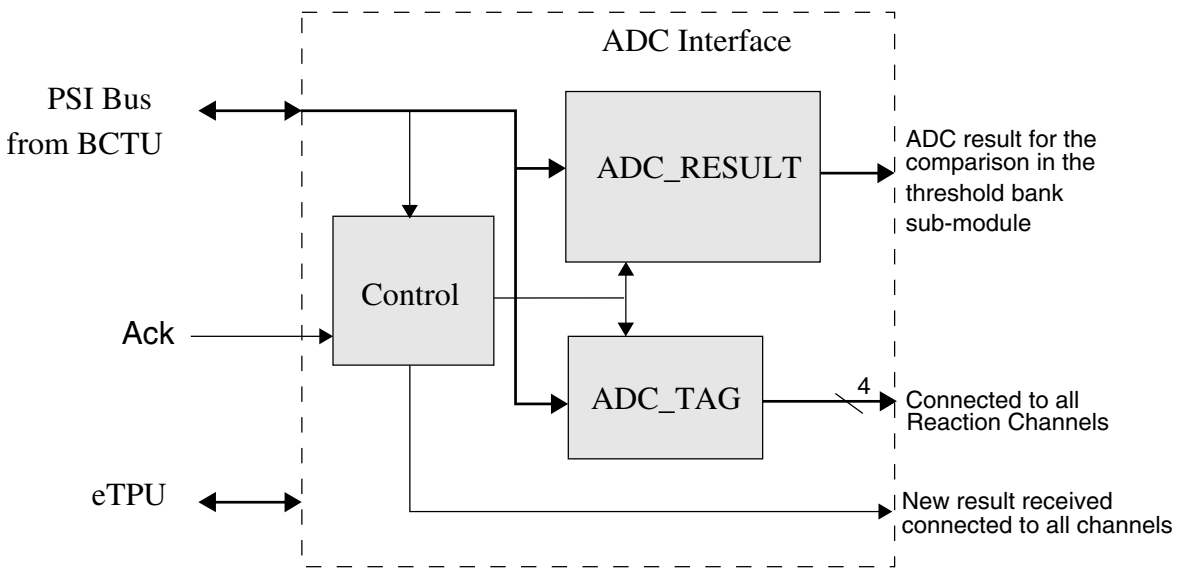

Figure 44-131. ADC Interface Block Diagram

The maximum throughput supported by the Reaction Module depends upon the TAG of the incoming ADC data. If only one Reaction Channel is addressed by the ADC TAG then the maximum supported ADC data rate is 1 sample for each 5 clock cycles. If two Reaction Channels are addressed by the same ADC TAG, thus having the same CHRR ADCR field and are active at the same time, the maximum supported ADC data rate is 1 sample for each 10 clock cycles. In general if (n) channels share the same TAG and are active at the same time the maximum supported ADC data rate is 5 x (n) clock cycles.

These limitations are related to the sharing of internal Reaction Module resources such as the Modulation Word bank. The ADC conversion data should remain stable in the ADC interface until it is used by all channels with matching TAG and CHRR ADCR fields.

Note that if all active channels have different CHRR ADCR fields, i.e. are assigned to different TAG, the maximum supported ADC rate is 5 clock cycles. If multiple channels have the same CHRR ADCR field but only one is active at a time, then the maximum supported ADC data rate is also 5 clock cycles.

44.5.6.2 On-the-fly ADC data Acquisition

The ADC Interface and the Threshold bank can operate in a learn mode, meaning that the received ADC result can be stored in the Threshold Bank and used for comparisons. This functionality allows the user to interactively calibrate the modulation levels or capture on-the-fly levels from the external application board for debug purposes. The THRR register is used for that purpose. See Figure 44-128 for more details about the register architecture. Figure 44-132 describes the main connections between the ADC interface and Threshold Bank sub-modules.

The routing of received ADC results to be stored in the Threshold Bank is independent from the routing of the same result to the Reaction Channels (see Figure 44-135). Thus the same ADC result can be used in a comparison and stored in the Threshold Bank.

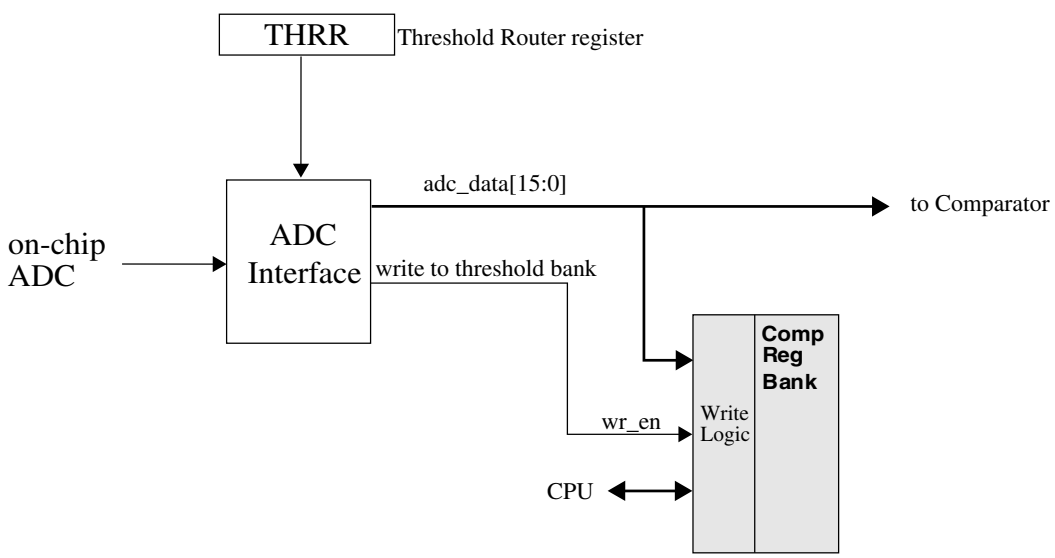

Figure 44-132. ADC interface and Threshold Bank interconnections

44.5.7 Prescalers

The Prescalers provide internal system clock divided signals to be used by internal timers. There are 2 prescalers in the Reaction Module. A 12-bit prescaler HPRE[11:0] and an 8-bit prescaler TPRE[7:0]. Both are defined in the Timer Configuration register TCR. The HPRE[11:0] is dedicated to the Hold timers within the Reaction Channels. The

TPRE[7:0] is used by the Shared Timer Bank counters. The HPRE[11:0] and TPRE[7:0] prescalers are enabled by HPREN and TPREN bits, respectively, in the Module Configuration register. Note that prescalers operates in a similar way regarding its activation. Once the prescaler is enabled by HPREN or TPREN bits in the Module Configuration Register it starts a new count sequence meaning that it is put in reset state and will generate the first prescaler tick after it reaches the programmed value defined by HPRE or TPRE fields.

44.5.8 Period / Delay Generator

This signal generator provides periodic pulses to support multi-channels operating in the threshold-period modulation modes (see Threshold low/Period Mode and Threshold high/Period Mode). There is an exclusive prescaler counter for period / delay counters. The modulation period is defined by the PER[15:0] bits in the Period Configuration register and supplied by internal period counter. This counter can be disabled if the field PER[15:0] is all 0.

Each channel receives a period pulse signal delayed from the others. The delay of the period signals between consecutive channels is defined by the field DLY[15:0] in the Period Shift Delay Configuration register. Channel 0 receives the period signal without delay. Channel 1 gets the channel 0 period signal delayed by DLY[15:0], channel 2 gets channel 1 signal delayed by the same amount, and so on. However, if the delay is zero, all period pulses occur at the same time.

Note

The correct period and delay times depend on the period prescaler setting.

The period pulses are generated for all available channels regardless if the threshold/period modulation mode is being executed. For instance, if channel 0 and 2 have Threshold/Period and channel 1 doesn't, the delay from 0 to 2 is "2 x DLY".

The following figure shows the architecture of the Period / Delay generator sub-block.

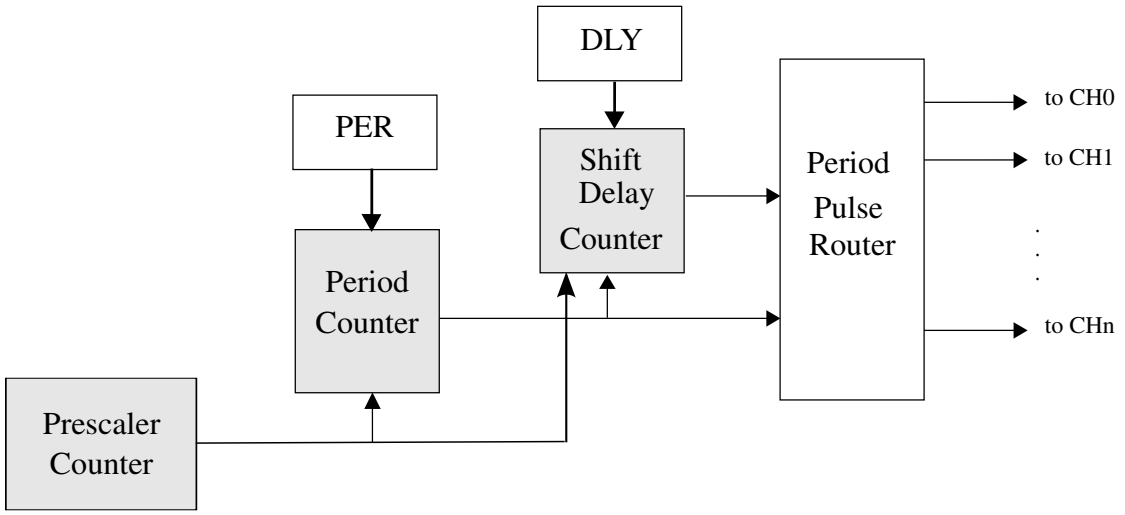

Figure 44-133. Period / Delay generator sub-block

44.5.9 Banked Mode Support

Banked Mode is a Reaction Module hardware configuration which allows the sharing of Reaction Channel output pins at the device I/O level. The banked mode architecture allows the stacking of up to four Reaction channels. The following figure shows the connection between two adjacent channels, CH0 and CH1. The CCR BSB bits are used to control the configuration of channel output logic. Thus if BSB[0] in Reaction Channel [0] is asserted to 1 and the channel is not in the active state, ch0_a output will be switched from CH[0] OUT[0] to CH[1] OUT[0]. If a channel is active, i.e. executing a modulation, it takes control over its outputs independent of BSB bits setting. The banked mode logic is extended to Reaction Channels CH[2] and CH[3] thus defining a group of 4 channels. For simplification the following figure shows only channels CH[0] and CH[1] logic.

Note

When CHEN=00 for CH0 (channel disabled), the BSB bits don't influence the channel output, which is driven by CH0's DOFF. Therefore, a banked injector driven by CH1 will have part of its controls off, even if CH1 is enabled.

To use BSB of CH0 in this case, an option is to program channel CH0 with CHEN=11 (channel enabled) and with SWMC=0 (modulation OFF).

Note

In case of using CH2 in banked mode with CH0, the intermediate channel CH1 should also be configured with CHEN different from 00.

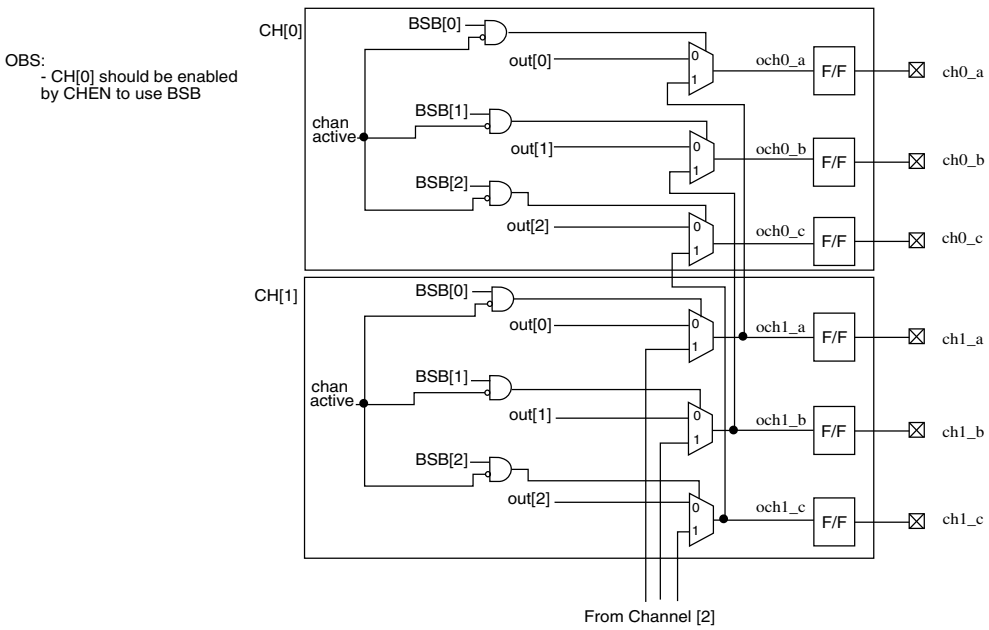

Figure 44-134. Banked Mode showing stacking of channels [0] and [1]

The Banked Mode support hardware is implemented on groups of up to 4 channels. The groups are defined as CH[3:0], CH[7:4], and CH[9:8].

Table 44-125. Banked Mode groups

CH3 → CH2 → CH1 → CH0
CH7 → CH6 → CH5 → CH4
CH9 → CH8

Thus CH[3], CH[7], and CH[9] do not connect to the subsequent channel which are CH[4], CH[8], and CH[0] respectively.

44.6 Modulation Modes

This section describes the modulation modes provided by the Reaction Module.

44.6.1 Threshold/Threshold Mode

This mode is programmed by using REACM2_MWBKx[MM] = 00. In this modulation mode the Reaction Channel tries to maintain the ADC results between two Threshold limits. The modulation actions are as follows:

- ADC result >= [THRESPT]: The Reaction Channel turns the outputs off by loading LOD[2:0] to the channel outputs.
- ADC result < [THRESPT + 1]: The Reaction Channel turns the outputs on by loading HOD[2:0] to the channel outputs.
- [THRESPT+1] <= ADC result < [THRESPT]: The Reaction Channel keeps the outputs unchanged.

The following figure indicates the threshold/threshold modulation mode.

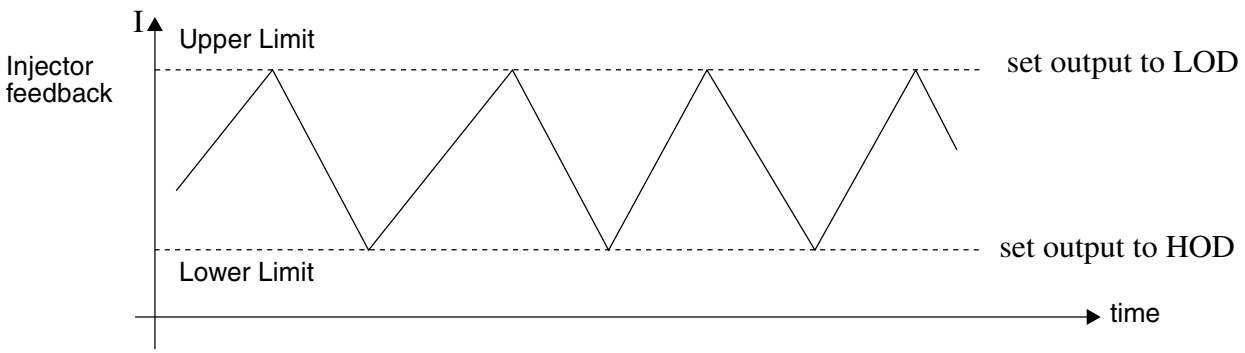

Figure 44-135. Threshold/Threshold Modulation Mode

There can be overshoots or undershoots in the real application related to the threshold limits. This occurs due to following:

- Feedback values are periodically sampled thus can present gaps on the measured values. For example when the sampling has been executed the value may have already passed the range defined by the limits;
- There is a delay between the sampling of feedback value and the reaction of the Reaction Channel. This is mainly caused by the ADC conversion time and its maximum sampling frequency.

The short circuit and open circuit detection are performed by monitoring the width of the ON pulse. For more details refer to Monitored Modulation.

44.6.2 Threshold/Hold-off Mode

This modulation mode is programmed by using REACM2_MWBKx[MM] = 01. In this mode the output pins are driven with HOD[2:0] until the ADC results matches or is greater than the programmed Threshold. The output controls are then driven with LOD[2:0] for a fixed amount of time defined by the hold timer. The initial modulation behavior can be controlled by using the REACM2_MWBKx[IOSS] bit as follows:

- When REACM2_MWBKx[IOSS] = 0, modulation starts with outputs driven with LOD until the hold timer expires.
- When REACM2_MWBKx[IOSS] = 1, modulation starts with outputs driven with HOD until the upper threshold level is reached.

Note that the upper threshold limit and the hold timer pointers are indicated by the Modulation Word in the REACM2_MWBK register.

Note

It is considered that in hold-off time the ADC samples are not reliable, therefore no comparison for MAXL or for output definition are performed. If these comparisons are necessary, the Threshold / Threshold modulation mode can be used.

The short circuit and open circuit detection are performed by monitoring the width of the ON pulse. For more details refer to Monitored Modulation

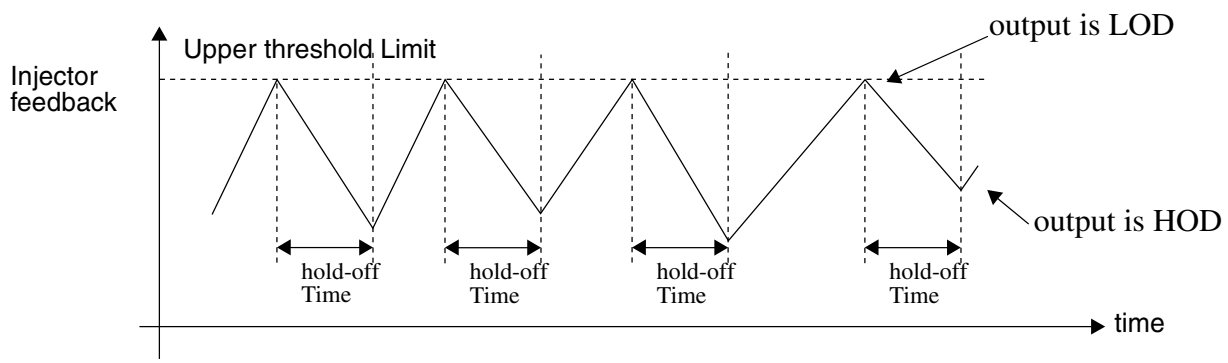

Figure 44-136. Threshold/hold-off Modulation Mode

44.6.3 Threshold/Hold-on Mode

This modulation mode is programmed by using REACM2_MWBKx[MM] = 10. In this mode the output pins are driven with LOD[2:0] until the ADC results is smaller than the programmed Threshold. The output controls are then driven with HOD[2:0] for a fixed

amount of time defined by the hold time. The exception for this defined ON time occurs if the value of an input sample surpasses the MAXL. In this case the output pins change to LOD[2:0] immediately.

The initial modulation behavior can be controlled by using the REACM2_MWBKx[IOSS] bit as follows:

- When REACM2_MWBKx[IOSS] = 0, modulation starts with outputs driven with LOD until the lower threshold level is reached.
- When REACM2_MWBKx[IOSS] = 1, modulation starts with outputs driven with HOD until the hold timer expires.

Note that the lower threshold limit and the hold timer pointers are indicated by the Modulation Word in the REACM2_MWBK registers.

The open circuit detection is performed by monitoring the minimum width of the OFF pulse. The short circuit is indicated by monitoring the ADC samples if the input sample surpasses the MAXL value. For more details refer to Monitored Modulation.

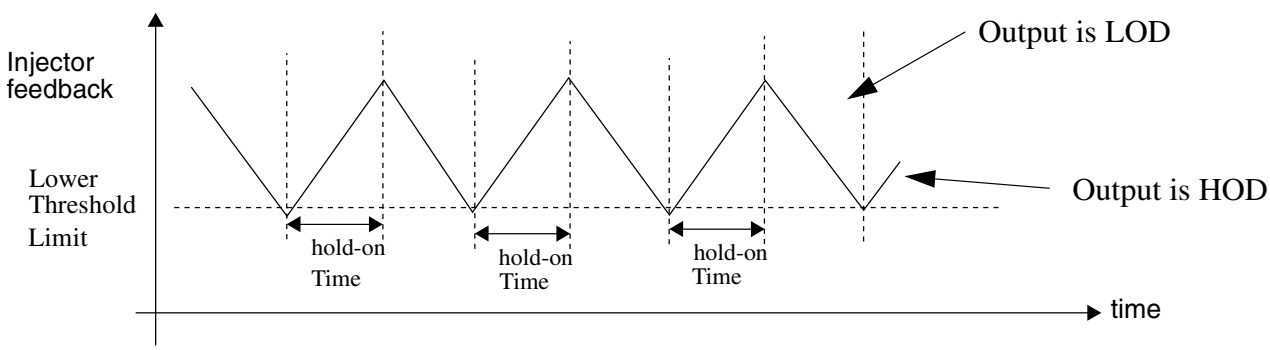

Figure 44-137. Threshold/Hold-on modulation mode

44.6.4 Threshold low/Period Mode

This modulation mode is programmed by using REACM2_MWBKx[MM] = 11 and REACM2_MWBKx[IOSS] = 0. In this modulation mode channel outputs start with LOD[2:0] and a low threshold comparison is performed until the ADC result is smaller than the programmed threshold. When the threshold level defined by THRESPT is achieved, the channel outputs states change to HOD[2:0] until the modulation period expires. The exception for this defined event occurs if the value of an input sample surpasses the MAXL. In this case the output pins change to LOD[2:0] immediately. Note that the lower threshold limit is indicated by the Modulation Word in the REACM2_MWBK registers, but the period time is given by the Period / Delay generator sub-block.

The following figure indicates the threshold low/period modulation mode.

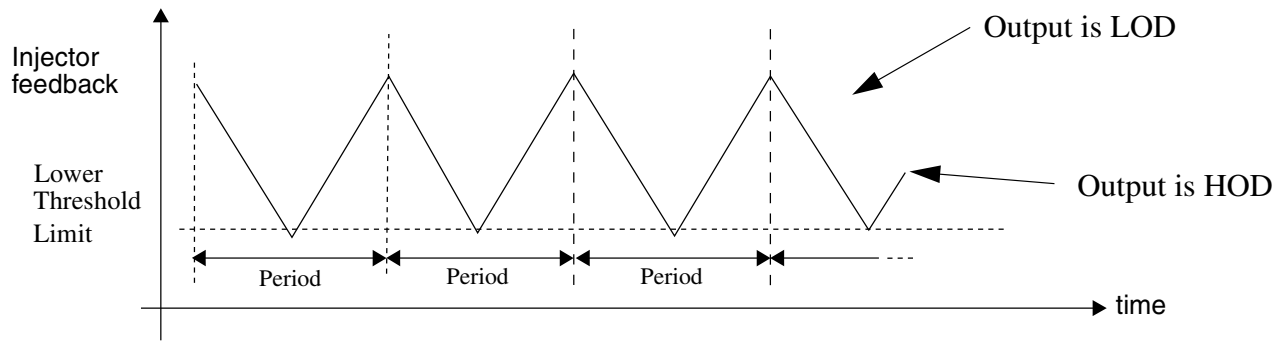

Figure 44-138. Threshold low/Period modulation mode

The open circuit detection is performed by monitoring the minimum width of the OFF pulse. The short circuit is indicated by monitoring the ADC samples if the input sample surpasses the MAXL value. For more details refer to Monitored Modulation.

44.6.5 Threshold high/Period Mode

This modulation mode is programmed by using REACM2_MWBKx[MM] = 11 and REACM2_MWBKx[IOSS] = 1. In this modulation mode channel outputs starts with HOD[2:0] and a high threshold comparison is performed until the ADC results matches or is greater than or equal to the programmed threshold. When the threshold level defined by THRESPT is achieved, the channel outputs state change to LOD[2:0] until the modulation period expires. Note that the high threshold limit is indicated by the Modulation Word in the REACM2_MWBK registers, but the period time is given by the Period / Delay generator sub-block.

The following figure indicates the threshold high/period modulation mode.

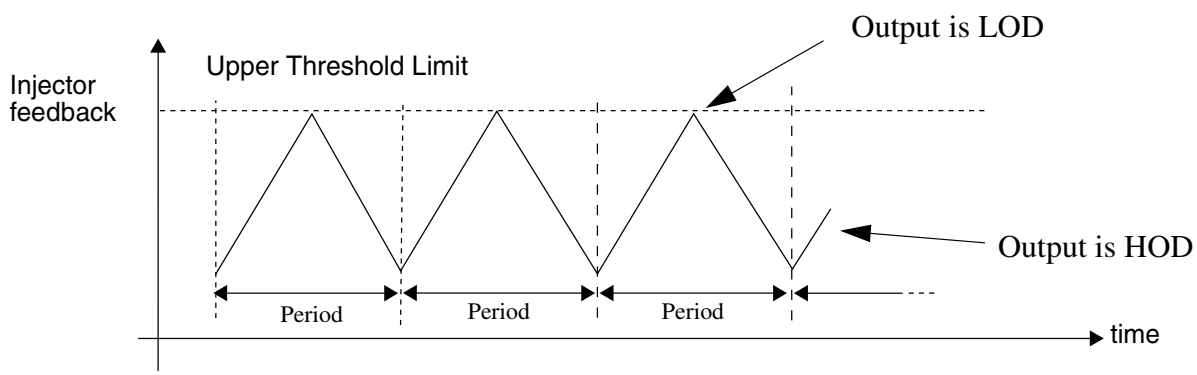

Figure 44-139. Threshold high/Period modulation mode

The short circuit and open circuit detection are performed by monitoring the width of the ON pulse. For more details refer to Monitored Modulation.

44.6.6 Limitations on the Modulation Process

This section describes the Channel limitations on the modulation process such as the width and distance between consecutive modulation pulses.

44.6.6.1 Minimum distance between consecutive Timer Control Pulses

The control signal generated by the external timer which controls the modulation process in a worst case scenario has a minimum distance of 40 system clock periods. This is required for the Reaction Channel state machine to properly re-start the modulation process and address the correct modulation word. The worst case scenario considers a Reaction Module with 10 channels and all channels being activated at the same time. If this minimum distance is violated the modulation on the second pulse will not be executed, meaning that the channel output will be defined by the DOFF field.

Note

No error flag is set if this violation occurs.

The following figure describes the channel behavior if the minimum time between two consecutive timer control pulse is violated.

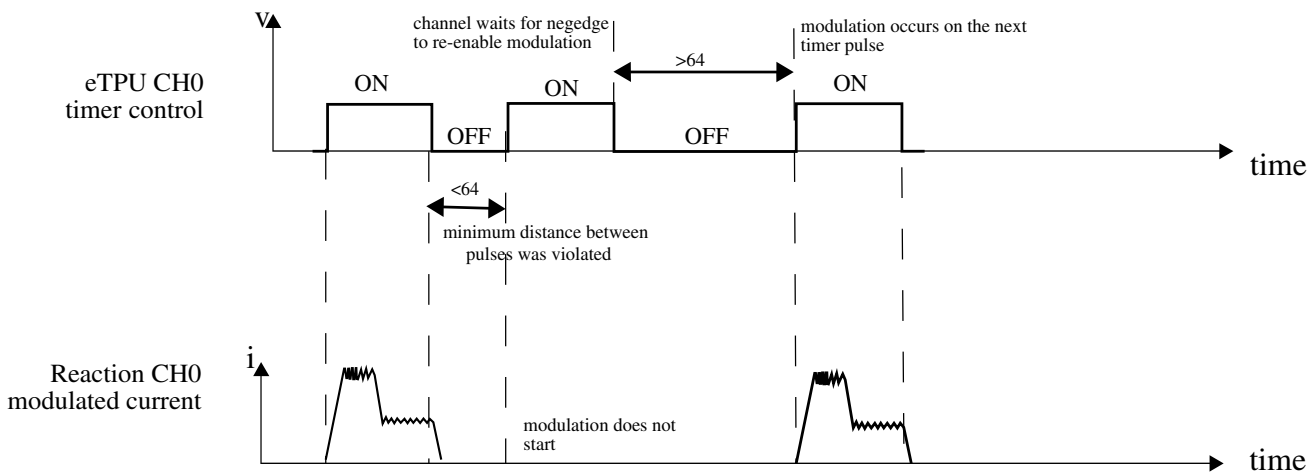

Figure 44-140. Limitation on the OFF modulation timing

44.6.6.2 Minimum Timer Control Pulse Width

There is no limitation on the Timer Control pulse minimum width. The channel just finishes the modulation process when the pulse ends even if the Modulation Words did not complete the expected sequence. Thus if a modulation phase is designed to have four Modulation Words starting from word 0, and the Timer Pulse ends at the second word (word 1) then the modulation process finishes at this point in time. The channel output is set to DOFF one clock cycle after the Timer Pulse ends. And the flag SQER is set because the SM bit field for the second modulation word is not 00. This flag occurs to indicate that the modulation was ended before the last phase of the sequence that uses the modulation word 3 and has SM=00.

The following figure describes the channel behavior when an early end of the Timer Control pulse occurs. Note that the channel output is driven to DOFF which causes the modulation to end. Note that an early end of pulse only affects the current modulation cycle. Meaning that on the next modulation cycle the modulation word 0 is executed first and all subsequent words are executed in the appropriate sequence.

Note

In some applications the modulation runs continuously and the input timer control signal is not used as a modulation pulse control but only as an enabling signal. Therefore, if the modulation is turned off, the REACM2 can issue a Modulation Word Sequence Error by setting SQER flag. In this case, this SQER flag can be ignored (masked) without prejudice.

An option, if the application permits, is to disable the REACM2 channel (CHEN=00), thus avoiding unwanted SQER error.

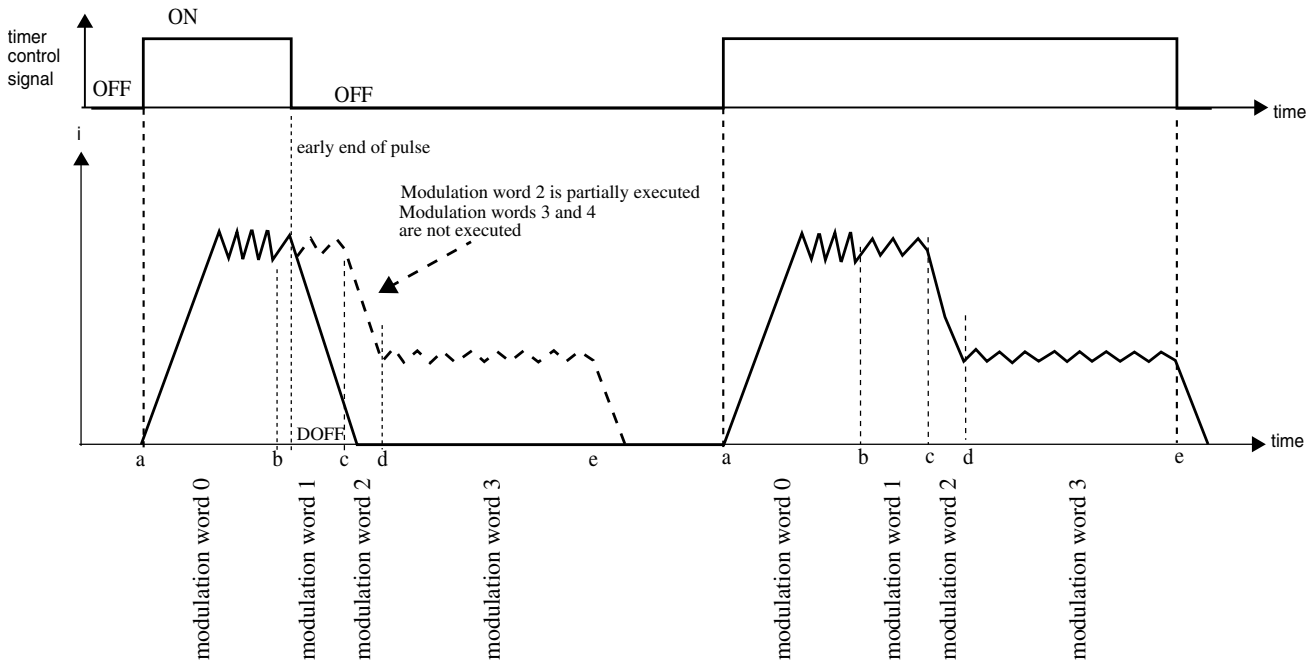

Figure 44-141. Early end of Timer Control pulse

44.6.6.3 CHOFF behavior during modulation

The CHOFF, channel output disable bit in REACM2_CHCRn, is intended to disable the channel immediately before a modulation cycle had ended. This is important on error conditions detected by the software, thus setting the channel outputs to a safe state defined by DOFF. It is important to note that re-activating the channel by setting CHOFF=0 does not imply that the channel outputs immediately return to the state defined by HOD and LOD on the modulation word being executed. Instead, the HOD and LOD are driven to the channel outputs only when one of the following conditions occur:

- A sequence advance event (time-out or threshold, depending on SM)
- A new sample is received (no matter whether the comparison matches or not)
- A hold-on/off time-out
- A period pulse occurs for the related modulation mode

44.6.6.4 Module initialization

In order to properly execute the modulation process the Reaction Module must be initialized with a correct sequence. One alternative is described as follows:

1. Make sure eTPU channels are at zero, inactive state
2. Setup BCTU module
3. Program the Modulation Words
4. Program the Threshold Bank
5. Program the Shared Timer Bank
6. Program the Hold Time Bank
7. Program Timer Configuration register
8. Program the Module Configuration register
9. Program the Period Shift Delay Configuration register
10. Program the Period Generator Configuration register
11. Program the Channel Router register
12. Program the Channel Configuration register
13. Start eTPU channels

It is important to note that the channel activation, by setting CHEN=01, should be done after all other registers were configured and before the input timer control signals are active. Violating this order may lead to errors when the modulation cycle is executed by the channel.

Note

If a glitch is introduced in the input timer control pulse, the channel stops to modulate and does not operate during the pulse just after the glitch. The glitch value for wrong operation ranges from 1 system clock to about 5 times the number of channels.

44.6.6.5 Potential glitches on the reaction channel outputs

Reaction channels outputs are digital signals that are controlled by several events that are not synchronized to each other. Due to this nature, there are a few cases when a glitch can occur at the channel outputs. If the channels outputs are going to be used by systems that are very slow compared to the generated PWM, these cases of glitches are not a problem.

The known cases of potential glitches are listed below:

- At the end of a modulation phase when a new modulation word will be used, a glitch can occur if the output has just changed prior to the end of the phase and the IOSS of the next phase forces a value that is the opposite of the last value.
- At the end of the whole modulation when the modulation is going to be disabled by the timer channel, a glitch can occur if the output has just changed to HOD prior to the disabling.
- If the threshold / threshold modulation mode is used with SM set to threshold (high) mode, at the end of the phase the output is switched off to LOD. If the modulation word for the next modulation phase has IOSS set to 1, a LOW glitch is generated. This can be avoided by setting HOD=LOD in the described previous modulation phase.

44.7 Monitored Modulation

The modulation executed by the Reaction Channel can be monitored by measuring the width of the PWM ON pulse or the OFF state.

44.7.1 Monitoring the ON Pulse Width

The modulation executed by the Reaction Channel can be monitored by measuring the width of the PWM pulses provided by the channel. If the pulse becomes too narrow it means that the load impedance is probably too low, thus indicating a possible short circuit. If the PWM pulses become too wide it may indicate an open circuit on the solenoid. These criteria can be used for threshold-threshold, threshold-hold-off, and threshold high-period modulation modes.

The PWM pulse is considered to start (rising edge) in the following cases:

- in the start of the modulation phase with IOSS=1 (threshold-threshold, threshold-hold-off, or threshold high-period modulation modes);
- when the hold-off time is over in the threshold-hold-off modulation mode;
- when the received sample is lower than the threshold LOW value (threshold-threshold, or threshold-hold-off modulation modes);

The PWM pulse to be monitored ends (falling edge) when the input sample value surpasses the threshold HIGH in the above modulation modes.

NOTE

When modulation word progresses to new modulation phase the current pulse width monitoring is stopped and a new one is started if necessary. Therefore there is no pulse width extension nor narrow pulse occurrence due to modulation phase progress.

The short detection has an additional configuration to set the SCDF flag. The SCDF flag is set if a single detection event occurs (REACM2_CHCR register field SDCM=0) or if two short detection events occur in a row (SDCM=1). For simplicity, the following descriptions are for single short detection case.

The limits for narrow and wide pulses are defined by RANGE_PWD and MIN_PWD registers (see Figure 44-140 and Figure 44-141). These values apply to all Reaction Channels. The PWM pulses are measured by the Hold timers within the Reaction Channels. This is possible only during idle periods of this timer, for example from the moment a hold-off time-out occurs until the maximum threshold is reached when HOD is being used for the channel output pins. During this period the hold counter is not used and thus it can measure pulse widths and compare them against pre-defined limits defined by RANGE_PWD and MIN_PWD registers, as shown in Figure 44-142.

Note

Consider an uncertainty of (+1) in the value MIN_PWD and (MIN_PWD + RANGE_PWD) when calculating the pulse width limits. The Hold timer prescaler contributes to this uncertainty.

For a programmed MIN_PWD value, a pulse wider than (MIN_PWD+1) does not set the SCDF flag.

For a programmed (RANGE_PWD + MIN_PWD) value, a pulse narrower than or equal to (RANGE_PWD + MIN_PWD + 1) does not set the OCDF flag.

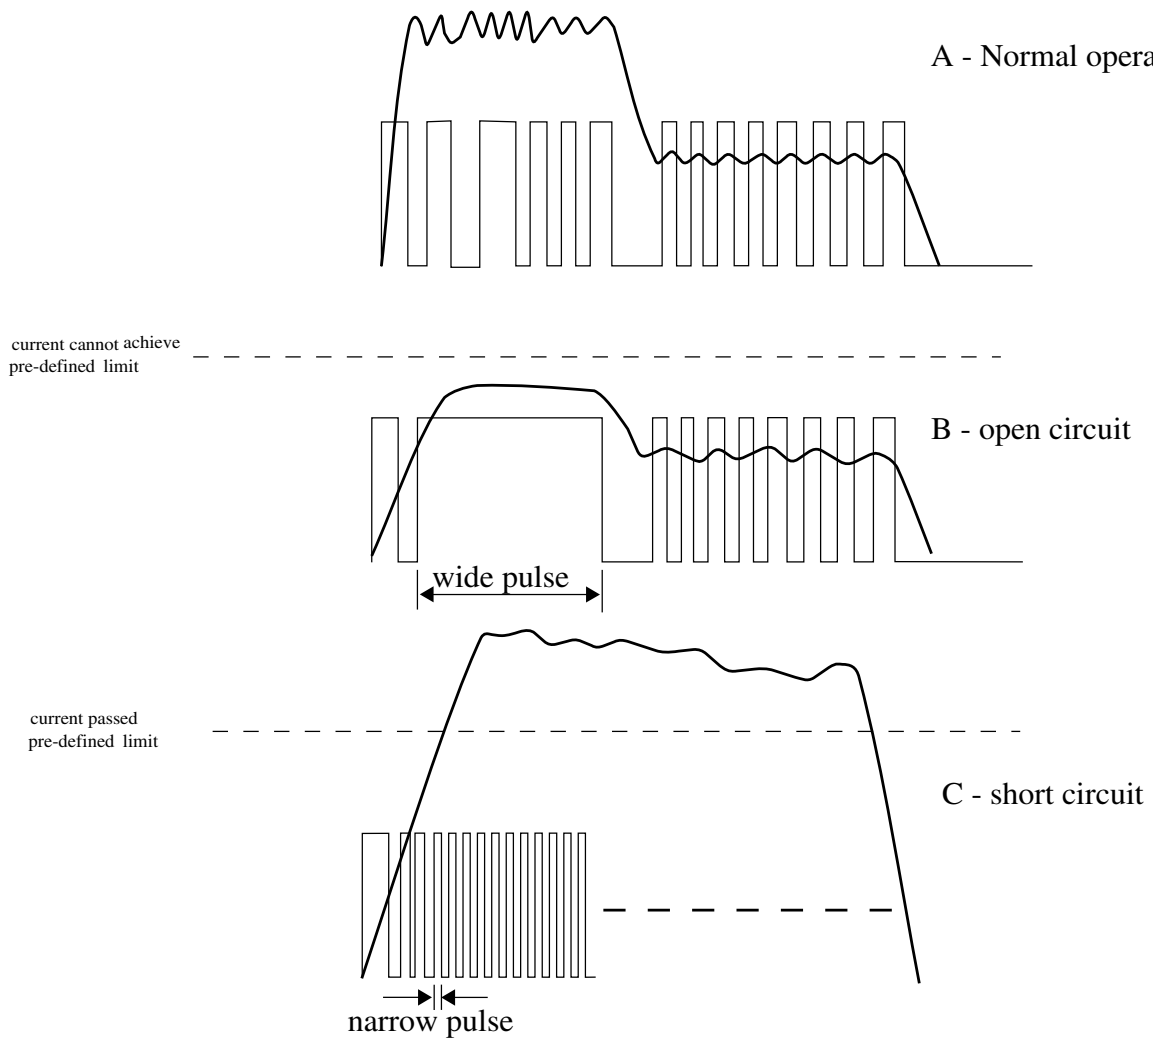

Figure 44-142. Fails detected by the pulse width monitoring

Figure 44-143 describes in more detail an open circuit detection using the Hold timer. Note that the Hold timer is used when the output is at the ON state, which means HOD is used to drive the outputs, thus hold-off functionally is not required at this moment. The Hold timer is loaded with MIN_PWD and starts counting. After a time-out occurs RANGE_PWD value is loaded and the Hold counter starts counting again. An open circuit is detected if the timer times-out on the second RANGE_PWD counting and the PWM pulse is still high, meaning that the outputs did not switch to LOD. In this case the OCDF flag is set in the Channel Status Register (REACM2_CHSR), of the corresponding channel.

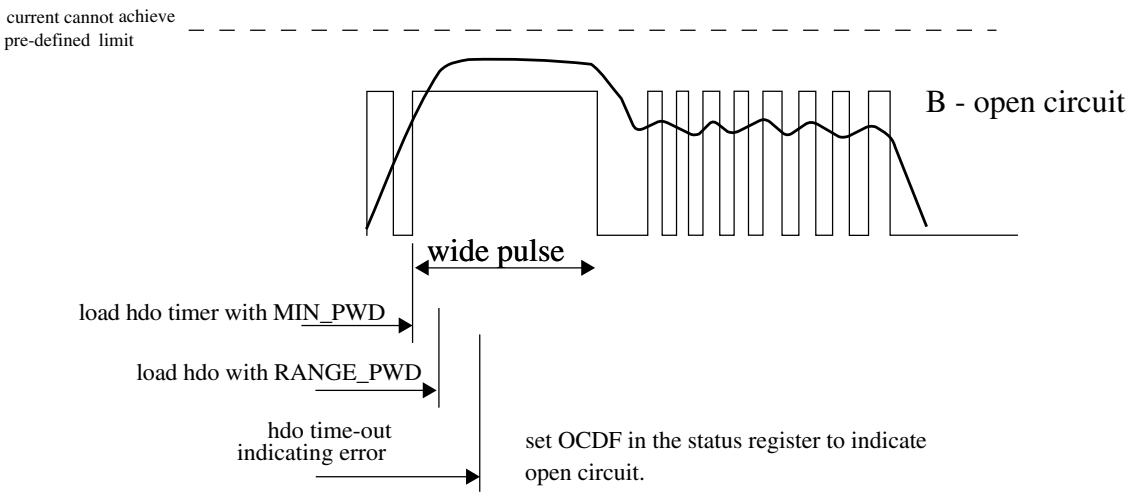

Figure 44-143. Open Circuit detection using Hold timer

Figure 44-144 describes how the Hold timer detects a short circuit. The Hold timer is loaded with the MIN_PWD value and enabled. The condition indicating that a short circuit occurred is that the Hold timer is still running and LOD is loaded to the channel output pins. That means the PWM pulse is too narrow and a short circuit has occurred. In this case the SCDF flag is set in the Channel Status Register (REACM2_CHSR) of the corresponding channel.

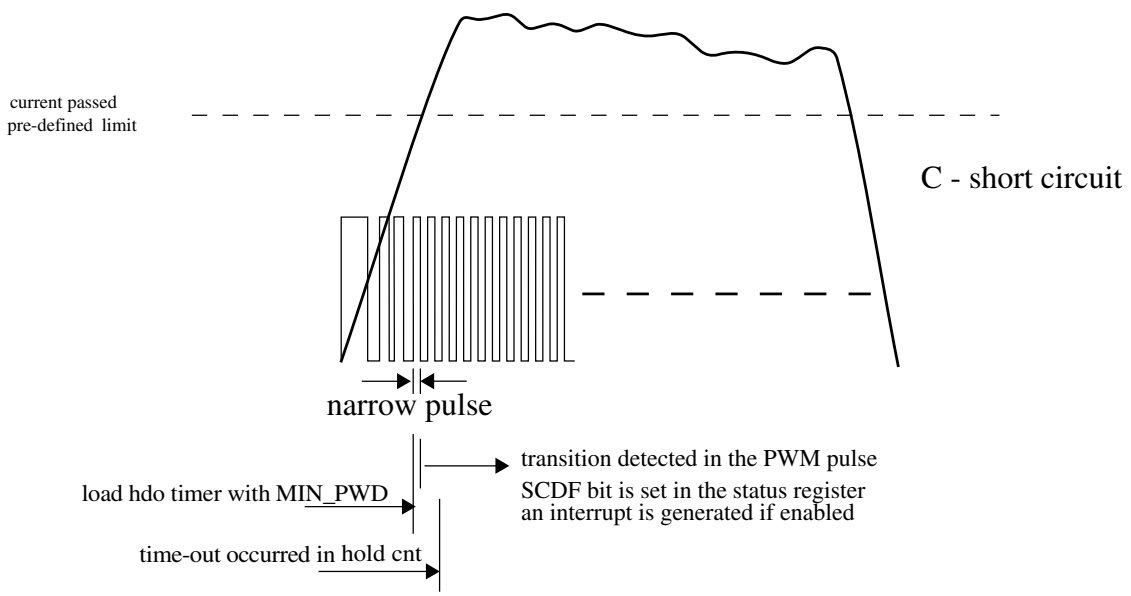

Figure 44-144. Short Circuit detection using Hold timer

Note

In order to define RANGE_PWD value it is required to consider that the Hold timer already measured MIN_PWD, thus actually the maximum allowed pulse width = (MIN_PWD + RANGE_PWD). In other words, RANGE_PWD = (maximum allowed pulse width - MIN_PWD).

IF MIN_PWD = 0x00 or RANGE_PWD = 0x00 no pulse width is performed.

The CHSR SCDF flag does not set if the pulse was finished by disabling the modulation (i.e. eTPU channel=0 or SWMC=0) or by disabling the channel, CHEN=00, even if it ended shorter than MIN_PWD. However this flag can set in some situations that really indicates a short pulse detection but it is the result of some internal condition of the reaction module. The known situations are listed below:

- When a modulation phase with MM=01 (threshold / holdoff) starts with IOSS=1 with the previous modulation phase set to SM=11 (advance on threshold).

The CHSR OCDF flag only sets when the channel is enabled (CHEN not null) and the eTPU channel signal or SWMC is active too. However, the OCDF flag can set in some cases when the CHOFF bit is set. In this case, this OCDF flag should be disregarded because it is a false indication of the detector.

There can be a conflict of resource allocation if the Hold timer is used as the timer for the sequencer mode (SM=10) because it is not possible to have the detection of minimum and maximum pulse widths. This configuration is only allowed to be used with the threshold-threshold modulation mode but the monitor of short / open circuit is not enabled. The RAER flag will be set for any other modulation mode.

NOTE

An application case is to use SM=10 with threshold / threshold modulation mode and IOSS=0. The channel output starts OFF and the SM hold timer can be configured to have a time-out before the threshold low is reached. If the threshold low is reached before the SM time-out event, the channel switches to ON but the short / open detection is not started.

44.7.2 Monitoring the OFF State Width and the ADC Maximum Value

The modulation executed by the Reaction Channel can be monitored by measuring the width of the OFF states of the PWM waveforms provided by the channel. If the OFF state becomes too narrow it means that the load impedance is probably too high, thus indicating a possible open circuit. And if the sample value surpasses the ADC_MAX_LIMIT value a short circuit condition is detected. These criteria can be used for threshold-hold-on, and threshold low-period modulation modes.

The open detection event should occur twice in a row to set the OCDF flag. This condition helps to avoid false set of the open circuit detection flag. However a single sample that surpasses the ADC_MAX_LIMIT is sufficient to set the MAXL flag

The time limit for narrow OFF state is defined by MIN_PWD register. This value applies to all Reaction Channels. The PWM OFF states are measured by the Hold timers within the Reaction Channels. This is possible only during idle periods of this timer, for example from the moment a hold-on time-out occurs until the minimum threshold is reached when LOD is being used for the channel output pins. During these periods the hold counter is not used and thus it can measure the OFF states widths and compare them against the pre-defined limit defined by MIN_PWD register, as shown in the figure below.

Note

Consider an uncertainty of (+1) in the value MIN_PWD when calculating the OFF state width limit. The Hold timer prescaler contributes to this uncertainty..

For a programmed MIN_PWD value, a pulse wider than (MIN_PWD+1) is not an open circuit event to set the SCDF flag.

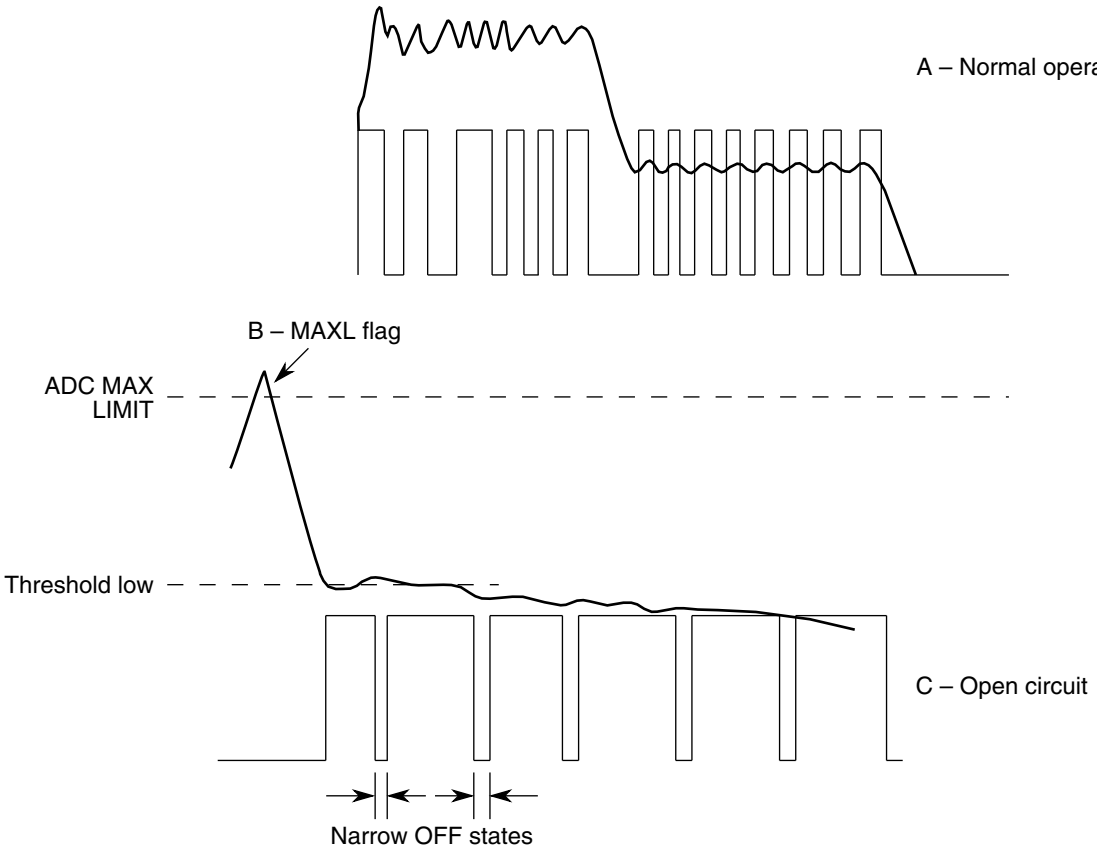

Figure 44-145. Fails detected by the OFF timing monitoring

The CHSR OCDF flag does not set if the OFF state was finished by disabling the modulation (i.e. eTPU channel=0 or SWMC=0) or by disabling the channel, CHEN=00, even if it ended shorter than MIN_PWD.

There can be a conflict of resource allocation if the Hold timer is used as the timer for the sequencer mode SM=10. In this case the RAER flag will be set to signal this conflict condition.

44.8 DMA support

The Reaction Module provides supports for one DMA channel per Reaction Channel. The DMA request signal is controlled by the DMAEN bit in the Channel Configuration Register (see Figure 44-133) and by the DMA bit in the Modulation Control Word. If the DMAEN=1 and the DMA = 1 then a DMA request is issued by the Reaction Channel. Note that the DMA request is deasserted if the DMA done signal is asserted even though the channel is still pointing to the same Modulation Control Word that generated the DMA request. In order for a new DMA request be issued after the DMA done is issued, the Reaction Channel must access a new Modulation Control Word or execute a new modulation cycle controlled by the timer input signal. The following figure shows the

DMA protocol executed by the Reaction Channel. The DMA request signal is asserted when the Modulation Word 1 is executed by the channel. This signal remains asserted until a DMA done signal is issued by the DMA controller.

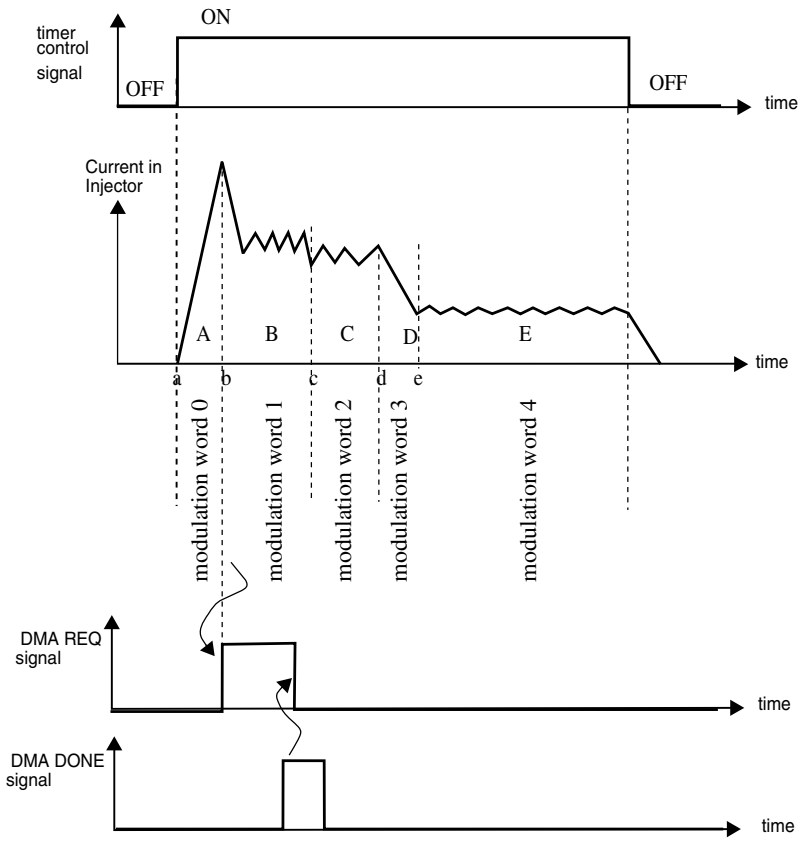

Figure 44-146. DMA Req/Done protocol

44.9 Reset Overview

The Reaction Module is reset whenever any MCU reset occurs. In order to re-initialize the Reaction Channels, the CHEN channel enable register should be used. Once disabled the channel output is set to DOFF state and the channel configuration can be changed safely. The disable/enable operation does not change the channel setup, thus the configuration registers remain at the state as before the channel was disabled. The Modulation Control word addressed by the channel after the enable bit is asserted is defined by the MODULATION ADDR field in the channel configuration register.

44.10 Reaction Module Interrupts

The Reaction Module issues one global interrupt signal and one interrupt signal per channel. If the Global interrupt signal is used, the resolution of the interrupt source needs to be performed by reading the Global Error Flag register to evaluate which channel issued the interrupt. After that the Channel Status register needs to be read to distinguish between the several interrupt sources by evaluating the flags: MAXL, OCDF, SCDF, TAER and SQER.

44.10.1 Interrupt sources

There are several sources of interrupts that indicates a faulty condition:

1. MAXL: maximum ADC result value was reached
2. OCDF: open circuit detected which indicates an open circuit, and thus, a potential malfunction in the circuitry controlled by the Reaction Module. Note that differently from the TAER, this flag does not indicate a faulty condition in the channel but in the circuit outside the SoC.
3. SCDF: short circuit detected which normally indicates a short circuit was detected on the off chip logic controlled by the reaction channel.
4. TAER: timer allocation error which indicates a required Timer resource was not allocated properly thus leading to faulty operation of the Reaction module.
5. SQER: sequencer error occurred meaning that the timer input signal was negated in a modulation phase with SM != 00.

44.10.2 Global Interrupt and Channel Interrupt

The following figure illustrates the relationship between the channel interrupts and the module global interrupt. The global interrupt summarizes the indication of error in the reaction module.

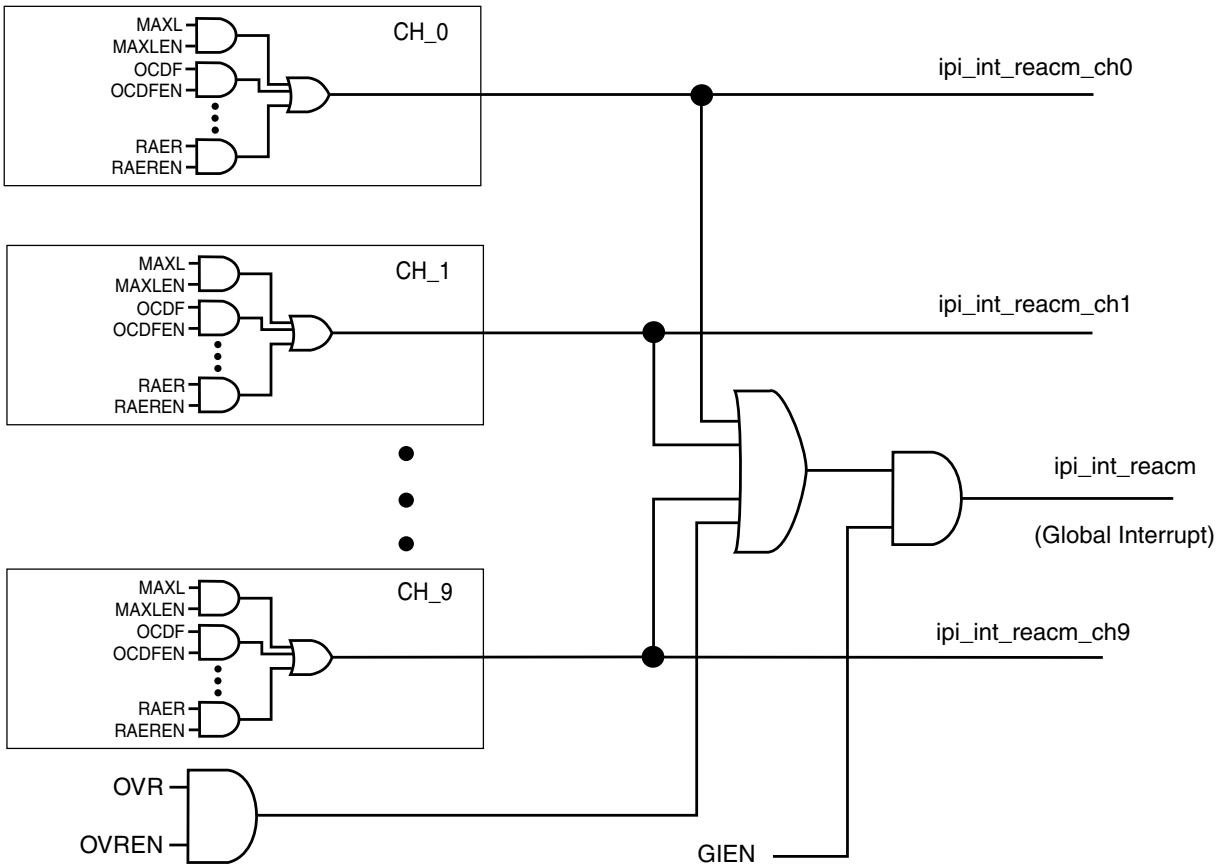

Figure 44-147. Channel Interrupt and Global Interrupt Diagram

44.11 Use cases

Figure 44-148 shows an example of the Reaction Module used to control an Injector solenoid. Note that this is a dual injector which is also called banked injector. Two Reaction channels are used to control this injector.

The injector Boost transistor on the top applies a higher voltage in order to minimize the time necessary for the injector to start injecting fuel. Transistors A and B control which injector is active in the injector bank. A sensor resistor is used to feed the current flowing through the solenoid back to the on-chip ADC. The current is sampled by the ADC and the result is sent to the Reaction Module, allowing closed loop control.

Note

This injector bank architecture does not allow both injectors to operate at the same time since the sensor in the feedback loop is shared by both injectors.

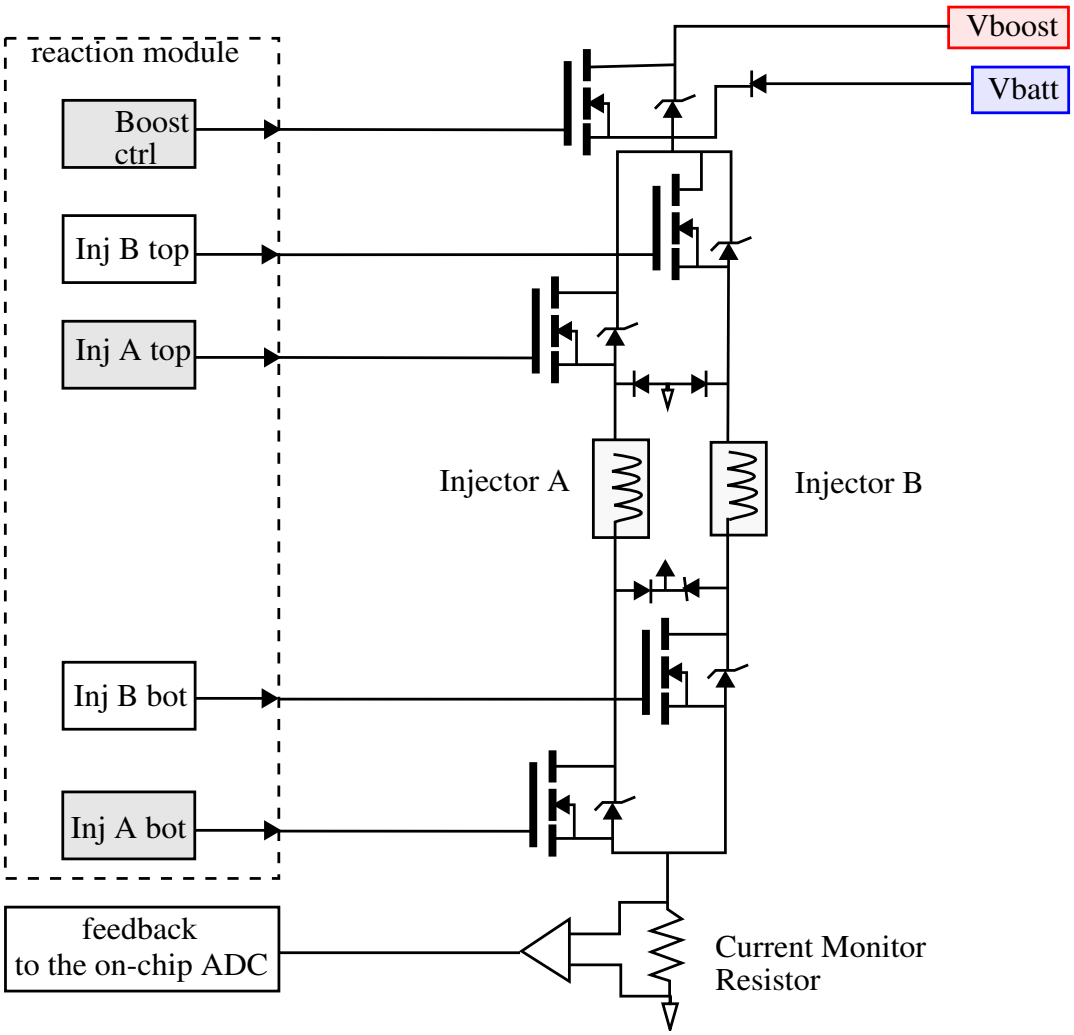

Figure 44-148. Boosted Banked Direct Injection with Passive Recirculation

Two eTPU channels are used to provide timing control signals, one for CH0 and one for CH1. The on-chip ADC monitors the sensor current periodically and sends the digitalized results to the Reaction Module. In a banked configuration as shown in this example one ADC channel is used to monitor both injectors current. Note that only one channel is *active* at a given time since the eTPU time windows are not *active* at the same time for both Reaction Channels. See Figure 44-149 for more details.

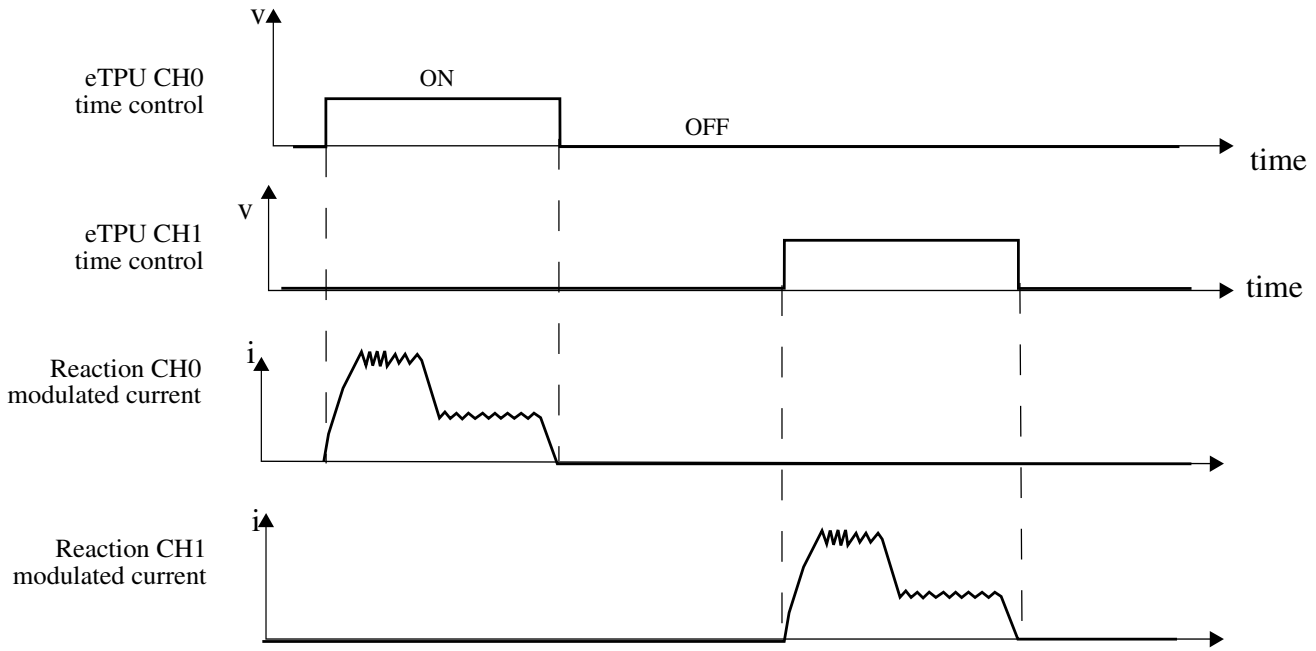

Figure 44-149. eTPU CH10/1 Controlling Reaction CH0/1

There are several possible configurations for a banked mode application. The objective on those configurations is to share hardware resources such as Reaction Module channels, ADC monitor inputs and MCU pins, among others related to the Injector driver which is not covered in detail in this document.

Figure 44-150 shows a more detailed diagram of the interconnection between the injector bank and the Reaction Module. Two reaction channels are used in this application. CH0 is used to control Injector A and CH1 is used to control Injector B. However, the Vboost/ Vbatt selection is controlled by CH0 ch0_a output only since, when VBoost driver is switched off, Vbatt power source is applied to the injectors by the direct bias of the diode connecting Vbatt to the injector bank.

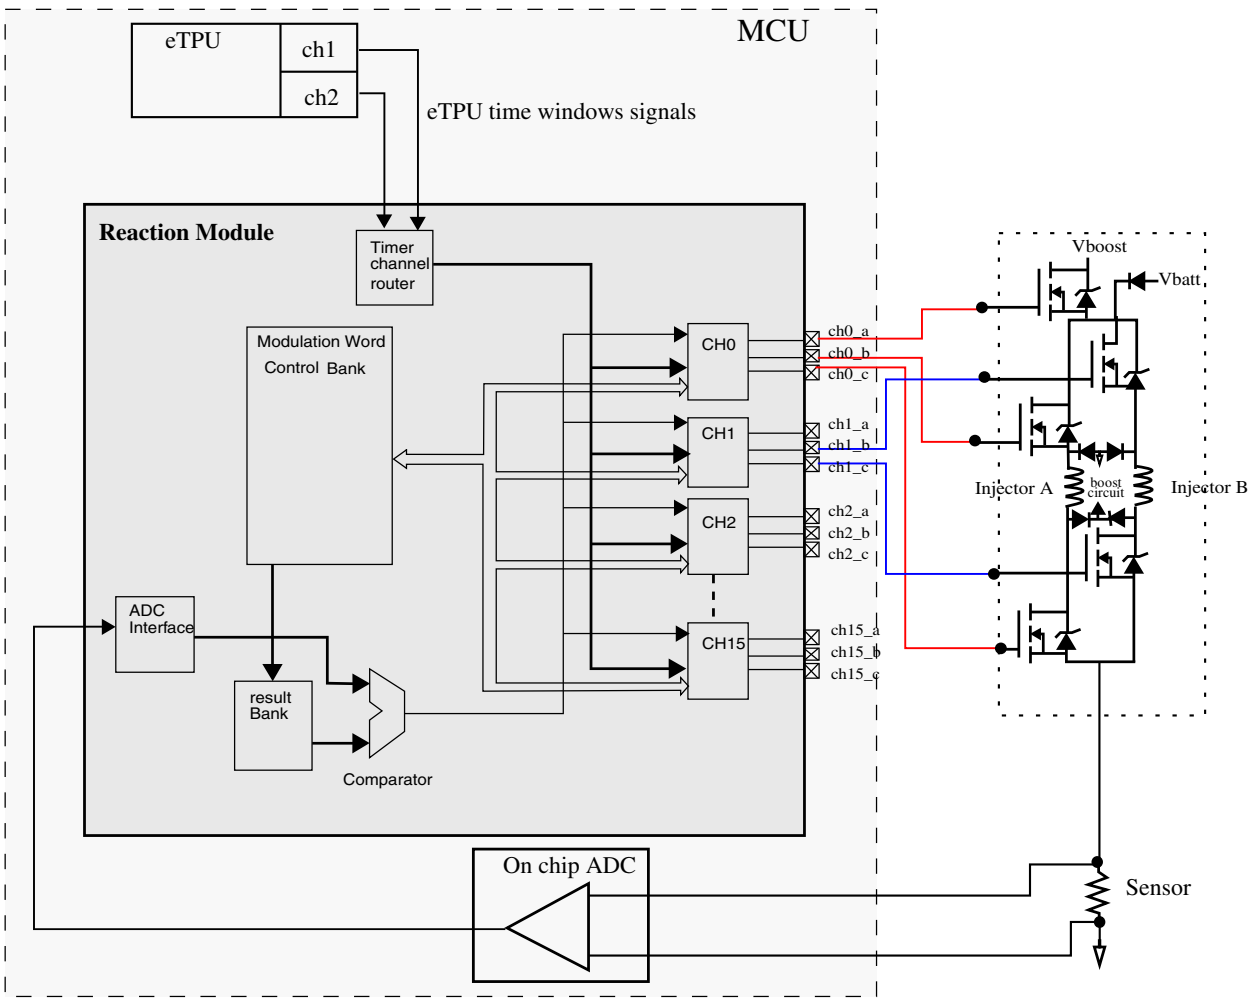

Figure 44-150. System Level Connection in a Banked Configuration

It is important to note that even if two reaction channels control different injectors they can share the data stored in the Modulation Word Control. In this case both channels should execute the same type of modulation and use the same threshold values. Note also that the data stored in the Threshold bank in this case is also shared between these channels. This is an important feature of the Reaction Module architecture since it allows the sharing of resources and therefore provides savings in size without compromising the module functionality.

Figure 44-151 shows an example of the required current levels through Injector A and B. In order to generate this waveform, the Reaction Module uses one Modulation Control Word for each one of the four phases of the waveform from A through D. In this example the Module should be configured in the following way:

1. Set the REACM2_CHRR0 CHIR[3:0]=0x0, thus routing eTPU channel 0 to Reaction Channel 0
2. Set the REACM2_CHRR1 CHIR[3:0]=0x1, thus routing eTPU channel 1 to Reaction Channel 1
3. Set the REACM2_CHRR0 ADCR[3:0]=0x0, thus routing ADC TAG 0 to Reaction Channel 0
4. Set the REACM2_CHRR1 ADCR[3:0]=0x0, thus routing ADC TAG 0 to Reaction Channel 1
5. Program Modulation Word Control bank according to Figure 44-152
6. Program Shared Timer Bank REACM2_STBK for addresses from 0 through 1 with timing intervals related to the duration of phases B and C respectively.
7. Program appropriate values in the Threshold Bank. Since threshold-threshold modulation is to be used in this example, 4 pairs of values should be provided for phases A,B,C and D respectively. Each pair corresponds to one address of the REACM2_THBK starting at address 0x0400.
8. Program configuration registers for both channels, REACM2_CHCR0/1. The parameters are DOFF[2:0] which defines the OFF state of the channel outputs and the MODULATION_ADDR = 0x0, which defines the address of the Modulation Control word. It is assumed that the Modulation Word zero is the first word to be accessed by both channels. Since 4 Modulation words will be used the addresses will be incremented by the Reaction Channel as needed, thus only the address for the first word is required. Note that MODULATION_ADDR=0x0 points to the first Modulation Word in the Modulation Word Bank.
9. Program the prescalers HPRE and TPRE in the REACM2_TCR register. Also enable the prescalers by setting the TPREN and HPREN bits in the REACM2_MCR register.
10. Enable channels CH0 and CH1 to start the modulation sequence by programing field CHEN=01 on REACM2_CHCR1/0 registers. At this time the Reaction channel CH0 accesses the Modulation Control word zero and switches to ON state as defined by the data stored in the HOD[2:0] field. Up to this point any activity in the eTPU channel or incoming ADC result is ignored by the Reaction module. After CHEN field is programed, the reaction channels wait until a timer window is initiated by eTPU for the modulation process to start.

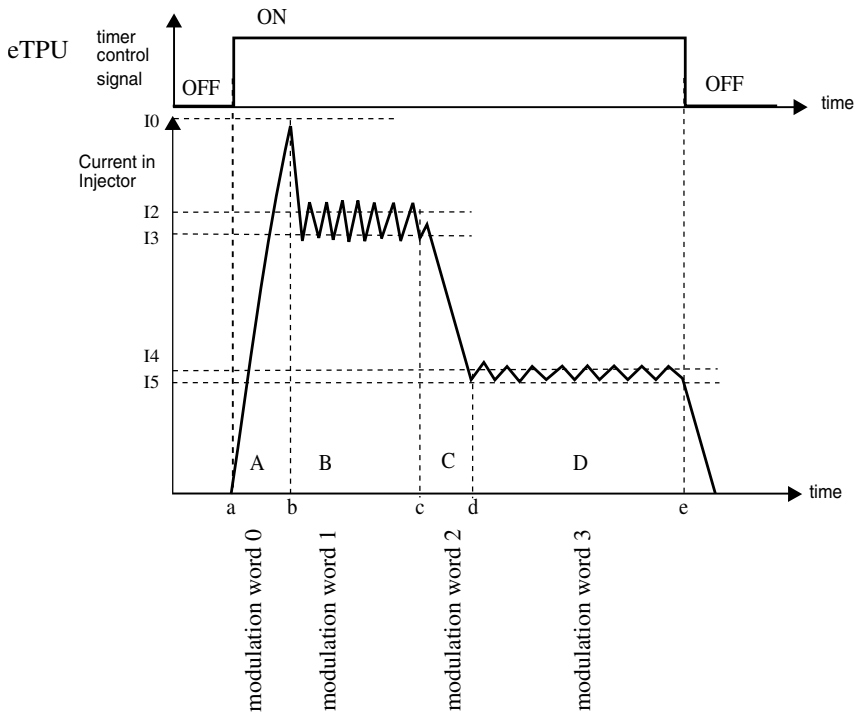

Figure 44-151. Modulation Phases1

The current through the injectors are initially zero since the reaction channel output is in the OFF state as configured by the DOFF[2:0] field. The eTPU timer window is at the OFF state as well. The modulation starts when the eTPU channel time window switches to ON state. Modulation *phase A* starts at this time as described in Figure 44-151. The modulation word 0 is used. In this application this phase corresponds to the *Boosted Peak phase*. This process allows the fuel injection to start sooner because of the sharp edge of the current which is important for a precise control of the fuel to be injected. *Phase A* is setup to execute a Threshold-Threshold modulation but note that only *I0* value is used since the phase advances when a certain current is achieved. Below is a description of the bit fields in the Modulation word in order to execute the modulation described in *phase A*:

- LOOP=0
- The initial value should be HOD (IOSS=1)
- Threshold-Threshold modulation mode is obtained with MM=00
- This phase ends when the threshold value *I0* is achieved (SM=11)
- Necessary to have HOD=111 for boosted operation and sensor active. LOD setting is not important in this case since it is not used
- *I0* is read from Threshold Bank by using THRESPT=0x0 that points to address 0 of this bank

- *I1* is read from Threshold Bank by using (THRESPT+1) = 0x1
- Hold timer is not used, therefore HDOFFPT can have any value (X).

At point b, *phase B* is initiated by the threshold being achieved from *phase A*. CH0 increments the Modulation Word address to MODILATION_ADDR = 0x1 and the second Modulation Word is read by the channel. As a result of the second Modulation Word decoding the *Vboost* voltage is disabled causing a *peak* modulation with *Vbatt*. The phase is called the *Peak Vbatt phase*. For *phase B* a Threshold-Threshold modulation is used with levels *I2* and *I3* during a period defined by *TB*. See Figure 44-152

A time-out event is received from the Shared Timer sub-module and a new Modulation Word is read. *Phase C* corresponds to the *re-circulation phase*. Energy from the injector is transferred back to the boost circuitry. In this phase the current cannot be measured because there is no current flowing through the sensor resistor. A Threshold-Threshold modulation mode is used. The Shared Timer is started at the beginning of this phase and *TC* delay is measured. The channel outputs are kept in the OFF state.

When the Shared Timer times out after *TC* delay the Modulation Word address is incremented, MODULATION_ADDR = 0x4 and the *Hold phase* is initiated. This phase is typically longer compared to the other phases and defines the amount of fuel that will be injected. Threshold-Threshold modulation mode is used between levels *I4* and *I5* and *Vbatt* is selected as the power supply. The phase ends based on the eTPU time window switching to *off* at point *e*. At this time the channel outputs are set to OFF and the channel points to MODULATION_ADDR = 0x0 which is the address of the first Modulation Word. Note that this address is not necessarily 0x0.

This modulation process is executed by a sequence of Modulation Words as described in Figure 44-152.

Modulation Control Word Bank (REACM2_MWBKn)

Note

[1] Any value

44.11.1 Advancing Modulation Phase on a Threshold level

The Modulation Phase may be set to advance when a specific threshold value is reached. The use case for this scenario is described in the following figure. This functionality is used to assure a specific current level was achieved before the Reaction Channel advances to the next modulation phase, thus making sure that the solenoid had the fastest opening speed.

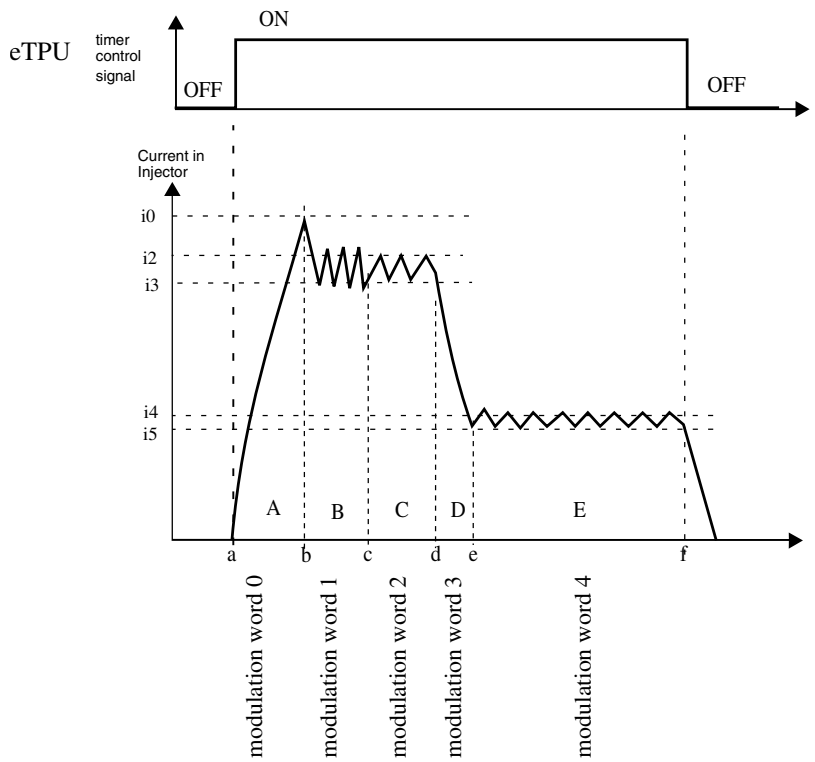

Figure 44-153. Advancing Modulation Phase on a Threshold level

In the example shown in the preceding figure the Modulation Word 0 has the field SM=11 meaning that it should advance if the ADC comparator, which compares ADC results and threshold values, is true. This means that the ADC result is greater or equal to the threshold value pointed by THRESPT Modulation Word 0 field. The advance from phase A to phase B in the preceding figure is described as follows:

- Initially at time *a* the Reaction Channel output is loaded with HOD[2:0] as indicated by IOSS value, both fields of modulation word 0.
- If ADC result >= [THRESPT] the Reaction Channel turns the outputs off by loading LOD[2:0] to the channel outputs and advance to the next modulation cycle at time *b*.

Note

The advance on threshold, SM=11, is intended to be used with IOSS=1, thus the advance occurs when the level from the ADC is greater or equal to the value pointed by THRESPT. IOSS=0 is a reserved value for this bit in this configuration and should not be used.

Note

In case of MM=01 (threshold/holdoff) on phase B, a glitch can occur in the beginning of this phase. To avoid this, on phase A it is necessary to set HOD=LOD. However, a false flag SCDF can be set at this time and should be discarded.

44.11.2 Controlling the LOOP function

The LOOP field in the Modulation Word controls the sequencing of Modulation Words to be executed by the channel. If LOOP = 1 and a phase is ended the next Modulation Word address returns to the initial modulation address programmed in the channel when the cycle was initiated. In this case a loop in the Modulation Bank is created. This loop ends when the cycle ends.

The following figure shows the sequence of Modulation Words within a Modulation Cycle if LOOP function is used. Note that an alternate modulated waveform is generated using only two Modulation Words, in this case Modulation Word 0 and Modulation Word 1.

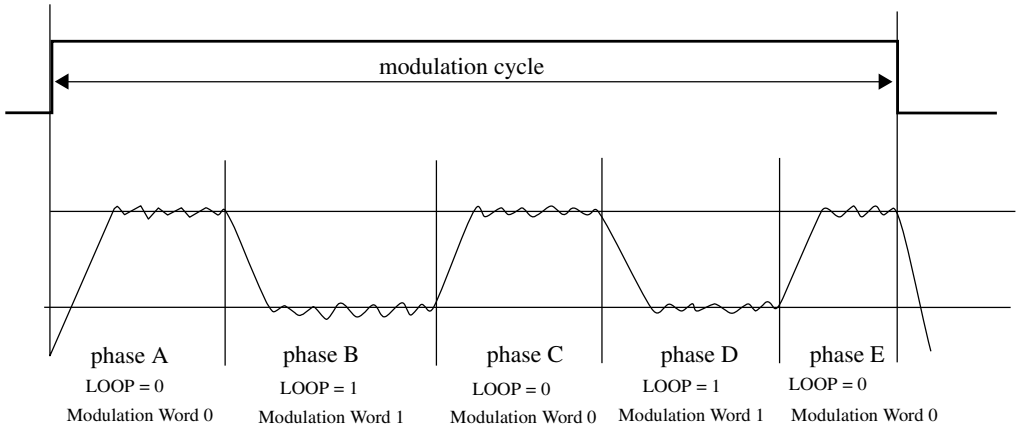

Figure 44-154. LOOP function used within a Modulation Cycle

NOTE

Due to the limit of 16 words for a channel modulation, after the 16th modulation word accesses, the sequence advance is executed by returning back to the first word of the sequence even with LOOP=0.

44.11.3 Banked Mode

The following figure describes the interconnection of four channels controlling two injector banks. Note that two output pins are not connected since the boost control is shared between channels [0] and [1] and channels [2] and [3].

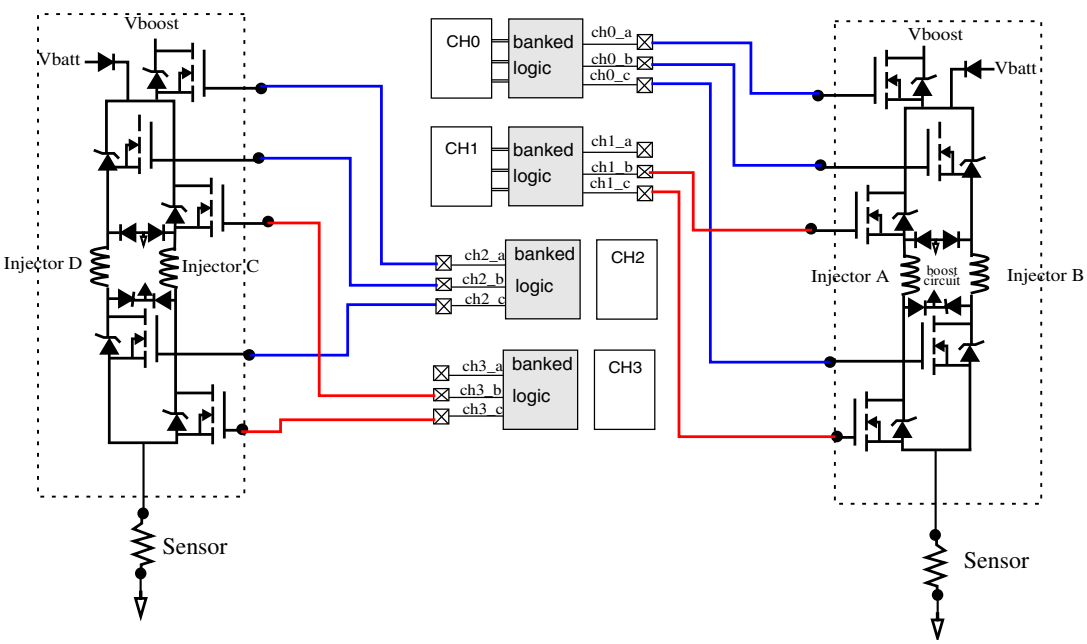

Figure 44-155. Four channels controlling two injector banks in banked mode.

Chapter 45
Input Glitch Filter (IGF)

45.1 Input Glitch Filter chip-specific module information

This device implements one cluster of Input Glitch Filter modules comprising of 32 input filter channels. (See the Filter Cluster section.)

- The inputs are connected to the pins through an input mux which is implemented in the IOMUX. See the Signal Multiplexing and Signal Description chapter.
- 32 filter channels
- 24-bit counters in each channel
- One 9-bit prescaler on channel 0
- The filtered output from Input Glitch Filter routes to both eTPU and eMIOS.

The following figure shows the interaction of the Input Glitch Filter with other modules in the device.

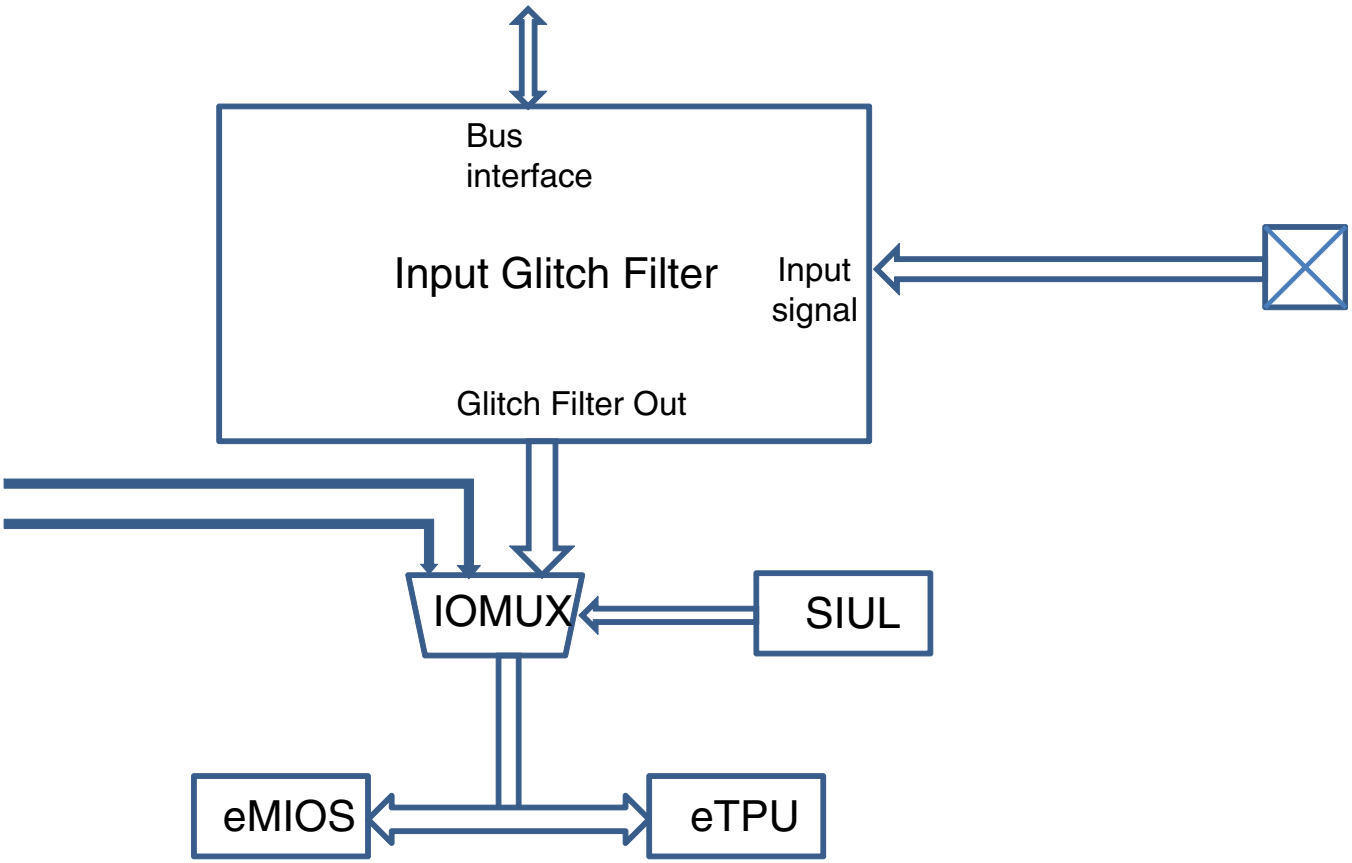

Figure 45-1. Input Glitch Filter SoC Interaction

45.2 Introduction

The Input Glitch Filter provides programmable glitch rejection filtering of digital input signals.

45.3 Filter Cluster

The MPC5746R has 32 Input Glitch Filters organized in to one filter cluster. The first filter in the cluster (Filter 0) has an internal prescaler. All other filters do not have an internal prescaler. There is no external prescaler for the filter cluster.

Each filter in the filter cluster uses a fixed range of addresses from 0x0000 to 0x003F. All filter registers (MCR, MSR, PRESR, RTHR, and FTHR) are placed in this range. The unused addresses in this range are reserved, thus if there is an access to these reserved addresses a transfer error occurs.

For Filters 1 to 31, which do not have an internal prescaler, the addresses for the PRESR register are reserved. For these filters, selection of the internal prescaler by setting MCR[PSSEL] = 0 selects the filter counter to the system clock rate as if the internal prescaler is programmed with zero.

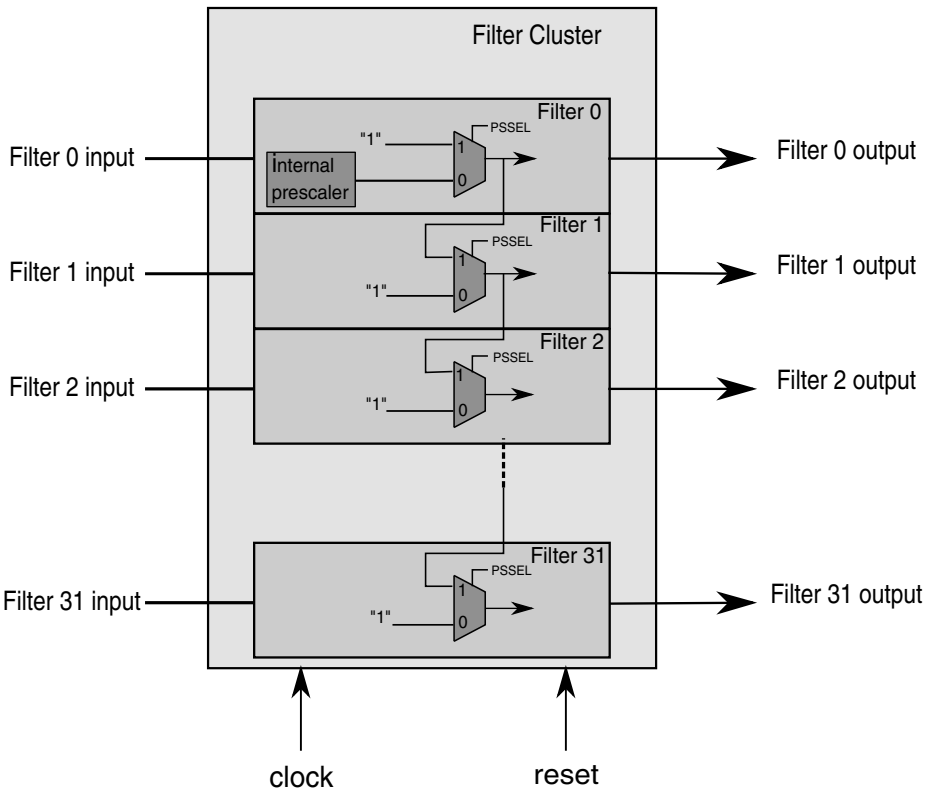

Figure 45-2. MPC5746R Input Glitch Filter Configuration

45.4 Block Diagram

The figure below is the block diagram for the Input Glitch Filter module.

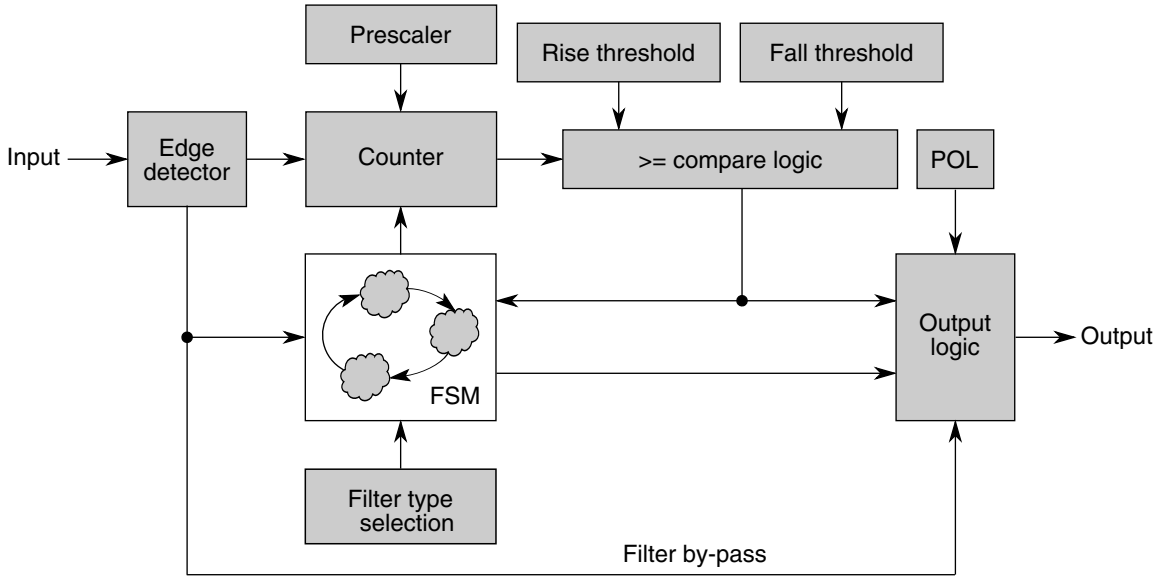

Figure 45-3. Input Glitch Filter block diagram

45.5 Input Glitch Filter overview

The Input Glitch Filter receives an input signal usually from a device PAD. Signals generated externally to the device are affected by environmental noise or glitches. The signal level has to be evaluated with some criteria in order to remove the noise which could affect the measurements done over this signal, such as transition time, period and level.

In a typical application, the Input Glitch Filter interfaces with one or more timer peripherals.

The strategy to remove glitches from an input signal is to monitor the level of the signal during a wide time window thus the glitches can be evaluated and removed.

The input signal should be stable for a certain amount of time before it can be used as a trigger or by a timer input channel. This strategy implies a delay on detecting a transition in the signal.

There is another strategy which is based on removing the glitches by introducing a blanking period after an edge is detected. In this strategy there is no delay from the edge detection in the input signal to the filtered signal, in the filter output. The strategy also allows input signals with different filter periods to be measured at the same time.

45.5.1 Interaction with other peripherals

The figure below shows an example of how the Input Glitch Filter interacts with on-chip peripherals.

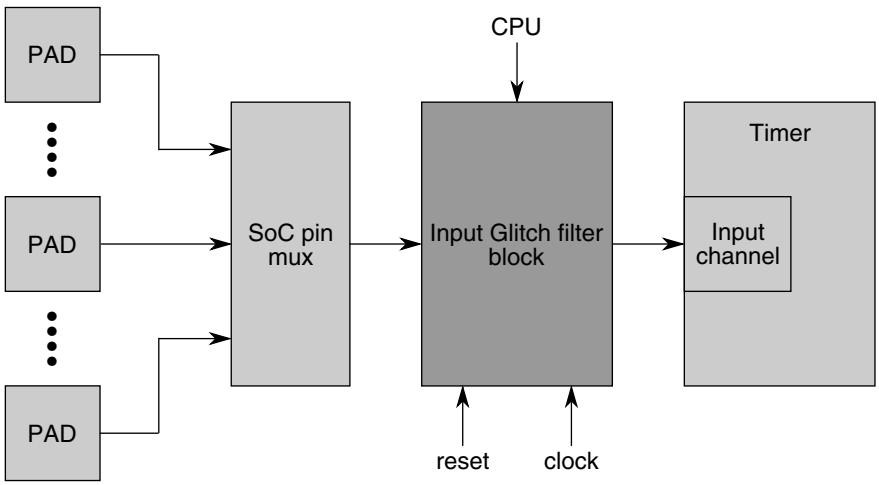

Figure 45-4. Input Glitch Filter application example

45.5.2 Mode of operation

The Input Glitch Filter has the following modes of operation:

- Configuration mode
- Normal mode
- Debug mode
- Low power mode

45.5.2.1 Configuration mode

The configuration mode is the initial mode of the Input Glitch filter after system reset is applied. The configuration mode is selected when FGEN = ‘0’ in the MCR register. The filter parameters such as rising and falling thresholds can be programmed when the filter is in configuration mode without disturbing the internal device logic since the filter output is kept at logic '0' state. Once FGEN is programmed with logic ‘1’ the filter enters the normal operating mode and is able to initiate the filtering process.

NOTE

The MDIS bit in the MCR register, if set to logic '1', makes the filter transition to low power mode independent of FGEN bit settings. Thus, in order to enter the configuration mode MDIS bit needs to be at logic '0'.

45.5.2.2 Normal mode

The normal mode of operation is entered when MCR register FGEN = ‘1’. In this mode the filter implements one of the filter types:

- Bypass filter
- Windowing filter
- Integrating filter
- Integrating-hold filter

These filter types are described in the following sections. Before entering the normal mode, the filter parameters, such as rise and fall thresholds, need to be programmed in the appropriate registers, as well as the type needs to be defined in the corresponding register.

NOTE

In the normal mode it is still possible to change the filter parameters, such as rise and fall thresholds. See section On-the-fly filter reconfiguration for more details.

45.5.2.3 Debug mode

The debug mode is entered when the MCR FRZ bit is set and a system level debug request occurs. Once the debug mode is entered, the internal filter counter is halted and the debug functions controlled by the FBP, FOH, and FOL bits are enabled. The filter output is frozen and remains at the state it was immediately before the debug mode was entered. The FOH and FOL MCR bits can be used to force the filter output to logic '1' or '0', respectively. These bits are self-negating, thus they always read as zero.

By setting the MCR FBP bit, the filter input state is copied to the filter output, thus allowing to control the filter output based on the filter input state. The output is forced during one clock cycle. After that the filter output remains at the new forced state until it is changed again by using a debug control bit or if the filter returns to the normal mode of operation.

NOTE

The system level debug request occurs when a specific event, or a series of events, occurs in one of the device sub-modules and is interpreted by the device debug logic as a debug request. The Input Glitch Filter is not capable of generating an event that causes the assertion of the system level debug request.

45.5.2.4 Low power mode

The low power mode is controlled by the MDIS bit in the MCR register or by the STOP signal which is the system level low power control signal. When entering low power mode the filter output remains unchanged at the state it was just before the low power mode was entered. Since the Input Glitch Filter clocks are stopped in this mode, the internal counter remains inactive. The description of this mode is covered in the Low Power Mode section of this document.

45.6 Memory map

The Input Glitch Filter registers are implemented in 32-bit. 8-bit write operations are allowed. The coherency in case of 8-bit access must be provided by the application software since there is no coherence mechanism built into the hardware.

NOTE

RESERVED bit registers, when available for write operations, should be written always with logic ‘0’. Read access does not return meaningful data from RESERVED bit registers.

45.6.1 Module Configuration Register (IGF_MCR*n*)

The Module Configuration register (MCR) provides access to low power, debug, and filter control bits.

Address: 0h base + 0h offset + (64d × i), where i=0d to 31d

IGF_MCR*n* field descriptions

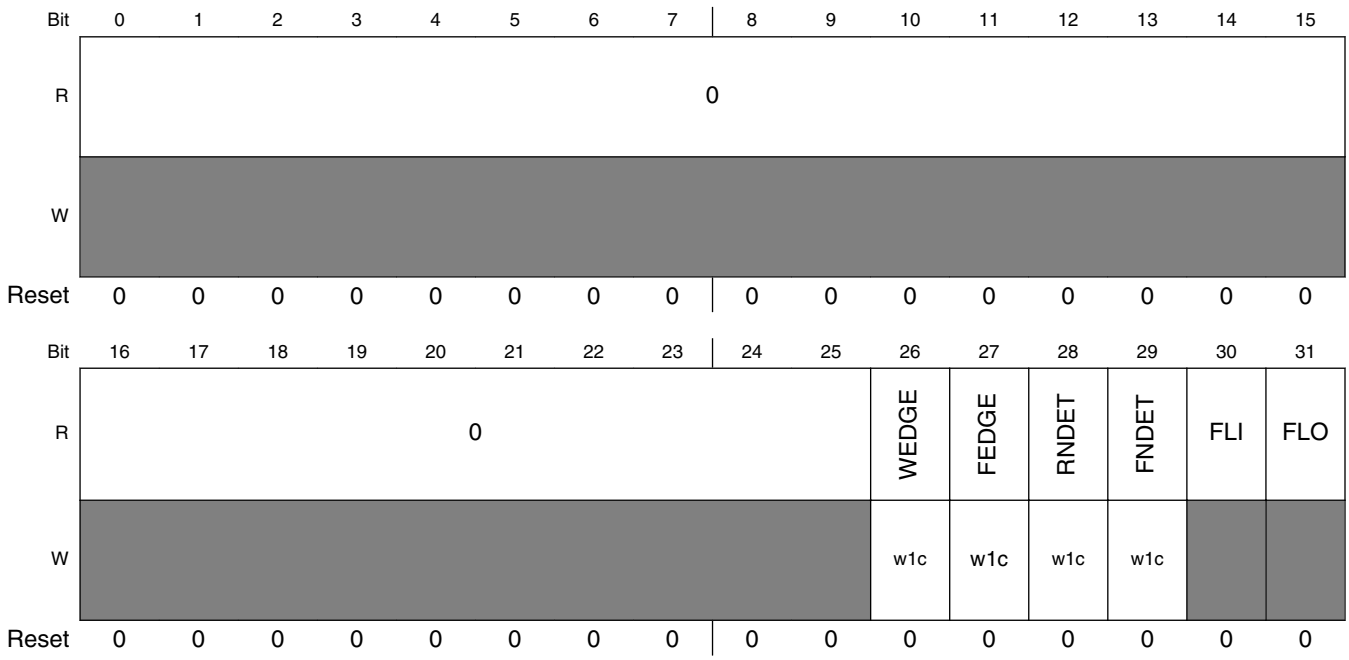
Field	Description
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 MDIS	Module Disable The MDIS bit forces the filter to enter a low power state. After this bit is asserted the clock for the module is removed thus filter operation is not possible. The access to filter registers is allowed. 0 Input Glitch Filter is not in low power mode due to MDIS bit 1 Input Glitch Filter is in low power mode
2 FRZ	Freeze bit for debug operation The FRZ bit enables the Input Glitch Filter to enter freeze mode (debug mode) when a system level signal request the module enters freeze (debug) mode. Once in freeze mode the filter operation is disabled meaning that transitions on the input signal will not propagate through the filter output. The bypass FBP bit can be used by the software to force the filter output to be the same as the filter input. In this mode FOH and FOL also can be used to define the filter output state.

Table continues on the next page...

IGF_MCR*n* field descriptions (continued)

Field	Description
	0 Freeze mode disabled 1 Freeze mode enabled
3 FBP	Force Bypass This bit is self-negated thus is only read as zero. Writing 1 to this bit while in freeze mode forces the filter to bypass the value in the input to the filter output, thus allowing a software control on the filter. This bit is functional only in freeze mode. 0 no filter bypass 1 transfer input signal value to the filter output
4 FOH	Force filter output high If set, this bit forces the Input Glitch Filter output to '1'. This bit is functional only in debug mode. It is self-negated thus always read as zero. 0 no action 1 forces the filter output to '1'
5 FOL	Force filter output low If set this bit forces the Input Glitch Filter output to '0'. This bit is functional only in debug mode. It is self-negated thus always read as zero. 0 no action 1 forces the filter output to '0'
6–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22 IMM	Immediate edge propagation control bit The IMM bit controls the propagation of an edge through the filter. If asserted, this bit defines that an edge at the filter input propagates through the filter output independent of the prescaler settings. In bypass mode the propagation delay is three system clock cycles. If negated, the signal propagation depends upon the prescaler settings. The filter hardware will only allow chages to this bit if the filter is disabled, FGEN = 0 0 edge propagation depends on prescaler 1 edge propagation within three system clock cycles
23 PSSEL	Prescaler selection bit The PSSEL selects if the prescaler used by the Input Glitch Filter is from internal source (internal prescaler counter) or from external source. The filter hardware will only allow changes to this bit if the filter is disabled, FGEN=0. 0 internal prescaler selected 1 external prescaler selected
24 POL	Output polarity bit This bit sets the polarity of the filter output to inverted or not inverted. The polarity control implemented by the POL bit is applied at the filter output stage thus also changing the reset state of the output, even if the filter is disabled by the FGEN bit. The filter hardware will only allow changes to this bit if the filter is disabled, FGEN=0.

Table continues on the next page...



IGF_MCR*n* field descriptions (continued)

Field	Description
	0 not inverted output 1 inverted output
25 FGEN	Filter global enable This control bit enables the filter operation, meaning that if the filter is enabled the filtering selected types are applied to the rising and falling edges of the input signal. If the filter is not enabled, then the filter output remains unchanged independent of the filter input signal. Note that the filter output state is affected by the POL bit when the filter is disabled. 0 filter is disabled: filter output keeps current state. 1 filter is enabled: filtering is applied to selected edges.
26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27–28 FFM	Falling edge filter type selection This bit field selects the filter type for the filter input signal falling edge. The filter hardware will only allow changes to this bit if the filter is disabled, FGEN=0. 00 bypass: edge is propagated to filter output without any filtering in three system clock cycles 01 windowing: windowing filter is selected for the falling edge 10 integrating: integrating filter is selected for the falling edge 11 integrating-hold: integrating-hold filter is selected for the falling edge
29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30–31 RFM	Rising edge filter type selection This bit field selects the filter type for the input signal rising edge. The filter hardware will only allow changes to this bit if the filter is disabled, FGEN=0. 00 bypass: edge is propagated to filter output without any filtering in three system clock cycles 01 windowing: windowing filter is selected for the rising edge 10 integrating: integrating filter is selected for the rising edge 11 integrating-hold: integrating-hold filter is selected for the rising edge

45.6.2 Module Status Register (IGF_MSR*n*)

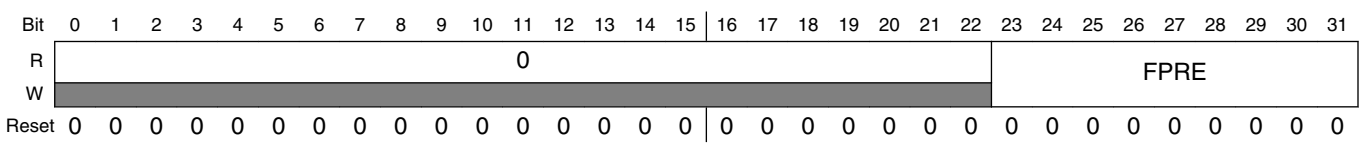
The Module status register (MSR) provides access to filter status bits and corresponding clear bits as well as access to the state of filter input and output signals.

Address: 0h base + 4h offset + (64d × i), where i=0d to 31d

IGF_MSR*n* field descriptions

Field	Description
0–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26 WEDGE	Filter is active waiting for an edge This bit is set when the filter is enabled but the internal counter is not active. It indicates that the filter is waiting for an edge to occur at the filter input. It is set by the Input Glitch Filter hardware and cleared by the software by writing 1 to the bit. Since the intention of this bit is to capture the dynamic of the filter hardware, it should be cleared after the read thus being able to capture a new event. 0 Input Glitch Filter is disabled or the internal counter is active 1 Input Glitch Filter is waiting for an edge
27 FEDGE	Filter is active processing an edge This bit is set during the filter active state thus when the filter internal counter is counting, processing an edge in a filtering mode. It is cleared by the software by writing 1 to the bit. Since the intention of this bit is to capture the dynamic of the filter hardware, it should be cleared after the read thus being able to capture a new event. 0 Input Glitch Filter internal counter is not active 1 Input Glitch Filter internal counter is active

Table continues on the next page...



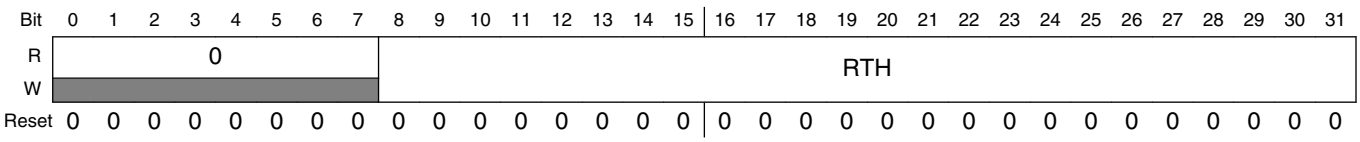
IGF_MSR*n* field descriptions (continued)

Field	Description
28 RNDET	Rise noise detected bit This bit indicates that the filter filtered out noise in the input signal after a rising edge was detected. The criteria to set this bit is when a rising edge is detected thus starting the filter counter and before this edge pass through the filter (if filter is in integrating filter types) or during a window (if filter is in windowing filter types) another edge occurs in the input signal. This bit is set by a noise detection and cleared by the software by writing 1 to this bit. 0 noise was not detected 1 noise was detected after a rising edge
29 FNDET	Fall noise detected bit This bit indicates that the filter filtered out noise in the input signal after a falling edge was detected. The criteria to set this bit is when a falling edge is detected, thus starting the filter counter, and, if the filter is in integrating types, before this edge passes through the filter, or, in windowing types, when another edge occurs in the input signal during a window. This bit is set by a noise detection and cleared by the software by writing 1 to this bit. 0 noise was not detected 1 noise was detected after a falling edge
30 FLI	Filter input The FLI bit follows the state of the filter input value as captured by the filter input logic, which is affected by the IMM bit and prescaler settings.
31 FLO	Filter output The FLO bit follows the state of the filter output value considering the POL bit state.

45.6.3 Prescaler Register (IGF_PRESR*n*)

The prescaler register (PRESR) provides access to the prescaler bits.

Address: 0h base + 10h offset + (64d × i), where i=0d to 0d



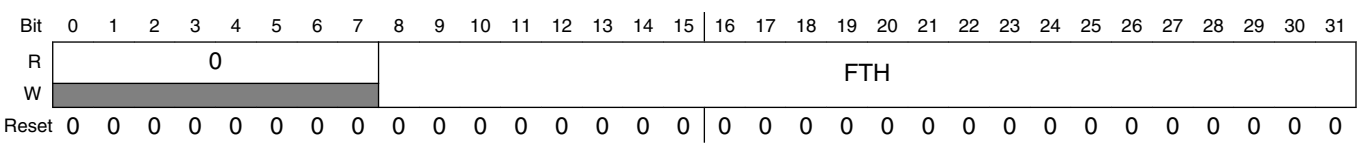
IGF_PRESR*n* field descriptions

Field	Description
0–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23–31 FPRE	Filter prescaler The prescaler defines the rate of the filter counter FCOUNT. The filter counter clock rate is defined by the formula: Filter counter clock = module clock / (FPRE + 1).

45.6.4 Rising edge Threshold Register (IGF_RTHR*n*)

The Rising edge Threshold register (RTHR) provides access to the rising edge threshold bits.

Address: 0h base + 1Ch offset + (64d × i), where i=0d to 31d



IGF_RTHR*n* field descriptions

Field	Description
0–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8–31 RTH	Rising edge threshold This bit field defines the filter counter threshold when a rising edge occurs is being filtered.

45.6.5 Falling edge Threshold Register (IGF_FTHR*n*)

The Falling edge Threshold register (FTHR) provides access to the falling edge threshold bits.

Address: 0h base + 20h offset + (64d × i), where i=0d to 31d

IGF_FTHR*n* field descriptions

Field	Description
0–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8–31 FTH	Falling edge threshold This bit field defines the filter counter threshold when a falling edge is being filtered.

45.7 Functional description

The following sections describe the Input Glitch Filter module functionality.

45.7.1 Input double sampling

The filter input is double sampled for clock domain translation thus avoiding asynchronous signals to propagate through the filter internal logic. This stage is composed by two flip-flops connected back to back. The delay caused by this logic is therefore two clock cycles.

Note that due to the synchronous nature of the Input Glitch Filter design, if a glitch smaller than one clock cycle occurs at the filter input it will not propagate to the filter internal logic and thus will not propagate to the filter output. Also, if clock is not applied to the filter (i.e. in low power mode) any transition at the filter input will not propagate to the filter output.

45.7.2 Filter types

The Input Glitch Filter implements three main filter types:

- Windowing
- Integrating
- Integrating hold

These filter types can be selected for the rising and falling edges independently, thus allowing different filter types to be selected for different edges (i.e. rising edge filtered with windowing filter and falling edge filtered with integrating).

45.7.2.1 Windowing filter

This filter type detects an edge (positive or negative edge) at the filter input and then mask out detection of subsequent edges over a period of time, which is defined as the blanking period, thus effectively behaving as a high pass filter. After an edge is detected the level at the filter input is propagated to the filter output within three clock cycles. The delay is caused by the synchronization stage at the input and by the filter output register stage. During the blanking period any transition at the filter input is disregarded. After the blanking period has elapsed, the filter compares the input level state with the filter output state. In case they are different a transition is inferred and re-evaluate according to the filter type assigned to that transition (positive or negative edges). Since, in this example, the windowing filter type is programed for both edges, the inferred negative edge is propagated to the filter output and another blanking period is initiated. The figure below describes the windowing filter type behavior.

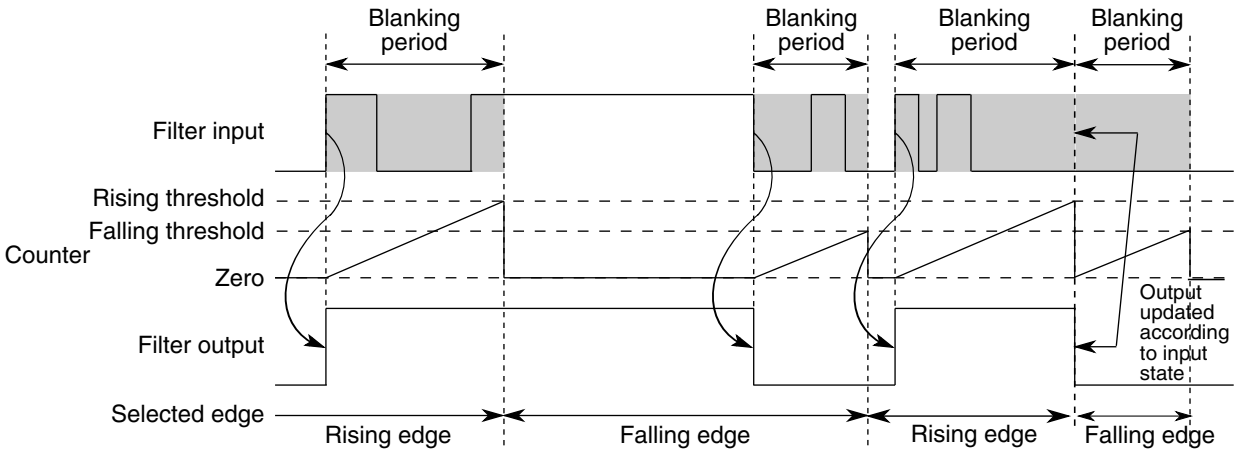


Figure 45-139. Windowing filter type

45.7.2.2 Integrating filter

The integrating filter behaves like a low-pass filter, thus removing high frequency bursts from the input signal. The input and output signals are compared and if they are at different states an internal filter counter is enabled.

The direction of the counter (up or down counting) is defined by the states of the input and output filter signals as follows:

- Filter output is at the same state as the filter input: down-counting
- Filter output is at different state as the filter input: up-counting

The counter is compared with the rising or falling threshold register according to:

- Rising threshold register is selected if the rising edge is being filtered.
- Falling threshold register is selected if the falling edge is being filtered.

The filter output changes state to the same state as the filter input:

- If filter counter reaches the selected threshold for the edge being filtered.

The internal counter is disabled and cleared:

- If filter counter reaches the selected threshold for the edge being filtered.

The figure below describes an example of the Integrating filter type operation.

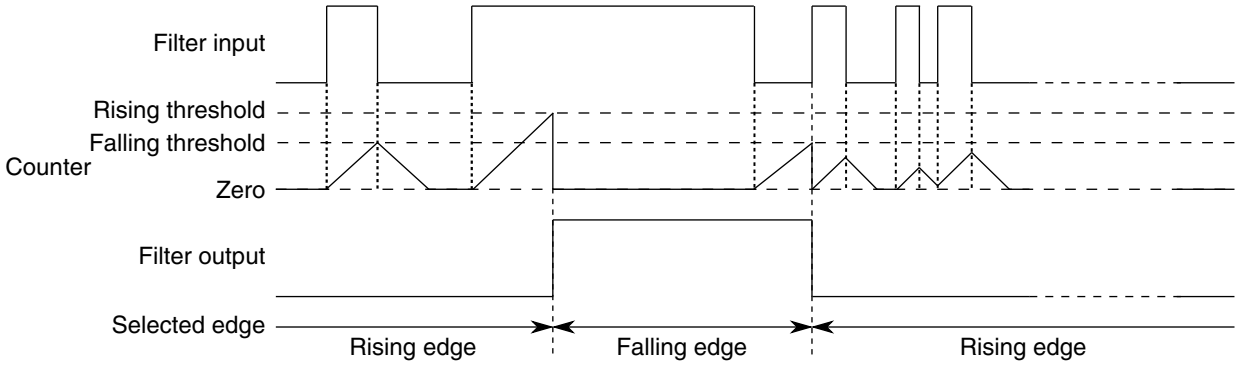

Figure 45-140. Integrating filter type

45.7.2.3 Integrating-hold filter

The integrating-hold filter type is similar to the integrating filter. The difference is the counter, which only counts in up direction instead of up-down in the integrating mode. In this filter configuration the input and output signals are compared and if they are at different states the filter counter is enabled. This counter is controlled by the state of the filter input and filter output signals as follows:

- Filter output is at the same state as the filter input: counter is in hold state (no-counting).
- Filter output is at different state as the filter input: counter is counting up.

The counter is compared with the rising or falling threshold register according to:

- Rising threshold register is selected if the rising edge is being filtered.
- Falling threshold register is selected if the falling edge is being filtered.

The filter output changes state to the same state as the filter input:

- If the filter counter reaches the selected threshold for the edge being filtered.

The internal counter is disabled and cleared:

- If the filter counter reaches the selected threshold for the edge being filtered.

The figure below shows an example of the Integrating-hold filter type operation.

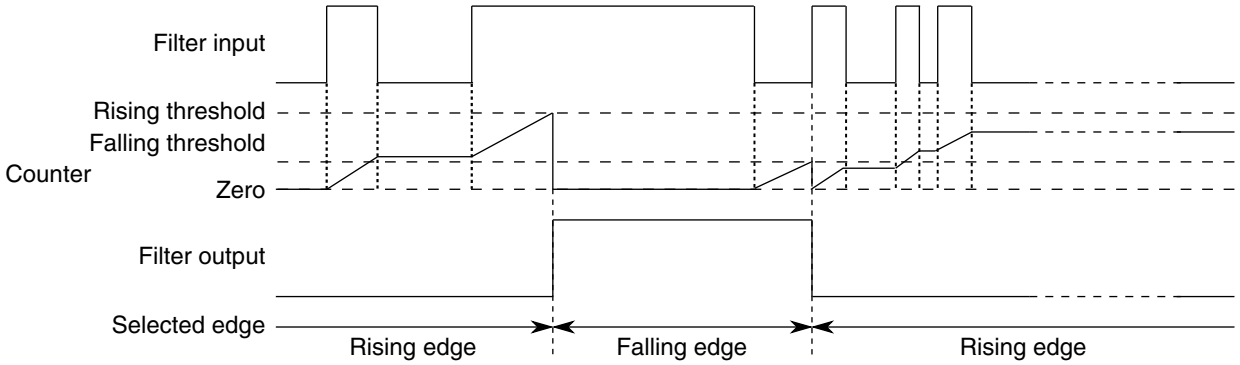

Figure 45-141. Integrating-hold filter type

45.7.2.4 Bypass filter

In the bypass filter type, the Input Glitch Filter immediately propagates any transition on the filter input to the filter output. This filter type does not provide any protection against glitches in the input signal. It is intended to be used in situations where the input signal is already filtered, or it is a glitch free signal, or the filter output is connected to a module that already has filtering capabilities. The bypass filter type is independently selected for rising or falling edges. Thus rising edges may be not filtered by the bypass filter type while the falling edges are filtered by any of the available filter types.

The bypass filter presents a delay in the edge propagation through the filter that is caused by the double sampling at the filter input and by the output filter register. Therefore, the total delay is three clock cycles.

45.7.2.5 Combined filter

The Input Glitch Filter allows the combination of filter types for different edges, positive and negative. As an example, the rising edges may be filtered using the windowing filter while the falling edges are filtered with an integrating filter. This configuration of the Input Glitch Filter is provided for situations where the noise present in the rising edges is different from the noise in the falling edges. Another use case is when the delay requirements of the input signal is different for rising and falling edges.

The figure below shows the combined filter operation. The windowing filter type is applied to the rising edges. The integrating filter is used for the falling edges.

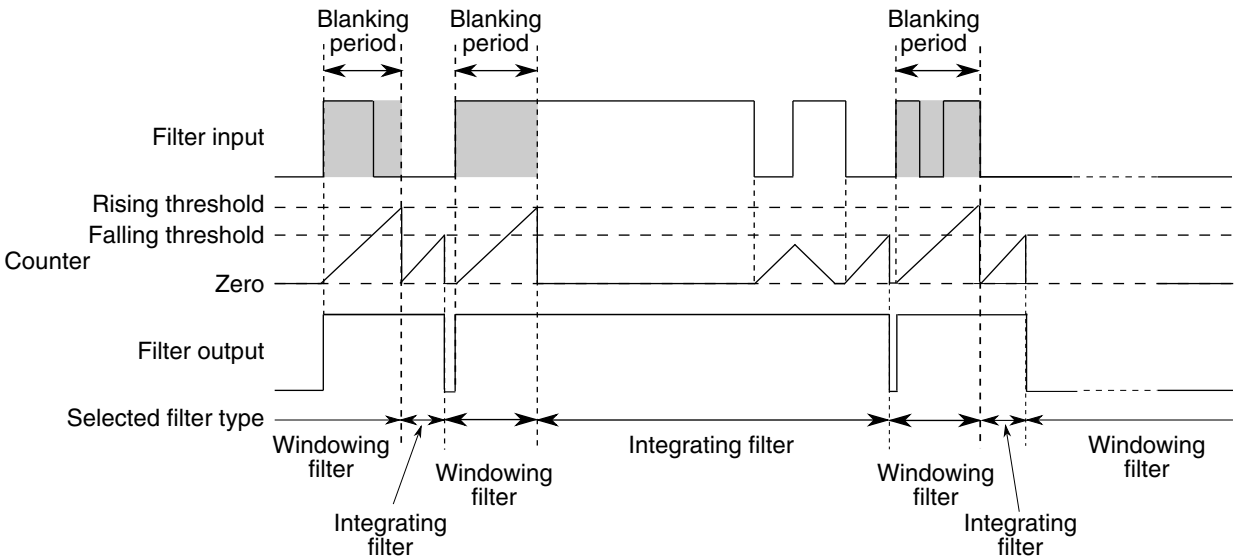

Figure 45-142. Combined filter type (windowing + integrating)

45.7.3 Application

This section describes several applications for the Input Glitch filter module.

45.7.3.1 Application use case 1: integrating filter

The integrating filter type is particularly useful in applications where glitches occur spuriously while the signal is expected to be in a steady state (either 1 or 0). Choosing correct up and down filter clock rates can ensure that the effects of spurious glitches can be completely eliminated, whilst minimizing propagation delays.

The application must be able to tolerate delays between the actual edge occurrence and the time that the signal is propagated through the filter logic. Because the delays are constants defined by the detection thresholds, application software may compensate for them, provided little or no noise occurs on the detected edge.

45.7.3.2 Application use case 2: windowing filter

The windowing filter type is particularly useful for removing noise bounce produced by a switch or sensor when its signal changes state. In this case, there is no propagation delay (except for the filter input synchronization logic and output register) between the filter input and filter output signals. This type of filter would not necessarily provide much immunity to spurious noise that occurred during the steady state portion of the signal. In

order to optimize the characteristics of this filter, the blanking period should be of the same magnitude as the expected input signal rate. Signals that change frequency can be accommodated by software by dynamically updating the blanking period.

45.7.3.3 Application use case 3: windowing filter

Safety applications may need to compare the inputs obtained from different input pins, but derived from a single external source. This form of redundancy may detect non-common mode faults that may occur in the portions of the SoC that route and process the incoming signal. Having two different instances of windowing filter used on each input pin will ensure that the signal edge timing for both input paths is equal. Applying different filter characteristics for each input path can enhance the ability to detect SoC fault conditions.

45.7.3.4 Application use case 4: combined filter

Some applications may have rising edge signals that exhibit different characteristics to falling edge signals which might require different filtering to optimize the filtering effect. For example the “first” rising edge may represent a true real time event with a fast slew rate that must be captured without delay, while the falling edge signal may have a slow slew rate with many noisy transitions. The Input Glitch Filter can apply, for example, a windowing filter on the rising edge to ensure no loss of real time information and an integrating filter on the falling edge to eliminate noise from being detected as a new rising transition.

45.7.3.5 Application use case 5: prescaler settings in windowing filter

The prescaler settings influence the timing for an edge to propagate through the filter. In windowing filter the IMM bit in the MCR register controls the way an edge is propagated through the filter. The figure below describes the windowing filter operation with regard to the IMM bit settings.

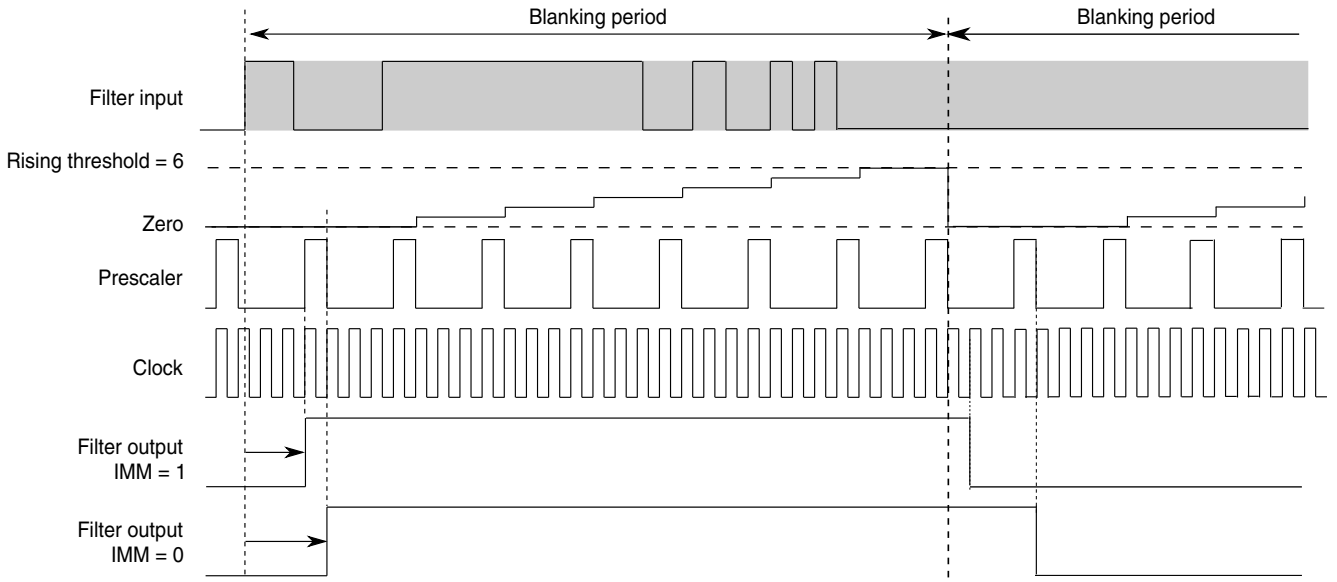

Figure 45-143. Input signal propagation through the filter in windowing filter type

If IMM = 0 then the input signal edges are propagated according to the prescaler ticks. If IMM = 1 then the input edges are propagated immediately (within 3 clock cycles) to the filter output.

45.7.3.6 Application use case 6: prescaler settings in bypass

The prescaler settings influence the timing for an input signal edge to propagate through the filter. In bypass, the IMM bit in the MCR register controls the way an edge is propagated through the filter. If IMM= 0, the prescaled clock is used to sample the input filter signal. The resolution the input signal is sampled is therefore related to the prescaler frequency. Glitches narrower than the prescaler period that are not aligned with the prescaler clock are not captured by the filter. If IMM = 1, the system clock is used to sample the filter input signal instead of the prescaled clock. In this case, the resolution of the sampled input signal is the system clock.

The figure below describes the filter input signal sampling behavior for IMM = 0 and IMM = 1.

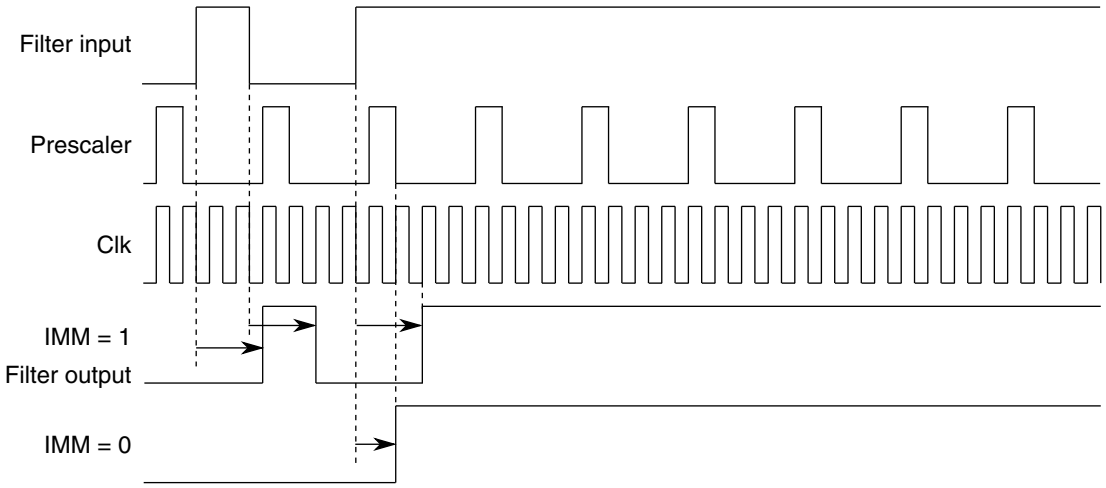

Figure 45-144. Input signal propagation through the filter in bypass

45.7.4 Programming guidelines

The following generalized procedure may be used to configure the Input Glitch Filter Block:

1. Program the SoC pin mux logic to route an external signal to the input of the selected glitch filter.
2. Enable the destination module to receive the Input Glitch filter output.
3. Enable the clock source at the SoC level.
4. Program the Glitch Filter counter prescaler(s) to the desired rate.
5. Select the filter type for each edge using MCR[FFM] and MCR[RFM].
6. Clear any status bits if necessary.
7. Enable the filter using MCR[FGEN]

45.7.5 On-the-fly filter reconfiguration

The architecture of the Input Glitch Filter allows for on the fly reconfiguration of filter parameters such as rise and fall threshold values.

If a parameter is changed it influences the filter operation immediately after the new parameter value was written. The main problem when changing parameters, such as a threshold value, when the filter is enabled is that the filter counter could lose a match due to the parameter change. A great or equal comparator is used in the threshold match logic which allows correct filter operation when the threshold parameters are changed. The figure below shows an example of changing the rising edge parameter value. Note that in this case the match occurs immediately after the parameter is changed since the new parameter value is below the current counter value.

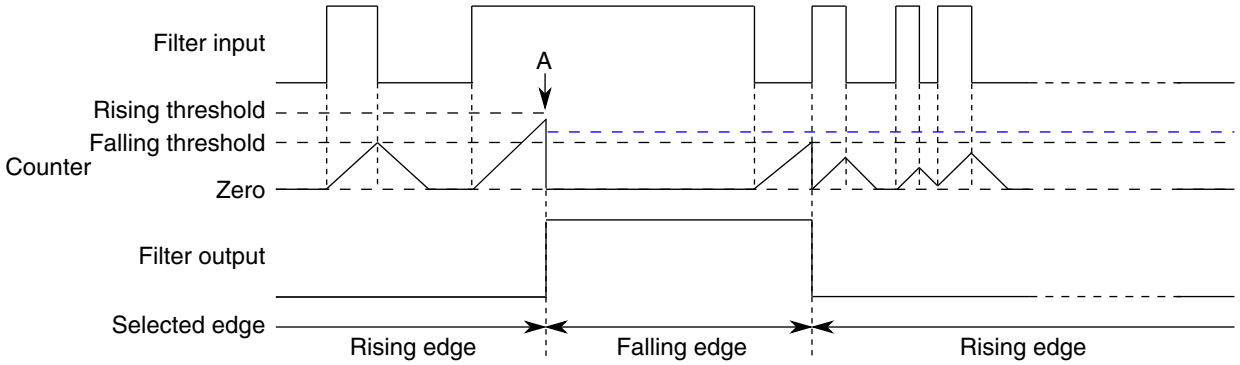

Figure 45-145. On-the-fly rising threshold parameter change

In the case shown in the figure above the match occurs immediately after the new rising threshold is programmed at ‘A’.

NOTE

Note that when changing the threshold values the match may not occur when the counter is equal to the threshold value (the old or the new programmed value). Instead, the match may occur in between the old and new programmed thresholds when the threshold re-programming instant A is done when the counter is greater than the new value. This is a transitory effect which may occur when the threshold value is changed and should be considered by the application.

45.8 Power saving mode

The Input Glitch Filter implements power saving mode thus allowing to reduce power consumption when device inputs connected to the filter are not used or the filter is not necessary to be functioning in a specific SoC mode of operation.

45.8.1 STOP mode

There are two ways for the Input Glitch filter to enter low power mode:

- MDIS bit
- STOP mode system request

The MDIS control bit in the MCR register, when set, disables the filter logic by stopping the module clock signals and thus halting the internal filter counter which reduces the dynamic power consumption of the module. The MDIS bit provides a selective control of the low power operation of each one of the Input Glitch Filter instances in the device.

The STOP mode system request is similar to MDIS operation with exception that it applies to all Input Glitch Filter instances in the device. It does not need to be enabled by any control bit in the Input Glitch filter module. The low power mode in this case is controlled by the assertion of the STOP signal which is a system wide low power control signal.

Chapter 46
Body Cross-triggering Unit (BCTU)

46.1 Body Cross-triggering Unit (BCTU) chip-specific module information

46.1.1 Overview

The BCTU interfaces between the eTPU, eMIOS, PIT, Reaction Module, and the SAR ADCs on the device. This BCTU is a collection of Event Configuration Registers that convert the events generated by the timer sources and pin events and trigger ADC conversion requests. The main enhancement is the increased number of trigger sources and the inclusion of a list to allow multiple ADC conversions from a single trigger.

The BCTU connects to the injection trigger inputs of the SAR ADCs. The input trigger sources to the BCTU are from the ETPU, EMIOS, PIT, and external pins and are defined in the table below. The trigger sources are connected directly to the BCTU, and there is no second level of multiplexing.

All SAR ADCs on the device connect to the BCTU, and the functionality for each SAR is orthogonal.

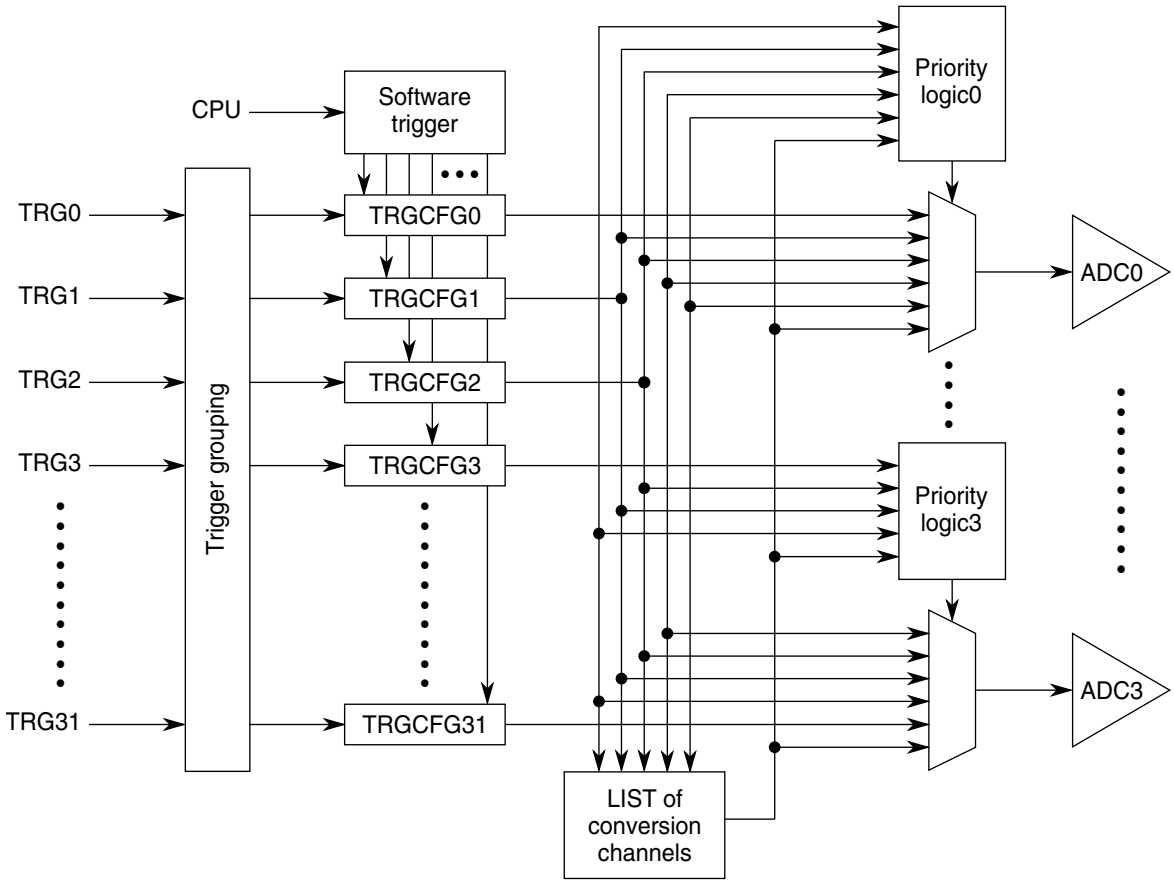
1. Package pins mentioned in above table have a safe state 1. So triggers get latched as soon ipg_clk starts coming to BCTU. These triggers will need to be cleared and pads will have to driven zero before configuring BCTU."
2. These pads have a high state 1. So triggers get latched as soon ipg_clk starts coming to BCTU. These triggers will need to be cleared and pads will have to driven zero before configuring BCTU.

The following figure shows how the BCTU is connected to other modules.

Figure 46-1. BCTU block diagram



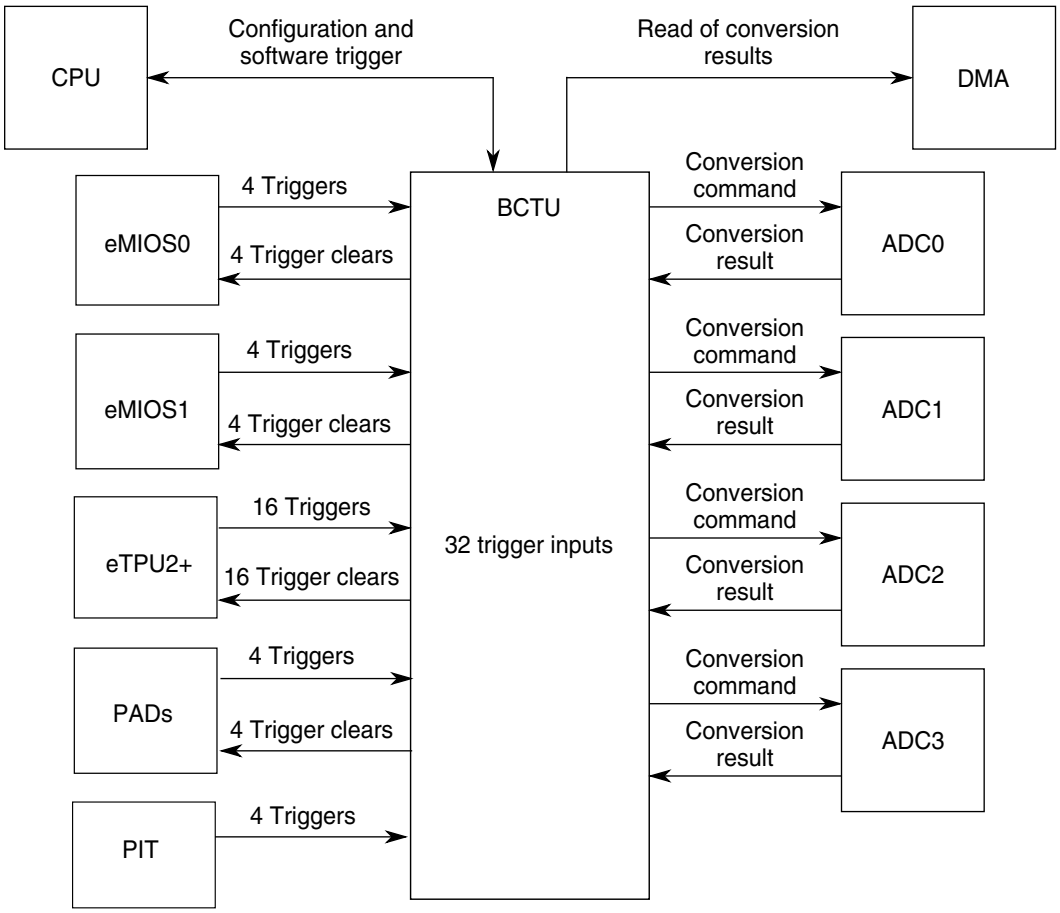


Figure 46-2. BCTU connections to other on chip modules

The following figures show the priority stages architecture using 32 trigger inputs.

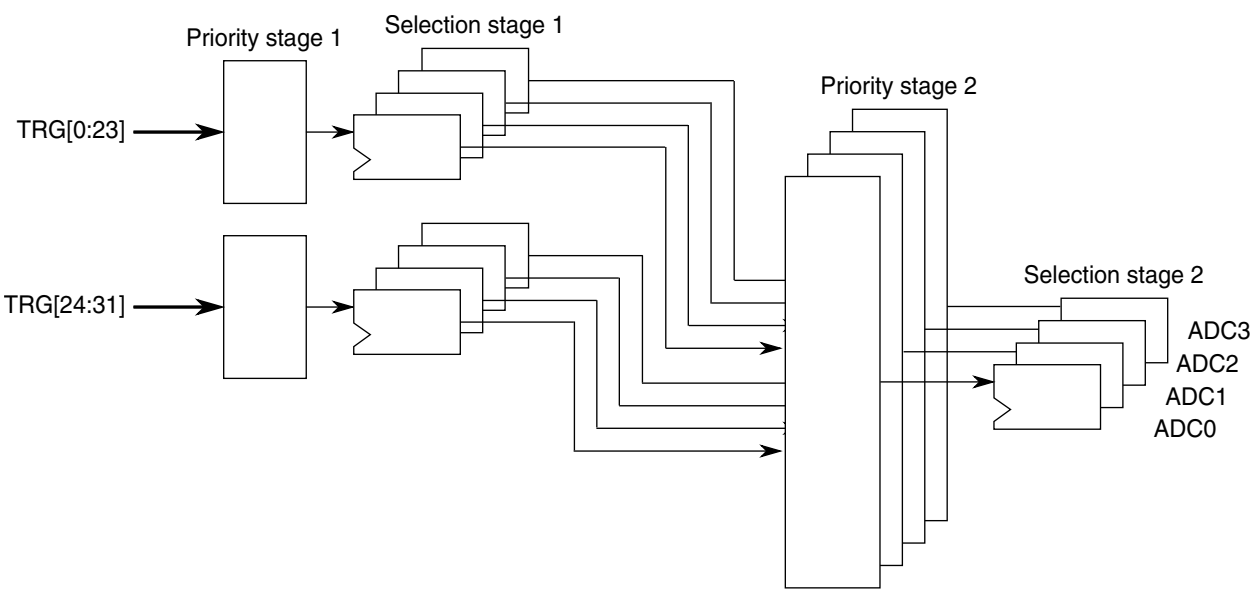

Figure 46-3. Priority stages architecture

46.1.2 Functional Description Summary

The enhanced BCTU allows synchronization between an ADC conversion and a timer event. Channels from the eMIOS modules, eTPU and PIT channels and package pins can be used to trigger an ADC conversion.

While the eTPU is triggered by channel output, BCTU is triggered by the eMIOS flag (eMIOS_Sn[FLAG]) rather than the channel output. The eMIOS flag can be cleared by a BCTU clear signal only if eMIOS_Cn[FEN] is not set.

46.2 Introduction

The Body Cross-triggering Unit (BCTU) is a module that is used to trigger the on chip ADCs. The trigger sources are generated by on chip timer modules. Usually in Body domain of applications the timers used are the enhanced Modular IO Sub-system (eMIOS), enhanced Time Processing Unit (ETPU), and the Programmable Interrupt Timer (PIT). In addition to triggering ADC single conversions, the BCTU also implements a LIST—a set of registers programmed by software that stores ADC channel numbers—that triggers several conversions based on a single trigger occurrence. The BCTU has 32 trigger inputs. The CPU can also be a source of conversion triggers, thus implementing a software trigger control. Up to 4 ADC modules are supported. The conversion results are stored in a register which is available for CPU read access. Figure below shows the BCTU top level diagram.

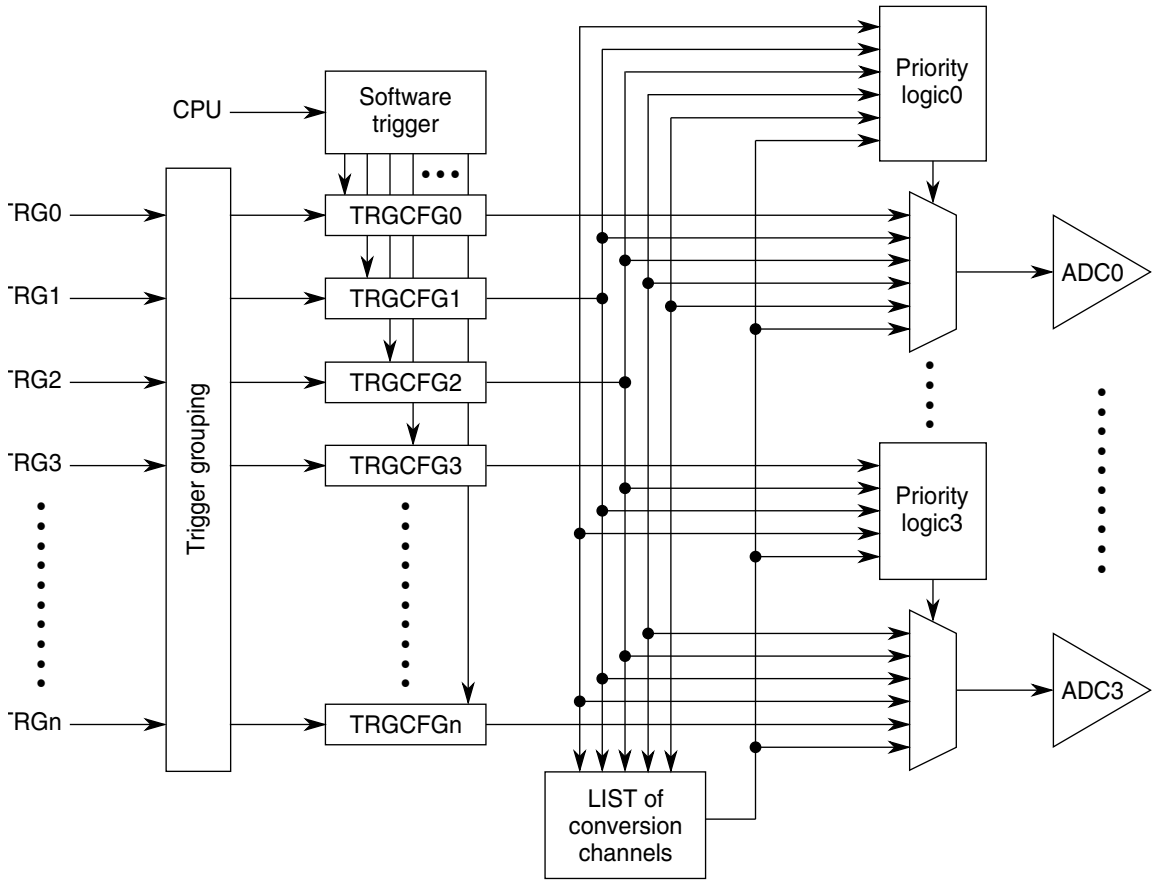

Figure 46-4. BCTU block diagram

46.3 BCTU overview

The BCTU receives several triggers from on chip timers and a software trigger controlled by the host CPU. These signals are used in order to generate the ADC trigger signals for up to 4 ADC modules. One trigger input selects one trigger configuration register. The trigger configuration register has the information about the target ADC and channel for the conversion. Alternatively a list of ADC channels can be associated with a trigger configuration register. In this case the target ADC converts a sequence of channels which are stored in the LIST.

The BCTU inputs are up to 32 trigger signals, which are level-sensitive; thus, if a logical level 1 is detected, an event is captured by the BCTU.

The figure above shows a high level BCTU block diagram. The BCTU hardware architecture consists of:

- Up to 32 conversion configuration registers TRGCFG
- One priority selection logic per ADC

- Up to 4 selection multiplexers to select one trigger at a time for each ADC
- A LIST of ADC channels

The priority logic is responsible for selecting among all active trigger inputs the one which is used to trigger an ADC conversion. The basic operation of the priority logic is to select the smallest trigger number as the higher priority. Thus if TRG[0] and TRG[1] are active TRG[0] is selected first and then TRG[1]. This priority scheme is used only if TRG[0] and TRG[1] target the same ADC. If a different ADC is selected by each trigger then there is no conflict and both triggers are selected at the same time. In addition to the trigger priority scheme the BCTU provides a LIST of channels that are used in a sequence of conversions. The LIST is a set of registers programmed by the software that stores ADC Channel numbers. The LIST also stores information of the last conversion to be executed in a sequence of conversions. A regular single conversion or a LIST of conversions are configured in the Trigger Configuration register. Since the ADC is selected by the ADC_SEL bit in the TRGCFG register for one single or a list of conversions, the LIST does not store the target ADC selection, thus all channels in the LIST refers to the ADCs specified in the TRGCFG register.

NOTE

Differently from the single command, the LIST can execute conversions on more than one ADC. Up to four ADCs can be addressed in a LIST.

46.4 BCTU Interacting with other peripherals

Figure below shows an example of how the BCTU interacts with on chip peripherals.

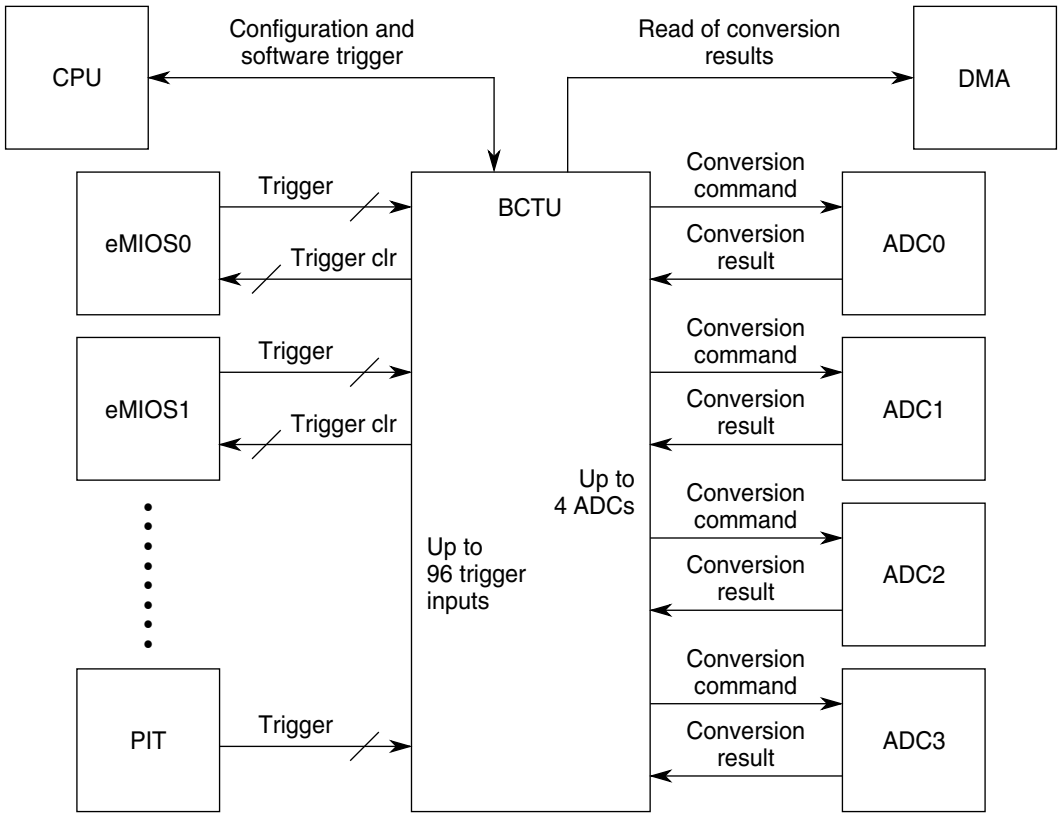

Figure 46-5. BCTU connections to other on chip modules

The timers (i.e. eMIOS, eTPU and PIT) generate triggers which are asserted at a specific time when the ADC conversion should be done. The transition, from zero to one, of these signals is captured by the BCTU logic and stored until the corresponding ADC conversion starts. At this time the BCTU asserts a trigger clear signal which clears both this internal captured trigger signal and the external trigger source if they are still asserted.

NOTE

Since the timer trigger may remain active until the corresponding conversion has initiated, there could be a case where another match occurs in the timer (i.e. eMIOS or PIT). The detection of that condition is not done by the BCTU logic. It is up to the application software to evaluate such a trigger overrun.

46.5 BCTU Modes of operation

The BCTU has following modes of operation, which are described below.

- Configuration mode

- Normal mode
- Low power mode

46.5.1 Configuration Mode

In the configuration mode the BCTU does not issue triggers to the ADCs connected to it. This mode allows for the software to program the TRGCFG registers, freely, without generating any spurious trigger to the ADCs. All trigger inputs are disabled. The exit from the configuration mode is made by setting the global enable bit GTRGEN in the MCR register. This procedure allows to enable all trigger inputs, which are already individually enabled by the TRIGEN bit in the TRGCFG register, with a single software access.

NOTE

In order to reinitialize the trigger input interface registers, the application software should clear all triggers by writing 1 to the TRG_FLAG bit in all TRGCFG registers before asserting the GTRGEN bit . This procedure clears the BCTU trigger input registers as well as the trigger sources that are connected to BCTU trigger clear signals (i.e. eMIOS).

46.5.2 Normal Mode

In the normal mode of operation the BCTU generates triggers for the ADCs based on trigger inputs from the on-chip timer modules. Due to backward compatibility reasons this is the mode selected coming out of reset.

46.5.3 Low Power Mode

The low power mode is entered when the MDIS bit in the MCR register is set. In this mode the BCTU is disabled, meaning that all trigger inputs are disregarded.

No triggers are issued to the ADCs connected to it. If MDIS is set any on going conversion is finished before the low power mode is entered. The TRG and NDATAx flags are not set when the module enters in low power mode.

If there are pending active triggers, they remain active (no trigger clear signal is issued). In this case it is up for the application software to clear the pending triggers, if required.

In the low power mode, the clocks for the BCTU module may be stopped, thus allowing to reduce the dynamic power consumption of the module. The exit from low power mode is made by clearing the MDIS bit in the MCR register. The module becomes immediately active after the MDIS bit is cleared, meaning that if the GTRGEN bit is set any active trigger input is processed and the corresponding ADC is triggered in order to execute a new conversion. In low power mode the ADCDRx registers are available for software read operation.

46.6 Memory Map

BCTU registers are implemented in 32-bit. 8-bit write operations are allowed. The coherency in this case must be provided by the application software since there is no coherence mechanism built into the BCTU hardware.

NOTE

RESERVED bit registers, when available for write operations, should be written always with logic ‘0’. Read access does not return meaningful data from RESERVED bit registers.

NOTE

Registers with write protection, if protection mechanism is active and an attempt for writing to those registers is done, will not cause any change to the register content and a transfer error will be issued.

46.6.1 Module Configuration Register (BCTU_MCR)

The Module Configuration register (MCR) provides access to low power, debug, trigger control, DMA control and Interrupt control bits.

Access: User read/write

Address: 0h base + 0h offset = 0h

BCTU_MCR field descriptions

Field	Description
0 Reserved	This field is reserved.
1 MDIS	Module Disable 0 Module is in normal mode. 1 Module is in low power mode.
2 FRZ	Freeze mode - for debug operation. The freeze mode disables all trigger inputs from timers but leave the software trigger enabled, thus allowing the software to trigger a conversion and read the conversion result.
3–4 Reserved	This field is reserved.
5 GTRGEN	Global Trigger Enable. Enables all trigger inputs at the same time. The individual trigger enable must be set in order for that trigger to become active.
6–11 Reserved	This field is reserved.
12 DMA3	ADC3DR data transferring by DMA. Enables DMA operation on transferring ADC3DR data when there is new data available in this register. 0 Disable DMA operation. 1 Enable DMA operation.

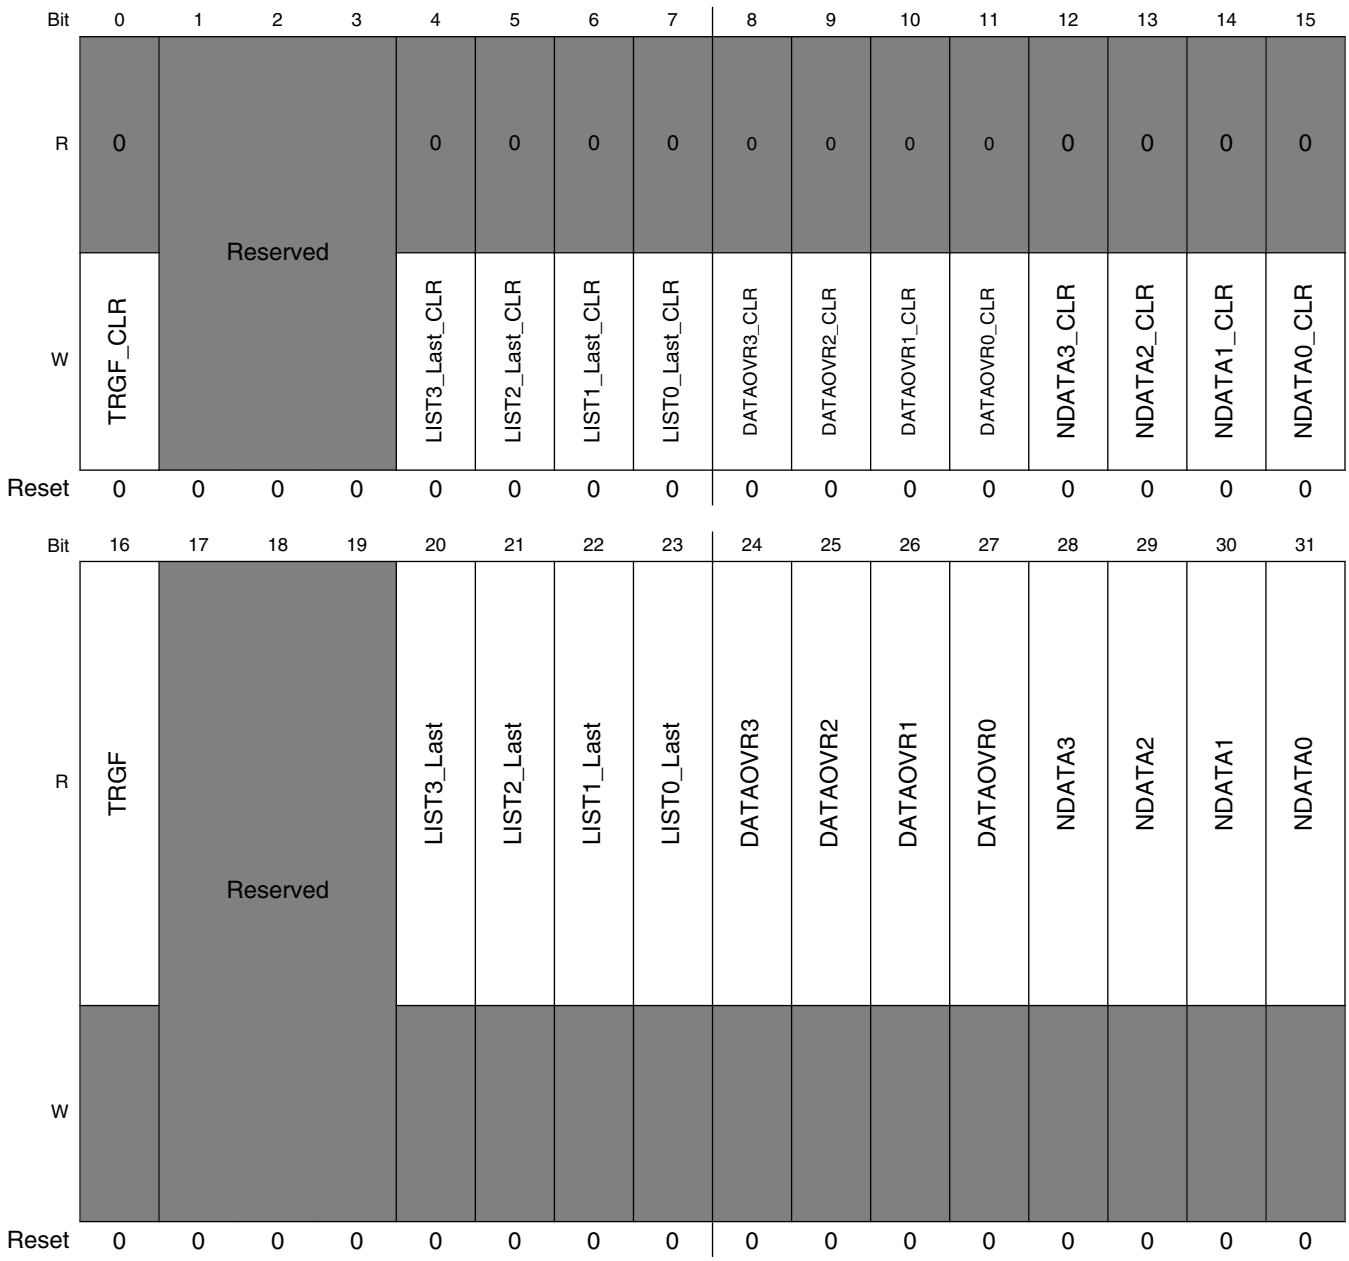
Table continues on the next page...

BCTU_MCR field descriptions (continued)

Field	Description
13 DMA2	ADC2DR data transferring by DMA. Enables DMA operation on transferring ADC2DR data when there is new data available in this register. 0 Disable DMA operation. 1 Enable DMA operation.
14 DMA1	ADC1DR data transferring by DMA. Enables DMA operation on transferring ADC1DR data when there is new data available in this register. 0 Disable DMA operation. 1 Enable DMA operation.
15 DMA0	ADC0DR data transferring by DMA. Enables DMA operation on transferring ADC0DR data when there is new data available in this register. 0 Disable DMA operation. 1 Enable DMA operation.
16–23 Reserved	This field is reserved.
24 TRGEN	Trigger interrupt request enable. Enables TRGF flag set in MSR register to generate interrupt request 0 Trigger interrupt request disabled. 1 Trigger interrupt request enabled. A request is generated if the TRGF flag bit in MSR register is set.
25 Reserved	This field is reserved.
26 LIST_IEN	LIST interrupt enable. If a LIST last conversion is executed an interrupt request is issued to the CPU if LIST_IEN is set. For the interrupt to occur the LIST and LAST flags must be set. 0 No interrupt request. 1 Interrupt request.
27 Reserved	This field is reserved.
28 IEN3	Interrupt enable bit for ADC3DR new data. This bit enables an interrupt request if the ADC3DR register is written by the hardware, meaning that there is new conversion data available. It also enables an interrupt request to be issued if there is an overrun in the ADC3DR register, meaning that the previous data in this register was overwritten by a new data. See also NDATA3 and DATAOVR3 in the MSR register. If DMA3 bit is set the interrupt for ADC3DR new data is disabled but the interrupt for ADC3DR data overrun remains enabled. In this case if an overrun condition occurs an interrupt request is generated. 0 Disable interrupt request. 1 Enable interrupt request.
29 IEN2	Interrupt enable bit for ADC2DR new data. This bit enables an interrupt request if the ADC2DR register is written by the hardware, meaning that there is new conversion data available. It also enables an interrupt request to be issued if there is an overrun in

Table continues on the next page...

BCTU_MCR field descriptions (continued)



Field	Description
	the ADC2DR register, meaning that the previous data in this register was overwritten by a new data. See also NDATA2 and DATAOVR2 in the MSR register. If DMA2 bit is set the interrupt for ADC2DR new data is disabled but the interrupt for ADC2DR data overrun remains enabled. In this case if an overrun condition occurs an interrupt request is generated. 0 Disable interrupt request. 1 Enable interrupt request.
30 IEN1	Interrupt enable bit for ADC1DR new data. This bit enables an interrupt request if the ADC1DR register is written by the hardware, meaning that there is new conversion data available. It also enables an interrupt request to be issued if there is an overrun in the ADC1DR register, meaning that the previous data in this register was overwritten by a new data. See also NDATA1 and DATAOVR1 in the MSR register. If DMA1 bit is set the interrupt for ADC1DR new data is disabled but the interrupt for ADC1DR data overrun remains enabled. In this case if an overrun condition occurs an interrupt request is generated. 0 Disable interrupt request. 1 Enable interrupt request.
31 IEN0	Interrupt enable bit for ADC0DR new data. This bit enables an interrupt request if the ADC0DR register is written by the hardware, meaning that there is new conversion data available. It also enables an interrupt request to be issued if there is an overrun in the ADC0DR register, meaning that the previous data in this register was overwritten by a new data. See also NDATA0 and DATAOVR0 in the MSR register. If DMA0 bit is set the interrupt for ADC0DR new data is disabled but the interrupt for ADC0DR data overrun remains enabled. In this case if an overrun condition occurs an interrupt request is generated. 0 Disable interrupt request. 1 Enable interrupt request.

46.6.2 Module Status register (BCTU_MSR)

The Status register provides software access to flags that indicate if conversion data is available for all ADCs. There are also indication of LIST status bits, such as last conversion command executed in a LIST.

Access: User read/write

Address: 0h base + 8h offset = 8h

BCTU_MSR field descriptions

Field	Description
0 TRGF_CLR	TRGF clear This bit is the clear for the TRGF flag bit 0 No action 1 Clears TRGF flag
1–3 Reserved	This field is reserved.

Table continues on the next page...

BCTU_MSR field descriptions (continued)

Field	Description
4 LIST3_Last_CLR	Clears LIST_Last flag for ADC3 0 No action 1 Clears LIST3_Last bit
5 LIST2_Last_CLR	Clears LIST_Last flag for ADC2 0 No action 1 Clears LIST2_Last bit
6 LIST1_Last_CLR	Clears LIST_Last flag for ADC1 0 no action 1 clears LIST1_Last flag
7 LIST0_Last_CLR	Clears LIST_Last flag for ADC0 0 no action 1 Clears LIST0_Last flag
8 DATAOVR3_ CLR	Clears DATAOVR3 flag 0 no action 1 Clears NDATA3 flag
9 DATAOVR2_ CLR	Clears DATAOVR2 flag 0 no action 1 Clears DATAOVR2 flag
10 DATAOVR1_ CLR	Clears DATAOVR1 flag 0 no action 1 Clears DATAOVR1 flag
11 DATAOVR0_ CLR	Clears DATAOVR0 flag 0 no action 1 Clears DATAOVR0 flag
12 NDATA3_CLR	Clears NDATA3 flag 0 No action 1 Clears NDATA3 flag
13 NDATA2_CLR	Clears NDATA2 flag 0 no action 1 Clears NDATA2 flag
14 NDATA1_CLR	Clears NDATA1 flag 0 no action 1 Clears NDATA1 flag
15 NDATA0_CLR	Clears NDATA0 flag 0 no action 1 Clears NDATA0 flag

Table continues on the next page...

BCTU_MSR field descriptions (continued)

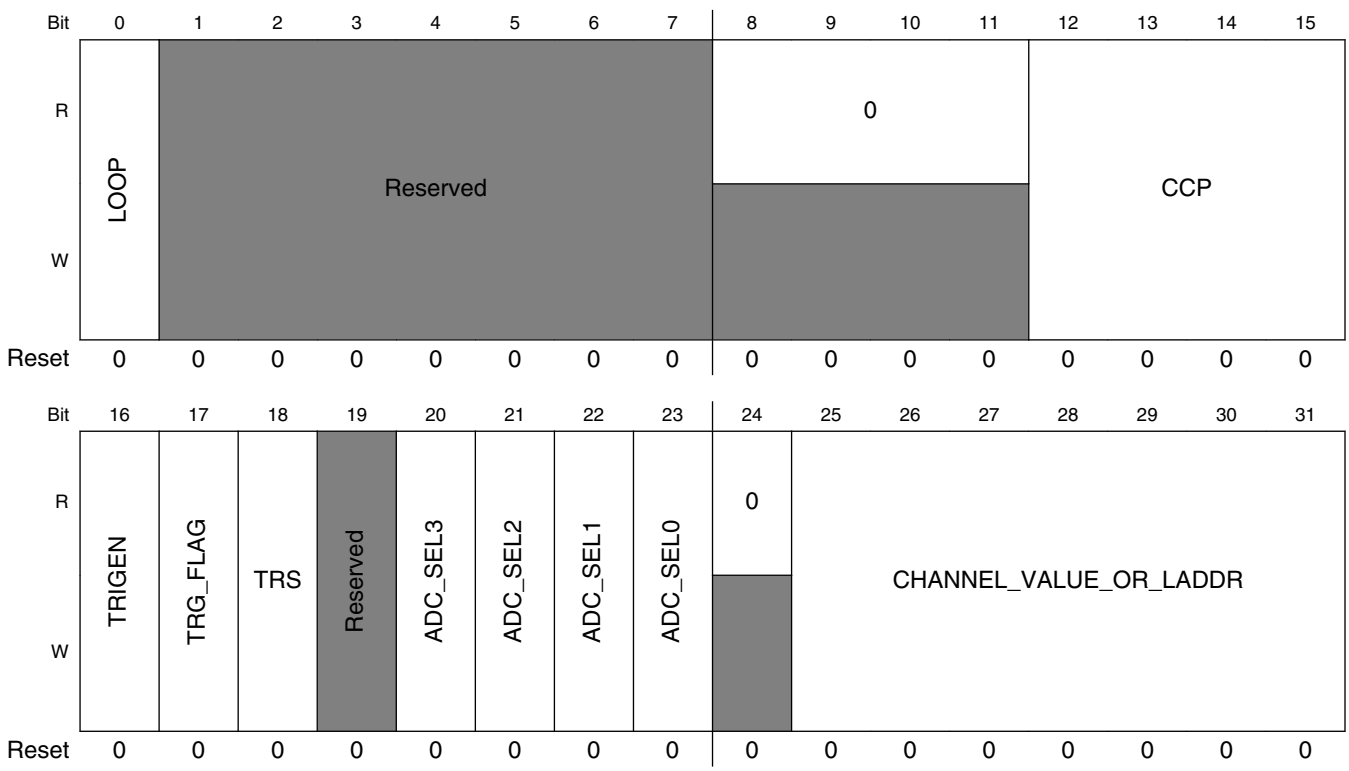
Field	Description
16 TRGF	Trigger Flag Indicates that at least one ADC was triggered. 0 ADC was not triggered 1 An ADC was triggered
17–19 Reserved	This field is reserved.
20 LIST3_Last	Execution of the last conversion in a LIST of conversions for ADC3 0 not the last conversion 1 last conversion in a LIST
21 LIST2_Last	Execution of the last conversion in a LIST of conversions for ADC2 0 not the last conversion 1 last conversion in a LIST
22 LIST1_Last	Execution of the last conversion in a LIST of conversions for ADC1 0 not the last conversion 1 last conversion in a LIST
23 LIST0_Last	Execution of the last conversion in a LIST of conversions for ADC0 0 not the last conversion 1 last conversion in a LIST
24 DATAOVR3	Data overrun for ADC3. Old data in the ADCDR3 register was overwritten 0 data not overwritten 1 data overwritten
25 DATAOVR2	Data overrun for ADC2. Old data in the ADCDR2 register was overwritten 0 data not overwritten 1 data overwritten
26 DATAOVR1	Data overrun for ADC1. Old data in the ADCDR1 register was overwritten 0 data not overwritten 1 data overwritten
27 DATAOVR0	Data overrun for ADC0. Old data in the ADCDR0 register was overwritten 0 data not overwritten 1 data overwritten
28 NDATA3	New conversion data is available for ADC3 0 no new data available 1 new data available
29 NDATA2	New conversion data is available for ADC2 0 no new data available 1 new data available

Table continues on the next page...

BCTU_MSR field descriptions (continued)

Field	Description
30 NDATA1	New conversion data is available for ADC1 0 no new data available 1 new data available
31 NDATA0	New conversion data is available for ADC0 0 no new data available 1 new data available

46.6.3 Trigger Configuration Register (BCTU_TRGCFG_*n*)



The Trigger Configuration register is a set of registers, one register per input trigger. This register controls the target ADC and ADC channel to be used in a conversion. It also controls if a LIST is used instead of a single ADC conversion command.

NOTE

x varies from 0 up to the number of input triggers.

Access: User read/write

Address: 0h base + 18h offset + (4d × i), where i=0d to 31d

BCTU_TRGCFG_*n* field descriptions

Field	Description
0 LOOP	LOOP bit The LOOP bit , defined if the current trigger should execute a loop, meaning that the conversion triggered by the input trigger is executed again until the LOOP bit is cleared. Each time the new conversion is triggered it should win the priority evaluation among all pending triggers. It is only executed if it is the highest priority triggered conversion at the moment the conversion starts.
1–7 Reserved	This field is reserved.
8–11 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
12–15 CCP	Conversion Configuration Pointer (CCP) The CCP field, if different from zero, points to a Conversion configuration register in the Conversion Configuration register bank.
16 TRIGEN	Trigger enable Enable/disable triggers from the input trigger (hardware) to initiate an ADC conversion. This bit does not disable software triggers. 0 disable hardware triggers 1 enable hardware triggers
17 TRG_FLAG	Clear timer flag through software 0 When written, indicates no action. When read, indicates that there is no ongoing ADC conversion initiated by this trigger. 1 When written, clears timer flag through software. Which means that any previous input trigger event is cleared, preventing a new ADC conversion to be initiated by this trigger source. When read, indicates that there is an ongoing ADC conversion initiated by this trigger.
18 TRS	Trigger resolution Selects single conversion or LIST of conversions 0 single conversion 1 List of conversions
19 Reserved	This field is reserved.
20 ADC_SEL3	Selects ADC 3 for conversion 0 does not selected ADC3 1 selects ADC3
21 ADC_SEL2	Selects ADC 2 for conversion 0 does not selected ADC2 1 selects ADC2
22 ADC_SEL1	Selects ADC 0 for conversion 0 does not selected ADC1 1 selects ADC1

Table continues on the next page...

BCTU_TRGCFG_*n* field descriptions (continued)

Field	Description
23 ADC_SEL0	Selects ADC 0 for conversion 0 does not selected ADC0 1 selects ADC0
24 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
25–31 CHANNEL_ VALUE_OR_ LADDR	Channel Value or List Address Value. If TRS = 0. this field is the ADC Channel selected for the conversion. If TRS = 1, this field represents the address of the first LIST position to be executed.

46.6.4 Write Protection register (BCTU_WRPROT)

Coming out from reset state the protection is enabled. In order to allow writes to protected registers it is necessary to write a special code in a 4-bit field. There are two possible codes that allow writes thus removing the protection. One 4-bit code that permanently disables the protection mechanism and another code that disables the protection during one write cycle to a protected register. After that the state of the protection code returns to its initial (protected) state.

Access: User read/write

Address: 0h base + 228h offset = 228h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	Reserved																												PROTEC_ CODE			
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

BCTU_WRPROT field descriptions

Field	Description
0–27 Reserved	This field is reserved.
28–31 PROTEC_CODE	The Protection code sets protection for the write protected registers There are two codes which disables the protection for the write protected registers. One code disables the write protection permanently and another code disables the protection for one write access only. **NOTE:** This field is writable only if the MCR[MDIS] bit is 0. 1010 This code defines that the protected registers are not in the protected mode, thus writes are enabled.

Table continues on the next page...

BCTU_WRPROT field descriptions (continued)

Field	Description
	1001 Protection temporarily deactivated. This code disables the protection for writes on the protected registers for one write cycle operation. After that the protection code is reset to the initial state "0000" thus restoring the protection for the protected registers. Protection is active for other values

46.6.5 Software Trigger register 1 (BCTU_SFTRGR1)

The Software Trigger register allows the software to trigger any of the conversions associated with the Trigger Configuration registers. In order to avoid ambiguity in the conversion results regarding the source of trigger (if from hardware or from the software) the trigger enable (TRIGEN) bit in the Trigger Configuration register should be cleared when the software trigger is used thus the trigger for that configuration register is only issued by the SFTRGR register. This register is write protected by the WRPROT register. If protection is enabled writes to this register do not modify the register content and generates a transfer error.

All bits in this register are set by the software and cleared by the hardware.

Access: User read/write; this register is write protected by the BCTU_WRPROT register.

Address: 0h base + 22Ch offset = 22Ch

46.6.6 Software Trigger register 1 (BCTU_SFTRGR3)

The Software Trigger register allows the software to trigger any of the conversions associated with the Trigger Configuration registers. In order to avoid ambiguity in the conversion results regarding the source of trigger (if from hardware or from the software) the trigger enable (TRIGEN) bit in the Trigger Configuration register should be cleared when the software trigger is used thus the trigger for that configuration register is only issued by the SFTRGR register. This register is write protected by the WRPROT register. If protection is enabled writes to this register do not modify the register content and generates a transfer error.

All bits in this register are set by the software and cleared by the hardware.

Access: User read/write; this register is write protected by the BCTU_WRPROT register.

Address: 0h base + 234h offset = 234h

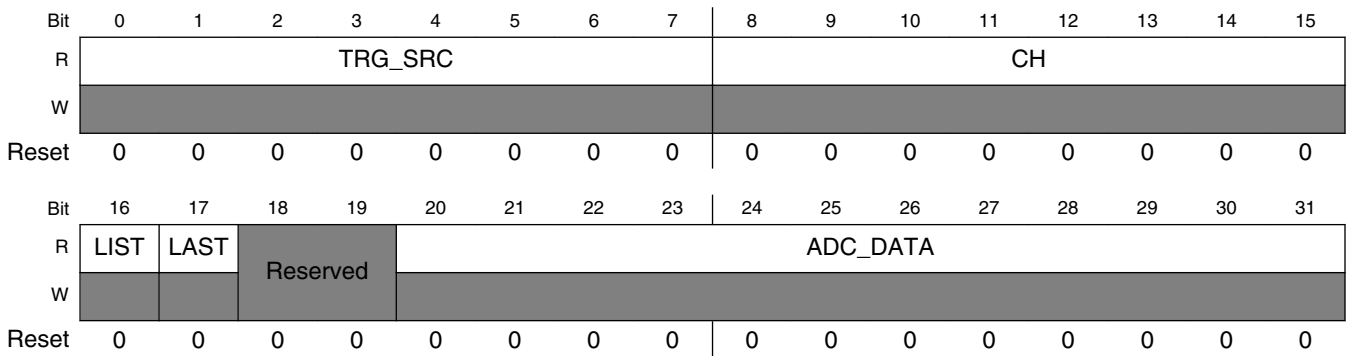
46.6.7 ADC0 Result Data register (BCTU_ADC0DR)

The ADC Result Data register allows software access to ADC conversion result data. It also indicates the ADC channel used in that conversion, the trigger source that initiated that conversion and LIST status indication in case the conversion was initiated from a LIST.

Access: User read

Address: 0h base + 23Ch offset = 23Ch

BCTU_ADC0DR field descriptions



Field	Description
0–7 TRG_SRC	Trigger number used to triggered the conversion
8–15 CH	ADC Channel used for the conversion
16 LIST	Indicates if the conversion was initiated by a LIST element or single conversion trigger 0: single conversion 0 single conversion 1 LIST
17 LAST	In case the conversion was done through a LIST, if set to 1, this bit indicates that the conversion result is the last conversion in the LIST. If the conversion was not controlled by a LIST this bit is always zero. 0 The conversion result is not the last coversion in a LIST 1 The conversion result is the last conversion in a LIST
18–19 Reserved	This field is reserved.
20–31 ADC_DATA	DATA from ADC conversion

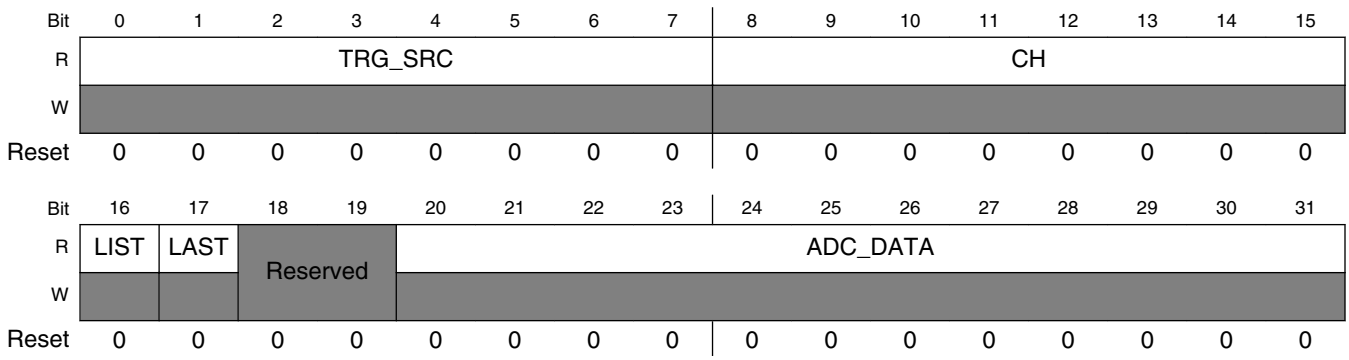
46.6.8 ADC1 result data register (BCTU_ADC1DR)

The ADC Result Data register allows software access to ADC conversion result data. It also indicates the ADC channel used in that conversion, the trigger source that initiated that conversion and LIST status indication in case the conversion was initiated from a LIST.

Access: User read

Address: 0h base + 240h offset = 240h

BCTU_ADC1DR field descriptions



Field	Description
0–7 TRG_SRC	Trigger number used to triggered the conversion
8–15 CH	ADC Channel used for the conversion
16 LIST	Indicates if the conversion was initiated by a LIST element or single conversion trigger 0 single conversion 1 LIST
17 LAST	In case the conversion was done through a LIST, if set to 1, this bit indicates that the conversion result is the last conversion in the LIST. If the conversion was not controlled by a LIST this bit is always zero. 0 The conversion result is not the last coversion in a LIST 1 The conversion result is the last conversion in a LIST
18–19 Reserved	This field is reserved.
20–31 ADC_DATA	DATA from ADC conversion

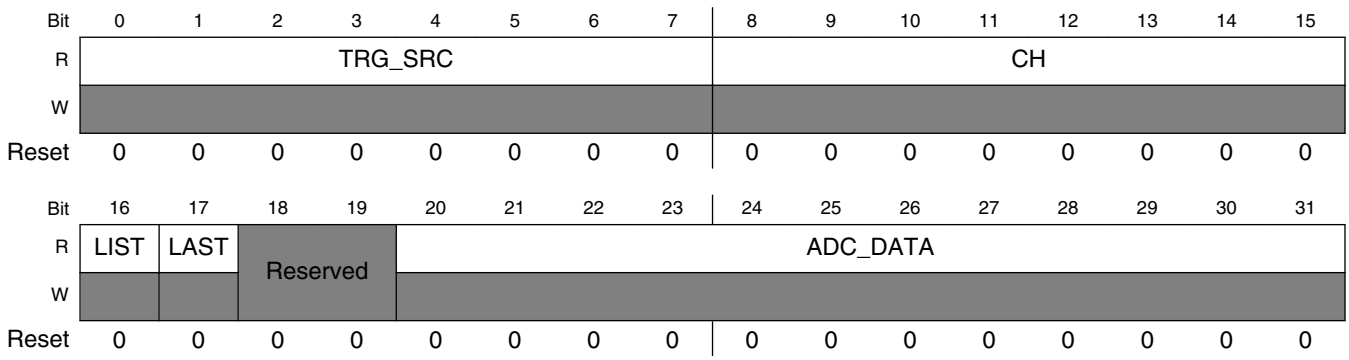
46.6.9 ADC2 result data register (BCTU_ADC2DR)

The ADC Result Data register allows software access to ADC conversion result data. It also indicates the ADC channel used in that conversion, the trigger source that initiated that conversion and LIST status indication in case the conversion was initiated from a LIST.

Access: User read

Address: 0h base + 244h offset = 244h

BCTU_ADC2DR field descriptions



Field	Description
0–7 TRG_SRC	Trigger number used to triggered the conversion
8–15 CH	ADC Channel used for the conversion
16 LIST	Indicates if the conversion was initiated by a LIST element or single conversion trigger 0 single conversion 1 LIST
17 LAST	In case the conversion was done through a LIST, if set to 1, this bit indicates that the conversion result is the last conversion in the LIST. If the conversion was not controlled by a LIST this bit is always zero. 0 The conversion result is not the last coversion in a LIST 1 The conversion result is the last conversion in a LIST
18–19 Reserved	This field is reserved.
20–31 ADC_DATA	DATA from ADC conversion

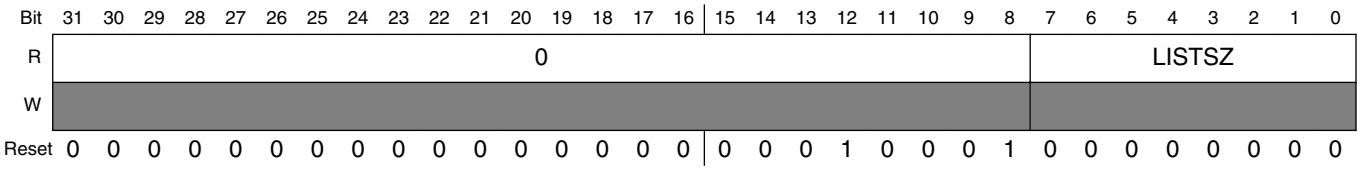
46.6.10 ADC3 result data register (BCTU_ADC3DR)

The ADC Result Data register allows software access to ADC conversion result data. It also indicates the ADC channel used in that conversion, the trigger source that initiated that conversion and LIST status indication in case the conversion was initiated from a LIST.

Access: User read

Address: 0h base + 248h offset = 248h

BCTU_ADC3DR field descriptions



Field	Description
0–7 TRG_SRC	Trigger number used to triggered the conversion
8–15 CH	ADC Channel used for the conversion
16 LIST	Indicates if the conversion was initiated by a LIST element or single conversion trigger 0 single conversion 1 LIST
17 LAST	In case the conversion was done through a LIST, if set to 1, this bit indicates that the conversion result is the last conversion in the LIST. If the conversion was not controlled by a LIST this bit is always zero. 0 The conversion result is not the last coversion in a LIST 1 The conversion result is the last conversion in a LIST
18–19 Reserved	This field is reserved.
20–31 ADC_DATA	DATA from ADC conversion

46.6.11 LIST Size Status register (BCTU_LISTSTAR)

Each element has the channel number used in one conversion.

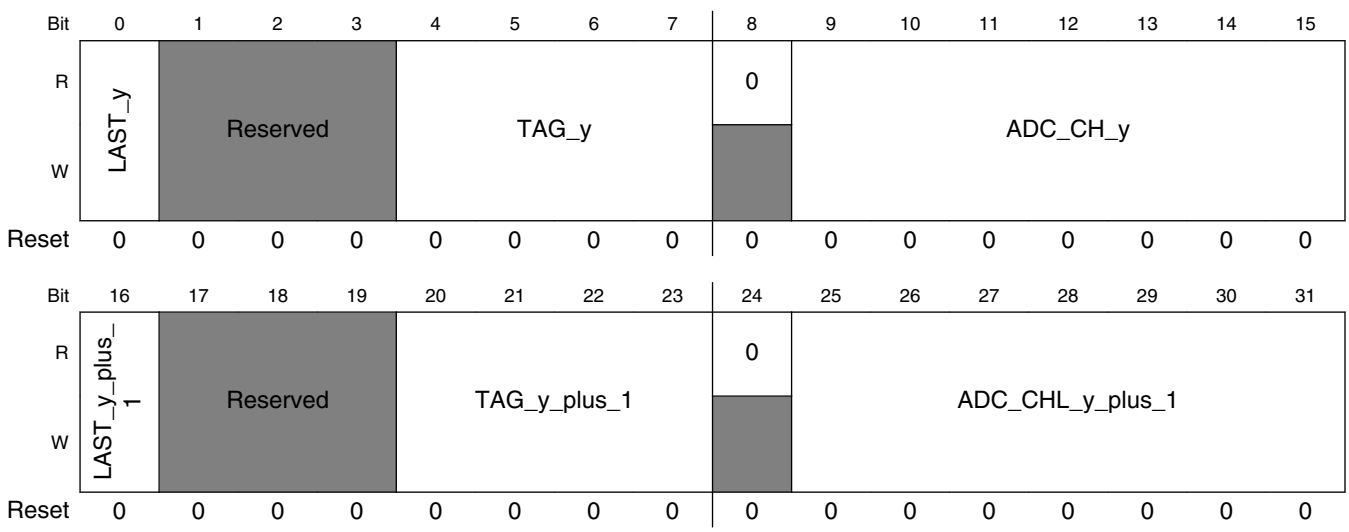
Access: User read

Address: 0h base + 24Ch offset = 24Ch

BCTU_LISTSTAR field descriptions

Field	Description
31–8 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
7–0 LISTSZ	Size of the LIST in number of elements. This field reflects the value of a hardware parameter.

46.6.12 LIST Channel Address Register (BCTU_LISTCHR_*n*)



The LIST channel address register corresponds to two LIST elements which stores the ADC channel number to be used in a conversion as well as the indication if that element corresponds to the last element of a LIST of conversion commands.

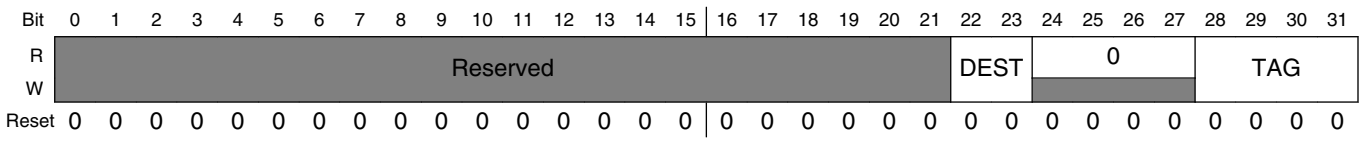
NOTE

y varies from 0 to 63.

Access: User read/write

Address: 0h base + 250h offset + (4d × i), where i=0d to 31d

BCTU_LISTCHR_*n* field descriptions



Field	Description
0 LAST_y	Last channel in the list of channels. 0 It is not the last channel in the list 1 This is the last channel in the List
1–3 Reserved	This field is reserved.
4–7 TAG_y	TAG for the n LIST element The TAG field is used in the Parallel Side Interface as an attribute to the WDATA bus. It is used by the external module connected to the PSI in order to correctly use the conversion result. TAG[3:0] used by the PSI to be transmitted along with the ADC conversion result.
8 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
9–15 ADC_CH_y	ADC channel selection. y indicates the position (address) of the ADC channel in the LIST of channels.
16 LAST_y_plus_1	Second to last channel in the list of channels.
17–19 Reserved	This field is reserved.
20–23 TAG_y_plus_1	TAG for the [y+1] LIST element. The TAG field is used in the Parallel Side Interface as an attribute to the WDATA bus. It is used by the external module connected to the PSI in order to correctly use the conversion result. TAG[3:0] used by the PSI to be transmitted along with the ADC conversion result.
24 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
25–31 ADC_CHL_y_ plus_1	ADC channel selection. y indicates the position (address) of the ADC channel in the LIST of channels.

46.6.13 Conversion configuration register (BCTU_CCR_*n*)

The CCR, conversion configuration register controls the destination of the conversion result. Possible choices are the result register and parallel side port, PSI interface to communicate with external SoC modules. These registers are organized in a Bank of registers. Each element in the bank is pointed by the CCP (conversion configuration pointer) field in the TRGCFG register.

Access: User read/write

Address: 0h base + 2D0h offset + (4d × i), where i=0d to 10d

BCTU_CCR_*n* field descriptions

Field	Description
0–21 Reserved	This field is reserved.
22–23 DEST	Destination selection The DEST field selects the destination of the conversion result. It points to the PSI as an alternate destination for the conversion results besides the result register. 00 conversion results are sent to result register 01 Reserved 10 conversion results are sent to the PSI and to result register 11 Reserved
24–27 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.
28–31 TAG	The TAG field is used in the Parallel Side Port as the TAG bits. The TAG filed has only meaning if the parallel side port is selected as the destination of the conversion result. It is copy as is to the TAG bits in the PSI. In this case this bit field is used for further addressing in the modules connected to the side port. The TAG filed is used in the PSI (Parallel Side Port) in order to allow further addressing capabilities for the modules connected to this interface.

46.7 Functional description

The following sections describes the BCTU functionality.

46.7.1 Trigger Configuration

The triggers from on-chip timers and software are configured in the TRGCFG (Trigger Configuration Register). Each trigger can be individually enabled by the TRIGEN bit in the TRGCFG_n registers. The target ADC and channel are also defined in this register. The TRS (Trigger Resolution bit) sets if either a single conversion is executed for the corresponding trigger or if the LIST of conversions should be executed. In the case of a LIST the channel/LADDR field is used as a pointer for the LIST element. If the LIST is used, multiple conversions are executed due to the corresponding trigger assertion.

A protocol is implemented such that when an input trigger is selected to issue an ADC conversion, the BCTU clears the corresponding trigger source when the ADC conversion is initiated.

NOTE

If a LIST is triggered the corresponding trigger will be cleared when the last conversion in the LIST is started.

The software trigger is controlled by the SFTRGR (Software Trigger Register). By writing to a bit in that register, an ADC conversion is triggered similar to a conversion initiated by an input trigger. A software triggered conversion does not require to be enabled by the TRIGEN bit in the TRGCFG register. Thus if any bit in the SFTRGR register is set, the corresponding conversion is triggered independent of the TRIGEN bit state. This functionality is useful such that it avoids conflict between software and hardware triggers.

NOTE

The software triggered conversion is enabled by the GTRGEN bit in the MCR register meaning that this bit needs to be set in order to allow a software conversion. This enable bit does not prevent the SFTRGR bits to be set, it just disables the conversion start. As soon as the GTRGEN bit is set the software conversions already triggered are initiated following the predefined priority scheme, i.e. from the lowest to the highest SFTRG bit number.

46.7.2 Trigger priority and multiplexing

The ADC triggers are prioritized based on the trigger number. The lower the trigger input number the higher is the priority associated with it. Thus TRG[0] is the highest priority trigger and TRG[95], in case 96 triggers are used, is the lowest priority. The trigger input priority scheme applies when the triggers occur at the same time or when the ADC is busy in a conversion. Thus there are two possible scenarios for the trigger priority selection: when there are no on-going conversions and when the ADC is executing a conversion.

The figure below describes the BCTU input triggers related to the ADC trigger signal generation. There is four clock cycles from the input trigger to the ADC trigger. This figure also shows the CLR[n] (clear) signal generated by the BCTU which clears the input trigger signal.

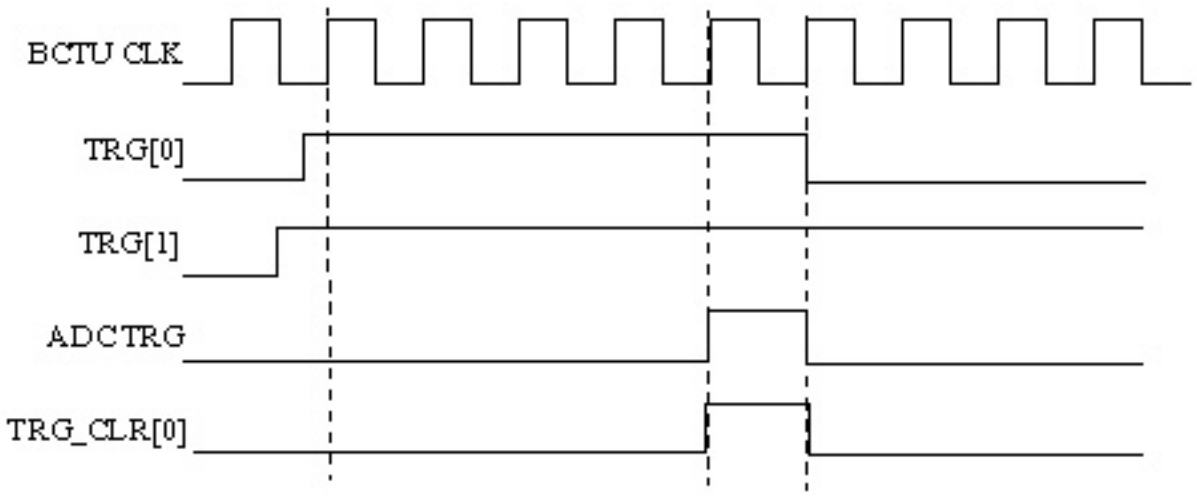


Figure 46-94. Input trigger to ADC trigger timing

The figure below describes the priority logic behavior in case TRG[0] and TRG[1] occur at the same time. Since TRG[0] has higher priority then it is selected for the ADC trigger generation. TRG[1] remains active (pending) until the conversion related to TRG[0] is executed. Note that if TRG[0] signal is asserted again, before the next trigger selection opportunity at the end of the current conversion, then it is selected one more time and TRG[1] remains asserted (pending) for more one ADC conversion time frame.

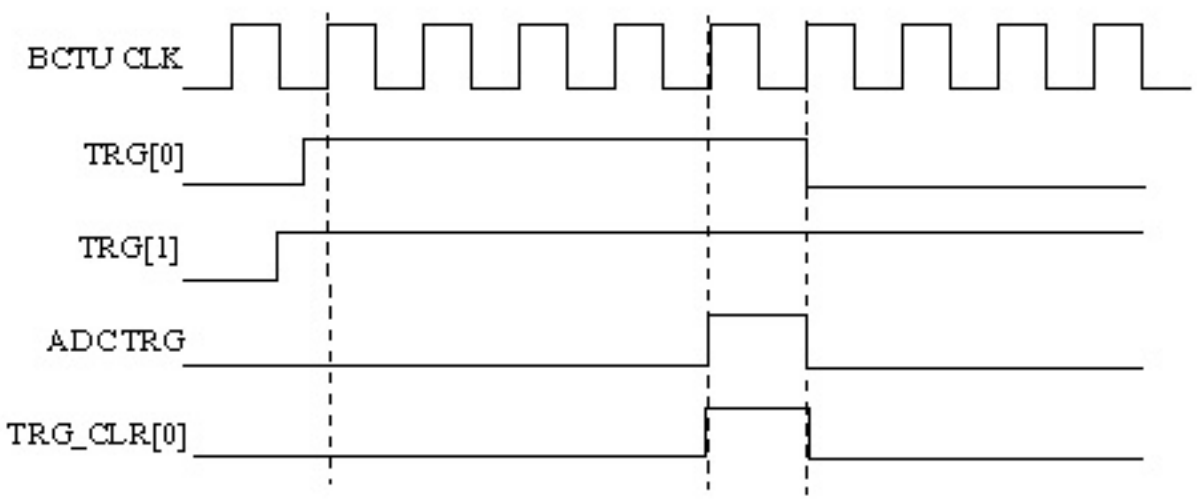

Figure 46-95. TRG[0] and TRG[1] priority example

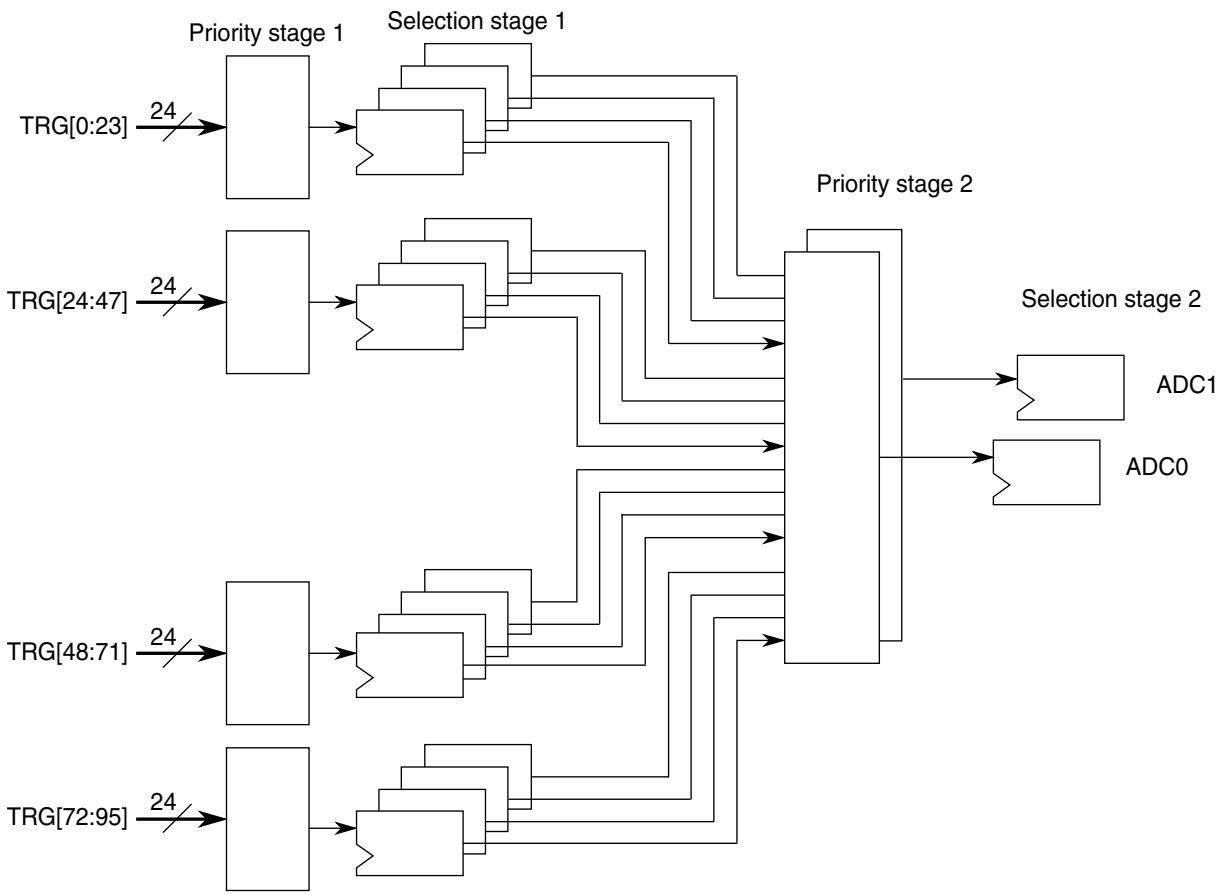
The figure below describes the pipeline and logic (combinational logic) stages architecture, which resolves the priority among trigger inputs into two pipeline stages. The sel logic 1 and 2,combinational logic, are responsible for selecting the priority among all 96 inputs. The pipeline stage 3 stores this result and connects to a pulse generator stage which generates the trigger for the ADCs. Another stage isolates any

combinational logic in the BCTU to the external modules, thus allowing a clean clock domain crossing to connected to the ADC clock domain. In this architecture the timing from input trigger to the ADC trigger is 4 BCTU clock cycles.

NOTE

Back to back conversions are executed with 3 BCTU clock delay since the trigger selection is done during the current conversion thus the next trigger is ready when the conversion ends. The 4 clock delays occurs only when there are no conversions being executed by the ADC and new trigger occurs at the BCTU input.



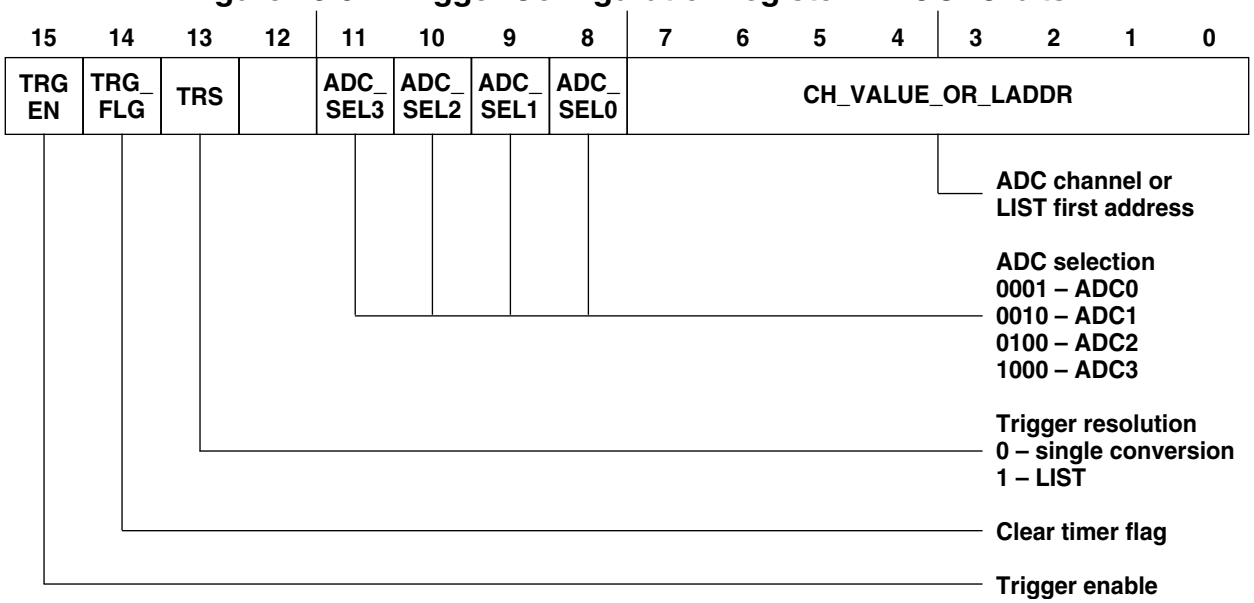


Figure 46-96. Priority stages architecture

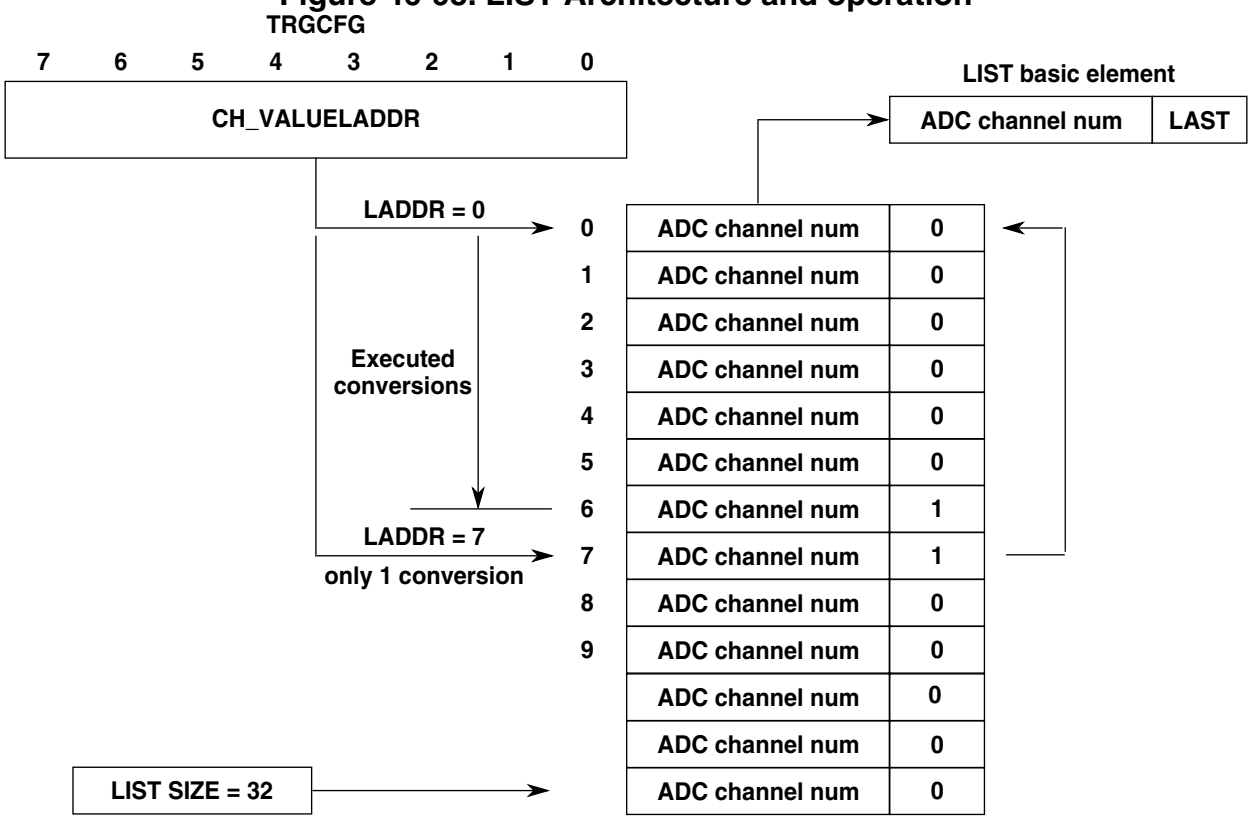
46.7.3 Conversion LIST

The figure below describes the bits of the Trigger Configuration register (TRGCFG). The TRS bit selects between a single conversion and a list of conversions. In case a list of conversions is selected the CH_VALUE/LADDR field is used as the list pointer. The TRG_EN and CLR_FLAG bits have similar functionality regardless of single or list of conversion.

Figure 46-97. Trigger Configuration register -TRGCFG bits



NOTE

ADC_SEL bits are one hot encoded, meaning that more than one ADC can be selected for a conversion. The multiple ADC selection is only valid for multiple parallel conversions LIST functionality. If more than one ADC is selected for a single conversion, instead of for a LIST, no conversion will be triggered by this register.

The figure below describes the LIST of channels architecture and operation. If the LADDR field in the TRGCFG register points to a LIST element then a sequence of conversions is initiated. The sequence of conversions are executed until the LAST field is set. The channel with the LAST field set is the last channel to be converted in a sequence of conversions.

Figure 46-98. LIST Architecture and operation

If LADDR points to a LIST element with the LAST field set, only one conversion is executed. In this case the LIST behaves such as a single conversion.

The LIST of channels has the following rules:

- A sequence of conversions is executed until the LAST field is evaluated as 1
- Conversions are executed in a sequence, thus other conversions for the same ADC are not allowed in parallel (the LIST is atomic)
- Two or more triggers for different ADCs may point to the LIST. In this case both LISTs are executed in parallel for the selected ADCs
- LADDR should point to a valid list address < LIST SIZE, otherwise address 0 is used
- After LIST SIZE -1 address is executed the list pointer wraps to address 0

46.7.4 ADC conversion results access

The access to ADC results can be done by the software using the flags and interrupt request or by the DMA interface. The interrupt request is based on the Status Register (MSR) flags. The results are available in the ADCxDR registers, one for each ADC. This register also indicates the channel used in the conversion and the trigger input that initiated that conversion. In order to give support for conversions from a LIST, two bits are available in the ADCxDR register, the LIST and LAST bits. The LIST bit indicates that the conversion was generated by a LIST element. The LAST bit indicates that the data is the last conversion of a LIST.

The software access to converted data can be based on interrupt request. An interrupt request is generated if the IENx bit in the MCR register is set and the corresponding DMAx bit is not set. In this case on each available conversion data in the ADCxDR register an interrupt request is asserted. The software can then check which is the source of the interrupt by reading the MSR register. Note that more then one conversion data may be available at the same time, since the conversions on different ADCs are executed in parallel. The NDATAx bit in the MSR register indicates which ADCxDR has a new conversion data available. The NDATAx flag can be cleared by using the NDATAx_CLR bit in the MSR register.

If DMA operation is selected by the DMA bit in the MCR register, a new data in the ADCxDR registers generates a DMA request. The NDATAx flag is also asserted in this case. A DMA DONE signal from the DMA controller de-asserts the DMA request and clears the NDATAx bit.

In order to allow DMA operation for all ADCxDR registers it is required one DMA channel per ADC, thus four DMA channels if four ADCs are used.

In case a new ADC conversion data is available before the old data had been read from the ADCxDR register then the DATAOVRx flag, new data overrun flag, is set indicating that the previous data in the ADCxDR register was overwritten by a new conversion result. The DATAOVRx flag also sets an interrupt request which is also enabled by the IENx bit. This interrupt request is asserted independently of the DMA bit settings. The DATAOVRx flag can only be cleared by the software writing 1 to the DATAOVRx_CLR bit.

46.7.5 Trigger clearing mechanism

There are two sources of ADC conversion triggers: hardware trigger, from the trigger inputs and software triggers, from SFTRGR register

A logical level 1 is detected in the input and captured into an input trigger register. This register remains set until the related conversion starts. At this time, the input trigger register is cleared. If another logical level 1 is detected while the trigger register is already set, the new level is not considered by the BCTU hardware. If a new logical level 1 occurs at the same time the trigger register is being cleared, then the register remains set and a new conversion is triggered by this input.

NOTE

The new triggered conversion will participate in the trigger priority selection thus may not trigger the next conversion.

The software trigger behaves similarly to the hardware trigger. The difference is that the trigger register is set by a CPU write operation. The trigger register is cleared by the BCTU hardware when the related conversion starts. If the CPU tries to set the trigger register by writing to the SFTRGR register corresponding bit, while the register is already set, the new attempt to set the register is not considered by the BCTU hardware. If a set occurs at the same time the hardware is attempting to clear the same trigger register, then the set has precedence and the register remains set. A new conversion will be triggered following the trigger priority criteria implemented in the hardware.

In case a LIST of conversions is triggered, instead of a single conversion, the trigger register is cleared at the start of the last conversion in the LIST.

46.7.6 On-the-fly reconfiguration of BCTU registers

The support for on-the-fly reconfiguration of triggers, specially for the Trigger Configuration register is done by the TRG_FLAG. If this bit field is read as 1, then the related trigger had started a conversion which is still ongoing. Therefore it is not safe to change the register bits.

The process of changing the Trigger Configuration register should start by clearing the TRIGEN bit. This will disable any new conversion be started by the corresponding trigger. After that the value of the TRG_FLAG bit should be evaluated. If this bit is set then it indicates that the current ongoing conversion or LIST execution was started by the trigger controlled by this register. The software should then read the TRGCFG register until the TRG_FLAG bit is cleared, which indicates that the on-going conversion had finished. After that the register can be modified safely. No conversions occur while the TRIGEN bit is cleared. In order to make sure that any trigger that occurred before the TRGCFG reconfiguration starts a new conversion, the application software should write 1 to the TRG_FLAG bit, thus clearing the trigger sources. Only triggers that occurred after this write operation was done are able to start a new conversion.

46.7.7 Multiple Parallel Conversions

The Multiple Parallel Conversions functionality is implemented using the LIST of channels. In order to execute this function more than one ADC should be selected in the TRGCFG register and the TRS bit must be set. In this case the TRGCFG CH_VALUE/ LADDR field points to an element in the LIST. The channels in the LIST are interpreted as referring to the ADCs selected in the TRGCFG register. The figure below describes the parallel conversion execution. Note that the channel numbers in the LIST are interpreted in pairs since two ADCs are selected, ADC0 and ADC1. If three ADC are selected, the LIST is interpreted in groups of three elements, being the order from ADC0 through ADC2.

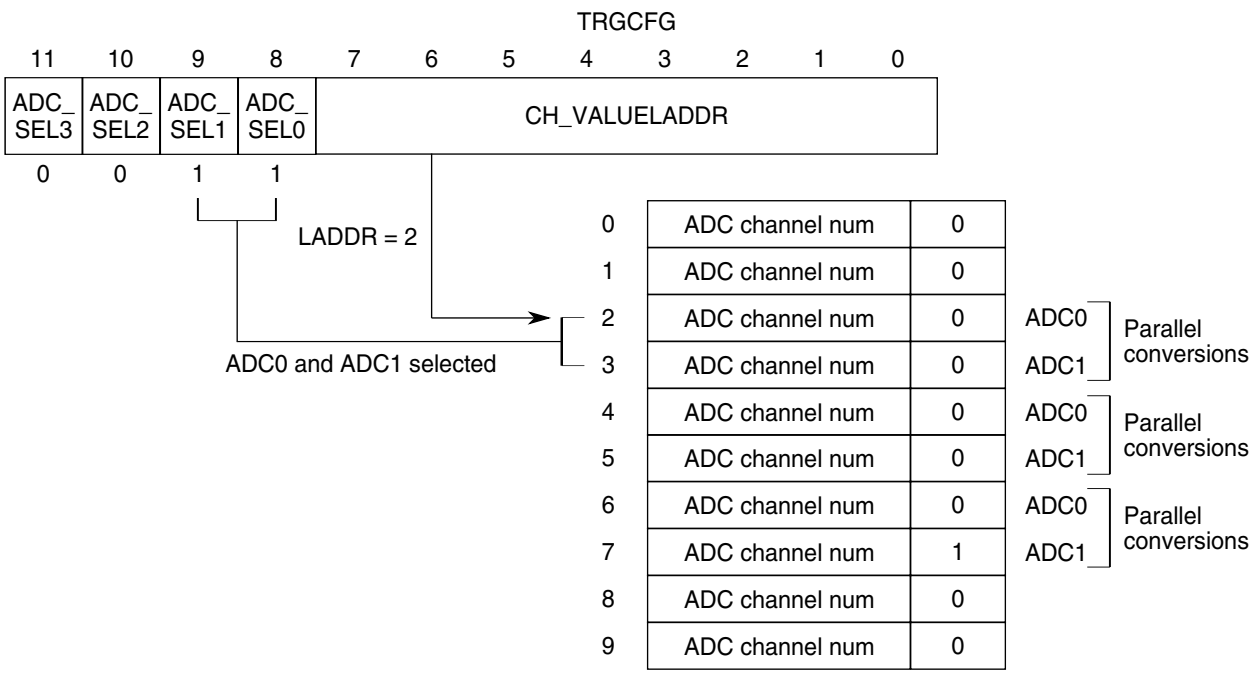


Figure 46-99. Multiple Parallel Conversions LIST operation

The Multiple Parallel Conversion (MPC) follows the same priority rules of a single conversion which is based on the trigger input number: the lower the trigger the higher the priority is. The difference is that a MPC cannot start until all the ADCs defined in the LIST are free. Thus if a MPC is triggered for ADC0 and ADC1, this LIST of conversions does not initiate until ADC0 and ADC1 are free. Note that if ADC0 is free but there is a higher priority trigger for ADC1 then the MPC does not start. If two MPC that have at least one ADC in common are triggered, the lower trigger number has higher priority. Note that the conflict in the priority only occurs if the triggered conversions are trying to use at least one ADC in common. If the MPCs are using different ADCs than there is no conflict and the MPCs are executed at the same time.

46.8 Interrupts and DMA requests

The BCTU module has several interrupts to signal input triggers and conversion results events. These interrupts can also be used as DMA requests.

Trigger interrupt : signals an ADC trigger event occurred, thus a conversion have started. This interrupt line is an or of all ADC triggers (up to four).

ADC data ready: these interrupts (up to four) signals when an ADC result is available. The software should read the BCTU_ADCx_DR register in order to access the ADC conversion result.

LIST interrupt: the LIST interrupt line signals when the LIST executed the last conversion. If the conversion from a LIST was transferred to the system memory then this interrupt signals to the software that all results, from a LIST, are ready to be processed. Note that this interrupt always occur along with the ADC data ready interrupt.

Chapter 47
CAN (FlexCAN)

47.1 CAN chip-specific module information

This section describes the implementation of this module in the device.

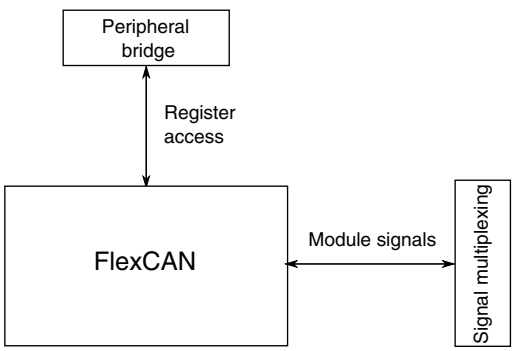

Figure 47-1. CAN chip-specific module information

47.1.1 FlexCAN modules on this chip

This device contains four FlexCAN module instances. Their differences are as follows.

Table 47-1. FlexCAN module instances

Instance name	Number of message buffers	CAN_CTRL2[TASD] reset value
CAN0	96	0b01100
CAN1	96	0b01100
CAN2	64	0b10000
CAN3	64	0b10000

47.1.2 Message buffer size

Each message buffer is 16 bytes.

47.1.3 Message buffer address offsets

The following table lists the address offsets of the message buffers for the CAN0 and CAN1.

For the CAN2 and CAN3, the message buffers go up to only MB63.

Table 47-2. Message buffer address offsets for CAN0 and CAN1

Offset	Message buffer
Base + 0x0080	MB0
Base + 0x0090	MB1
Base + 0x00A0	MB2
Base + 0x00B0	MB3
Base + 0x00C0	MB4

47.1.4 Reset value of MDIS bit

The CAN_MCR[MDIS] bit is set after reset. Therefore, FlexCAN module is disabled following a reset.

47.1.5 FlexCAN Clocking

The clock to each CAN module can be gated on and off using the MC_ME[PCTL] bits. These bits are cleared after any reset, which disables the clock to the corresponding module. The appropriate clock enable bit should be set by software at the beginning of the FlexCAN initialization routine to enable the module clock before attempting to initialize any of the FlexCAN registers.

47.1.6 FlexCAN Interrupts

The FlexCAN has multiple sources of interrupt requests. However, some of these sources are OR'd together to generate a single interrupt request. See below for the mapping of the individual interrupt sources to the interrupt request.

Table 47-3. Interrupts for CAN modules

Request	Sources
Message buffer	Message buffers 0-63
Bus off	Bus off
Error	• Bit1 error • Bit0 error • Acknowledge error • Cyclic redundancy check (CRC) error • Form error • Stuffing error • Transmit error warning • Receive error warning

For the mapping of interrupt requests and sources, see section Interrupt sources in the Interrupt Controller chapter.

47.1.7 FlexCAN CLKSRC

This signal is not used on the MPC5746R. The clock source selection is controlled by MC_CGM_AC8_SC in the Clock Generation Module chapter.

47.1.8 FlexCAN RAM to memory map address mapping

Use the following table to convert from the memory map address to the location in the physical FlexCAN RAM where the error is to be injected, defined in CAN_ERRIAR[INJADDR].

Table 47-4. FlexCAN RAM to memory map address mapping

RAM contents	Injection address	Memory map
FlexCAN Registers	Not mapped	-
MBs	0x0000	0x0080

47.2 Introduction

The FlexCAN module is a communication controller implementing the CAN protocol according to the ISO 11898-1 standard and CAN 2.0 B protocol specifications. A general block diagram is shown in the following figure, which describes the main subblocks implemented in the FlexCAN module, including one associated memory for storing message buffers, Receive Global Mask registers, Receive Individual Mask registers, Receive FIFO filters, and Receive FIFO ID filters. The functions of the submodules are described in subsequent sections.

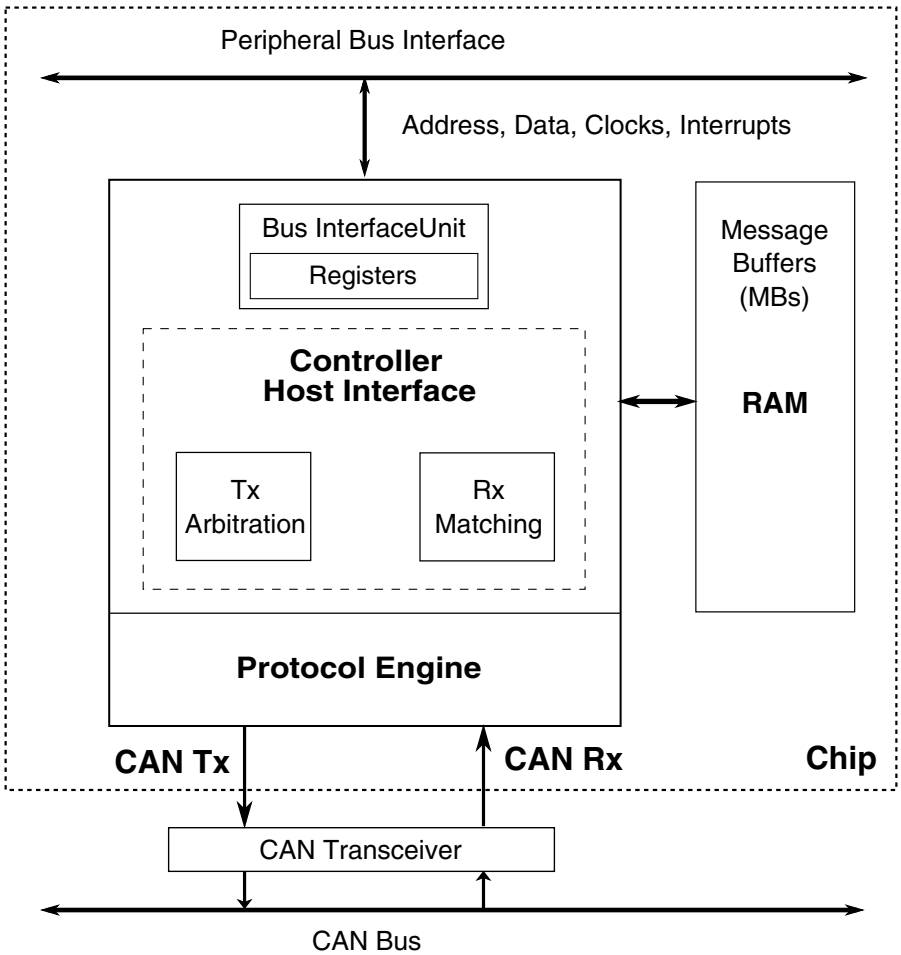

Figure 47-2. FlexCAN block diagram

47.2.1 Overview

The CAN protocol was primarily designed to be used as a vehicle serial data bus, meeting the specific requirements of this field:

- Real-time processing
- Reliable operation in the EMI environment of a vehicle
- Cost-effectiveness
- Required bandwidth

The FlexCAN module is a full implementation of the CAN protocol specification, the CAN 2.0 version B protocol, which supports both standard and extended message frames. The message buffers are stored in an embedded RAM dedicated to the FlexCAN module. See the chip configuration details for the actual number of message buffers configured in the chip.

The Protocol Engine (PE) submodule manages the serial communication on the CAN bus:

- Requesting RAM access for receiving and transmitting message frames
- Validating received messages
- Performing error handling

The Controller Host Interface (CHI) sub-module handles message buffer selection for reception and transmission, taking care of arbitration and ID matching algorithms.

The Bus Interface Unit (BIU) sub-module controls the access to and from the internal interface bus, in order to establish connection to the CPU and to other blocks. Clocks, address and data buses, interrupt outputs, DMA and test signals are accessed through the BIU.

47.2.2 FlexCAN module features

The FlexCAN module includes these distinctive features:

- Full implementation of the CAN protocol specification, Version 2.0 B
    - Standard data frames
    - Extended data frames
    - Zero to eight bytes data length
    - Programmable bit rate up to 1 Mb/sec
    - Content-related addressing
- Compliant with the ISO 11898-1 standard
- Flexible mailboxes of zero to eight bytes data length
- Each mailbox configurable as receive or transmit, all supporting standard and extended messages
- Individual Rx Mask registers per mailbox
- Full-featured Rx FIFO with storage capacity for up to six frames and automatic internal pointer handling with DMA support
- Transmission abort capability
- Flexible message buffers (MBs), totaling 96 message buffers of 8 bytes data length each, configurable as Rx or Tx

- RAM not used by reception or transmission structures can be used as general purpose RAM space
- Listen-Only mode capability
- Programmable Loop-Back mode supporting self-test operation
- Programmable transmission priority scheme: lowest ID, lowest buffer number, or highest priority
- Time stamp based on 16-bit free-running timer
- Global network time, synchronized by a specific message
- Maskable interrupts
- Independence from the transmission medium (an external transceiver is assumed)
- Short latency time due to an arbitration scheme for high-priority messages
- Low power modes
- Remote request frames may be handled automatically or by software
- CAN bit time settings and configuration bits can only be written in Freeze mode
- Tx mailbox status (Lowest priority buffer or empty buffer)
- Identifier Acceptance Filter Hit Indicator (IDHIT) register for received frames
- SYNCH bit available in Error in Status 1 register to inform that the module is synchronous with CAN bus
- CRC status for transmitted message
- Rx FIFO Global Mask register
- Selectable priority between mailboxes and Rx FIFO during matching process
- Powerful Rx FIFO ID filtering, capable of matching incoming IDs against either 128 extended, 256 standard, or 512 partial (8 bit) IDs, with up to 32 individual masking capability
- 100% backward compatibility with previous FlexCAN version
- Supports detection and correction of errors in memory read accesses. Each byte of FlexCAN memory is associated to 5 parity bits and the error correction mechanism ensures that in this 13-bit word, errors in one bit can be corrected (correctable errors) and errors in 2 bits can be detected but not corrected (non-correctable errors)

47.2.3 Modes of operation

The FlexCAN module has these functional modes:

- Normal mode (User or Supervisor):

  In Normal mode, the module operates receiving and/or transmitting message frames, errors are handled normally, and all CAN Protocol functions are enabled. User and Supervisor Modes differ in the access to some restricted control registers.

- Freeze mode:

  Freeze mode is enabled when the FRZ bit in MCR is asserted. If enabled, Freeze mode is entered when MCR[HALT] is set or when Debug mode is requested at chip level and MCR[FRZ_ACK] is asserted by the FlexCAN. In this mode, no transmission or reception of frames is done and synchronicity to the CAN bus is lost. See Freeze mode for more information.

- Loop-Back mode:

  The module enters this mode when the LPB field in the Control 1 Register is asserted. In this mode, FlexCAN performs an internal loop back that can be used for self-test operation. The bit stream output of the transmitter is internally fed back to the receiver input. The Rx CAN input pin is ignored and the Tx CAN output goes to the recessive state (logic '1'). FlexCAN behaves as it normally does when transmitting and treats its own transmitted message as a message received from a remote node. In this mode, FlexCAN ignores the bit sent during the ACK slot in the CAN frame acknowledge field to ensure proper reception of its own message. Both transmit and receive interrupts are generated.

- Listen-Only mode:

  The module enters this mode when the LOM field in the Control 1 Register is asserted. In this mode, transmission is disabled, all error counters are frozen, and the module operates in a CAN Error Passive mode. Only messages acknowledged by another CAN station will be received. If FlexCAN detects a message that has not been acknowledged, it will flag a BIT0 error (without changing the REC), as if it was trying to acknowledge the message.

For low-power operation, the FlexCAN module has:

- Module Disable mode:

This low-power mode is entered when the MDIS bit in the MCR Register is asserted by the CPU and the LPM_ACK is asserted by the FlexCAN. When disabled, the module requests to disable the clocks to the CAN Protocol Engine and Controller Host Interface submodules. Exit from this mode is done by negating the MDIS bit in the MCR register. See Module Disable mode for more information.

- Stop mode:

  This low power mode is entered when Stop mode is requested at chip level and the LPM_ACK bit in the MCR Register is asserted by the FlexCAN. When in Stop Mode, the module puts itself in an inactive state and then informs the CPU that the clocks can be shut down globally. Exit from this mode happens when the Stop mode request is removed. See Stop mode for more information.

47.3 FlexCAN signal descriptions

The FlexCAN module has two I/O signals connected to the external chip pins. These signals are summarized in the following table and described in more detail in the next subsections.

Table 47-5. FlexCAN signal descriptions

Signal	Description	I/O
CAN Rx	CAN Receive Pin	Input
CAN Tx	CAN Transmit Pin	Output

47.3.1 CAN Rx

This pin is the receive pin from the CAN bus transceiver. Dominant state is represented by logic level 0. Recessive state is represented by logic level 1.

47.3.2 CAN Tx

This pin is the transmit pin to the CAN bus transceiver. Dominant state is represented by logic level 0. Recessive state is represented by logic level 1.

47.4 Memory map/register definition

This section describes the registers and data structures in the FlexCAN module. The base address of the module depends on the particular memory map of the chip.

47.4.1 FlexCAN memory mapping

The memory map for the FlexCAN module is shown in the following table.

The address space occupied by FlexCAN has 128 bytes for registers starting at the module base address, followed by embedded RAM starting at address offset 0x0080.

Each individual register is identified by its complete name and the corresponding mnemonic. The access type can be Supervisor (S) or Unrestricted (U). Most of the registers can be configured to have either Supervisor or Unrestricted access by programming the SUPV field in the MCR register. These registers are identified as S/U in the Access column of Table 47-6.

Table 47-6. Register access and reset information

Register	Access type	Affected by hard reset	Affected by soft reset
Module Configuration Register (CAN_MCR)	S	Yes	Yes
Control 1 register (CAN_CTRL1)	S/U	Yes	No
Free Running Timer register (CAN_TIMER)	S/U	Yes	Yes
Rx Mailboxes Global Mask register (CAN_RXMGMASK)	S/U	No	No
Rx Buffer 14 Mask register (CAN_RX14MASK)	S/U	No	No
Rx Buffer 15 Mask register (CAN_RX15MASK)	S/U	No	No
Error Counter Register (CAN_ECR)	S/U	Yes	Yes
Error and Status 1 Register (CAN_ESR1)	S/U	Yes	Yes
Interrupt Masks 2 register (CAN_IMASK2)	S/U	Yes	Yes
Interrupt Masks 1 register (CAN_IMASK1)	S/U	Yes	Yes
Interrupt Flags 2 register (CAN_IFLAG2)	S/U	Yes	Yes
Interrupt Flags 1 register (CAN_IFLAG1)	S/U	Yes	Yes
Control 2 Register (CAN_CTRL2)	S/U	Yes	No
Error and Status 2 Register (CAN_ESR2)	S/U	Yes	Yes
CRC Register (CAN_CRCR)	S/U	Yes	Yes
Rx FIFO Global Mask register (CAN_RXFGMASK)	S/U	No	No
Rx FIFO Information Register (CAN_RXFIR)	S/U	No	No
CAN Bit Timing Register (CAN_CBT)	S/U	Yes	No
Interrupt Masks 3 register (CAN_IMASK3)	S/U	Yes	Yes

Table continues on the next page...

Table 47-6. Register access and reset information (continued)

Register	Access type	Affected by hard reset	Affected by soft reset
Interrupt Flags 3 register (CAN_IFLAG3)	S/U	Yes	Yes
Message buffers	S/U	No	No
Rx Individual Mask Registers	S/U	No	No
Memory Error Control register (CAN_MECR)	S/U	Yes	Yes
Error Injection Address register (CAN_ERRIAR)	S/U	Yes	Yes
Error Injection Data Pattern register (CAN_ERRIDPR)	S/U	Yes	Yes
Error Injection Parity Pattern register (CAN_ERRIPPR)	S/U	Yes	Yes
Error Report Address register (CAN_RERRAR)	S/U	Yes	Yes
Error Report Data register (CAN_RERRDR)	S/U	Yes	Yes
Error Report Syndrome register (CAN_RERRSYNR)	S/U	Yes	Yes
Error Status register (CAN_ERRSR)	S/U	Yes	Yes

The FlexCAN module can store CAN messages for transmission and reception using mailboxes and Rx FIFO structures.

The table below shows the FlexCAN memory map.

The address range from offset 0x80 to 0x67F allocates the ninety-six 128-bit Message Buffers (MBs).

CAN memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	Module Configuration Register (CAN_MCR)	32	R/W	See section	47.4.2/1842
4	Control 1 register (CAN_CTRL1)	32	R/W	0000_0000h	47.4.3/1847
8	Free Running Timer (CAN_TIMER)	32	R/W	0000_0000h	47.4.4/1851
10	Rx Mailboxes Global Mask Register (CAN_RXMGMASK)	32	R/W	Undefined	47.4.5/1851
14	Rx 14 Mask register (CAN_RX14MASK)	32	R/W	Undefined	47.4.6/1853
18	Rx 15 Mask register (CAN_RX15MASK)	32	R/W	Undefined	47.4.7/1853
1C	Error Counter (CAN_ECR)	32	R/W	0000_0000h	47.4.8/1854
20	Error and Status 1 register (CAN_ESR1)	32	R/W	See section	47.4.9/1856
24	Interrupt Masks 2 register (CAN_IMASK2)	32	R/W	0000_0000h	47.4.10/ 1862
28	Interrupt Masks 1 register (CAN_IMASK1)	32	R/W	0000_0000h	47.4.11/ 1862
2C	Interrupt Flags 2 register (CAN_IFLAG2)	32	R/W	0000_0000h	47.4.12/ 1863
30	Interrupt Flags 1 register (CAN_IFLAG1)	32	R/W	0000_0000h	47.4.13/ 1864

Table continues on the next page...

CAN memory map (continued)

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
34	Control 2 register (CAN_CTRL2)	32	R/W	See section	47.4.14/ 1867

47.4.2 Module Configuration Register (CAN_MCR)

This register defines global system configurations, such as the module operation modes and the maximum message buffer configuration.

Address: 0h base + 0h offset = 0h

CAN_MCR field descriptions

Field	Description
0 MDIS	Module Disable This bit controls whether FlexCAN is enabled or not. When disabled, FlexCAN disables the clocks to the CAN Protocol Engine and Controller Host Interface sub-modules. This bit is not affected by soft reset. 0 Enable the FlexCAN module. 1 Disable the FlexCAN module.
1 FRZ	Freeze Enable The FRZ bit specifies the FlexCAN behavior when the HALT bit in the CAN_MCR Register is set or when Debug mode is requested at chip level. When FRZ is asserted, FlexCAN is enabled to enter Freeze mode. Negation of this bit field causes FlexCAN to exit from Freeze mode. This bit is set by hardware when a non-correctable error is detected and NCEFAFRZ bit in CAN_MECR register is asserted. 0 Not enabled to enter Freeze mode. 1 Enabled to enter Freeze mode.
2 RFEN	Rx FIFO Enable This bit controls whether the Rx FIFO feature is enabled or not. When RFEN is set, MBs 0 to 5 cannot be used for normal reception and transmission because the corresponding memory region (0x80-0xDC) is used by the FIFO engine as well as additional MBs (up to 32, depending on CAN_CTRL2[RFFN] setting) which are used as Rx FIFO ID Filter Table elements. RFEN also impacts the definition of the minimum number of peripheral clocks per CAN bit as described in the table "Minimum Ratio Between Peripheral Clock Frequency and CAN Bit Rate" (see Arbitration and matching timing). This bit can be written in Freeze mode only because it is blocked by hardware in other modes. 0 Rx FIFO not enabled. 1 Rx FIFO enabled.
3 HALT	Halt FlexCAN

Table continues on the next page...

CAN_MCR field descriptions (continued)

Field	Description
	Assertion of this bit puts the FlexCAN module into Freeze mode. The CPU should clear it after initializing the Message Buffers and the Control Registers CAN_CTRL1 and CAN_CTRL2. No reception or transmission is performed by FlexCAN before this bit is cleared. Freeze mode cannot be entered while FlexCAN is in a low power mode. The HALT bit is set by hardware when a non-correctable error is detected and NCEFAFRZ bit in CAN_MECR register is asserted. 0 No Freeze mode request. 1 Enters Freeze mode if the FRZ bit is asserted.
4 NOTRDY	FlexCAN Not Ready This read-only bit indicates that FlexCAN is either in Disable mode, Stop mode or Freeze mode. It is negated once FlexCAN has exited these modes. This bit is not affected by soft reset. 0 FlexCAN module is either in Normal mode, Listen-Only mode or Loop-Back mode. 1 FlexCAN module is either in Disable mode, Stop mode or Freeze mode.
5 Reserved	This field is reserved. When writing to this field, always write the reset value.
6 SOFTRST	Soft Reset When this bit is asserted, FlexCAN resets its internal state machines and some of the memory mapped registers. The SOFTRST bit can be asserted directly by the CPU when it writes to the MCR Register. Because soft reset is synchronous and has to follow a request/acknowledge procedure across clock domains, it may take some time to fully propagate its effect. The SOFTRST bit remains asserted while reset is pending, and is automatically negated when reset completes. Therefore, software can poll this bit to know when the soft reset has completed. Soft reset cannot be applied while clocks are shut down in a low power mode. The module should be first removed from low power mode, and then soft reset can be applied. This bit is not affected by soft reset. 0 No reset request. 1 Resets the registers affected by soft reset.
7 FRZACK	Freeze Mode Acknowledge This read-only bit indicates that FlexCAN is in Freeze mode and its prescaler is stopped. The Freeze mode request cannot be granted until current transmission or reception processes have finished. Therefore the software can poll the FRZACK bit to know when FlexCAN has actually entered Freeze mode. If Freeze Mode request is negated, then this bit is negated after the FlexCAN prescaler is running again. If Freeze mode is requested while FlexCAN is in a low power mode, then the FRZACK bit will be set only when the low-power mode is exited. See Section "Freeze Mode". This bit is not affected by soft reset. **NOTE:** FRZACK will be asserted within 178 CAN bits from the freeze mode request by the CPU, and negated within 2 CAN bits after the freeze mode request removal (see Section "Protocol Timing"). 0 FlexCAN not in Freeze mode, prescaler running. 1 FlexCAN in Freeze mode, prescaler stopped.
8 SUPV	Supervisor Mode This bit configures the FlexCAN to be either in Supervisor or User mode. The registers affected by this bit are marked as S/U in the Access Type column of the module memory map. Reset value of this bit is 1, so the affected registers start with Supervisor access allowance only. This bit can be written only in Freeze mode because it is blocked by hardware in other modes.

CAN_MCR field descriptions (continued)

Field	Description
	0 FlexCAN is in User mode. Affected registers allow both Supervisor and Unrestricted accesses. 1 FlexCAN is in Supervisor mode. Affected registers allow only Supervisor access. Unrestricted access behaves as though the access was done to an unimplemented register location.
9 Reserved	This field is reserved. When writing to this field, always write the reset value.
10 WRNEN	Warning Interrupt Enable When asserted, this bit enables the generation of the TWRNINT and RWRNINT flags in the Error and Status Register 1 (ESR1). If WRNEN is negated, the TWRNINT and RWRNINT flags will always be zero, independent of the values of the error counters, and no warning interrupt will ever be generated. This bit can be written in Freeze mode only because it is blocked by hardware in other modes. 0 TWRNINT and RWRNINT bits are zero, independent of the values in the error counters. 1 TWRNINT and RWRNINT bits are set when the respective error counter transitions from less than 96 to greater than or equal to 96.
11 LPMACK	Low-Power Mode Acknowledge This read-only bit indicates that FlexCAN is in a low-power mode (Disable mode, Stop mode). A low-power mode cannot be entered until all current transmission or reception processes have finished, so the CPU can poll the LPMACK bit to know when FlexCAN has actually entered low power mode. This bit is not affected by soft reset. **NOTE:** LPMACK will be asserted within 180 CAN bits from the low-power mode request by the CPU, and negated within 2 CAN bits after the low-power mode request removal (see Section "Protocol Timing"). 0 FlexCAN is not in a low-power mode. 1 FlexCAN is in a low-power mode.
12 Reserved	This field is reserved. When writing to this field, always write the reset value.
13 Reserved	This field is reserved. When writing to this field, always write the reset value.
14 SRXDIS	Self Reception Disable This bit defines whether FlexCAN is allowed to receive frames transmitted by itself. If this bit is asserted, frames transmitted by the module will not be stored in any MB, regardless if the MB is programmed with an ID that matches the transmitted frame, and no interrupt flag or interrupt signal will be generated due to the frame reception. This bit can be written only in Freeze mode because it is blocked by hardware in other modes. 0 Self reception enabled. 1 Self reception disabled.
15 IRMQ	Individual Rx Masking And Queue Enable This bit indicates whether Rx matching process will be based either on individual masking and queue or on masking scheme with CAN_RXMGMASK, CAN_RX14MASK, CAN_RX15MASK and CAN_RXFGMASK. This bit can be written in Freeze mode only because it is blocked by hardware in other modes. 0 Individual Rx masking and queue feature are disabled. For backward compatibility with legacy applications, the reading of C/S word locks the MB even if it is EMPTY. 1 Individual Rx masking and queue feature are enabled.

Table continues on the next page...

CAN_MCR field descriptions (continued)

Field	Description
16 DMA	DMA Enable The DMA Enable bit controls whether the DMA feature is enabled or not. The DMA feature can only be used in Rx FIFO, consequently the bit CAN_MCR[RFEN] must be asserted. When DMA and RFEN are set, the CAN_IFLAG1[BUF5I] generates the DMA request and no RX FIFO interrupt is generated. This bit can be written in Freeze mode only as it is blocked by hardware in other modes. 0 DMA feature for RX FIFO disabled. 1 DMA feature for RX FIFO enabled.
17 Reserved	This field is reserved.
18 LPRIOEN	Local Priority Enable This bit is provided for backwards compatibility with legacy applications. It controls whether the local priority feature is enabled or not. It is used to expand the ID used during the arbitration process. With this expanded ID concept, the arbitration process is done based on the full 32-bit word, but the actual transmitted ID still has 11-bit for standard frames and 29-bit for extended frames. This bit can be written only in Freeze mode because it is blocked by hardware in other modes. 0 Local Priority disabled. 1 Local Priority enabled.
19 AEN	Abort Enable When asserted, this bit enables the Tx abort mechanism. This mechanism guarantees a safe procedure for aborting a pending transmission, so that no frame is sent in the CAN bus without notification. This bit can be written only in Freeze mode because it is blocked by hardware in other modes. **NOTE:** When CAN_MCR[AEN] is asserted, only the abort mechanism (see Transmission abort mechanism) must be used for updating Mailboxes configured for transmission. **CAUTION:** Writing the Abort code into Rx Mailboxes can cause unpredictable results when the CAN_MCR[AEN] is asserted. 0 Abort disabled. 1 Abort enabled.
20 Reserved	This field is reserved.
21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22–23 IDAM	ID Acceptance Mode This 2-bit field identifies the format of the Rx FIFO ID Filter Table elements. Note that all elements of the table are configured at the same time by this field (they are all the same format). See Section "Rx FIFO Structure". This field can be written only in Freeze mode because it is blocked by hardware in other modes. 00 Format A: One full ID (standard and extended) per ID Filter Table element. 01 Format B: Two full standard IDs or two partial 14-bit (standard and extended) IDs per ID Filter Table element. 10 Format C: Four partial 8-bit Standard IDs per ID Filter Table element. 11 Format D: All frames rejected.
24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

CAN_MCR field descriptions (continued)

Field	Description
25–31 MAXMB	Number Of The Last Message Buffer This 7-bit field defines the number of the last Message Buffers that will take part in the matching and arbitration processes. The reset value (0x0F) is equivalent to a 16 MB configuration. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Number of the last MB = MAXMB **NOTE:** MAXMB must be programmed with a value smaller than or equal to the number of available Message Buffers. Additionally, the definition of MAXMB value must take into account the region of MBs occupied by Rx FIFO and its ID filters table space defined by RFFN bit in CAN_CTRL2 register. MAXMB also impacts the definition of the minimum number of peripheral clocks per CAN bit as described in Table "Minimum Ratio Between Peripheral Clock Frequency and CAN Bit Rate" (see Arbitration and matching timing).

47.4.3 Control 1 register (CAN_CTRL1)

This register is defined for specific FlexCAN control features related to the CAN bus, such as bit-rate, programmable sampling point within an Rx bit, Loop Back mode, Listen-Only mode, Bus Off recovery behavior and interrupt enabling (Bus-Off, Error, Warning). It also determines the Division Factor for the clock prescaler.

The CAN bit timing variables (PRESDIV, PROPSEG, PSEG1, PSEG2 and RJW) can also be configured in CAN_CBT register, which extends the range of all these variables. If CAN_CBT[BTF] is set, PRESDIV, PROPSEG, PSEG1, PSEG2 and RJW fields of CAN_CTRL1 become read only.

The contents of this register are not affected by soft reset.

NOTE

The CAN bit variables in CAN_CTRL1 and in CAN_CBT are stored in the same register.

Address: 0h base + 4h offset = 4h

CAN_CTRL1 field descriptions

Field	Description
0–7 PRESDIV	Prescaler Division Factor This 8-bit field defines the ratio between the PE clock frequency and the Serial Clock (Sclock) frequency. The Sclock period defines the time quantum of the CAN protocol. For the reset value, the Sclock frequency is equal to the PE clock frequency. The Maximum value of this field is 0xFF, that gives a minimum Sclock frequency equal to the PE clock frequency divided by 256. See Section "Protocol Timing". This field can be written only in Freeze mode because it is blocked by hardware in other modes. Sclock frequency = PE clock frequency / (PRESDIV + 1)
8–9 RJW	Resync Jump Width This 2-bit field defines the maximum number of time quanta that a bit time can be changed by one re-synchronization. One time quantum is equal to the Sclock period. The valid programmable values are 0–3. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Resync Jump Width = RJW + 1.
10–12 PSEG1	Phase Segment 1 This 3-bit field defines the length of Phase Segment 1 in the bit time. The valid programmable values are 0–7. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Phase Buffer Segment 1 = (PSEG1 + 1) × Time-Quanta.
13–15 PSEG2	Phase Segment 2 This 3-bit field defines the length of Phase Segment 2 in the bit time. The valid programmable values are 1–7. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Phase Buffer Segment 2 = (PSEG2 + 1) × Time-Quanta.
16 BOFFMSK	Bus Off Interrupt Mask This bit provides a mask for the Bus Off Interrupt BOFFINT in CAN_ESR1 register. 0 Bus Off interrupt disabled. 1 Bus Off interrupt enabled.
17 ERRMSK	Error Interrupt Mask This bit provides a mask for the Error Interrupt ERRINT in the CAN_ESR1 register. 0 Error interrupt disabled. 1 Error interrupt enabled.
18 Reserved	This field is reserved.

Table continues on the next page...

CAN_CTRL1 field descriptions (continued)

Field	Description
19 LPB	Loop Back Mode This bit configures FlexCAN to operate in Loop-Back mode. In this mode, FlexCAN performs an internal loop back that can be used for self test operation. The bit stream output of the transmitter is fed back internally to the receiver input. The Rx CAN input pin is ignored and the Tx CAN output goes to the recessive state (logic 1). FlexCAN behaves as it normally does when transmitting, and treats its own transmitted message as a message received from a remote node. In this mode, FlexCAN ignores the bit sent during the ACK slot in the CAN frame acknowledge field, generating an internal acknowledge bit to ensure proper reception of its own message. Both transmit and receive interrupts are generated. This bit can be written only in Freeze mode because it is blocked by hardware in other modes. **NOTE:** In this mode, the CAN_MCR[SRXDIS] cannot be asserted because this will impede the self reception of a transmitted message. 0 Loop Back disabled. 1 Loop Back enabled.
20 TWRNMSK	Tx Warning Interrupt Mask This bit provides a mask for the Tx Warning Interrupt associated with the TWRNINT flag in the Error and Status Register 1 (ESR1). This bit is read as zero when CAN_MCR[WRNEN] bit is negated. This bit can be written only if CAN_MCR[WRNEN] bit is asserted. 0 Tx Warning Interrupt disabled. 1 Tx Warning Interrupt enabled.
21 RWRNMSK	Rx Warning Interrupt Mask This bit provides a mask for the Rx Warning Interrupt associated with the RWRNINT flag in the Error and Status Register 1 (ESR1). This bit is read as zero when CAN_MCR[WRNEN] bit is negated. This bit can be written only if CAN_MCR[WRNEN] bit is asserted. 0 Rx Warning Interrupt disabled. 1 Rx Warning Interrupt enabled.
22 Reserved	This field is reserved.
23 Reserved	This field is reserved.
24 SMP	CAN Bit Sampling This bit defines the sampling mode of CAN bits at the Rx input. It can be written in Freeze mode only because it is blocked by hardware in other modes. **NOTE:** For proper operation, to assert SMP it is necessary to guarantee a minimum value of 2 TQs in CAN_CTRL1[PSEG1] (or CAN_CBT[EPSEG1]). 0 Just one sample is used to determine the bit value. 1 Three samples are used to determine the value of the received bit: the regular one (sample point) and 2 preceding samples; a majority rule is used.
25 BOFFREC	Bus Off Recovery This bit defines how FlexCAN recovers from Bus Off state. If this bit is negated, automatic recovering from Bus Off state occurs according to the CAN Specification 2.0B. If the bit is asserted, automatic recovering from Bus Off is disabled and the module remains in Bus Off state until the bit is negated by the user. If the

Table continues on the next page...

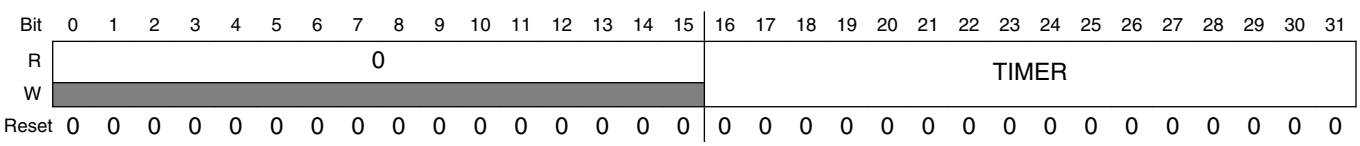
CAN_CTRL1 field descriptions (continued)

Field	Description
	negation occurs before 128 sequences of 11 recessive bits are detected on the CAN bus, then Bus Off recovery happens as if the BOFFREC bit had never been asserted. If the negation occurs after 128 sequences of 11 recessive bits occurred, then FlexCAN will re-synchronize to the bus by waiting for 11 recessive bits before joining the bus. After negation, the BOFFREC bit can be re-asserted again during Bus Off, but it will be effective only the next time the module enters Bus Off. If BOFFREC was negated when the module entered Bus Off, asserting it during Bus Off will not be effective for the current Bus Off recovery. 0 Automatic recovering from Bus Off state enabled. 1 Automatic recovering from Bus Off state disabled.
26 TSYN	Timer Sync This bit enables a mechanism that resets the free-running timer each time a message is received in Message Buffer 0. This feature provides means to synchronize multiple FlexCAN stations with a special “SYNC” message, that is, global network time. If the RFEN bit in CAN_MCR is set (Rx FIFO enabled), the first available Mailbox, according to CAN_CTRL2[RFFN] setting, is used for timer synchronization instead of MB0. This bit can be written in Freeze mode only because it is blocked by hardware in other modes. 0 Timer Sync feature disabled 1 Timer Sync feature enabled
27 LBUF	Lowest Buffer Transmitted First This bit defines the ordering mechanism for Message Buffer transmission. When asserted, the CAN_MCR[LPRIOEN] bit does not affect the priority arbitration. This bit can be written in Freeze mode only because it is blocked by hardware in other modes. 0 Buffer with highest priority is transmitted first. 1 Lowest number buffer is transmitted first.
28 LOM	Listen-Only Mode This bit configures FlexCAN to operate in Listen-Only mode. In this mode, transmission is disabled, all error counters described in CAN_ECR register are frozen and the module operates in a CAN Error Passive mode. Only messages acknowledged by another CAN station will be received. If FlexCAN detects a message that has not been acknowledged, it will flag a BIT0 error without changing the receive error counter (RXERRCNT) in CAN_ECR register, as if it was trying to acknowledge the message. Listen-Only mode is acknowledged by the state of CAN_ESR1[FLTCONF] field indicating Passive Error. There can be some delay between the Listen-Only mode request and acknowledge. This bit can be written in Freeze mode only because it is blocked by hardware in other modes. 0 Listen-Only mode is deactivated. 1 FlexCAN module operates in Listen-Only mode.
29–31 PROPSEG	Propagation Segment This 3-bit field defines the length of the Propagation Segment in the bit time. The valid programmable values are 0–7. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Propagation Segment Time = (PROPSEG + 1) × Time-Quanta. Time-Quantum = one Sclock period.

47.4.4 Free Running Timer (CAN_TIMER)

This register represents a 16-bit free running counter that can be read and written by the CPU. The timer starts from 0x0 after Reset, counts linearly to 0xFFFF, and wraps around.

The timer is incremented by the CAN bit clock, which defines the baud rate on the CAN bus. During a message transmission/reception, it increments by one for each bit that is received or transmitted. When there is no message on the bus, it counts using the previously programmed baud rate. The timer is not incremented during Disable, Stop and Freeze modes.



The timer value is captured when the second bit of the identifier field of any frame is on the CAN bus. This captured value is written into the Time Stamp entry in a message buffer after a successful reception or transmission of a message.

If bit CAN_CTRL1[TSYN] is asserted, the Timer is reset whenever a message is received in the first available Mailbox, according to CAN_CTRL2[RFFN] setting.

The CPU can write to this register anytime. However, if the write occurs at the same time that the Timer is being reset by a reception in the first Mailbox, then the write value is discarded.

Reading this register affects the Mailbox Unlocking procedure, see Section "Mailbox Lock Mechanism".

Address: 0h base + 8h offset = 8h

CAN_TIMER field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 TIMER	Timer Value Contains the free-running counter value.

47.4.5 Rx Mailboxes Global Mask Register (CAN_RXMGMASK)

This register is located in RAM.

RXMGMASK is provided for legacy application support.

- When the CAN_MCR[IRMQ] bit is negated, RXMGMASK is always in effect (the bits in the MG field will mask the Mailbox filter bits).
- When the CAN_MCR[IRMQ] bit is asserted, RXMGMASK has no effect (the bits in the MG field will not mask the Mailbox filter bits).

RXMGMASK is used to mask the filter fields of all Rx MBs, excluding MBs 14-15, which have individual mask registers.

This register can only be written in Freeze mode as it is blocked by hardware in other modes.

Address: 0h base + 10h offset = 10h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

1	1	0	-	-	MG[28:0]	MG[31:29]
1	1	1	MG[31]	MG[30]	MG[28:0]	MG[29]

1. RTR bit of the Incoming Frame. It is saved into an auxiliary MB called Rx Serial Message Buffer (Rx SMB).
2. If the CTRL2[EACEN] bit is negated, the RTR bit of Mailbox is never compared with the RTR bit of the incoming frame.
3. If the CAN_CTRL2[EACEN] bit is negated, the IDE bit of Mailbox is always compared with the IDE bit of the incoming frame.

0 The corresponding bit in the filter is "don't care."
1 The corresponding bit in the filter is checked.

1. RTR bit of the Incoming Frame. It is saved into an auxiliary MB called Rx Serial Message Buffer (Rx SMB).
2. If the CTRL2[EACEN] bit is negated, the RTR bit of Mailbox is never compared with the RTR bit of the incoming frame.
3. If the CAN_CTRL2[EACEN] bit is negated, the IDE bit of Mailbox is always compared with the IDE bit of the incoming frame.

47.4.6 Rx 14 Mask register (CAN_RX14MASK)

This register is located in RAM.

RX14MASK is provided for legacy application support. When the CAN_MCR[IRMQ] bit is asserted, RX14MASK has no effect.

RX14MASK is used to mask the filter fields of Message Buffer 14.

This register can only be programmed while the module is in Freeze mode as it is blocked by hardware in other modes.

Address: 0h base + 14h offset = 14h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

CAN_RX15MASK field descriptions

Field	Description
0–31 RX15M	Rx Buffer 15 Mask Bits Each mask bit masks the corresponding Mailbox 15 filter field in the same way that RXMGMASK masks other Mailboxes' filters. See the description of the CAN_RXMGMASK register. 0 The corresponding bit in the filter is "don't care." 1 The corresponding bit in the filter is checked.

47.4.8 Error Counter (CAN_ECR)

This register has two 8-bit fields reflecting the value of the FlexCAN error counters:

- Transmit Error Counter (TXERRCNT field)
- Receive Error Counter (RXERRCNT field)

The Fault Confinement State (FLTCONF field in Error and Status Register 1 - CAN_ESR1) is updated based on TXERRCNT and RXERRCNT counters. TXERRCNT and RXERRCNT counters can be written in Freeze mode only. The rules for increasing and decreasing these counters are described in the CAN protocol and are completely implemented in the FlexCAN module.

The following are the basic rules for FlexCAN bus state transitions:

- If the value of TXERRCNT or RXERRCNT increases to be greater than or equal to 128, the FLTCONF field in the Error and Status Register is updated to reflect "Error Passive" state.
- If the FlexCAN state is "Error Passive", and either TXERRCNT or RXERRCNT decrements to a value less than or equal to 127 while the other already satisfies this condition, the FLTCONF field in the Error and Status Register is updated to reflect "Error Active" state.
- If the value of TXERRCNT increases to be greater than 255, the FLTCONF field in the Error and Status Register is updated to reflect "Bus Off" state, and an interrupt may be issued. The value of TXERRCNT is then reset to zero.

- If FlexCAN is in "Bus Off' state, then TXERRCNT is cascaded together with another internal counter to count the 128th occurrences of 11 consecutive recessive bits on the bus. Hence, TXERRCNT is reset to zero and counts in a manner where the internal counter counts 11 such bits and then wraps around while incrementing the TXERRCNT. When TXERRCNT reaches the value of 128, the FLTCONF field in the Error and Status Register is updated to be "Error Active" and both error counters are reset to zero. At any instance of dominant bit following a stream of less than 11 consecutive recessive bits, the internal counter resets itself to zero without affecting the TXERRCNT value.
- If during system start-up, only one node is operating, then its TXERRCNT increases in each message it is trying to transmit, as a result of acknowledge errors (indicated by the ACKERR bit in the Error and Status Register). After the transition to "Error Passive" state, the TXERRCNT does not increment anymore by acknowledge errors. Therefore the device never goes to the "Bus Off" state.
- If the RXERRCNT increases to a value greater than 127, it is not incremented further, even if more errors are detected while being a receiver. At the next successful message reception, the counter is set to a value between 119 and 127 to resume to "Error Active" state.

Address: 0h base + 1Ch offset = 1Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	Reserved								Reserved								RXERRCNT								TXERRCNT

CAN_ECR field descriptions

Field	Description
0–7 Reserved	This field is reserved.
8–15 Reserved	This field is reserved.
16–23 RXERRCNT	Receive Error Counter Receive Error Counter for all errors detected in received messages. The RXERRCNT counter is read-only except in Freeze mode, where it can be written by the CPU.
24–31 TXERRCNT	Transmit Error Counter Transmit Error Counter for all errors detected in transmitted messages. The TXERRCNT counter is read-only except in Freeze mode, where it can be written by the CPU.

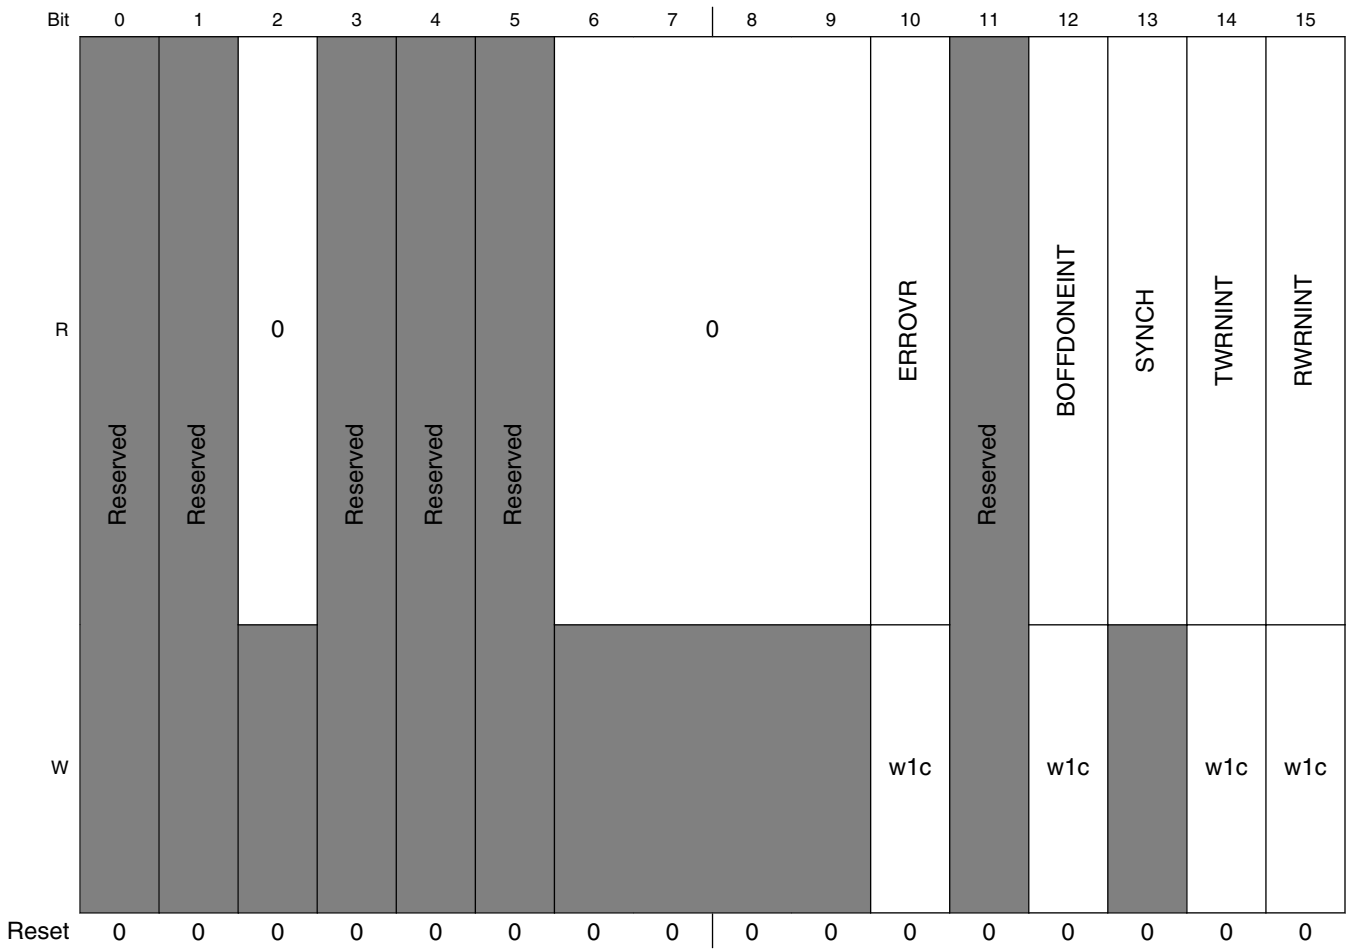
47.4.9 Error and Status 1 register (CAN_ESR1)

This register reports various error conditions detected in the reception and transmission of a CAN frame, some general status of the device and it is the source of some interrupts to the CPU.

The reported error conditions are BIT1ERR, BIT0ERR, ACKKERR, CRCERR, FRMERR and STFERR.

An error detected in a single CAN frame may be reported by one or more error flags. Also, error reporting is cummulative in case more error events happen in the next frames while the CPU does not attempt to read this register.

TXWRN, RXWRN, IDLE, TX, FLTCONF, RX and SYNCH are status bits.



BOFFINT, BOFFDONEINT, ERRINT, TWRNINT and RWRNINT are interrupt bits. It is recommended the CPU to use the following procedure when servicing interrupt requests generated by these bits:

- Read this register to capture all error condition and status bits. This action clear the respective bits that were set since the last read access.
- Write 1 to clear the interrupt bit that has triggered the interrupt request.
- Write 1 to clear the ERR_OVR bit if it is set.

Starting from all error flags cleared, a first error event sets the ERRINT (provided the corresponding mask bit is asserted). If other error events in subsequent frames happen before the CPU to serve the interrupt request, the ERR_OVR bit is set to indicate that errors from different frames had accumulated.

SYNCH	IDLE	TX	RX	FlexCAN State
0	0	0	0	Not synchronized to CAN bus

3 Reserved	This field is reserved.
4 Reserved	This field is reserved.
5 Reserved	This field is reserved.
6–9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
10 ERROVR	Error Overrun bit This bit indicates that an error condition occurred when any error flag is already set. This bit is cleared by writing it to 1.

Table continues on the next page...

CAN_ESR1 field descriptions (continued)

Field	Description
	0 Overrun has not occurred. 1 Overrun has occured.
11 Reserved	This field is reserved.
12 BOFFDONEINT	Bus Off Done Interrupt This bit is set when the Tx Error Counter (TXERRCNT) has finished counting 128 occurrences of 11 consecutive recessive bits on the CAN bus and is ready to leave Bus Off. If the corresponding mask bit in the Control 2 Register (BOFFDONEMSK) is set, an interrupt is generated to the CPU. This bit is cleared by writing it to 1. Writing 0 has no effect. 0 No such occurrence. 1 FlexCAN module has completed Bus Off process.
13 SYNCH	CAN Synchronization Status This read-only flag indicates whether the FlexCAN is synchronized to the CAN bus and able to participate in the communication process. It is set and cleared by the FlexCAN. See the table in the overall CAN_ESR1 register description. 0 FlexCAN is not synchronized to the CAN bus. 1 FlexCAN is synchronized to the CAN bus.
14 TWRNINT	Tx Warning Interrupt Flag If the WRNEN bit in CAN_MCR is asserted, the TWRNINT bit is set when the TXWRN flag transitions from 0 to 1, meaning that the Tx error counter reached 96. If the corresponding mask bit in the Control 1 Register (CAN_CTRL1[TWRNMSK]) is set, an interrupt is generated to the CPU. This bit is cleared by writing it to 1. When WRNEN is negated, this flag is masked. CPU must clear this flag before disabling the bit. Otherwise it will be set when the WRNEN is set again. Writing 0 has no effect. This flag is not generated during Bus Off state. This bit is not updated during Freeze mode. 0 No such occurrence. 1 The Tx error counter transitioned from less than 96 to greater than or equal to 96.
15 RWRNINT	Rx Warning Interrupt Flag If the WRNEN bit in CAN_MCR is asserted, the RWRNINT bit is set when the RXWRN flag transitions from 0 to 1, meaning that the Rx error counters reached 96. If the corresponding mask bit in the Control 1 Register (CAN_CTRL1[RWRNMSK]) is set, an interrupt is generated to the CPU. This bit is cleared by writing it to 1. When WRNEN is negated, this flag is masked. CPU must clear this flag before disabling the bit. Otherwise it will be set when the WRNEN is set again. Writing 0 has no effect. This bit is not updated during Freeze mode. 0 No such occurrence. 1 The Rx error counter transitioned from less than 96 to greater than or equal to 96.
16 BIT1ERR	Bit1 Error This bit indicates when an inconsistency occurs between the transmitted and the received bit in a message. **NOTE:** This bit is not set by a transmitter in case of arbitration field or ACK slot, or in case of a node sending a passive error flag that detects dominant bits. 0 No such occurrence. 1 At least one bit sent as recessive is received as dominant.

Table continues on the next page...

CAN_ESR1 field descriptions (continued)

Field	Description
17 BIT0ERR	Bit0 Error This bit indicates when an inconsistency occurs between the transmitted and the received bit in a message. 0 No such occurrence. 1 At least one bit sent as dominant is received as recessive.
18 ACKERR	Acknowledge Error This bit indicates that an Acknowledge Error has been detected by the transmitter node, that is, a dominant bit has not been detected during the ACK SLOT. 0 No such occurrence. 1 An ACK error occurred since last read of this register.
19 CRCERR	Cyclic Redundancy Check Error This bit indicates that a CRC Error has been detected by the receiver node, that is, the calculated CRC is different from the received. 0 No such occurrence. 1 A CRC error occurred since last read of this register.
20 FRMERR	Form Error This bit indicates that a Form Error has been detected by the receiver node, that is, a fixed-form bit field contains at least one illegal bit. 0 No such occurrence. 1 A Form Error occurred since last read of this register.
21 STFERR	Stuffing Error This bit indicates that a Stuffing Error has been detected by the receiver node. 0 No such occurrence. 1 A Stuffing Error occurred since last read of this register.
22 TXWRN	TX Error Warning This bit indicates when repetitive errors are occurring during message transmission and is affected by the value of TXERRCNT in CAN_ECR register only. This bit is not updated during Freeze mode. 0 No such occurrence. 1 TXERRCNT is greater than or equal to 96.
23 RXWRN	Rx Error Warning This bit indicates when repetitive errors are occurring during message reception and is affected by the value of RXERRCNT in CAN_ECR register only. This bit is not updated during Freeze mode. 0 No such occurrence. 1 RXERRCNT is greater than or equal to 96.
24 IDLE	This bit indicates when CAN bus is in IDLE state. See the table in the overall CAN_ESR1 register description. 0 No such occurrence. 1 CAN bus is now IDLE.

Table continues on the next page...

CAN_ESR1 field descriptions (continued)

Field	Description
25 TX	FlexCAN In Transmission This bit indicates if FlexCAN is transmitting a message. See the table in the overall CAN_ESR1 register description. 0 FlexCAN is not transmitting a message. 1 FlexCAN is transmitting a message.
26–27 FLTCONF	Fault Confinement State This 2-bit field indicates the Confinement State of the FlexCAN module. If the LOM bit in the Control Register 1 is asserted, after some delay that depends on the CAN bit timing the FLTCONF field will indicate “Error Passive”. The very same delay affects the way how FLTCONF reflects an update to CAN_ECR register by the CPU. It may be necessary up to one CAN bit time to get them coherent again. This bit field is affected by soft reset, but if the LOM bit is asserted, its reset value lasts just one CAN bit. After this time, FLTCONF reports "Error Passive". 00 Error Active 01 Error Passive 1x Bus Off
28 RX	FlexCAN In Reception This bit indicates if FlexCAN is receiving a message. See the table in the overall CAN_ESR1 register description. 0 FlexCAN is not receiving a message. 1 FlexCAN is receiving a message.
29 BOFFINT	Bus Off Interrupt This bit is set when FlexCAN enters ‘Bus Off’ state. If the corresponding mask bit in the Control Register 1 (CAN_CTRL1[BOFFMSK]) is set, an interrupt is generated to the CPU. This bit is cleared by writing it to 1. Writing 0 has no effect. 0 No such occurrence. 1 FlexCAN module entered Bus Off state.
30 ERRINT	Error Interrupt This bit indicates that at least one of the Error Bits (BIT1ERR, BIT0ERR, ACKERR. CRCERR, FRMERR or STFERR) is set. If the corresponding mask bit CAN_CTRL1[ERRMSK] is set, an interrupt is generated to the CPU. This bit is cleared by writing it to 1. Writing 0 has no effect. 0 No such occurrence. 1 Indicates setting of any Error Bit in the Error and Status Register.
31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

47.4.10 Interrupt Masks 2 register (CAN_IMASK2)

This register allows any number of a range of the 32 Message Buffer Interrupts to be enabled or disabled for MB63 to MB32. It contains one interrupt mask bit per buffer, enabling the CPU to determine which buffer generates an interrupt after a successful transmission or reception, that is, when the corresponding CAN_IFLAG2 bit is set.

Address: 0h base + 24h offset = 24h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

CAN_IMASK2 field descriptions

Field	Description
0–31 BUF63TO32M	Buffer MB $_i$ Mask Each bit enables or disables the corresponding FlexCAN Message Buffer Interrupt for MB63 to MB32. **NOTE:** Setting or clearing a bit in the CAN_IMASK2 Register can assert or negate an interrupt request, if the corresponding IFLAG2 bit is set. 0 The corresponding buffer Interrupt is disabled. 1 The corresponding buffer Interrupt is enabled.

47.4.11 Interrupt Masks 1 register (CAN_IMASK1)

This register allows any number of a range of the 32 Message Buffer Interrupts to be enabled or disabled for MB31 to MB0. It contains one interrupt mask bit per buffer, enabling the CPU to determine which buffer generates an interrupt after a successful transmission or reception, that is, when the corresponding CAN_IFLAG1 bit is set.

Address: 0h base + 28h offset = 28h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	BUF31TO0M

CAN_IMASK1 field descriptions

Field	Description
0–31 BUF31TO0M	Buffer MB $_i$ Mask Each bit enables or disables the corresponding FlexCAN Message Buffer Interrupt for MB31 to MB0. **NOTE:** Setting or clearing a bit in the CAN_IMASK1 Register can assert or negate an interrupt request, if the corresponding IFLAG1 bit is set. 0 The corresponding buffer Interrupt is disabled. 1 The corresponding buffer Interrupt is enabled.

47.4.12 Interrupt Flags 2 register (CAN_IFLAG2)

This register defines the flags for the 32 Message Buffer interrupts for MB63 to MB32. It contains one interrupt flag bit per buffer. Each successful transmission or reception sets the respective CAN_IFLAG2 bit. If the corresponding CAN_IMASK2 bit is set, an interrupt will be generated. The interrupt flag must be cleared by writing 1 to it. Writing 0 has no effect.

Before updating CAN_MCR[MAXMB] field, CPU must service the CAN_IFLAG2 bits whose MB value is greater than the MAXMB to be updated; otherwise, they will remain set and be inconsistent with the number of MBs available.

Address: 0h base + 2Ch offset = 2Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

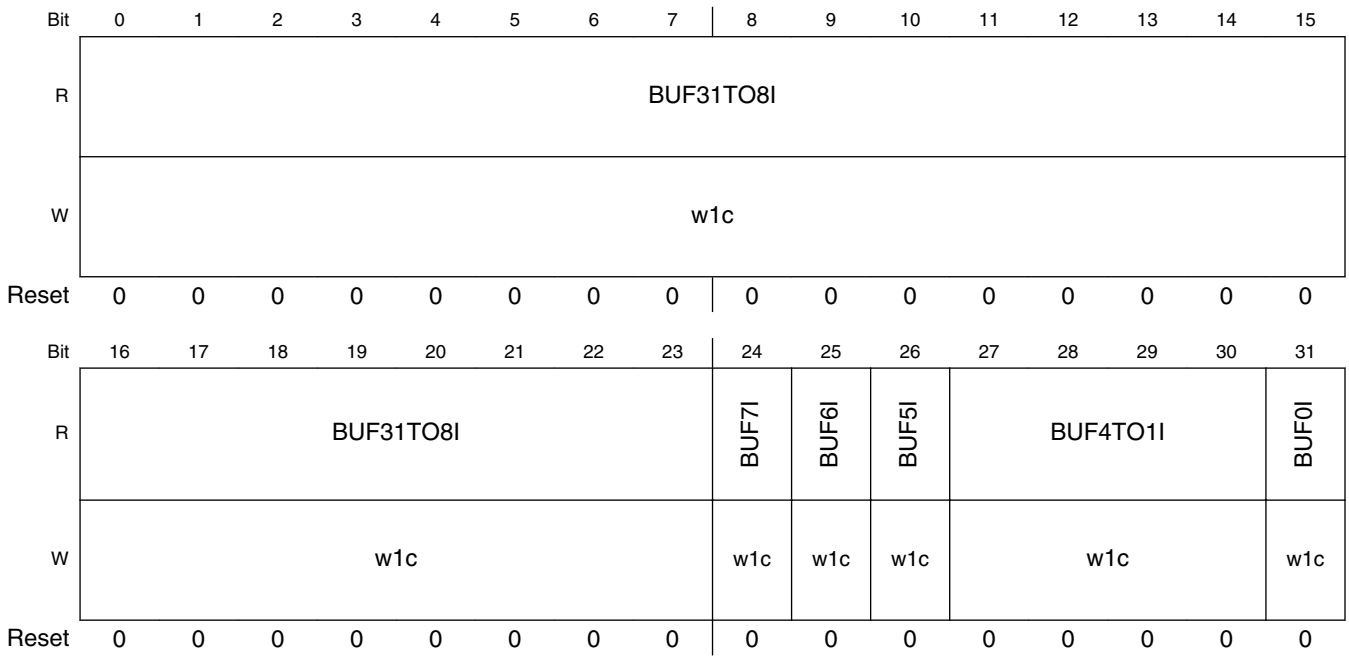
CAN_IFLAG2 field descriptions

Field	Description
0–31 BUF63TO32I	Buffer MB $_i$ Interrupt Each bit flags the corresponding FlexCAN Message Buffer interrupt for MB63 to MB32. 0 The corresponding buffer has no occurrence of successfully completed transmission or reception. 1 The corresponding buffer has successfully completed transmission or reception.

47.4.13 Interrupt Flags 1 register (CAN_IFLAG1)

This register defines the flags for the 32 Message Buffer interrupts for MB31 to MB0. It contains one interrupt flag bit per buffer. Each successful transmission or reception sets the corresponding CAN_IFLAG1 bit. If the corresponding CAN_IMASK1 bit is set, an interrupt will be generated. The interrupt flag must be cleared by writing 1 to it. Writing 0 has no effect. There is an exception when DMA for Rx FIFO is enabled, as described below.



The BUF7I to BUF5I flags are also used to represent FIFO interrupts when the Rx FIFO is enabled. When the bit CAN_MCR[RFEN] is set and the bit CAN_MCR[DMA] is negated, the function of the 8 least significant interrupt flags changes: BUF7I, BUF6I and BUF5I indicate operating conditions of the FIFO, BUF0I is used to empty FIFO, and BUF4I to BUF1I bits are reserved.

Before enabling the CAN_MCR[RFEN], the CPU must service the IFLAG bits asserted in the Rx FIFO region; see Section "Rx FIFO". Otherwise, these IFLAG bits will mistakenly show the related MBs now belonging to FIFO as having contents to be serviced. When the CAN_MCR[RFEN] bit is negated, the FIFO flags must be cleared. The same care must be taken when an CAN_CTRL2[RFFN] value is selected extending Rx FIFO filters beyond MB7. For example, when RFFN is 0x8, the MB0-23 range is occupied by Rx FIFO filters and related IFLAG bits must be cleared.

When both the CAN_MCR[RFEN] and CAN_MCR[DMA] bits are asserted (DMA feature for Rx FIFO enabled), the function of the 8 least significant interrupt flags (BUF7I - BUF0I) are changed to support the DMA operation. BUF7I and BUF6I are not used, as well as, BUF4I to BUF1I. BUF5I indicates operating condition of FIFO, and BUF0I is used to empty FIFO. Moreover, BUF5I does not generate a CPU interrupt, but generates a DMA request. IMASK1 bits in Rx FIFO region are not considered when bit CAN_MCR[DMA] is enabled. In addition the CPU must not clear the flag BUF5I when DMA is enabled. Before enabling the bit CAN_MCR[DMA], the CPU must service the IFLAGs asserted in the Rx FIFO region. When the bit CAN_MCR[DMA] is negated, the FIFO must be empty.

Before updating CAN_MCR[MAXMB] field, CPU must service the CAN_IFLAG1 bits whose MB value is greater than the CAN_MCR[MAXMB] to be updated; otherwise, they will remain set and be inconsistent with the number of MBs available.

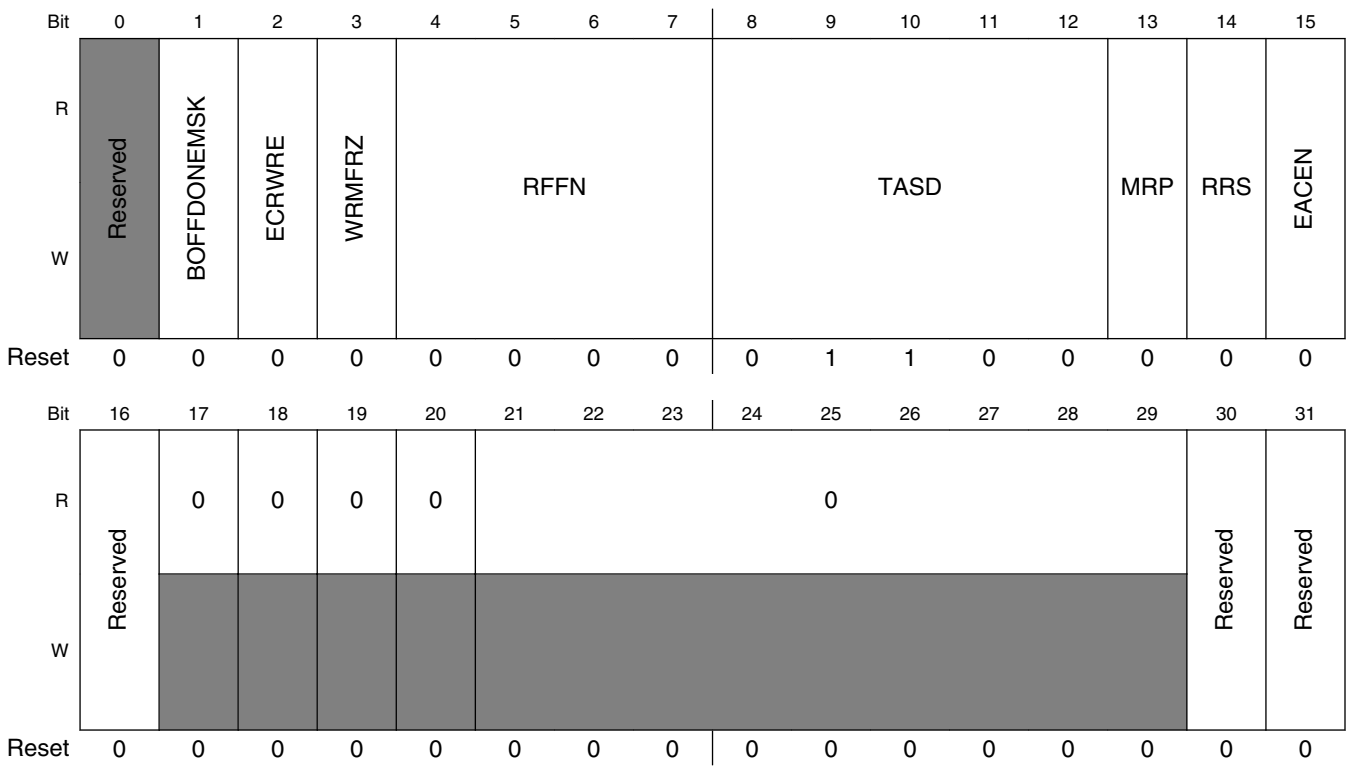
Address: 0h base + 30h offset = 30h

CAN_IFLAG1 field descriptions

Field	Description
0–23 BUF31TO8I	Buffer MB_i Interrupt Each bit flags the corresponding FlexCAN Message Buffer interrupt for MB31 to MB8. 0 The corresponding buffer has no occurrence of successfully completed transmission or reception. 1 The corresponding buffer has successfully completed transmission or reception.
24 BUF7I	Buffer MB7 Interrupt Or "Rx FIFO Overflow" When the RFEN bit in the CAN_MCR register is cleared (Rx FIFO disabled), this bit flags the interrupt for MB7. **NOTE:** This flag is cleared by the FlexCAN whenever the bit CAN_MCR[RFEN] is changed by CPU writes. The BUF7I flag represents "Rx FIFO Overflow" when CAN_MCR[RFEN] is set. In this case, the flag indicates that a message was lost because the Rx FIFO is full. Note that the flag will not be asserted when the Rx FIFO is full and the message was captured by a Mailbox. 0 No occurrence of MB7 completing transmission/reception when MCR[RFEN]=0, or of Rx FIFO overflow when MCR[RFEN]=1 1 MB7 completed transmission/reception when MCR[RFEN]=0, or Rx FIFO overflow when MCR[RFEN]=1
25 BUF6I	Buffer MB6 Interrupt Or "Rx FIFO Warning" When the RFEN bit in the CAN_MCR register is cleared (Rx FIFO disabled), this bit flags the interrupt for MB6. **NOTE:** This flag is cleared by the FlexCAN whenever the bit CAN_MCR[RFEN] is changed by CPU writes.

Table continues on the next page...

CAN_IFLAG1 field descriptions (continued)



Field	Description
	The BUF6I flag represents "Rx FIFO Warning" when CAN_MCR[RFEN] is set. In this case, the flag indicates when the number of unread messages within the Rx FIFO is increased to 5 from 4 due to the reception of a new one, meaning that the Rx FIFO is almost full. Note that if the flag is cleared while the number of unread messages is greater than 4, it does not assert again until the number of unread messages within the Rx FIFO is decreased to be equal to or less than 4. 0 No occurrence of MB6 completing transmission/reception when MCR[RFEN]=0, or of Rx FIFO almost full when MCR[RFEN]=1 1 MB6 completed transmission/reception when MCR[RFEN]=0, or Rx FIFO almost full when MCR[RFEN]=1
26 BUF5I	Buffer MB5 Interrupt Or "Frames available in Rx FIFO" When the RFEN bit in the MCR is cleared (Rx FIFO disabled), this bit flags the interrupt for MB5. **NOTE:** This flag is cleared by the FlexCAN whenever the bit MCR[RFEN] is changed by CPU writes. When MCR[RFEN] is set (Rx FIFO enabled), the BUF5I flag represents "Frames available in Rx FIFO" and indicates that at least one frame is available to be read from the Rx FIFO. When the MCR[DMA] bit is enabled, this flag generates a DMA request and the CPU must not clear this bit by writing 1 in BUF5I. 0 No occurrence of MB5 completing transmission/reception when MCR[RFEN]=0, or of frame(s) available in the FIFO, when MCR[RFEN]=1 1 MB5 completed transmission/reception when MCR[RFEN]=0, or frame(s) available in the Rx FIFO when MCR[RFEN]=1. It generates a DMA request in case of MCR[RFEN] and MCR[DMA] are enabled.
27–30 BUF4TO1I	Buffer MB $_i$ Interrupt Or "reserved" When the RFEN bit in the CAN_MCR register is cleared (Rx FIFO disabled), these bits flag the interrupts for MB4 to MB1. **NOTE:** These flags are cleared by the FlexCAN whenever the bit CAN_MCR[RFEN] is changed by CPU writes. The BUF4TO1I flags are reserved when CAN_MCR[RFEN] is set. 0 The corresponding buffer has no occurrence of successfully completed transmission or reception when MCR[RFEN]=0. 1 The corresponding buffer has successfully completed transmission or reception when MCR[RFEN]=0.
31 BUF0I	Buffer MB0 Interrupt Or Clear FIFO bit When the RFEN bit in MCR is cleared (Rx FIFO disabled), this bit flags the interrupt for MB0. If the Rx FIFO is enabled, this bit is used to trigger the clear FIFO operation. This operation empties FIFO contents. Before performing this operation the CPU must service all FIFO related IFLAGs. When the bit MCR[DMA] is enabled this operation also clears the BUF5I flag and consequently abort the DMA request. The clear FIFO operation occurs when the CPU writes 1 in BUF0I. It is only allowed in Freeze Mode and is blocked by hardware in other conditions. 0 The corresponding buffer has no occurrence of successfully completed transmission or reception when MCR[RFEN]=0. 1 The corresponding buffer has successfully completed transmission or reception when MCR[RFEN]=0.

47.4.14 Control 2 register (CAN_CTRL2)

This register complements Control1 Register providing control bits for memory write access in Freeze Mode, for extending FIFO filter quantity, and for adjust the operation of internal FlexCAN processes like matching and arbitration.

The contents of this register are not affected by soft reset.

Address: 0h base + 34h offset = 34h

CAN_CTRL2 field descriptions

Field	Description
0 Reserved	This field is reserved.
1 BOFFDONEMSK	Bus Off Done Interrupt Mask This bit provides a mask for the Bus Off Done Interrupt in CAN_ESR1 register. 0 Bus Off Done interrupt disabled. 1 Bus Off Done interrupt enabled.
2 ECRWRE	Error-correction Configuration Register Write Enable This bit enables the CAN_MECR register to be updated. This bit is automatically set to 0 if the protocol described in section Detection and Correction of Memory Errors is not followed.

Table continues on the next page...

CAN_CTRL2 field descriptions (continued)

Field	Description
	0 Disable update. 1 Enable update.
3 WRMFRZ	Write-Access To Memory In Freeze Mode Enable unrestricted write access to FlexCAN memory in Freeze mode. This bit can only be written in Freeze mode and has no effect out of Freeze mode. CAN_MCR[RFEN] bit must not be set during FlexCAN memory initialization. 0 Maintain the write access restrictions. 1 Enable unrestricted write access to FlexCAN memory.
4–7 RFFN	Number Of Rx FIFO Filters This 4-bit field defines the number of Rx FIFO filters, as shown in the following table. The maximum selectable number of filters is determined by the chip. This field can only be written in Freeze mode as it is blocked by hardware in other modes. This field must not be programmed with values that make the number of Message Buffers occupied by Rx FIFO and ID Filter exceed the number of Mailboxes present, defined by CAN_MCR[MAXMB]. **NOTE:** Each group of eight filters occupies a memory space equivalent to two Message Buffers which means that the more filters are implemented the less Mailboxes will be available. Considering that the Rx FIFO occupies the memory space originally reserved for MB0-5, RFFN should be programmed with a value corresponding to a number of filters not greater than the number of available memory words which can be calculated as follows: (SETUP_MB - 6) × 4 where SETUP_MB is the least between the parameter NUMBER_OF_MB and CAN_MCR[MAXMB]. The number of remaining Mailboxes available will be: (SETUP_MB - 8) - (RFFN × 2) If the Number of Rx FIFO Filters programmed through RFFN exceeds the SETUP_MB value (memory space available) the exceeding ones will not be functional. **NOTE:** • The number of the last remaining available mailboxes is defined by the least value between the NUMBER_OF_MB minus 1 and the CAN_MCR[MAXMB] field. • If Rx Individual Mask Registers are not enabled then all Rx FIFO filters are affected by the Rx FIFO Global Mask.

RFFN[3:0]	Number of Rx FIFO filter elements	Message Buffers occupied by Rx FIFO and ID Filter Table	Remaining Available Mailboxes	Rx FIFO ID Filter Table Elements Affected by Rx Individual Masks	Rx FIFO ID Filter Table Elements Affected by Rx FIFO Global Mask
0x0	8	MB 0-7	MB 8-63	Elements 0-7	none

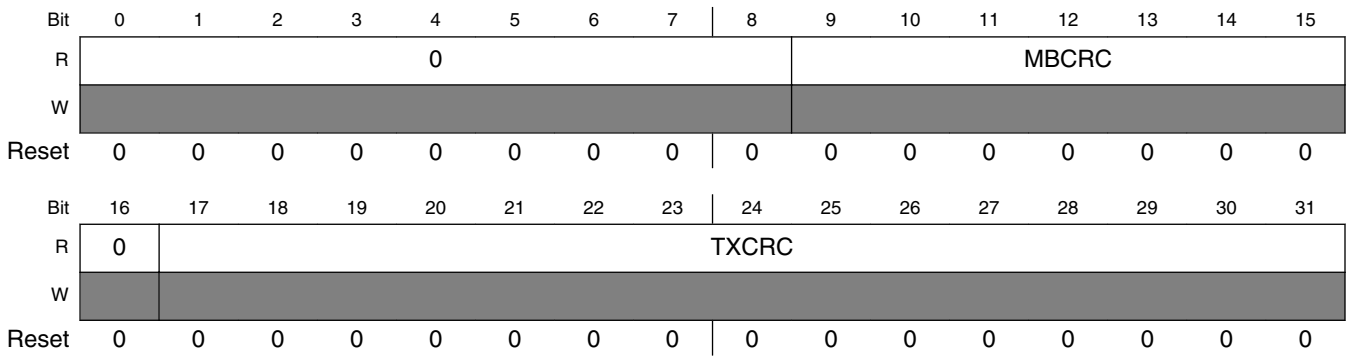
CAN_ESR2 field descriptions

Field	Description
0–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
9–15 LPTM	Lowest Priority Tx Mailbox If CAN_ESR2[VPS] is asserted, this field indicates the lowest number inactive Mailbox (see the CAN_ESR2[IMB] bit description). If there is no inactive Mailbox then the Mailbox indicated depends on CAN_CTRL1[LBUF] bit value. If CAN_CTRL1[LBUF] bit is negated then the Mailbox indicated is the one that has the greatest arbitration value (see the "Highest priority Mailbox first" section). If CAN_CTRL1[LBUF] bit is asserted then the Mailbox indicated is the highest number active Tx Mailbox. If a

Table continues on the next page...



CAN_ESR2 field descriptions (continued)

Field	Description
	Tx Mailbox is being transmitted it is not considered in LPTM calculation. If CAN_ESR2[IMB] is not asserted and a frame is transmitted successfully, LPTM is updated with its Mailbox number.
16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
17 VPS	Valid Priority Status This bit indicates whether CAN_ESR2[IMB] and CAN_ESR2[LPTM] contents are currently valid or not. It is asserted upon every complete Tx arbitration process unless the CPU writes to Control and Status word of a Mailbox that has already been scanned, that is, it is behind Tx Arbitration Pointer, during the Tx arbitration process. If there is no inactive Mailbox and only one Tx Mailbox that is being transmitted then VPS is not asserted. This bit is negated upon the start of every Tx arbitration process or upon a write to Control and Status word of any Mailbox. **NOTE:** CAN_ESR2[VPS] is not affected by any CPU write into Control Status (C/S) of a MB that is blocked by abort mechanism. When CAN_MCR[AEN] is asserted, the abort code write in C/S of a MB that is being transmitted (pending abort), or any write attempt into a Tx MB with CAN_IFLAG set is blocked. 0 Contents of IMB and LPTM are invalid. 1 Contents of IMB and LPTM are valid.
18 IMB	Inactive Mailbox If ESR2[VPS] is asserted, this bit indicates whether there is any inactive Mailbox (CODE field is either 0b1000 or 0b0000). This bit is asserted in the following cases: • During arbitration, if an CAN_ESR2[LPTM] is found and it is inactive. • If CAN_ESR2[IMB] is not asserted and a frame is transmitted successfully. This bit is cleared in all start of arbitration (see Section "Arbitration process"). **NOTE:** CAN_ESR2[LPTM] mechanism have the following behavior: if an MB is successfully transmitted and CAN_ESR2[IMB]=0 (no inactive Mailbox), then CAN_ESR2[VPS] and CAN_ESR2[IMB] are asserted and the index related to the MB just transmitted is loaded into CAN_ESR2[LPTM]. 0 If ESR2[VPS] is asserted, the ESR2[LPTM] is not an inactive Mailbox. 1 If ESR2[VPS] is asserted, there is at least one inactive Mailbox. LPTM content is the number of the first one.
19–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

47.4.16 CRC Register (CAN_CRCR)

This register provides information about the CRC of transmitted messages. This register is updated at the same time the Tx Interrupt Flag is asserted.

Address: 0h base + 44h offset = 44h

CAN_CRCR field descriptions

Field	Description
0–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
9–15 MBCRC	CRC Mailbox This field indicates the number of the Mailbox corresponding to the value in CAN_CRCR[TXCRC] field.
16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
17–31 TXCRC	Transmitted CRC value This field indicates the CRC value of the last transmitted message.

47.4.17 Rx FIFO Global Mask register (CAN_RXFGMASK)

This register is located in RAM.

If Rx FIFO is enabled, RXFGMASK is used to mask the Rx FIFO ID Filter Table elements that do not have a corresponding RXIMR according to CAN_CTRL2[RFFN] field setting.

This register can only be written in Freeze mode as it is blocked by hardware in other modes.

Address: 0h base + 48h offset = 48h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

* Notes:
- x = Undefined at reset.

CAN_RXFGMASK field descriptions

Field	Description
0–31 FGM	Rx FIFO Global Mask Bits These bits mask the ID Filter Table elements bits in a perfect alignment. The following table shows how the FGM bits correspond to each IDAF field.

Rx FIFO ID Filter Table Elements Format (CAN_MCR[IDAM])	Identifier Acceptance Filter Fields					
	RTR	IDE	RXIDA	RXIDB [1]	RXIDC [2]	Reserved
A	FGM[31]	FGM[30]	FGM[29:1]	-	-	FGM[0]
B	FGM[31], FGM[15]	FGM[30], FGM[14]	-	FGM[29:16], FGM[13:0]		-
C	-	-		-	FGM[31:24], FGM[23:16], FGM[15:8], FGM[7:0]	

1. If CAN_MCR[IDAM] field is equivalent to the format B only the fourteen most significant bits of the Identifier of the incoming frame are compared with the Rx FIFO filter.
2. If CAN_MCR[IDAM] field is equivalent to the format C only the eight most significant bits of the Identifier of the incoming frame are compared with the Rx FIFO filter.

0 The corresponding bit in the filter is "don't care."
1 The corresponding bit in the filter is checked.

1. If CAN_MCR[IDAM] field is equivalent to the format B only the fourteen most significant bits of the Identifier of the incoming frame are compared with the Rx FIFO filter.
2. If CAN_MCR[IDAM] field is equivalent to the format C only the eight most significant bits of the Identifier of the incoming frame are compared with the Rx FIFO filter.

47.4.18 Rx FIFO Information Register (CAN_RXFIR)

RXFIR provides information on Rx FIFO.

This register is the port through which the CPU accesses the output of the RXFIR FIFO located in RAM. The RXFIR FIFO is written by the FlexCAN whenever a new message is moved into the Rx FIFO as well as its output is updated whenever the output of the Rx FIFO is updated with the next message. See Section "Rx FIFO" for instructions on reading this register.

Address: 0h base + 4Ch offset = 4Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

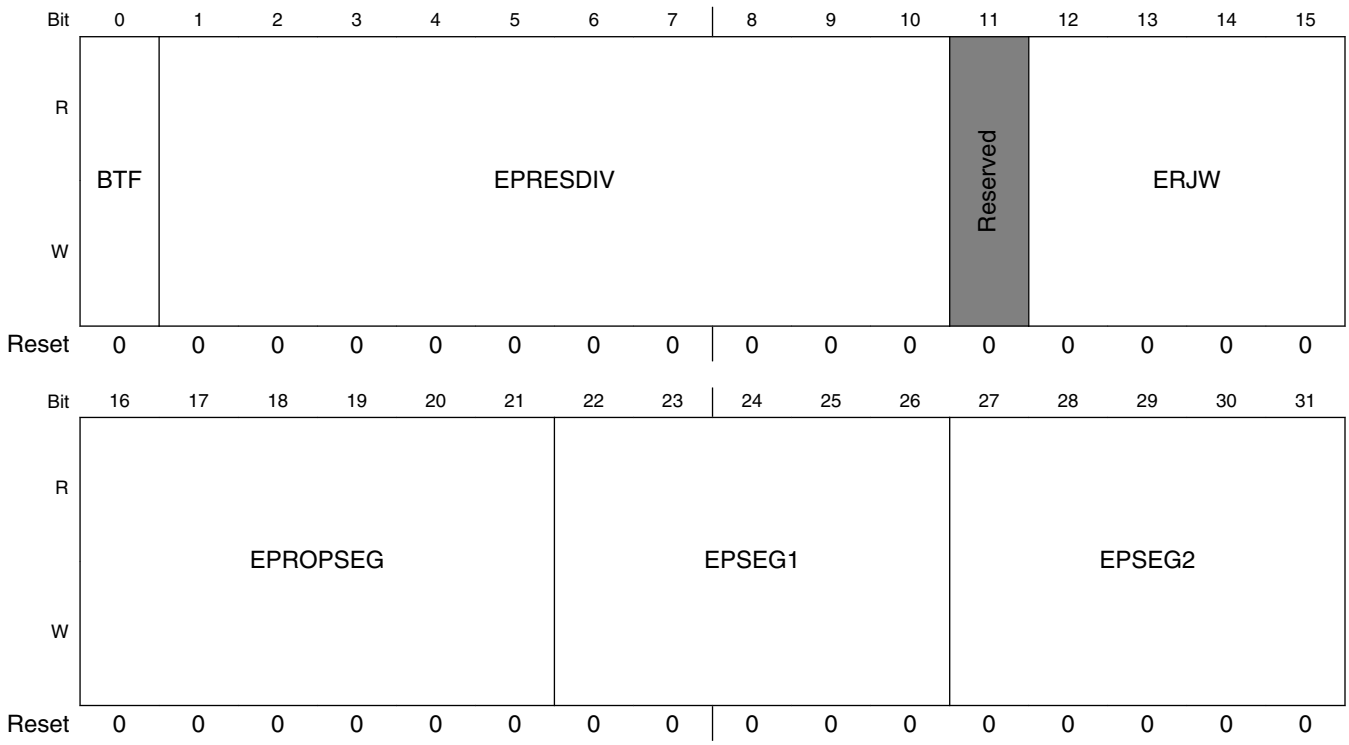
* Notes:
- x = Undefined at reset.

CAN_RXFIR field descriptions

Field	Description
0–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23–31 IDHIT	Identifier Acceptance Filter Hit Indicator This field indicates which Identifier Acceptance Filter was hit by the received message that is in the output of the Rx FIFO. If multiple filters match the incoming message ID then the first matching IDAF found (lowest number) by the matching process is indicated. This field is valid only while the CAN_IFLAG1[BUF5I] is asserted.

47.4.19 CAN Bit Timing Register (CAN_CBT)

This register is an alternative way to store the CAN bit timing variables described in CAN_CTRL1 register. EPRESDIV, EPROPSEG, EPSEG1, EPSEG2 and ERJW are extended versions of PRESDIV, PROPSEG, PSEG1, PSEG2 and RJW bit fields respectively.



The BTF bit selects the use of the timing variables defined in this register.

The contents of this register are not affected by soft reset.

NOTE

The CAN bit variables in CAN_CTRL1 and in CAN_CBT are stored in the same register.

Address: 0h base + 50h offset = 50h

CAN_CBT field descriptions

Field	Description
0 BTF	Bit Timing Format Enable Enables the use of extended CAN bit timing fields EPRESDIV, EPROPSEG, EPSEG1, EPSEG2 and ERJW replacing the CAN bit timing variables defined in CAN_CTRL1 register. This field can be written in Freeze mode only. 0 Extended bit time definitions disabled. 1 Extended bit time definitions enabled.
1–10 EPRESDIV	Extended Prescaler Division Factor This 10-bit field defines the ratio between the PE clock frequency and the Serial Clock (Sclock) frequency when CAN_CBT[BTF] bit is asserted, otherwise it has no effect. It extends the CAN_CTRL1[PRESDIV] value range. The Sclock period defines the time quantum of the CAN protocol. For the reset value, the Sclock frequency is equal to the PE clock frequency (see Protocol timing). This field can be written only in Freeze mode because it is blocked by hardware in other modes. Sclock frequency = PE clock frequency / (EPRESDIV + 1)
11 Reserved	This field is reserved.
12–15 ERJW	Extended Resync Jump Width This 4-bit field defines the maximum number of time quanta that a bit time can be changed by one re-synchronization when CAN_CBT[BTF] bit is asserted, otherwise it has no effect. It extends the CAN_CTRL1[RJW] value range.

Table continues on the next page...

CAN_CBT field descriptions (continued)

Field	Description
	One time quantum is equal to the Sclock period. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Resync Jump Width = ERJW + 1.
16–21 EPROPSEG	Extended Propagation Segment This 6-bit field defines the length of the Propagation Segment in the bit time when CAN_CBT[BTF] bit is asserted, otherwise it has no effect. It extends the CAN_CTRL1[PROPSEG] value range. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Propagation Segment Time = (EPROPSEG + 1) × Time-Quanta. Time-Quantum = one Sclock period.
22–26 EPSEG1	Extended Phase Segment 1 This 5-bit field defines the length of Phase Segment 1 in the bit time when CAN_CBT[BTF] bit is asserted, otherwise it has no effect. It extends the CAN_CTRL1[PSEG1] value range. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Phase Buffer Segment 1 = (EPSEG1 + 1) × Time-Quanta. Time-Quantum = one Sclock period.
27–31 EPSEG2	Extended Phase Segment 2 This 5-bit field defines the length of Phase Segment 2 in the bit time when CAN_CBT[BTF] bit is asserted, otherwise it has no effect. It extends the CAN_CTRL1[PSEG2] value range. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Phase Buffer Segment 1 = (EPSEG2 + 1) × Time-Quanta. Time-Quantum = one Sclock period.

47.4.20 Interrupt Masks 3 Register (CAN_IMASK3)

This register allows any number of a range of the 32 Message Buffer Interrupts to be enabled or disabled for MB95 to MB64. It contains one interrupt mask bit per buffer, enabling the CPU to determine which buffer generates an interrupt after a successful transmission or reception, that is, when the corresponding CAN_IFLAG3 bit is set.

Address: 0h base + 6Ch offset = 6Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	BUF95TO64M																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

CAN_IMASK3 field descriptions

Field	Description
0–31 BUF95TO64M	Buffer MB $_i$ Mask Each bit enables or disables the corresponding FlexCAN Message Buffer Interrupt for MB95 to MB64.

CAN_IMASK3 field descriptions (continued)

Field	Description
	NOTE: Setting or clearing a bit in the CAN_IMASK3 Register can assert or negate an interrupt request, if the corresponding CAN_IFLAG3 bit is set. 0 The corresponding buffer Interrupt is disabled. 1 The corresponding buffer Interrupt is enabled.

47.4.21 Interrupt Flags 3 Register (CAN_IFLAG3)

This register defines the flags for the 32 Message Buffer interrupts for MB95 to MB64. It contains one interrupt flag bit per buffer. Each successful transmission or reception sets the corresponding CAN_IFLAG3 bit. If the corresponding CAN_IMASK3 bit is set, an interrupt will be generated. The interrupt flag must be cleared by writing 1 to it. Writing 0 has no effect.

Before updating CAN_MCR[MAXMB] field, CPU must service the CAN_IFLAG3 bits whose MB value is greater than the MAXMB to be updated; otherwise, they will remain set and be inconsistent with the number of MBs available.

Address: 0h base + 74h offset = 74h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

CAN_IFLAG3 field descriptions

Field	Description
0–31 BUF95TO64	Buffer MB $_i$ Interrupt Each bit flags the corresponding FlexCAN Message Buffer interrupt for MB95 to MB64. 0 The corresponding buffer has no occurrence of successfully completed transmission or reception 1 The corresponding buffer has successfully completed transmission or reception

47.4.22 Rx Individual Mask Registers (CAN_RXIMR*n*)

The RX Individual Mask Registers are used to store the acceptance masks for ID filtering in Rx MBs and the Rx FIFO.

When the Rx FIFO is disabled (CAN_MCR[RFEN] bit is negated), an individual mask is provided for each available Rx Mailbox on a one-to-one correspondence. When the Rx FIFO is enabled (CAN_MCR[RFEN] bit is asserted), an individual mask is provided for each Rx FIFO ID Filter Table Element on a one-to-one correspondence depending on the setting of CAN_CTRL2[RFFN] (see Rx FIFO).

CAN_RXIMR0 stores the individual mask associated to either MB0 or ID Filter Table Element 0, CAN_RXIMR1 stores the individual mask associated to either MB1 or ID Filter Table Element 1 and so on.

CAN_RXIMR registers can only be accessed by the CPU while the module is in Freeze mode, otherwise, they are blocked by hardware. These registers are not affected by reset. They are located in RAM and must be explicitly initialized prior to any reception.

Address: 0h base + 880h offset + (4d × i), where i=0d to 95d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

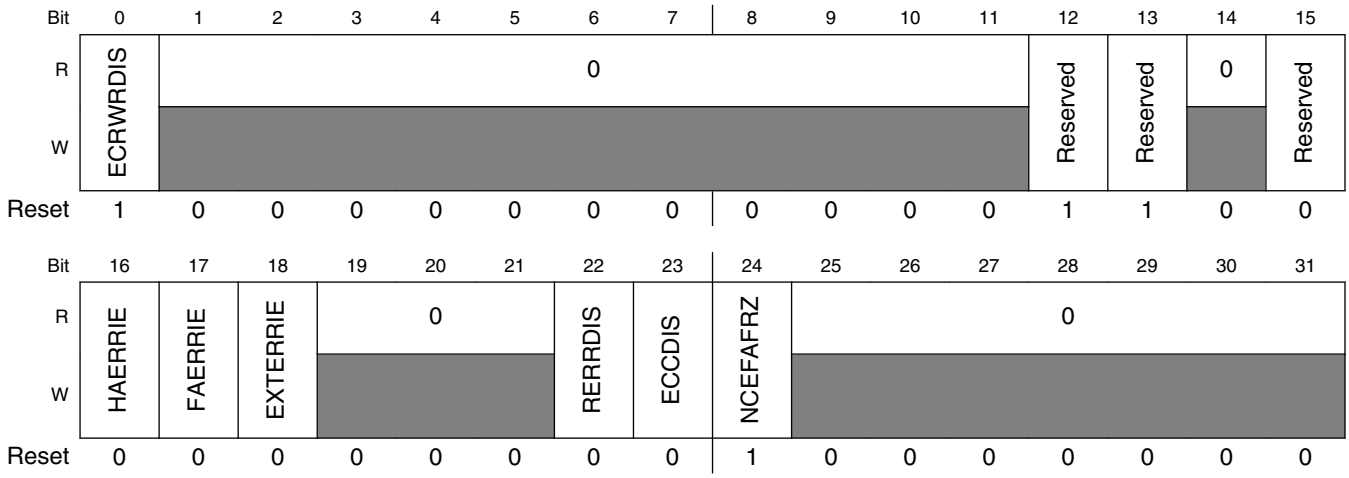
* Notes:
- x = Undefined at reset.

CAN_RXIMR*n* field descriptions

Field	Description
0–31 MI	Individual Mask Bits Each Individual Mask Bit masks the corresponding bit in both the Mailbox filter and Rx FIFO ID Filter Table element in distinct ways. For Mailbox filters, see the RXMGMASK register description. For Rx FIFO ID Filter Table elements, see the RXFGMASK register description. 0 The corresponding bit in the filter is "don't care." 1 The corresponding bit in the filter is checked.



47.4.23 Memory Error Control Register (CAN_MECR)

This register contains control bits for memory error detection and correction (ECC).

NOTE

When bit CTRL2[ECRWRE] is 0, writes in this register are blocked, except in the ECRWRDIS bit.

Address: 0h base + AE0h offset = AE0h

CAN_MECR field descriptions

Field	Description
0 ECRWRDIS	Error Configuration Register Write Disable Disables writes on this register. This bit is automatically set to 1 (disabled) when CTRL2[ECRWRE] is enabled. The protocol described in section Detection and Correction of Memory Errors must be followed. 0 Write is enabled. 1 Write is disabled.
1–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12 Reserved	This field is reserved. When writing to this field, always write the reset value.
13 Reserved	This field is reserved. When writing to this field, always write the reset value.
14 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15 Reserved	This field is reserved. When writing to this field, always write the reset value.
16 HAERRIE	Host Access Error Injection Enable Enables the injection of errors only in memory reads issued by the host (CPU). 0 Injection is disabled. 1 Injection is enabled.
17 FAERRIE	FlexCAN Access Error Injection Enable Enables the injection of errors only in memory reads issued by the FlexCAN internal processes. 0 Injection is disabled. 1 Injection is enabled.
18 EXTERRIE	Extended Error Injection Enable Memory accesses performed by internal FlexCAN processes are 64-bit. This bit extends the error injection on 32-bit memory accesses to the complementary 32-bit word using the same 32-bit error injection data

Table continues on the next page...

CAN_MECR field descriptions (continued)

Field	Description
	and parity words. See Error Injection Data Pattern Register (CAN_FCERRIDPR) and Error Injection Parity Pattern Register (CAN_FCERRIPPR) 0 Error injection is applied only to the 32-bit word. 1 Error injection is applied to the 64-bit word.
19–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22 RERRDIS	Error Report Disable Disables the update of the error report registers. The update of error-related flags and the generation of bus transfer errors are still active. **NOTE:** When reading the report registers, this bit must be set to assure coherence on the consecutive register reads. 0 Enable updates of the error report registers. 1 Disable updates of the error report registers.
23 ECCDIS	Error Correction Disable Disables completely the memory detection and correction mechanism. Besides disabling the error report mechanism, it also stops the update of the error-related flags and generation of bus transfer errors. The parity bits continue being calculated and written into memory on write transactions. 0 Enable memory error correction. 1 Disable memory error correction.
24 NCEFAFRZ	Non-Correctable Errors In FlexCAN Access Put Device In Freeze Mode Determines the response when a non-correctable error is detected in a memory read performed by FlexCAN internal processes. In this case, entering Freeze mode prevents corrupted data from being treated as valid by FlexCAN internal processes. 0 Keep normal operation. 1 Put FlexCAN in Freeze mode (according to the "Freeze mode" section).
25–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

47.4.24 Error Injection Address Register (CAN_ERRIAR)

This register holds the address where error is to be injected.

See the chip-specific FlexCAN information for the FlexCAN RAM to memory map address mapping table.

Address: 0h base + AE4h offset = AE4h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

CAN_ERRIDPR field descriptions

Field	Description
0–31 DFLIP	Data flip pattern Bits set to 1 in the flip pattern cause the corresponding data bit in the word read from memory to invert.

47.4.26 Error Injection Parity Pattern Register (CAN_ERRIPPR)

Holds the error pattern to be injected in parity bits read from memory along with data word.

Bits set to 1 in the flip pattern cause the corresponding parity bit in the word read from memory to invert.

Address: 0h base + AECh offset = AECh

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

CAN_ERRIPPR field descriptions

Field	Description
0–2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3–7 PFLIP3	Parity Flip Pattern For Byte 3 (most significant)
8–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11–15 PFLIP2	Parity Flip Pattern For Byte 2
16–18 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
19–23 PFLIP1	Parity Flip Pattern For Byte 1
24–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27–31 PFLIP0	Parity Flip Pattern For Byte 0 (Least Significant)

47.4.27 Error Report Address Register (CAN_RERRAR)

Reports the address used for an access in which an error (correctable or non-correctable) was detected, and also reports the identification of the source of that access.

This address is always reported using a 32-bit alignment. Non-aligned accesses (ERRADDR[1:0] non-0) are reported with the address aligned and data is reported in RERRDR accordingly shifted. In case of errors detected in accesses larger than 32-bit (as performed by FlexCAN internal processes), the address of the 32-bit word which the error was detected is reported. In case of errors detected in more than one 32-bit word, only the least significant address is reported.

Address: 0h base + AF0h offset = AF0h

CAN_RERRAR field descriptions

Field	Description
0–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 NCE	Non-Correctable Error Indicates that the report is due to an non-correctable error. 0 Reporting a correctable-error 1 Reporting a non-correctable error
8–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13–15 SAID	SAID[2] — Identification of the requestor of the memory read request: • 0 = Requested by FlexCAN internal processes • 1 = Requested by Host (CPU) SAID[1] — Details of FlexCAN operation: • 0 = Move • 1 = Scanning SAID[0] — Operation that requested the memory read: • 0 = Transmission • 1 = Reception
16–17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
18–31 ERRADDR	Address Where The Error Was Detected See the description of the Error Injection Address Register (ERRIAR).

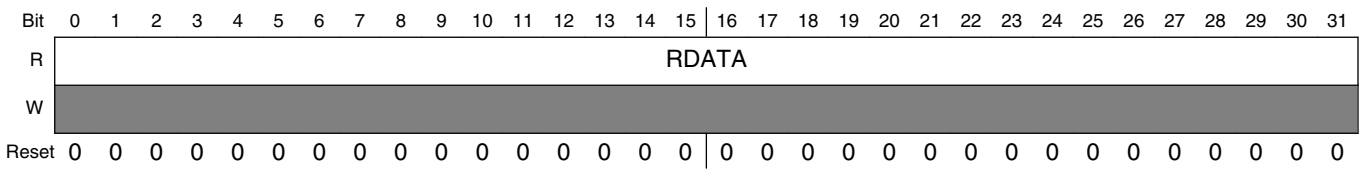

Table 47-130. Source of memory access

SAID[2:0]	Error during...
0	Move-out FlexCAN access
1	Move-in
2	Tx Arbitration
3	Rx Matching
4	Move-out Host access
5-7	Reserved

47.4.28 Error Report Data Register (CAN_RERRDR)

Reports the raw data (unmodified by the correction performed by ECC logic) read from memory with error. The value reported does not represent the transient values of the BUSY bit (see the “Message Buffer Code for Rx buffers” table) when reading a Message Buffer.

Address: 0h base + AF4h offset = AF4h

CAN_RERRDR field descriptions

Field	Description
0–31 RDATA	Raw data word read from memory with error

47.4.29 Error Report Syndrome Register (CAN_RERRSYNR)

Holds the syndrome detected in a memory read with error. It also reports the bytes which were read in this 32-bit read transaction.

Each SYNDn field indicates the type of error and which bit in byte (n) is affected by the error. (SYND3 corresponds to the most significant byte in the data word read from memory; SYND0 corresponds to the least significant.)

Table 47-133. Syndrome Definition

SYNDn (hex)	Type	Bit affected
00	-	none (no error)
01	Code	0
02	Code	1
04	Code	2
07	Data	5
08	Code	3
0E	Data	7
10	Code	4
13	Data	2

Table continues on the next page...

Table 47-133. Syndrome Definition (continued)

SYNDn (hex)	Type	Bit affected
15	Data	6
16	Data	1
19	Data	3
1A	Data	4
1C	Data	0
06	-	All-zeros non-correctable error
1F	-	All-ones non-correctable error
All others	-	Non-correctable error

Each BEn field indicates which byte in the 32-bit word reported was effectively read. The syndrome bits are calculated for all bytes, even for the non-read ones. Errors detected in non-read bytes are indicated (see the "Error Indication" section) and reported (see the "Error Reporting" section).

Address: 0h base + AF8h offset = AF8h

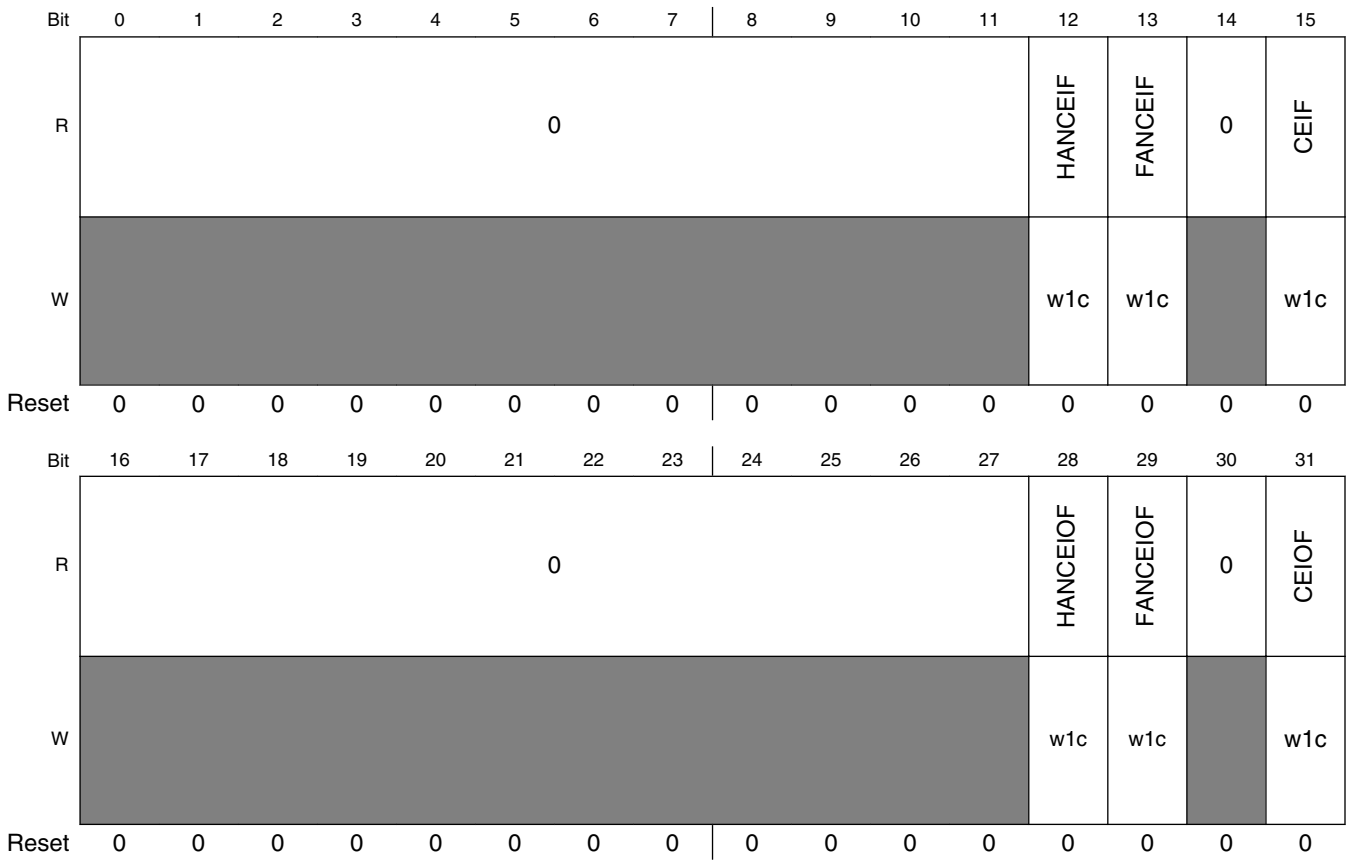
9–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...



CAN_RERRSYNR field descriptions (continued)

Field	Description
11–15 SYND2	Error Syndrome For Byte 2 See the "Syndrome Definition" table.
16 BE1	Byte Enabled For Byte 1 0 The byte was not read. 1 The byte was read.
17–18 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
19–23 SYND1	Error Syndrome for Byte 1 See the "Syndrome Definition" table.
24 BE0	Byte Enabled For Byte 0 (least significant) 0 The byte was not read. 1 The byte was read.
25–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27–31 SYND0	Error Syndrome For Byte 0 (least significant) See the "Syndrome Definition" table.

47.4.30 Error Status Register (CAN_ERRSR)

Holds the status bits of the error correction and detection operations. These flags can be cleared by writing 1 to them. Writing 0 has no effect.

Address: 0h base + AFCh offset = AFCh

CAN_ERRSR field descriptions

Field	Description
0–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12 HANCEIF	Host Access With Non-Correctable Error Interrupt Flag Indicates that a non-correctable error was detected in a memory read initiated by Host. A bus transfer error is asserted for that access.No interrupt is associated to this flag. 0 No non-correctable errors were detected in Host accesses so far. 1 A non-correctable error was detected in a Host access.
13 FANCEIF	FlexCAN Access With Non-Correctable Error Interrupt Flag

Table continues on the next page...

CAN_ERRSR field descriptions (continued)

Field	Description
	Indicates that a non-correctable error was detected in a memory read initiated by FlexCAN internal processes.No interrupt is associated to this flag. 0 No non-correctable errors were detected in FlexCAN accesses so far. 1 A non-correctable error was detected in a FlexCAN access.
14 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15 CEIF	Correctable Error Interrupt Flag Indicates that a correctable error was detected in a memory read. 0 No correctable errors were detected so far. 1 A correctable error was detected.
16–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28 HANCEIOF	Host Access With Non-Correctable Error Interrupt Overrun Flag Indicates that a non-correctable error was detected in a memory read initiated by Host when HANCEIF was set. No interrupt is associated to this flag. See Error Indication. 0 No overrun on non-correctable errors in Host access 1 Overrun on non-correctable errors in Host access
29 FANCEIOF	FlexCAN Access With Non-Correctable Error Interrupt Overrun Flag Indicates that a non-correctable error was detected in a memory read initiated by FlexCAN internal processes when FANCEIF was set. No interrupt is associated to this flag. See Error Indication. 0 No overrun on non-correctable errors in FlexCAN access 1 Overrun on non-correctable errors in FlexCAN access
30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 CEIOF	Correctable Error Interrupt Overrun Flag Indicates that a correctable error was detected in a memory read when CEIF was set. No interrupt is associated to this flag. See Error Indication. 0 No overrun on correctable errors 1 Overrun on correctable errors

47.4.31 Message buffer structure

The message buffer structure used by the FlexCAN module is represented in the following figure. Both Extended (29-bit identifier) and Standard (11-bit identifier) frames used in the CAN specification (Version 2.0 Part B) are represented. Each individual MB is formed by 16 bytes.

The memory area from 0x80 to 0x67F is used by the mailboxes.

Table 47-135. Message buffer structure

	0	1	2	3	4	7	8	9	10	11	12	13	14	15	16	23	24	31
0x0	EDL	BRS	ESI		CODE			SRR	IDE	RTR	DLC				TIME STAMP			
0x4	PRIO				ID (Standard/Extended)										ID (Extended)			
0x8	Data Byte 0							Data Byte 1							Data Byte 2		Data Byte 3	
0xC	Data Byte 4							Data Byte 5							Data Byte 6		Data Byte 7	
	= Unimplemented or Reserved																	

CODE - Message Buffer Code

This 4-bit field can be accessed (read or write) by the CPU and by the FlexCAN module itself, as part of the message buffer matching and arbitration process. The encoding is shown in Table 47-136 and Table 47-137. See Functional description for additional information.

Table 47-136. Message buffer code for Rx buffers

CODE description	Rx code BEFORE receive new frame	SRV[1]	Rx code AFTER successful reception[2]	RRS[3]	Comment
0b0000: INACTIVE - MB is not active.	INACTIVE	-	-	-	MB does not participate in the matching process.
0b0100: EMPTY - MB is active and empty.	EMPTY	-	FULL	-	When a frame is received successfully (after the Move-in) process), the CODE field is automatically updated to FULL.

Table continues on the next page...

Table 47-136. Message buffer code for Rx buffers (continued)

CODE description	Rx code BEFORE receive new frame	SRV[1]	Rx code AFTER successful reception[2]	RRS[3]	Comment
0b0010: FULL - MB is full.	FULL	Yes	FULL	-	The act of reading the C/S word followed by unlocking the MB (SRV) does not make the code return to EMPTY. It remains FULL. If a new frame is moved to the MB after the MB was serviced, the code still remains FULL. See Matching process for matching details related to FULL code.
		No	OVERRUN	-	If the MB is FULL and a new frame is moved to this MB before the CPU services it, the CODE field is automatically updated to OVERRUN. See Matching process for details about overrun behavior.
0b0110: OVERRUN - MB is being overwritten into a full buffer.	OVERRUN	Yes	FULL	-	If the CODE field indicates OVERRUN and CPU has serviced the MB, when a new frame is moved to the MB then the code returns to FULL.
		No	OVERRUN	-	If the CODE field already indicates OVERRUN, and another new frame must be moved, the MB will be overwritten again, and the code will remain OVERRUN. See Matching process for details about overrun behavior.

Table continues on the next page...

Table 47-136. Message buffer code for Rx buffers (continued)

CODE description	Rx code BEFORE receive new frame	SRV[1]	Rx code AFTER successful reception[2]	RRS[3]	Comment
0b1010: RANSWER[4] - A frame was configured to recognize a Remote Request Frame and transmit a Response Frame in return.	RANSWER	-	TANSWER(0b1110)	0	A Remote Answer was configured to recognize a remote request frame received. After that an MB is set to transmit a response frame. The code is automatically changed to TANSWER (0b1110). See Matching process for details. If CAN_CTRL2[RRS] is negated, transmit a response frame whenever a remote request frame with the same ID is received.
		-	-	1	This code is ignored during matching and arbitration process. See Matching process for details.
CODE[0]=1: BUSY - FlexCAN is updating the contents of the MB. The CPU must not access the MB.	BUSY[5]	-	FULL	-	Indicates that the MB is being updated. It will be negated automatically and does not interfere with the next CODE.
		-	OVERRUN	-	

1. SRV: Serviced MB. MB was read and unlocked by reading TIMER or other MB.
2. A frame is considered a successful reception after the frame to be moved to MB (move-in process). See Move-in for details.
3. Remote Request Stored bit, see "Control 2 Register (CAN_CTRL2)" for details.
4. Code 0b1010 is not considered Tx and an MB with this code should not be aborted.
5. Note that for Tx MBs, the BUSY bit should be ignored upon read, except when AEN bit is set in the MCR register. If this bit is asserted, the corresponding MB does not participate in the matching process.

Table 47-137. Message buffer code for Tx buffers

CODE Description	Tx Code BEFORE tx frame	MB RTR	Tx Code AFTER successful transmission	Comment
0b1000: INACTIVE - MB is not active	INACTIVE	-	-	MB does not participate in arbitration process.

Table continues on the next page...

Table 47-137. Message buffer code for Tx buffers (continued)

CODE Description	Tx Code BEFORE tx frame	MB RTR	Tx Code AFTER successful transmission	Comment
0b1001: ABORT - MB is aborted	ABORT	-	-	MB does not participate in arbitration process.
0b1100: DATA - MB is a Tx Data Frame (MB RTR must be 0)	DATA	0	INACTIVE	Transmit data frame unconditionally once. After transmission, the MB automatically returns to the INACTIVE state.
0b1100: REMOTE - MB is a Tx Remote Request Frame (MB RTR must be 1)	REMOTE	1	EMPTY	Transmit remote request frame unconditionally once. After transmission, the MB automatically becomes an Rx Empty MB with the same ID.
0b1110: TANSWER - MB is a Tx Response Frame from an incoming Remote Request Frame	TANSWER	-	RANSWER	This is an intermediate code that is automatically written to the MB by the CHI as a result of a match to a remote request frame. The remote response frame will be transmitted unconditionally once, and then the code will automatically return to RANSWER (0b1010). The CPU can also write this code with the same effect. The remote response frame can be either a data frame or another remote request frame depending on the RTR bit value. See Matching process and Arbitration process for details.

SRR - Substitute Remote Request

Fixed recessive bit, used only in extended format. It must be set to one by the user for transmission (Tx Buffers) and will be stored with the value received on the CAN bus for Rx receiving buffers. It can be received as either recessive or dominant. If FlexCAN receives this bit as dominant, then it is interpreted as an arbitration loss.

1 = Recessive value is compulsory for transmission in extended format frames

0 = Dominant is not a valid value for transmission in extended format frames

IDE - ID Extended Bit

This field identifies whether the frame format is standard or extended.

1 = Frame format is extended

0 = Frame format is standard

RTR - Remote Transmission Request

This bit affects the behavior of remote frames and is part of the reception filter. See Table 47-136, Table 47-137, and the description of the RRS bit in Control 2 Register (CAN_CTRL2) for additional details.

If FlexCAN transmits this bit as '1' (recessive) and receives it as '0' (dominant), it is interpreted as an arbitration loss. If this bit is transmitted as '0' (dominant), then if it is received as '1' (recessive), the FlexCAN module treats it as a bit error. If the value received matches the value transmitted, it is considered a successful bit transmission.

1 = Indicates the current MB may have a remote request frame to be transmitted if MB is Tx. If the MB is Rx then incoming remote request frames may be stored.

0 = Indicates the current MB has a data frame to be transmitted. In Rx MB it may be considered in matching processes.

DLC - Length of Data in Bytes

This 4-bit field is the length (in bytes) of the Rx or Tx data, which is located in offset 0x8 through 0xF of the MB space (see Table 47-135) . In reception, this field is written by the FlexCAN module, copied from the DLC (Data Length Code) field of the received frame. In transmission, this field is written by the CPU and corresponds to the DLC field value of the frame to be transmitted. When RTR = 1, the frame to be transmitted is a remote frame and does not include the data field, regardless of the DLC field (see Table 47-138).

TIME STAMP - Free-Running Counter Time Stamp

This 16-bit field is a copy of the Free-Running Timer, captured for Tx and Rx frames at the time when the beginning of the Identifier field appears on the CAN bus.

PRIO - Local priority

This 3-bit field is used only when LPRIO_EN bit is set in CAN_MCR, and it only makes sense for Tx mailboxes. These bits are not transmitted. They are appended to the regular ID to define the transmission priority. See Arbitration process.

ID - Frame Identifier

In standard frame format, only the 11 most significant bits (3 to 13) are used for frame identification in both receive and transmit cases. The 18 least significant bits are ignored. In extended frame format, all bits are used for frame identification in both receive and transmit cases.

DATA BYTE 0 to 7 - Data Field

Up to eight bytes can be used for a data frame.

For Rx frames, the data is stored as it is received from the CAN bus. DATA BYTE (*n*) is valid only if *n* is less than DLC as shown in the table below.

Table 47-138. DATA BYTEs validity

DLC	Valid DATA BYTEs
0	none
1	DATA BYTE 0
2	DATA BYTE 0 to 1
3	DATA BYTE 0 to 2
4	DATA BYTE 0 to 3
5	DATA BYTE 0 to 4
6	DATA BYTE 0 to 5
7	DATA BYTE 0 to 6
8 or above	DATA BYTE 0 to 7

47.4.32 Rx FIFO structure

When the CAN_MCR[RFEN] bit is set, the memory area from 0x80 to 0xDC (which is normally occupied by MBs 0–5) is used by the reception FIFO engine.

The region 0x80-0x8C contains the output of the FIFO which must be read by the CPU as a message buffer. This output contains the oldest message that has been received but not yet read. The region 0x90-0xDC is reserved for internal use of the FIFO engine.

An additional memory area, which starts at 0xE0 and may extend up to 0x2DC (normally occupied by MBs 6–37) depending on the CAN_CTRL2[RFFN] field setting, contains the ID filter table (configurable from 8 to 128 table elements) that specifies filtering criteria for accepting frames into the FIFO.

Out of reset, the ID filter table flexible memory area defaults to 0xE0 and extends only to 0xFC, which corresponds to MBs 6 to 7 for RFFN = 0, for backward compatibility with previous versions of FlexCAN.

The following shows the Rx FIFO data structure.

Table 47-139. Rx FIFO structure

	0 3 7 8 9 10 11 12 13 14 15 16 23 24 31							
0x80	IDHIT			SRR	IDE	RTR	DLC	TIME STAMP
0x84		ID standard					ID extended	
0x88	Data byte 0		Data byte 1				Data byte 2	Data byte 3
0x8C	Data byte 4		Data byte 5				Data byte 6	Data byte 7
0x90 to 0xDC	Reserved							
0xE0	ID filter table element 0							
0xE4	ID filter table element 1							
0xE8 to 0x2D4	ID filter table elements 2 to 125							
0x2D8	ID filter table element 126							
0x2DC	ID filter table element 127							
	= Unimplemented or reserved							

Each ID filter table element occupies an entire 32-bit word and can be compounded by one, two, or four Identifier Acceptance Filters (IDAF) depending on the CAN_MCR[IDAM] field setting. The following figures show the IDAF indexation.

The following table shows the three different formats of the ID table elements. Note that all elements of the table must have the same format. See Rx FIFO for more information.

Table 47-140. ID table structure

	0 1 2 7 8 15 16 17 18 23 24 30 31						
A	RTR	IDE	RXIDA (standard = 2–12, extended = 2–30)				
B	RTR	IDE	RXIDB_0 (standard = 2–12, extended = 2–15)	RTR	IDE	RXIDB_1 (standard = 18–28, extended = 18–31)	
C	RXIDC_0 (std/ext = 0–7)		RXIDC_1 (std/ext = 8–15)		RXIDC_2 (std/ext = 16–23)		RXIDC_3 (std/ext = 24–31)
	= Unimplemented or Reserved						

RTR — Remote Frame

This bit specifies if Remote Frames are accepted into the FIFO if they match the target ID.

1 = Remote Frames can be accepted and data frames are rejected

0 = Remote Frames are rejected and data frames can be accepted

IDE — Extended Frame

Specifies whether extended or standard frames are accepted into the FIFO if they match the target ID.

1 = Extended frames can be accepted and standard frames are rejected

0 = Extended frames are rejected and standard frames can be accepted

RXIDA — Rx Frame Identifier (Format A)

Specifies an ID to be used as acceptance criteria for the FIFO. In the standard frame format, only the 11 most significant bits (2 to 12) are used for frame identification. In the extended frame format, all bits are used.

RXIDB_0, RXIDB_1 — Rx Frame Identifier (Format B)

Specifies an ID to be used as acceptance criteria for the FIFO. In the standard frame format, the 11 most significant bits (a full standard ID) (2 to 12 and 18 to 28) are used for frame identification. In the extended frame format, all 14 bits of the field are compared to the 14 most significant bits of the received ID.

RXIDC_0, RXIDC_1, RXIDC_2, RXIDC_3 — Rx Frame Identifier (Format C)

Specifies an ID to be used as acceptance criteria for the FIFO. In both standard and extended frame formats, all 8 bits of the field are compared to the 8 most significant bits of the received ID.

IDHIT — Identifier Acceptance Filter Hit Indicator

This 9-bit field indicates which Identifier Acceptance Filter was hit by the received message that is in the output of the Rx FIFO. See Rx FIFO for more information.

47.5 Functional description

The FlexCAN module is a CAN protocol engine with a very flexible mailbox system for transmitting and receiving CAN frames. The mailbox system is composed by a set of Message Buffers (MB) that store configuration and control data, time stamp, message ID and data (see Message buffer structure). The memory corresponding to the first 38 MBs can be configured to support a FIFO reception scheme with a powerful ID filtering

mechanism, capable of checking incoming frames against a table of IDs (up to 128 extended IDs or 256 standard IDs or 512 8-bit ID slices), with individual mask register for up to 32 ID Filter Table elements.

Simultaneous reception through FIFO and mailbox is supported. For mailbox reception, a matching algorithm makes it possible to store received frames only into MBs that have the same ID programmed on its ID field. A masking scheme makes it possible to match the ID programmed on the MB with a range of IDs on received CAN frames. For transmission, an arbitration algorithm decides the prioritization of MBs to be transmitted based on the message ID (optionally augmented by 3 local priority bits) or the MB ordering.

Before proceeding with the functional description, an important concept must be explained. A Message Buffer is said to be "active" at a given time if it can participate in both the Matching and Arbitration processes. An Rx MB with a 0b0000 code is inactive (refer to Table 47-136). Similarly, a Tx MB with a 0b1000 or 0b1001 code is also inactive (refer to Table 47-137).

47.5.1 Transmit process

To transmit a CAN frame, the CPU must prepare a Message Buffer for transmission by executing the following procedure:

1. Check whether the respective interrupt bit is set and clear it.
2. If the MB is active (transmission pending), write the ABORT code (0b1001) to the CODE field of the Control and Status word to request an abortion of the transmission. Wait for the corresponding IFLAG bit to be asserted by polling the CAN_IFLAG register or by the interrupt request if enabled by the respective IMASK bit. Then read back the CODE field to check if the transmission was aborted or transmitted (see Transmission abort mechanism). If backwards compatibility is desired (CAN_MCR[AEN] bit is negated), just write the INACTIVE code (0b1000) to the CODE field to inactivate the MB but then the pending frame may be transmitted without notification (see Mailbox inactivation).
3. Write the ID word.
4. Write the data bytes.
5. Write the DLC, Control, and CODE fields of the Control and Status word to activate the MB.

When the MB is activated, it participates in the arbitration process and is eventually transmitted according to its priority.

At the end of the successful transmission, the value of the Free Running Timer is written into the Time Stamp field, the CODE field in the Control and Status word is updated, the CRC Register is updated, a status flag is set in the Interrupt Flag Register and an interrupt is generated if allowed by the corresponding Interrupt Mask Register bit. The new CODE field after transmission depends on the code that was used to activate the MB (see Table 47-136 and Table 47-137 in Message buffer structure).

When the Abort feature is enabled (CAN_MCR[AEN] is asserted), after the Interrupt Flag is asserted for a Mailbox configured as transmit buffer, the Mailbox is blocked. Therefore the CPU is not able to update it until the Interrupt Flag is negated by CPU. This means that the CPU must clear the corresponding IFLAG bit before starting to prepare this MB for a new transmission or reception.

47.5.2 Arbitration process

The arbitration process scans the Mailboxes searching the Tx one that holds the message to be sent in the next opportunity. This Mailbox is called the *arbitration winner*.

The scan starts from the lowest number Mailbox and runs toward the higher ones.

The arbitration process is triggered in the following events:

- From the CRC field of the CAN frame. The start point depends on the CAN_CTRL2[TASD] field value.
- During the Error Delimiter field of a CAN frame.
- During the Overload Delimiter field of a CAN frame.
- When the winner is inactivated and the CAN bus has still not reached the first bit of the Intermission field.
- When there is CPU write to the C/S word of a winner MB and the CAN bus has still not reached the first bit of the Intermission field.
- When CHI is in Idle state and the CPU writes to the C/S word of any MB.
- When FlexCAN exits Bus Off state.
- Upon leaving Freeze mode or Low Power mode.

If the arbitration process does not manage to evaluate all Mailboxes before the CAN bus has reached the first bit of the Intermission field the temporary arbitration winner is invalidated and the FlexCAN will not compete for the CAN bus in the next opportunity.

The arbitration process selects the winner among the active Tx Mailboxes at the end of the scan according to both CAN_CTRL1[LBUF] and CAN_MCR[LPRIOEN] bits settings.

47.5.2.1 Lowest-number Mailbox first

If CAN_CTRL1[LBUF] bit is asserted the first (lowest number) active Tx Mailbox found is the arbitration winner. CAN_MCR[LPRIOEN] bit has no effect when CAN_CTRL1[LBUF] is asserted.

47.5.2.2 Highest-priority Mailbox first

If CAN_CTRL1[LBUF] bit is negated, then the arbitration process searches the active Tx Mailbox with the highest priority, which means that this Mailbox's frame would have a higher probability to win the arbitration on CAN bus when multiple external nodes compete for the bus at the same time.

The sequence of bits considered for this arbitration is called the *arbitration value* of the Mailbox. The highest-priority Tx Mailbox is the one that has the lowest arbitration value among all Tx Mailboxes.

If two or more Mailboxes have equivalent arbitration values, the Mailbox with the lowest number is the arbitration winner.

The composition of the arbitration value depends on CAN_MCR[LPRIOEN] bit setting.

47.5.2.2.1 Local Priority disabled

If CAN_MCR[LPRIOEN] bit is negated the arbitration value is built in the exact sequence of bits as they would be transmitted in a CAN frame (see the following table) in such a way that the Local Priority is disabled.

Table 47-141. Composition of the arbitration value when Local Priority is disabled

Format	Mailbox Arbitration Value (32 bits)				
Standard (IDE = 0)	Standard ID (11 bits)	RTR (1 bit)	IDE (1 bit)	- (18 bits)	- (1 bit)
Extended (IDE = 1)	Extended ID[28:18] (11 bits)	SRR (1 bit)	IDE (1 bit)	Extended ID[17:0] (18 bits)	RTR (1 bit)

47.5.2.2.2 Local Priority enabled

If Local Priority is desired CAN_MCR[LPRIOEN] must be asserted. In this case the Mailbox PRIO field is included at the very left of the arbitration value (see the following table).

Table 47-142. Composition of the arbitration value when Local Priority is enabled

Format	Mailbox Arbitration Value (35 bits)					
Standard (IDE = 0)	PRIO (3 bits)	Standard ID (11 bits)	RTR (1 bit)	IDE (1 bit)	- (18 bits)	- (1 bit)
Extended (IDE = 1)	PRIO (3 bits)	Extended ID[28:18] (11 bits)	SRR (1 bit)	IDE (1 bit)	Extended ID[17:0] (18 bits)	RTR (1 bit)

As the PRIO field is the most significant part of the arbitration value Mailboxes with low PRIO values have higher priority than Mailboxes with high PRIO values regardless the rest of their arbitration values.

Note that the PRIO field is not part of the frame on the CAN bus. Its purpose is only to affect the internal arbitration process.

47.5.2.3 Arbitration process (continued)

After the arbitration winner is found, its content is copied to a hidden auxiliary MB called Tx Serial Message Buffer (Tx SMB), which has the same structure as a normal MB but is not user accessible. This operation is called move-out and after it is done, write access to the C/S word of the corresponding MB is blocked (if the AEN bit in CAN_MCR register is asserted). Write access is restored in the following events:

- After the MB is transmitted and the corresponding IFLAG bit is cleared by the CPU
- FlexCAN enters in Freeze mode or Bus Off
- FlexCAN loses the bus arbitration or there is an error during the transmission

At the first opportunity window on the CAN bus, the message on the Tx SMB is transmitted according to the CAN protocol rules.

Arbitration process can be triggered in the following situations:

- During Rx and Tx frames from CAN CRC field to end of frame. CAN_CTRL2[TASD] bit value may be changed to optimize the arbitration start point.

- During CAN BusOff state from TX_ERR_CNT=124 to 128. CAN_CTRL2[TASD] bit value may be changed to optimize the arbitration start point.
- During C/S write by CPU in BusIdle. First C/S write starts arbitration process and a second C/S write during this same arbitration restarts the process. If other C/S writes are performed, Tx arbitration process is pending. If there is no arbitration winner after the arbitration process has finished, then the TX arbitration machine begins a new arbitration process. If there is a pending arbitration and BusIdle state starts then an arbitration process is triggered. In this case the first and second C/S write in BusIdle will not restart the arbitration process. It is possible that there is not enough time to finish arbitration in WaitForBusIdle state and the next state is Idle. In this case the scan is not interrupted, and it is completed during BusIdle state. During this arbitration C/S write does not cause arbitration restart.
- Arbitration winner deactivation during a valid arbitration window.
- Upon exiting Freeze mode (first bit of the WaitForBusIdle state). If there is a re-synchronization during WaitForBusIdle, the arbitration process is restarted.

Arbitration process stops in the following situations:

- All Mailboxes were scanned
- A Tx active Mailbox is found in case of Lowest Buffer feature enabled
- Arbitration winner inactivation or abort during any arbitration process
- There was not enough time to finish Tx arbitration process (for instance, when a deactivation was performed near the end of frame). In this case arbitration process is pending.
- Error or Overload flag in the bus
- Low Power or Freeze mode request in Idle state

Arbitration is considered pending as described below:

- It was not possible to finish arbitration process in time
- C/S write during arbitration if write is performed in a MB whose number is lower than the Tx arbitration pointer
- Any C/S write if there is no Tx Arbitration process in progress
- Rx Match has just updated a Rx Code to Tx Code
- Entering Busoff state

C/S write during arbitration has the following effect:

- If C/S write is performed in the arbitration winner, a new process is restarted immediately.
- If C/S write is performed in a MB whose number is higher than the Tx arbitration pointer, the ongoing arbitration process will scan this MB as normal.

47.5.3 Receive process

To be able to receive CAN frames into a Mailbox, the CPU must prepare it for reception by executing the following steps:

1. If the Mailbox is active (either Tx or Rx) inactivate the Mailbox (see Mailbox inactivation), preferably with a safe inactivation (see Transmission abort mechanism).
2. Write the ID word
3. Write the EMPTY code (0b0100) to the CODE field of the Control and Status word to activate the Mailbox.

After the MB is activated, it will be able to receive frames that match the programmed filter. At the end of a successful reception, the Mailbox is updated by the *move-in* process (see Move-in) as follows:

1. The received Data field (8 bytes at most for Classical CAN message format) is stored.
2. The received Identifier field is stored.
3. The value of the Free Running Timer at the time of the second bit of frame's Identifier field is written into the Mailbox's Time Stamp field.
4. The received SRR, IDE, RTR and DLC fields are stored.
5. The CODE field in the Control and Status word is updated (see Table 47-136 and Table 47-137 in Section Message buffer structure).
6. A status flag is set in the Interrupt Flag Register and an interrupt is generated if allowed by the corresponding Interrupt Mask Register bit.

The recommended way for CPU servicing (read) the frame received in an Mailbox is using the following procedure:

1. Read the Control and Status word of that Mailbox.
2. Check if the BUSY bit is deasserted, indicating that the Mailbox is locked. Repeat step 1) while it is asserted. See Mailbox lock mechanism.
3. Read the contents of the Mailbox. Once Mailbox is locked now, its contents won't be modified by FlexCAN Move-in processes. See Move-in.

4. Acknowledge the proper flag at IFLAG registers.
5. Read the Free Running Timer. It is optional but recommended to unlock Mailbox as soon as possible and make it available for reception.

The CPU should poll for frame reception by the status flag bit for the specific Mailbox in one of the IFLAG Registers and not by the CODE field of that Mailbox. Polling the CODE field does not work because once a frame was received and the CPU services the Mailbox (by reading the C/S word followed by unlocking the Mailbox), the CODE field will not return to EMPTY. It will remain FULL, as explained in Table 47-136 . If the CPU tries to workaround this behavior by writing to the C/S word to force an EMPTY code after reading the Mailbox without a prior *safe inactivation*, a newly received frame matching the filter of that Mailbox may be lost.

CAUTION

In summary: *never do polling by reading directly the C/S word of the Mailboxes. Instead, read the IFLAG registers.*

Note that the received frame's Identifier field is always stored in the matching Mailbox, thus the contents of the ID field in an Mailbox may change if the match was due to masking. When CAN_MCR[SRXDIS] bit is asserted, FlexCAN will not store frames transmitted by itself in any MB, even if it contains a matching Rx Mailbox, and no interrupt flag or interrupt signal will be generated. Otherwise, when CAN_MCR[SRXDIS] bit is deasserted, FlexCAN can receive frames transmitted by itself if there exists a matching Rx Mailbox.

To be able to receive CAN frames through the Rx FIFO, the CPU must enable and configure the Rx FIFO during Freeze mode (see Rx FIFO). Upon receiving the Frames Available in Rx FIFO interrupt (see the description of the BUF5I bit "Frames available in Rx FIFO" bit in the CAN_IFLAG1 register), the CPU should service the received frame using the following procedure:

1. Read the Control and Status word (optional: needed only if a mask was used for IDE and RTR bits)
2. Read the ID field (optional: needed only if a mask was used)
3. Read the Data field
4. Read the CAN_RXFIR register (optional)
5. Clear the Frames Available in Rx FIFO interrupt by writing 1 to CAN_IFLAG1[BUF5I] bit (mandatory: releases the MB and allows the CPU to read the next Rx FIFO entry)

When CAN_MCR[DMA] is asserted, upon receiving a frame in FIFO, CAN_IFLAG1[BUF5I] generates a DMA request and does not generate a CPU interrupt (see Rx FIFO under DMA Operation). The CAN_IMASK1 bits in Rx FIFO region are not used.

The DMA controller must service the received frame using the following procedure:

1. Read the Control and Status word (read 0x80 address, optional)
2. Read the ID field (read 0x84 address, optional)
3. Read all Data Bytes (start read at 0x88 address, optional)
4. Read the last Data Bytes (read 0x8C address is mandatory)

47.5.4 Matching process

The matching process scans the MB memory looking for Rx MBs programmed with the same ID as the one received from the CAN bus. If the FIFO is enabled, the priority of scanning can be selected between Mailboxes and FIFO filters. The matching starts from the lowest number Message Buffer toward the higher ones. If no match is found within the first structure then the other is scanned subsequently. In the event that the FIFO is full, the matching algorithm always looks for a matching MB outside the FIFO region.

As the frame is being received, it is stored in a hidden auxiliary MB called Rx Serial Message Buffer (Rx SMB).

The matching process start point depends on the following conditions:

- If the received frame is a remote frame, the start point is the CRC field of the frame
- If the received frame is a data frame with DLC field equal to zero, the start point is the CRC field of the frame
- If the received frame is a data frame with DLC field different than zero, the start point is the DATA field of the frame

If a matching ID is found in the FIFO table or in one of the Mailboxes, the contents of the Rx SMB are transferred to the FIFO or to the matched Mailbox by the move-in process. If any CAN protocol error is detected then no match results are transferred to the FIFO or to the matched Mailbox at the end of reception.

The matching process scans all matching elements of both Rx FIFO (if enabled) and the active Rx Mailboxes (CODE is EMPTY, FULL, OVERRUN or RANSWER) in search of a successful comparison with the matching elements of the Rx SMB that is receiving the

frame on the CAN bus. The Rx SMB has the same structure of a Mailbox. The reception structures (Rx FIFO or Mailboxes) associated with the matching elements that had a successful comparison are the *matched structures*. The *matching winner* is selected at the end of the scan among those matched structures and depends on conditions described ahead. See the following table.

Table 47-143. Matching architecture

Structure	SMB[RTR]	CTRL2[RRS]	CTRL2[EACEN]	MB[IDE]	MB[RTR]	MB[ID[1]]	MB[CODE]
Mailbox	0	-	0	cmp[2]	no_cmp[3]	cmp_msk[4]	EMPTY or FULL or OVERRUN
Mailbox	0	-	1	cmp_msk	cmp_msk	cmp_msk	EMPTY or FULL or OVERRUN
Mailbox	1	0	-	cmp	no_cmp	cmp	RANSWER
Mailbox	1	1	0	cmp	no_cmp	cmp_msk	EMPTY or FULL or OVERRUN
Mailbox	1	1	1	cmp_msk	cmp_msk	cmp_msk	EMPTY or FULL or OVERRUN
FIFO[5]	-	-	-	cmp_msk	cmp_msk	cmp_msk	-

1. For Mailbox structure, If SMB[IDE] is asserted, the ID is 29 bits (ID Standard + ID Extended). If SMB[IDE] is negated, the ID is only 11 bits (ID Standard). For FIFO structure, the ID depends on IDAM.
2. cmp: Compares the Rx SMB contents with the MB contents regardless the masks.
3. no_cmp: The Rx SMB contents are not compared with the MB contents.
4. cmp_msk: Compares the Rx SMB contents with MB contents taking into account the masks.
5. SMB[IDE] and SMB[RTR] are not taken into account when IDAM is type C.

A reception structure is *free-to-receive* when any of the following conditions is satisfied:

- The CODE field of the Mailbox is EMPTY
- The CODE field of the Mailbox is either FULL or OVERRUN and it has already been serviced (the C/S word was read by the CPU and unlocked as described in Mailbox lock mechanism)
- The CODE field of the Mailbox is either FULL or OVERRUN and an inactivation (see Mailbox inactivation) is performed
- The Rx FIFO is not full

The scan order for Mailboxes and Rx FIFO is from the matching element with lowest number to the higher ones.

The matching winner search for Mailboxes is affected by the CAN_MCR[IRMQ] bit. If it is negated, the matching winner is the first matched Mailbox regardless if it is free-to-receive or not. If it is asserted, the matching winner is selected according to the priority below:

1. the first free-to-receive matched Mailbox;
2. the last non free-to-receive matched Mailbox.

It is possible to select the priority of scan between Mailboxes and Rx FIFO by the CAN_CTRL2[MRP] bit.

If the selected priority is Rx FIFO first:

- If the Rx FIFO is a matched structure and is free-to-receive, then the Rx FIFO is the matching winner regardless of the scan for Mailboxes
- Otherwise (the Rx FIFO is not a matched structure or is not free-to-receive), then the matching winner is searched among Mailboxes as described above

If the selected priority is Mailboxes first:

- If a free-to-receive matched Mailbox is found, it is the matching winner regardless of the scan for Rx FIFO
- If no matched Mailbox is found, then the matching winner is searched in the scan for the Rx FIFO
- If both conditions above are not satisfied and a non free-to-receive matched Mailbox is found, then the matching winner determination is conditioned by the CAN_MCR[IRMQ] bit:
- - If CAN_MCR[IRMQ] bit is negated, the matching winner is the first matched Mailbox
  - If CAN_MCR[IRMQ] bit is asserted, the matching winner is the Rx FIFO if it is a free-to-receive matched structure; otherwise, the matching winner is the last non free-to-receive matched Mailbox

See the following table for a summary of matching possibilities.

Table 47-144. Matching possibilities and resulting reception structures

RFEN	IRMQ	MRP	Matched in MB	Matched in FIFO	Reception structure	Description
No FIFO, only MB, match is always MB first						
0	0	X[1]	None[2]	-[3]	None	Frame lost by no match
0	0	X	Free[4]	-	FirstMB	
0	1	X	None	-	None	Frame lost by no match
0	1	X	Free	-	FirstMb	
0	1	X	NotFree	-	LastMB	Overrun
FIFO enabled, no match in FIFO is as if FIFO does not exist						
1	0	X	None	None[5]	None	Frame lost by no match
1	0	X	Free	None	FirstMB	

Table continues on the next page...

Table 47-144. Matching possibilities and resulting reception structures (continued)

RFEN	IRMQ	MRP	Matched in MB	Matched in FIFO	Reception structure	Description
1	1	X	None	None	None	Frame lost by no match
1	1	X	Free	None	FirstMb	
1	1	X	NotFree	None	LastMB	Overrun
FIFO enabled, Queue disabled						
1	0	0	X	NotFull[6]	FIFO	
1	0	0	None	Full[7]	None	Frame lost by FIFO full (FIFO Overflow)
1	0	0	Free	Full	FirstMB	
1	0	0	NotFree	Full	FirstMB	
1	0	1	None	NotFull	FIFO	
1	0	1	None	Full	None	Frame lost by FIFO full (FIFO Overflow)
1	0	1	Free	X	FirstMB	
1	0	1	NotFree	X	FirtsMb	Overrun
FIFO enabled, Queue enabled						
1	1	0	X	NotFull	FIFO	
1	1	0	None	Full	None	Frame lost by FIFO full (FIFO Overflow)
1	1	0	Free	Full	FirstMB	
1	1	0	NotFree	Full	LastMb	Overrun
1	1	1	None	NotFull	FIFO	
1	1	1	Free	X	FirstMB	
1	1	1	NotFree	NotFull	FIFO	
1	1	1	NotFree	Full	LastMb	Overrun

1. This is a don't care condition.
2. Matched in MB "None" means that the frame has not matched any MB (free-to-receive or non-free-to-receive).
3. This is a forbidden condition.
4. Matched in MB "Free" means that the frame matched at least one MB free-to-receive regardless of whether it has matched MBs non-free-to-receive.
5. Matched in FIFO "None" means that the frame has not matched any filter in FIFO. It is as if the FIFO didn't exist (CAN_CTRL2[RFEN]=0).
6. Matched in FIFO "NotFull" means that the frame has matched a FIFO filter and has empty slots to receive it.
7. Matched in FIFO "Full" means that the frame has matched a FIFO filter but couldn't store it because it has no empty slots to receive it.

If a non-safe Mailbox inactivation (see Mailbox inactivation) occurs during matching process and the Mailbox inactivated is the temporary matching winner, then the temporary matching winner is invalidated. The matching elements scan is not stopped nor

restarted, it continues normally. The consequence is that the current matching process works as if the matching elements compared before the inactivation did not exist, therefore a message may be lost.

Suppose, for example, that the FIFO is disabled, IRMQ is enabled and there are two MBs with the same ID, and FlexCAN starts receiving messages with that ID. Let us say that these MBs are the second and the fifth in the array. When the first message arrives, the matching algorithm finds the first match in MB number 2. The code of this MB is EMPTY, so the message is stored there. When the second message arrives, the matching algorithm finds MB number 2 again, but it is not "free-to-receive", so it keeps looking, finds MB number 5 and stores the message there. If yet another message with the same ID arrives, the matching algorithm finds out that there are no matching MBs that are "free-to-receive", so it decides to overwrite the last matched MB, which is number 5. In doing so, it sets the CODE field of the MB to indicate OVERRUN.

The ability to match the same ID in more than one MB can be exploited to implement a reception queue (in addition to the full featured FIFO) to allow more time for the CPU to service the MBs. By programming more than one MB with the same ID, received messages are queued into the MBs. The CPU can examine the Time Stamp field of the MBs to determine the order in which the messages arrived.

Matching to a range of IDs is possible by using ID Acceptance Masks. FlexCAN supports individual masking per MB. See the description of the Rx Individual Mask Registers (CAN_RXIMRx). During the matching algorithm, if a mask bit is asserted, then the corresponding ID bit is compared. If the mask bit is negated, the corresponding ID bit is a "don't care". Note that the Individual Mask Registers are implemented in RAM, so they are not initialized out of reset. Also, they can only be programmed while the module is in Freeze mode; otherwise, they are blocked by hardware.

FlexCAN also supports an alternate masking scheme with only four mask registers (CAN_RXFGMASK, CAN_RXMGMASK, CAN_RX14MASK and CAN_RX15MASK) for backwards compatibility with legacy applications. This alternate masking scheme is enabled when the IRMQ bit in the CAN_MCR Register is negated.

47.5.5 Move process

There are two types of move process: move-in and move-out.

47.5.5.1 Move-in

The move-in process is the copy of a message received by an Rx SMB to a Rx Mailbox or FIFO that has matched it. If the move destination is the Rx FIFO, attributes of the message are also copied to the CAN_RXFIR FIFO. Each Rx SMB has its own move-in process, but only one is performed at a given time as described ahead. The move-in starts only when the message held by the Rx SMB has a corresponding matching winner (see Matching process) and all of the following conditions are true:

- The CAN bus has reached or let past either:
  - The second bit of Intermission field next to the frame that carried the message that is in the Rx SMB
  - The first bit of an overload frame next to the frame that carried the message that is in the Rx SMB
- There is no ongoing matching process
- The destination Mailbox is not locked by the CPU
- There is no ongoing move-in process from another Rx SMB. If more than one move-in processes are to be started at the same time both are performed and the newest substitutes the oldest.

The term *pending move-in* is used throughout the documentation and stands for a move-to-be that still does not satisfy all of the aforementioned conditions.

The move-in is cancelled and the Rx SMB is able to receive another message if any of the following conditions is satisfied:

- The destination Mailbox is inactivated after the CAN bus has reached the first bit of Intermission field next to the frame that carried the message and its matching process has finished
- There is a previous pending move-in to the same destination Mailbox
- The Rx SMB is receiving a frame transmitted by the FlexCAN itself and the self-reception is disabled (CAN_MCR[SRXDIS] bit is asserted)
- Any CAN protocol error is detected

Note that the pending move-in is not cancelled if the module enters Freeze or Low-Power mode. It only stays on hold waiting for exiting Freeze and Low-Power mode and to be unlocked. If an MB is unlocked during Freeze mode, the move-in happens immediately.

The move-in process is the execution by the FlexCAN of the following steps:

1. Push IDHIT into the RXFIR FIFO if the message is destined to the Rx FIFO.
2. Read DATA0-3 and DATA4-7 words from the Rx SMB.
3. Write DATA0-3 and DATA4-7 words to the Rx Mailbox
4. Read the Control/Status and ID words from the Rx SMB.
5. Write Control/Status and ID words to the Rx Mailbox, and update the CODE field.

The move-in process is not atomic, in such a way that it is immediately cancelled by the inactivation of the destination Mailbox (see Mailbox inactivation) and in this case the Mailbox may be left partially updated, thus incoherent. The exception is if the move-in destination is an Rx FIFO Message Buffer, then the process cannot be cancelled.

The BUSY Bit (least significant bit of the CODE field) of the destination Message Buffer is asserted while the move-in is being performed to alert the CPU that the Message Buffer content is temporarily incoherent.

47.5.5.2 Move-out

The move-out process is the copy of the content from a Tx Mailbox to the Tx SMB when a message for transmission is available (see Section "Arbitration process"). The move-out occurs in the following conditions:

- The first bit of Intermission field
- During Bus Off state when TX Error Counter is in the 124 to 128 range
- During Bus Idle state
- During Wait For Bus Idle state

The move-out process is not atomic. Only the CPU has priority to access the memory concurrently out of Bus Idle state. In Bus Idle, the move-out has the lowest priority to the concurrent memory accesses.

47.5.6 Data coherence

In order to maintain data coherency and FlexCAN proper operation, the CPU must obey the rules described in Transmit process and Receive process.

47.5.6.1 Transmission abort mechanism

The abort mechanism provides a safe way to request the abortion of a pending transmission. A feedback mechanism is provided to inform the CPU if the transmission was aborted or if the frame could not be aborted and was transmitted instead.

Two primary conditions must be fulfilled in order to abort a transmission:

- CAN_MCR[AEN] bit must be asserted
- The first CPU action must be the writing of abort code (0b1001) into the CODE field of the Control and Status word.

Active MBs configured for transmission must be aborted first before they can be updated. If the abort code is written to a Mailbox that is currently being transmitted or to a Mailbox that was already loaded into the Tx SMB for transmission, the write operation is blocked and the transmission is not disturbed. However, the abort request is captured and kept pending until one of the following conditions is satisfied:

- The module loses the bus arbitration
- There is an error during the transmission
- The module is put into Freeze mode
- The module enters the BusOff state
- There is an overload frame

If none of the conditions above are reached, the MB is transmitted correctly, the interrupt flag is set in the IFLAG register, and an interrupt to the CPU is generated (if enabled). The abort request is automatically cleared when the interrupt flag is set. On the other hand, if one of the above conditions is reached, the frame is not transmitted; therefore, the abort code is written into the CODE field, the interrupt flag is set in the IFLAG, and an interrupt is (optionally) generated to the CPU.

If the CPU writes the abort code before the transmission begins internally, then the write operation is not blocked; therefore, the MB is updated and the interrupt flag is set. In this way the CPU just needs to read the abort code to make sure the active MB was *safely inactivated*. Although the AEN bit is asserted and the CPU wrote the abort code, in this case the MB is inactivated and not aborted, because the transmission did not start yet. One Mailbox is only aborted when the abort request is captured and kept pending until one of the previous conditions are satisfied.

The abort procedure can be summarized as follows:

- CPU checks the corresponding IFLAG and clears it, if asserted.
- CPU writes 0b1001 into the CODE field of the C/S word.
- CPU waits for the corresponding IFLAG indicating that the frame was either transmitted or aborted.
- CPU reads the CODE field to check if the frame was either transmitted (CODE=0b1000) or aborted (CODE=0b1001).
- It is necessary to clear the corresponding IFLAG in order to allow the MB to be reconfigured.

47.5.6.2 Mailbox inactivation

Inactivation is a mechanism provided to protect the Mailbox against updates by the FlexCAN internal processes, thus allowing the CPU to rely on Mailbox data coherence after having updated it, even in Normal mode.

Inactivation of transmission Mailboxes must be performed just when MCR[AEN] bit is deasserted.

If a Mailbox is inactivated, it participates in neither the arbitration process nor the matching process until it is reactivated. See Transmit process and Receive process for more detailed instructions on how to inactivate and reactivate a Mailbox.

To inactivate a Mailbox, the CPU must update its CODE field to INACTIVE (either 0b0000 or 0b1000).

Because the user is not able to synchronize the CODE field update with the FlexCAN internal processes, an inactivation can have the following consequences:

- A frame in the bus that matches the filtering of the inactivated Rx Mailbox may be lost without notice, even if there are other Mailboxes with the same filter
- A frame containing the message within the inactivated Tx Mailbox may be transmitted without setting the respective IFLAG

In order to perform a *safe inactivation* and avoid the above consequences for Tx Mailboxes, the CPU must use the Transmission Abort mechanism (see Transmission abort mechanism).

The inactivation automatically unlocks the Mailbox (see Mailbox lock mechanism).

NOTE

Message Buffers that are part of the Rx FIFO cannot be inactivated. There is no write protection on the FIFO region by FlexCAN. CPU must maintain data coherency in the FIFO region when RFEN is asserted.

47.5.6.3 Mailbox lock mechanism

Other than Mailbox inactivation, FlexCAN has another data coherence mechanism for the receive process. When the CPU reads the Control and Status word of an Rx MB with codes FULL or OVERRUN, FlexCAN assumes that the CPU wants to read the whole MB in an atomic operation, and therefore it sets an internal lock flag for that MB. The lock is released when the CPU reads the Free Running Timer (global unlock operation),

or when it reads the Control and Status word of another MB regardless of its code. A CPU write into the C/S word also unlocks the MB, but this procedure is not recommended for normal unlock use because it cancels a pending-move and potentially may lose a received message. The MB locking prevents a new frame from being written into the MB while the CPU is reading it.

NOTE

The locking mechanism applies only to Rx MBs that are not part of the FIFO and have a code different than INACTIVE (0b0000) or EMPTY[1] (0b0100). Also, Tx MBs can not be locked.

Suppose, for example, that the FIFO is disabled and the second and the fifth MBs of the array are programmed with the same ID, and FlexCAN has already received and stored messages into these two MBs. Suppose now that the CPU decides to read MB number 5 and at the same time another message with the same ID is arriving. When the CPU reads the Control and Status word of MB number 5, this MB is locked. The new message arrives and the matching algorithm finds out that there are no "free-to-receive" MBs, so it decides to override MB number 5. However, this MB is locked, so the new message can not be written there. It will remain in the Rx SMB waiting for the MB to be unlocked, and only then will be written to the MB.

If the MB is not unlocked in time and yet another new message with the same ID arrives, then the new message overwrites the one on the Rx SMB and there will be no indication of lost messages either in the CODE field of the MB or in the Error and Status Register.

While the message is being moved-in from the Rx SMB to the MB, the BUSY bit on the CODE field is asserted. If the CPU reads the Control and Status word and finds out that the BUSY bit is set, it should defer accessing the MB until the BUSY bit is negated.

Note

If the BUSY bit is asserted or if the MB is empty, then reading the Control and Status word does not lock the MB.

Inactivation takes precedence over locking. If the CPU inactivates a locked Rx MB, then its lock status is negated and the MB is marked as invalid for the current matching round. Any pending message on the Rx SMB will not be transferred anymore to the MB. An MB is unlocked when the CPU reads the Free Running Timer Register (see Section "Free Running Timer Register (CAN_TIMER)"), or the C/S word of another MB.

Lock and unlock mechanisms have the same functionality in both Normal and Freeze modes.

1. In previous FlexCAN versions, reading the C/S word locked the MB even if it was EMPTY. This behavior is maintained when the IRMQ bit is negated.

An unlock during Normal or Freeze mode results in the move-in of the pending message. However, the move-in is postponed if an unlock occurs during a low power mode (see Modes of operation), and it takes place only when the module resumes to Normal or Freeze modes.

47.5.7 Rx FIFO

The Rx FIFO is receive-only and is enabled by asserting the CAN_MCR[RFEN] bit. The reset value of this bit is zero to maintain software backward compatibility with previous versions of the module that did not have the FIFO feature.

The FIFO is 6-message deep. The memory region occupied by the FIFO structure (both Message Buffers and FIFO engine) is described in Rx FIFO structure. The CPU can read the received messages sequentially, in the order they were received, by repeatedly reading a Message Buffer structure at the output of the FIFO.

The CAN_IFLAG1[BUF5I] (Frames available in Rx FIFO) is asserted when there is at least one frame available to be read from the FIFO. An interrupt is generated if it is enabled by the corresponding mask bit. Upon receiving the interrupt, the CPU can read the message (accessing the output of the FIFO as a Message Buffer) and the CAN_RXFIR register and then clear the interrupt. If there are more messages in the FIFO the act of clearing the interrupt updates the output of the FIFO with the next message and update the CAN_RXFIR with the attributes of that message, reissuing the interrupt to the CPU. Otherwise, the flag remains negated. The output of the FIFO is only valid whilst the CAN_IFLAG1[BUF5I] is asserted.

The CAN_IFLAG1[BUF6I] (Rx FIFO Warning) is asserted when the number of unread messages within the Rx FIFO is increased to 5 from 4 due to the reception of a new one, meaning that the Rx FIFO is almost full. The flag remains asserted until the CPU clears it.

The CAN_IFLAG1[BUF7I] (Rx FIFO Overflow) is asserted when an incoming message was lost because the Rx FIFO is full. Note that the flag will not be asserted when the Rx FIFO is full and the message was captured by a Mailbox. The flag remains asserted until the CPU clears it.

Clearing one of those three flags does not affect the state of the other two.

An interrupt is generated if an IFLAG bit is asserted and the corresponding mask bit is asserted too.

A powerful filtering scheme is provided to accept only frames intended for the target application, reducing the interrupt servicing work load. The filtering criteria is specified by programming a table of up to 128 32-bit registers, according to CAN_CTRL2[RFFN] setting, that can be configured to one of the following formats (see also Rx FIFO structure):

- Format A: 128 IDAFs (extended or standard IDs including IDE and RTR)
- Format B: 256 IDAFs (standard IDs or extended 14-bit ID slices including IDE and RTR)
- Format C: 512 IDAFs (standard or extended 8-bit ID slices)

Note

A chosen format is applied to all entries of the filter table. It is not possible to mix formats within the table.

Every frame available in the FIFO has a corresponding IDHIT (Identifier Acceptance Filter Hit Indicator) that can read in the IDHIT field from C/S word, as shown in the Rx FIFO Structure description. Another way the CPU can obtain this information is by accessing the CAN_RXFIR register. The CAN_RXFIR[IDHIT] field refers to the message at the output of the FIFO and is valid while the CAN_IFLAG1[BUF5I] flag is asserted. The CAN_RXFIR register must be read only before clearing the flag, which guarantees that the information refers to the correct frame within the FIFO.

Up to 32 elements of the filter table are individually affected by the Individual Mask Registers (CAN_RXIMRx), according to the setting of CAN_CTRL2[RFFN], allowing very powerful filtering criteria to be defined. If the CAN_MCR[IRMQ] bit is negated, then the FIFO filter table is affected by CAN_RXFGMASK.

47.5.7.1 Rx FIFO under DMA Operation

The receive-only FIFO can support DMA, this feature is enabled by asserting both the CAN_MCR[RFEN] and CAN_MCR[DMA] bits. The reset value of CAN_MCR[DMA] bit is zero to maintain backward compatibility with previous versions of the module that did not have the DMA feature.

The DMA controller can read the received message by reading a Message Buffer structure at the FIFO output port at the 0x80-0x8C address range.

When CAN_MCR[DMA] is asserted the CPU must not access the FIFO output port address range. Before enabling the CAN_MCR[DMA], the CPU must service the IFLAGs asserted in the Rx FIFO region. Otherwise, these IFLAGs may show that the FIFO has data to be serviced, and mistakenly generate a DMA request. Before disabling the CAN_MCR[DMA], the CPU must perform a clear FIFO operation.

The CAN_IFLAG1[BUF5I] (Frames available in Rx FIFO) is asserted when there is at least one frame available to be read from the FIFO, consequently a DMA request is generated simultaneously. Upon receiving the request, the DMA controller can read the message (accessing the output of the FIFO as a Message Buffer). The DMA reading process must end by reading address 0x8C, which clears the CAN_IFLAG1[BUF5I] and updates both the FIFO output with the next message (if FIFO is not empty) and the CAN_RXFIR register with the attributes of the new message. If there are more messages stored in the FIFO, the CAN_IFLAG1[BUF5I] will be re-asserted and another DMA request is issued. Otherwise, the flag remains negated.

NOTE

CAN_RXFIR register contents cannot be read after DMA completes the FIFO read. The IDHIT information is also available in the C/S word at address 0x080 (see Rx FIFO structure.

The CAN_IFLAG1[BUF6I] and CAN_IFLAG1[BUF7I] are not used when the DMA feature is enabled.

When FlexCAN is working with DMA, the CPU does not receive any Rx FIFO interruption and must not clear the related IFLAGs. In addition, the related IMASKs are not used to mask the generation of DMA requests.

47.5.7.2 Clear FIFO Operation

When CAN_MCR[RFEN] is asserted, the clear FIFO operation is a feature used to empty FIFO contents. With CAN_MCR[RFEN] asserted the Clear FIFO occurs when the CPU writes 1 in CAN_IFLAG1[BUF0I]. This operation can only be performed in Freeze Mode and is blocked by hardware in other modes. This operation does not clear the FIFO IFLAGs, consequently the CPU must service all FIFO IFLAGs before execute the clear FIFO task.

When Rx FIFO is working with DMA, the clear FIFO operation clears the CAN_IFLAG1[BUF5I] and the DMA request is canceled.

CAUTION

Clear FIFO operation does not clear IFLAGs, except when CAN_MCR[DMA] is asserted, in this case only the CAN_IFLAG1[BUF5I] is cleared.

47.5.8 CAN protocol related features

This section describes the CAN protocol related features.

47.5.8.1 Remote frames

Remote frame is a special kind of frame. The user can program a mailbox to be a Remote Request Frame by configuring the mailbox as Transmit with the RTR bit set to '1'. After the remote request frame is transmitted successfully, the mailbox becomes a Receive Message Buffer, with the same ID as before.

When a remote request frame is received by FlexCAN, it can be treated in three ways, depending on Remote Request Storing (CTRL2[RRS]) and Rx FIFO Enable (MCR[RFEN]) bits:

- If RRS is negated the frame's ID is compared to the IDs of the Transmit Message Buffers with the CODE field 0b1010. If there is a matching ID, then this mailbox frame will be transmitted. Note that if the matching mailbox has the RTR bit set, then FlexCAN will transmit a remote frame as a response. The received remote request frame is not stored in a receive buffer. It is only used to trigger a transmission of a frame in response. The mask registers are not used in remote frame matching, and all ID bits (except RTR) of the incoming received frame should match. In the case that a remote request frame is received and matches a mailbox, this message buffer immediately enters the internal arbitration process, but is considered as a normal Tx mailbox, with no higher priority. The data length of this frame is independent of the DLC field in the remote frame that initiated its transmission.
- If RRS is asserted the frame's ID is compared to the IDs of the receive mailboxes with the CODE field 0b0100, 0b0010 or 0b0110. If there is a matching ID, then this mailbox will store the remote frame in the same fashion of a data frame. No automatic remote response frame will be generated. The mask registers are used in the matching process.
- If RFEN is asserted FlexCAN will not generate an automatic response for remote request frames that match the FIFO filtering criteria. If the remote frame matches one of the target IDs, it will be stored in the FIFO and presented to the CPU. Note that for

filtering formats A and B, it is possible to select whether remote frames are accepted or not. For format C, remote frames are always accepted (if they match the ID). Remote Request Frames are considered as normal frames, and generate a FIFO overflow when a successful reception occurs and the FIFO is already full.

47.5.8.2 Overload frames

FlexCAN does transmit overload frames due to detection of following conditions on CAN bus:

- Detection of a dominant bit in the first/second bit of Intermission
- Detection of a dominant bit at the 7th bit (last) of End of Frame field (Rx frames)
- Detection of a dominant bit at the 8th bit (last) of Error Frame Delimiter or Overload Frame Delimiter

47.5.8.3 Time stamp

The value of the Free Running Timer is sampled at the beginning of the Identifier field on the CAN bus, and is stored at the end of "move-in" in the TIME STAMP field, providing network behavior with respect to time.

The Free Running Timer is clocked by the FlexCAN bit-clock, which defines the baud rate on the CAN bus. During a message transmission/reception, it increments by one for each bit that is received or transmitted. When there is no message on the bus, it counts using the previously programmed baud rate.

The Free Running Timer is not incremented during Disable, Stop, and Freeze modes. It can be reset upon a specific frame reception, enabling network time synchronization. See the TSYN description in Control 1 Register (CAN_CTRL1).

47.5.8.4 Protocol timing

The following figure shows the structure of the clock generation circuitry that feeds the CAN Protocol Engine (PE) submodule.

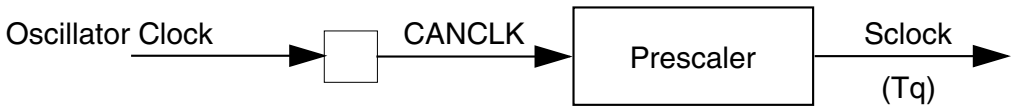


Figure 47-128. CAN engine clocking scheme

The FlexCAN module supports a variety of means to setup bit timing parameters that are required by the CAN protocol. The Control 1 Register (CAN_CTRL1) has various fields used to control bit timing parameters: PRESDIV, PROPSEG, PSEG1, PSEG2 and RJW.

The CAN Bit Timing register (CAN_CBT) extends the range of the CAN bit timing variables in CAN_CTRL1.

The PRESDIV field (as well as its extended range EPRESDIV) defines the Prescaler Value (see the equation below) that generates the Serial Clock (Sclock), whose period defines the 'time quantum' used to compose the CAN waveform. A time quantum (Tq) is the atomic unit of time handled by the CAN engine.

$$Tq = \frac{(\text{PRESDIV} + 1)}{f_{\text{CANCLK}}}$$

The bit rate, which defines the rate the CAN message is either received or transmitted, is given by the formula:

$$\text{CAN Bit Time} = (\text{Number of Time Quanta in 1 bit time}) * Tq$$

$$\text{Bit Rate} = \frac{1}{\text{CAN Bit Time}}$$

A bit time is subdivided into three segments[2] (see Figure 47-129 and Table 47-145):

- SYNC_SEG: This segment has a fixed length of one time quantum. Signal edges are expected to happen within this section

2. For further explanation of the underlying concepts, see ISO 11898-1. See also the CAN 2.0A/B protocol specification for bit timing.

- Time Segment 1: This segment includes the Propagation Segment and the Phase Segment 1 of the CAN standard. It can be programmed by setting the PROPSEG and the PSEG1 fields of the CAN_CTRL1 Register so that their sum (plus 2) is in the range of 4 to 16 time quanta. When CAN_CBT[BTF] bit is asserted, FlexCAN uses EPROPSEG and EPSEG1 fields from CAN_CBT register so that their sum (plus 2) is in the range of 2 to 96 time quanta.
- Time Segment 2: This segment represents the Phase Segment 2 of the CAN standard. It can be programmed by setting the PSEG2 field of the CAN_CTRL1 Register (plus 1) to be 2 to 8 time quanta long. When CAN_CBT[BTF] bit is asserted, FlexCAN uses EPSEG2 fields of CAN_CBT register so that its value (plus 1) is in the range of 2 to 32 time quanta. The Time Segnment 2 cannot be smaller than the Information Processing Time (IPT), which value is 2 time quanta in FlexCAN.

NOTE

The bit time defined by the above time segments must not be smaller than 5 time quanta. For bit time calculations, use an Information Processing Time (IPT) of 2, which is the value implemented in the FlexCAN module.

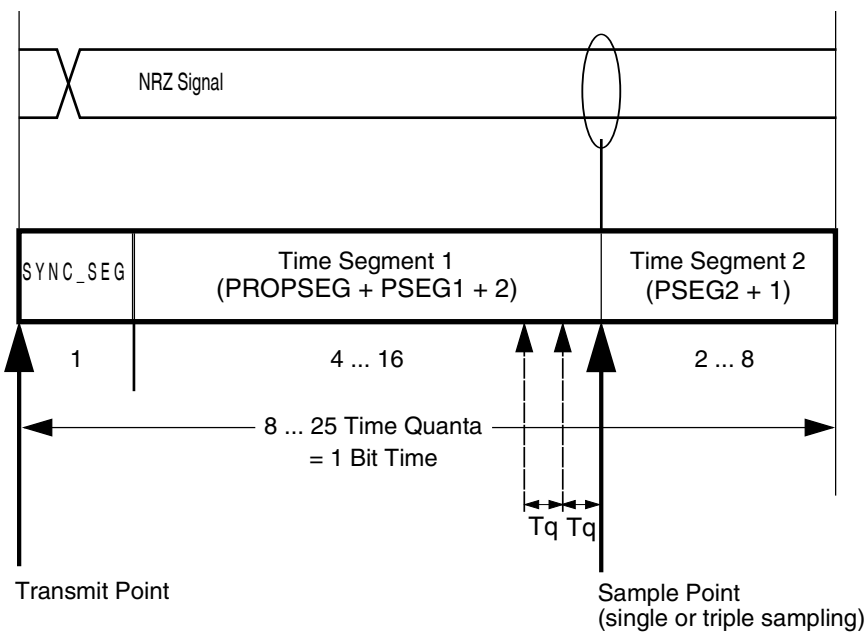

Figure 47-129. Segments within the bit time (example using CAN_CTRL1 bit timing variables for Classical CAN format)

Table 47-145. Time segment syntax

Syntax	Description
SYNC_SEG	System expects transitions to occur on the bus during this period.
TSEG1	Corresponds to the sum of PROPSEG and PSEG1.
TSEG2	Corresponds to the PSEG2 value.
Transmit Point	A node in transmit mode transfers a new value to the CAN bus at this point.
Sample Point	A node samples the bus at this point. If the three samples per bit option is selected, then this point marks the position of the third sample.

The following table gives some examples of the CAN compliant segment settings for Classical CAN format (Bosch CAN 2.0B) messages.

Table 47-146. Bosch CAN 2.0B standard compliant bit time segment settings

Time segment 1	Time segment 2	Re-synchronization jump width
5 .. 10	2	1 .. 2
4 .. 11	3	1 .. 3
5 .. 12	4	1 .. 4
6 .. 13	5	1 .. 4
7 .. 14	6	1 .. 4
8 .. 15	7	1 .. 4
9 .. 16	8	1 .. 4

Note

The user must ensure the bit time settings are in compliance with the CAN Protocol standard (ISO 11898-1).

Whenever CAN bit is used as a measure of time duration (e.g. estimating the occurrence of a CAN bit event in a message), the number of peripheral clocks in one CAN bit (NumClkBit) can be calculated as:

$$\text{NumClkBit} = \frac{f_{SYS}}{f_{CANCLK}} \text{ X } (\text{PRESDIV} + 1) \text{ X } (\text{PROPSEG} + \text{PSEG1} + \text{PSEG2} + 4)$$

where:

- NumClkBit is the number of peripheral clocks in one CAN bit;
- f_{CANCLK} is the Protocol Engine (PE) Clock (see Figure "CAN Engine Clocking Scheme"), in Hz;
- f_{SYS} is the frequency of operation of the system (CHI) clock, in Hz;

- PSEG1 is the value in CAN_CTRL1[PSEG1] field;
- PSEG2 is the value in CAN_CTRL1[PSEG2] field;
- PROPSEG is the value in CAN_CTRL1[PROPSEG] field;
- PRESDIV is the value in CAN_CTRL1[PRESDIV] field.

The formula above is also applicable to the alternative CAN bit timing variables described in the CAN Bit Timing Register (CAN_CBT).

For example, 180 CAN bits = (180 x NumClkBit) peripheral clock periods.

47.5.8.5 Arbitration and matching timing

During normal reception and transmission, the matching, arbitration, move-in and move-out processes are executed during certain time windows inside the CAN frame, as shown in the following figures.

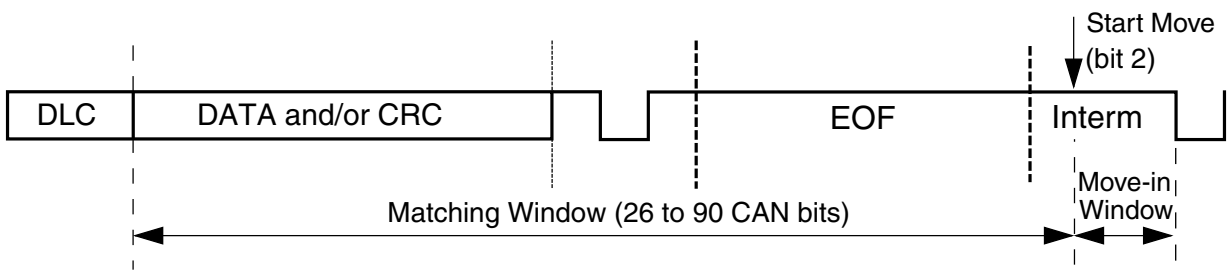

Figure 47-130. Matching and move-in time windows

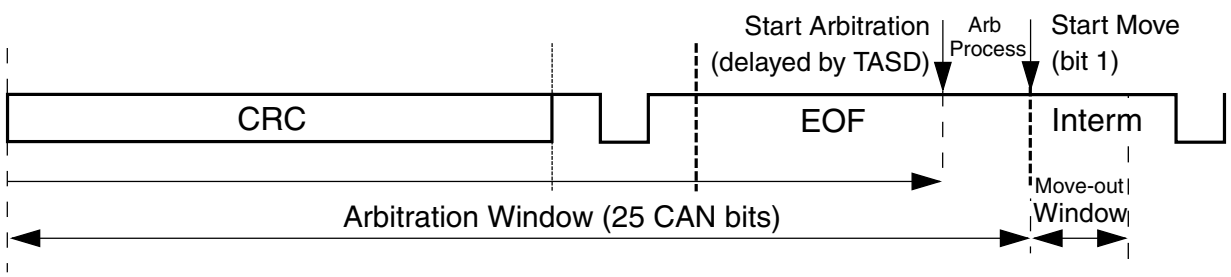

Figure 47-131. Arbitration and move-out time windows

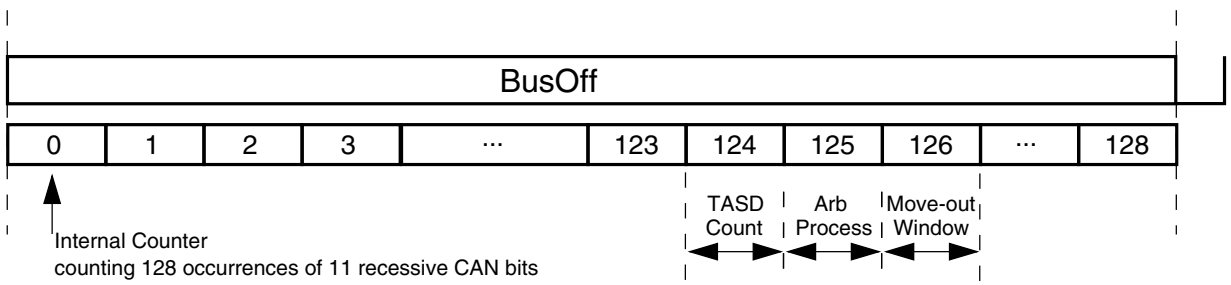

Figure 47-132. Arbitration at the end of bus off and move-out time windows

NOTE

In the preceding figures, the matching and arbitration timing does not take into account the delay caused by the concurrent memory access due to the CPU or other internal FlexCAN sub-blocks.

47.5.8.6 Tx Arbitration start delay

The Tx Arbitration Start Delay (TASD) bit field in Control 2 register (CAN_CTRL2[TASD]) is a variable that indicates the number of CAN bits used by FlexCAN to delay the Tx Arbitration process start point from the first bit of CRC field of the current frame. This variable can be written only in Freeze mode because it is blocked by hardware in other modes.

The transmission performance is impacted by the ability of the CPU to reconfigure Message Buffers (MBs) for transmission after the end of the internal Arbitration process, where FlexCAN finds the winner MB for transmission (see Arbitration process). If the Arbitration ends too early before the first bit of Intermission field, then there is a chance that the CPU reconfigures some Tx MBs and the winner MB is no longer the best candidate to be transmitted.

TASD is useful to optimize the transmission performance by defining the Arbitration start point, as shown in the next figure, based on factors such as:

- The peripheral-to-oscillator clock ratio
- CAN bit timing variables that determine the CAN bit rate
- The number of Message Buffers (MBs) in use by the Matching and Arbitration processes.

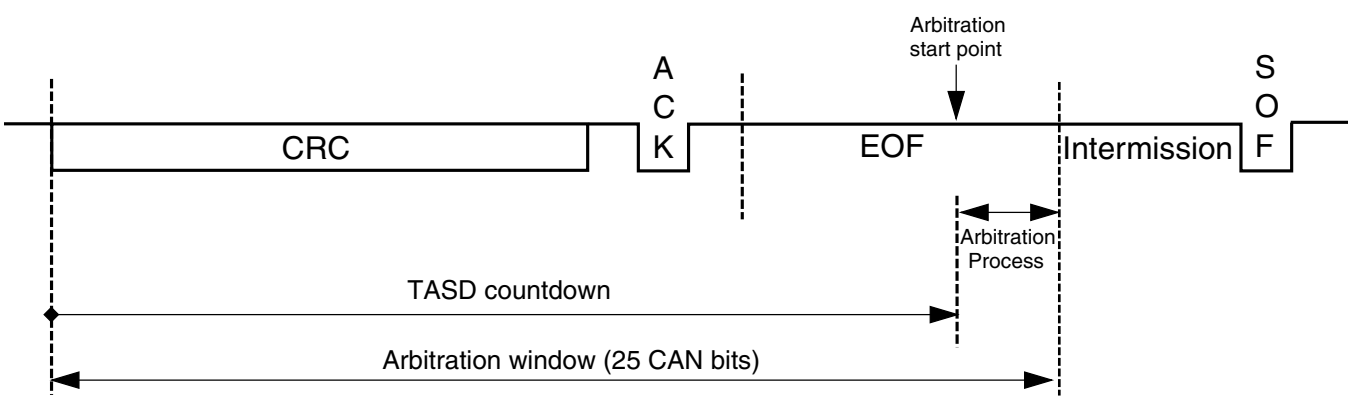

Figure 47-133. Optimal Tx Arbitration start point

The duration of an Arbitration process, in terms of CAN bits, is directly proportional to the number of available MBs and to the CAN bit rate, and inversely proportional to the peripheral clock frequency.

The optimal Arbitration timing is that in which the last MB is scanned right before the first bit of the Intermission field of a CAN frame. For instance, if there are few MBs and the peripheral/oscillator clock ratio is high and the CAN baud rate is low, then the Arbitration can be placed closer to the frame's end, adding more delay to its start point, and vice-versa.

If TASD is set to 0 then the Arbitration start is not delayed and more time is reserved for Arbitration. On the other hand, if TASD is close to 24 then the CPU can configure a Tx MB later and less time is reserved for Arbitration. If too little time is reserved for Arbitration the FlexCAN may be not be able to find a winner MB in time to be transmitted with the best chance to win the bus arbitration against external nodes on the CAN bus.

The optimal TASD value can be calculated as follows:

$$TASD = 25 - \left(\frac{f_{CANCLK} \times [\, MAXMB + 3 - (RFEN \times 8) - (RFEN \times RFFN \times 2)\,] \times 2}{f_{SYS} \times [1 + (PSEG1 + 1) + (PSEG2 + 1) + (PROPSEG + 1)\,] \times (PRESDIV + 1)} \right)$$

where:

- MAXMB is the value in CAN_CTRL1[MAXMB] field
- f_{CANCLK} is the oscillator clock, in Hz
- f_{SYS} is the peripheral clock, in Hz
- RFEN is the value in CAN_CTRL1[RFEN] bit
- RFFN is the value in CAN_CTRL2[RFFN] field
- PSEG1 is the value in CAN_CTRL1[PSEG1] field
- PSEG2 is the value in CAN_CTRL1[PSEG2] field
- PROPSEG is the value in CAN_CTRL1[PROPSEG] field
- PRESDIV is the value in CAN_CTRL1[PRESDIV] field

See also Protocol timing for more details.

47.5.9 Clock domains and restrictions

The FlexCAN module has two clock domains asynchronous to each other:

- The Bus Domain feeds the Control Host Interface (CHI) submodule and is derived from the peripheral clock.
- The Oscillator Domain feeds the CAN Protocol Engine (PE) submodule and is derived directly from a crystal oscillator clock, so that very low jitter performance can be achieved on the CAN bus.

When CAN_CTRL1[CLKSRC] bit is set, synchronous operation occurs because both domains are connected to the peripheral clock (creating a 1:1 ratio between the peripheral and oscillator clocks).

When the two domains are connected to clocks with different frequencies and/or phases, there are restrictions on the frequency relationship between the two clock domains. In the case of asynchronous operation, the Bus Domain clock frequency must always be greater than the Oscillator Domain clock frequency.

NOTE

Asynchronous operation with a 1:1 ratio between peripheral and oscillator clocks is not allowed.

When doing matching and arbitration, FlexCAN needs to scan the whole Message Buffer memory during the time slot of one CAN frame, comprised of a number of CAN bits. In order to have sufficient time to do that, the following requirements must be observed:

- The peripheral clock frequency can not be smaller than the oscillator clock frequency
- There must be a minimum number of peripheral clocks per CAN bit, as specified in the table shown below

Table 47-147. Minimum number of peripheral clocks per CAN bit

Number of Mailboxes	Value of CAN_MCR[RFEN] bit	Minimum number of peripheral clocks per CAN bit
16	0	16
32	0	16
64	0	25
96	0	37
16	1	16
32	1	17
64	1	30
96	1	42

The minimum number of peripheral clocks per CAN bit specified in the preceding table determines the minimum peripheral clock frequency for a given number of Mailboxes and for an expected CAN bit rate. The CAN bit rate depends on the number of time quanta in a CAN bit, that can be defined by adjusting one or more of the bit timing values

contained in either the Control 1 Register (CAN_CTRL1) or CAN Bit Time register (CAN_CBT). The time quantum (Tq) is defined in Protocol timing. The minimum number of time quanta per CAN bit must be 8; therefore, the oscillator clock frequency should be at least 8 times the CAN bit rate.

47.5.10 Modes of operation details

The FlexCAN module has functional modes and low-power modes. See Modes of operation for an introductory description of all the modes of operation. The following sub-sections contain functional details on Freeze mode and the low-power modes.

CAUTION

"Permanent Dominant" failure on CAN Bus line is not supported by FlexCAN. If a Low-Power request or Freeze mode request is done during a "Permanent Dominant", the corresponding acknowledge can never be asserted.

47.5.10.1 Freeze mode

This mode is requested either by the CPU through the assertion of the HALT bit in the CAN_MCR Register or when the chip is put into Debug mode. In both cases it is also necessary that the FRZ bit is asserted in the CAN_MCR Register and the module is not in a low-power mode. This mode is also requested by FlexCAN through the automatic assertion of both HALT and FRZ bits when CAN_MECR[NCEFAFRZ] bit is set and a non-correctable error is detected in a memory read access performed by FlexCAN internal processes (see Response to Errors).

The acknowledgement is obtained through the assertion by the FlexCAN of FRZ_ACK bit in the same register. The CPU must only consider the FlexCAN in Freeze mode when both request and acknowledgement conditions are satisfied.

When Freeze mode is requested, FlexCAN does the following:

- Waits to be in either Intermission, Passive Error, Bus Off or Idle state
- Waits for all internal activities like arbitration, matching, move-in and move-out to finish. A pending move-in does not prevent going to Freeze mode.
- Ignores the Rx input pin and drives the Tx pin as recessive
- Stops the prescaler, thus halting all CAN protocol activities

- Grants write access to the Error Counters Register, which is read-only in other modes
- Sets the NOT_RDY and FRZ_ACK bits in CAN_MCR

After requesting Freeze mode, the user must wait for the FRZ_ACK bit to be asserted in CAN_MCR before executing any other action, otherwise FlexCAN may operate in an unpredictable way. In Freeze mode, all memory mapped registers are accessible.

Exiting Freeze mode is done in one of the following ways:

- CPU negates the FRZ bit in the CAN_MCR Register
- The chip is removed from Debug Mode and/or the HALT bit is negated

The FRZ_ACK bit is negated after the protocol engine recognizes the negation of the freeze request. When out of Freeze mode, FlexCAN tries to re-synchronize to the CAN bus by waiting for 11 consecutive recessive bits.

47.5.10.2 Module Disable mode

This low power mode is normally used to temporarily disable a complete FlexCAN block, with no power consumption. It is requested by the CPU through the assertion of the CAN_MCR[MDIS] bit, and the acknowledgement is obtained through the assertion by the FlexCAN of the CAN_MCR[LPMACK] bit. The CPU must only consider the FlexCAN in Disable mode when both request and acknowledgement conditions are satisfied.

If the module is disabled during Freeze mode, it requests to disable the clocks to the PE and CHI sub-modules, sets the LPMACK bit and negates the FRZACK bit.

If the module is disabled during transmission or reception, FlexCAN does the following:

- Waits to be in either Idle or Bus Off state, or else waits for the third bit of Intermission and then checks it to be recessive
- Waits for all internal activities like arbitration, matching, move-in and move-out to finish. A pending move-in is not taken into account.
- Ignores its Rx input pin and drives its Tx pin as recessive
- Shuts down the clocks to the PE and CHI sub-modules
- Sets the NOTRDY and LPMACK bits in CAN_MCR

The Bus Interface Unit continues to operate, enabling the CPU to access memory mapped registers, except the Rx Mailboxes Global Mask Registers, the Rx Buffer 14 Mask Register, the Rx Buffer 15 Mask Register, the Rx FIFO Global Mask Register. The Rx FIFO Information Register, the Message Buffers, the Rx Individual Mask Registers, and the reserved words within RAM may not be accessed when the module is in Disable Mode. Exiting from this mode is done by negating the MDIS bit by the CPU, which causes the FlexCAN to request to resume the clocks and negate the LPMACK bit after the CAN protocol engine recognizes the negation of disable mode requested by the CPU.

47.5.10.3 Stop mode

This is a system low-power mode in which all chip clocks can be stopped for maximum power savings. The Stop mode is globally requested by the CPU and the acknowledgement is obtained through the assertion by the FlexCAN of a Stop Acknowledgement signal. The CPU must only consider the FlexCAN in Stop mode when both request and acknowledgement conditions are satisfied.

If FlexCAN receives the global Stop mode request during Freeze mode, it sets the LPMACK bit, negates the FRZACK bit and then sends the Stop Acknowledge signal to the CPU, in order to shut down the clocks globally.

If Stop mode is requested during transmission or reception, FlexCAN does the following:

- Waits to be in either Idle or Bus Off state, or else waits for the third bit of Intermission and checks it to be recessive
- Waits for all internal activities like arbitration, matching, move-in and move-out to finish. A pending move-in is not taken into account.
- Ignores its Rx input pin and drives its Tx pin as recessive
- Sets the NOTRDY and LPMACK bits in CAN_MCR
- Sends a Stop Acknowledge signal to the CPU, so that it can shut down the clocks globally

Stop mode is exited when the CPU resumes the clocks and removes the Stop Mode request.

After the CAN protocol engine recognizes the negation of the Stop mode request, the FlexCAN negates the LPMACK bit. FlexCAN will then wait for 11 consecutive recessive bits to synchronize to the CAN bus.

47.5.11 Interrupts

The module has many interrupt sources: interrupts due to message buffers and interrupts due to the ORed interrupts from MBs, Bus Off, Bus Off Done, Error, Tx Warning, and Rx Warning.

Each one of the message buffers can be an interrupt source, if its corresponding IMASK bit is set. There is no distinction between Tx and Rx interrupts for a particular buffer, under the assumption that the buffer is initialized for either transmission or reception. Each of the buffers has an assigned flag bit in the CAN_IFLAG registers. The bit is set when the corresponding buffer completes a successful transfer and is cleared when the CPU writes it to 1 (unless another interrupt is generated at the same time).

Note

It must be guaranteed that the CPU clears only the bit causing the current interrupt. For this reason, bit manipulation instructions (BSET) must not be used to clear interrupt flags. These instructions may cause accidental clearing of interrupt flags which are set after entering the current interrupt service routine.

If the Rx FIFO is enabled (CAN_MCR[RFEN] = 1) and DMA is disabled (CAN_MCR[DMA] = 0), the interrupts corresponding to MBs 0 to 7 have different meanings. Bit 7 of the CAN_IFLAG1 register becomes the "FIFO Overflow" flag; bit 6 becomes the "FIFO Warning" flag, bit 5 becomes the "Frames Available in FIFO" flag and bits 4-0 are unused. See the description of the Interrupt Flags 1 Register (CAN_IFLAG1) for more information.

If both Rx FIFO and DMA are enabled (CAN_MCR[RFEN] and CAN_MCR[DMA] = 1) the FlexCAN does not generate any FIFO interrupt. The bit 5 of the CAN_IFLAG1 register still indicates "Frames Available in FIFO" and generates a DMA request. The bits 7, 6, 4-0 are unused.

For a combined interrupt where multiple MB interrupt sources are OR'd together, the interrupt is generated when any of the associated MBs (or FIFO, if applicable) generates an interrupt. In this case, the CPU must read the CAN_IFLAG registers to determine which MB or FIFO source caused the interrupt.

The interrupt sources for Bus Off, Bus Off Done, Error, Tx Warning and Rx Warning generate interrupts like the MB interrupt sources, and can be read from CAN_ESR1 register. The Bus Off, Error, Tx Warning, and Rx Warning interrupt mask bits are located in the CAN_CTRL1 Register.

47.5.12 Bus interface

The CPU access to FlexCAN registers are subject to the following rules:

- Unrestricted read and write access to supervisor registers (registers identified with S/U in Table "Module Memory Map" in Supervisor Mode or with S only) results in access error.
- Read and write access to implemented reserved address space results in access error.
- Write access to positions whose bits are all currently read-only results in access error. If at least one of the bits is not read-only then no access error is issued. Write permission to positions or some of their bits can change depending on the mode of operation or transitory state. Refer to register and bit descriptions for details.
- Read and write access to unimplemented address space results in access error.
- Read and write access to RAM located positions during Low Power Mode results in access error.
- If MAXMB in CAN MCR register is programmed with a value smaller than the available number of MBs, then the unused memory space can be used as general purpose RAM space. Note that reserved words within RAM cannot be used. As an example, suppose FlexCAN's RAM can support up to 16 MBs, CAN_CTRL2[RFFN] is 0x0, and CAN_MCR[MAXMB] is programmed with zero. The maximum number of MBs in this case becomes one. The RAM starts at 0x0080, and the space from 0x0080 to 0x008F is used by the one MB. The memory space from 0x0090 to 0x017F is available. The space between 0x0180 and 0x087F is reserved. The space from 0x0880 to 0x0883 is used by the one Individual Mask and the available memory in the Mask Registers space would be from 0x0884 to 0x08BF. From 0x08C0 through 0x09DF there are reserved words for internal use which cannot be used as general purpose RAM. As a general rule, free memory space for general purpose depends only on MAXMB.

47.5.13 Detection and Correction of Memory Errors

FlexCAN supports detection and correction of errors in memory read accesses. Each byte of FlexCAN memory is associated to 5 parity bits that ensure a Hamming distance of 4. The error correction mechanism ensures that in this 13-bit word, errors in one bit can be corrected (correctable errors) and errors in 2 bits can be detected but not corrected (non-correctable errors). Errors in more than 2 bits may not be detected. In case of non-

correctable errors, the corrupted data is not changed by the error correction logic. When a read access is performed, the parity bits are used to calculate a syndrome, which indicates the error in each byte.

FlexCAN detects a non-correctable error in the event either an all-zeros or an all-ones read occurs. See CAN_RERRSYNR register description.

Memory errors are indicated to the Host through status register (Error Status Register (CAN_ERRSR)) and bus transfer errors, and reported through report registers (Error Report Address Register (CAN_RERRAR), Error Report Data Register (CAN_RERRDR) and Error Report Syndrome Register (CAN_RERRSYNR)).

The error detection and correction mechanism can be activated or not, controlled by the ECCDIS bit in Memory Error Control Register (CAN_MECR). When disabled, updates on indications and reporting registers are stopped, but the parity bits are still calculated and written along with data in memory write operations to ensure that memory has consistent parity bits associated to the data.

NOTE

All FlexCAN memory must be initialized before starting its operation in order to have the parity bits in memory properly updated. The WRMFRZ bit in Control 2 Register (CAN_CTRL2) grants write access to all memory positions that require initialization, ranging from 0x080 to 0xADF. The RXMGMASK, RX14MASK, RX15MASK, and RXFGMASK registers need to be initialized as well. The CAN_MCR[RFEN] bit must not be set during memory initialization.

To avoid accidentally changing the critical error correction configuration, this protocol must be followed to enable the update of the Memory Error Control Register (CAN_MECR):

1. By default, ECRWRE bit in Control 2 Register (CAN_CTRL2) is 0 and ECRWRDIS bit in Memory Error Control Register (CAN_MECR) is 1.
2. Set ECRWRE bit in Control 2 Register (CAN_CTRL2).
3. Clear ECRWRDIS bit in Memory Error Control Register (CAN_MECR).
4. All writes to Memory Error Control Register (CAN_MECR) must keep ECRWRDIS cleared.
5. After configuration is done, lock the Memory Error Control Register (CAN_MECR) by either setting ECRWRDIS or clearing ECRWRE.

47.5.13.1 Sources of the Memory Access

The FlexCAN memory can be accessed by two major sources (or requestors):

- by Host (CPU): the largest word accessed is 32-bit wide
- by FlexCAN internals processes (Rx Matching, Tx Arbitration, Move-in on reception, Move-out on transmission): the largest word accessed is 64-bit wide

The way that non-correctable errors are indicated and reported depends on the source of access.

47.5.13.2 Error Indication

Memory errors are indicated by flags HANCEIF, FANCEIF, CEIF in the Error Status Register (CAN_ERRSR). Non-correctable errors detected in memory reads requested by Host are indicated separatedly than the ones detected in requests by FlexCAN internal processes. FlexCAN makes no distinction of the source of the access when correctable errors are detected. There are 3 independent flags for these 3 cases. If both non-correctable and correctable errors are found in different bytes in the same read operation, both flags are set.

A non-correctable error detected in Host access is also indicated as a bus transfer error. A bus wait request may be asserted to extend the memory transaction to the moment the report registers are updated. This indication cannot be masked.

Each indication flag has one Overrun flag in Error Status Register (CAN_ERRSR). The Overrun flags do not request interrupts. Overrun flags for non-correctable errors indicate that other errors of the same nature were detected after current error being treated, while overrun flags for correctable errors indicate that other errors of the same nature were detected before the current error being treated. This is the recommended handling sequence for error indication:

1. Get error report information from report registers
2. Use this information to take proper measures in the application
3. Clear the HANCEIF, FANCEIF, CEIF flags
4. If the Overrun flag is active:
    a. Alert application that at least one error could not be handled
    b. Clear the Overrun flag

The FlexCAN internal processes can access memory in transactions larger than 32-bits. For the indication, this kind of access is considered a consecutive sequence of 32-bit accesses. If errors are found in 2 or more 32-bit words the Interrupt and Overrun flags are set simultaneously.

47.5.13.3 Error Reporting

The report registers Error Report Address Register (CAN_RERRAR), Error Report Data Register (CAN_RERRDR) and Error Report Syndrome Register (CAN_RERRSYNR) provide detailed information about the address read, raw data and syndrome read with error and indicated by the flags described in Error Indication. The address, data and syndrome registers are updated simultaneously along with the error flags, according to these rules:

1. If any of the 2 non-correctable error flags is currently set, the report registers are not updated (the previous non-correctable error reporting is preserved)
2. Otherwise (either no error flag is currently set or only the correctable error flag is currently set), the report registers are updated according to the new error; or according to the most severe of new errors if non-correctable and correctable errors are simultaneously detected

Reporting of errors detected in accesses larger than 32-bit follows the rules described in Error Indication and in the Error Report Address Register (CAN_RERRAR) description.

The address reported in CAN_RERRAR and defined in CAN_ERRIAR are not the same listed in the module memory map. The relation between the reported addresses and the respective ones in the module memory map is shown in the Error Injection Address Register (CAN_ERRIAR) description.

Addresses reported when reading memory portions organized as FIFOs, such as the Rx FIFO Structure and the Rx FIFO Information Register (CAN_RXFIR), refer to the address of the specific entry accessed in the FIFO, not to the FIFO base address.

To assure coherence of the error report registers it is necessary to turn off the report update by setting the CAN_MECR[RERRDIS] bit before reading the report registers.

47.5.13.4 Response to Errors

Correctable errors have no consequence on FlexCAN operation because affected data is corrected before its use by the host or FlexCAN internal processes.

For host-initiated reads, a non-correctable error may affect the host, but does not affect FlexCAN operation.

Non-correctable errors detected on memory reads requested by the FlexCAN internal processes may result in incorrect operation depending on the state of the NCEFAFRZ bit in CAN_MECR register, as follows:

- During reception (either Matching or Move-in processes), when a non-correctable error occurs, an incorrect destination may be selected to store the incoming frame, a corrupted frame may be stored in the correct destination, or both. In case NCEFAFRZ is set, FlexCAN stops operation automatically and enters in Freeze mode to prevent corrupted data from being treated as valid by FlexCAN internal processes. When NCEFAFRZ is negated, FlexCAN continues working and a corrupted frame is received.
- During Arbitration process, when a non-correctable error occurs, either a non-highest priority Tx Message Buffer may be mistakenly selected for transmission or its data may be corrupted. In case NCEFAFRZ is set, FlexCAN stops operation automatically and enters in Freeze mode before starting the Move-out. When NCEFAFRZ is negated, FlexCAN proceeds to Move-out with a corrupted frame that will be transmitted on the CAN bus.
- During Move-out process, when a non-correctable error occurs, a corrupted frame is copied from the selected Tx MB that won the Arbitration to the Tx SMB (hardware buffer not located in RAM) for transmission. In case NCEFAFRZ is set, FlexCAN stops operation automatically and enters in Freeze mode before starting the transmission. When NCEFAFRZ is negated, the corrupted frame is transferred from the Tx SMB to the Protocol Engine (PE) sub-block and is transmitted on the CAN bus.

When NCEFAFRZ is set and FlexCAN enters in Freeze Mode, only the CPU can cause FlexCAN to exit Freeze mode and resume Normal Mode. The assertion of the CAN_MECR[NCEFAFRZ] bit is the only way to prevent corrupted frames from being transmitted on the CAN bus up to the Move-out internal process.

The error report registers can provide information to the application for a customized handling of these situations.

47.5.13.5 Error Injection

The error injection registers CAN_ERRIAR, CAN_ERRIDPR, and CAN_ERRIPPR are used to inject errors in memory reads in order to force errors and consequently update the indication and reporting registers. The relation between the error injection addresses and the respective ones in the module memory map is shown in the CAN_ERRIAR description.

The injection is done by flipping the data and parity bits correspondent to the bits in 1 in CAN_ERRIDPR and CAN_ERRIPPR. Injection can be selected specifically for memory accesses requested by Host or by FlexCAN internal processes.

In case of accesses larger than 32-bits, the EXTERRIE bit in Memory Error Control Register (CAN_MECR) extends the injection pattern, replicating it in 32-bit words to fill the width of the access.

NOTE

It is very unlikely, but error injection may correct a bit with error. This will not raise the error flags and reports as expected.

To ensure coherence among error injection registers and avoid spurious error injections, the HAERRIE and FAERRIE bits in Memory Error Control Register (CAN_MECR) must be cleared while configuring the memory injection registers.

47.6 Initialization/application information

This section provide instructions for initializing the FlexCAN module.

47.6.1 FlexCAN initialization sequence

The FlexCAN module may be reset in three ways:

- Chip level hard reset, which resets all memory mapped registers asynchronously
- SOFTRST bit in MCR, which resets some of the memory mapped registers synchronously. See Table 47-6 to see what registers are affected by soft reset.

Soft reset is synchronous and has to follow an internal request/acknowledge procedure across clock domains. Therefore, it may take some time to fully propagate its effects. The CAN_MCR[SOFTRST] bit remains asserted while soft reset is pending, so software can poll this bit to know when the reset has completed. Also, soft reset can not be applied while clocks are shut down in a low power mode. The low power mode should be exited and the clocks resumed before applying soft reset.

When the module is enabled (CAN_MCR[MDIS] bit negated), FlexCAN automatically goes to Freeze mode. In Freeze mode, FlexCAN is un-synchronized to the CAN bus, the HALT and FRZ bits in CAN_MCR Register are set, the internal state machines are disabled and the FRZACK and NOTRDY bits in the CAN_MCR Register are set. The Tx pin is in recessive state and FlexCAN does not initiate any transmission or reception of CAN frames. Note that the Message Buffers and the Rx Individual Mask Registers are not affected by reset, so they are not automatically initialized.

For any configuration change/initialization it is required that FlexCAN is put into Freeze mode (see Freeze mode). The following is a generic initialization sequence applicable to the FlexCAN module:

- Initialize the Module Configuration Register (CAN_MCR)
  - Enable the individual filtering per MB and reception queue features by setting the IRMQ bit
  - Enable the warning interrupts by setting the WRNEN bit
  - If required, disable frame self reception by setting the SRXDIS bit
  - Enable the Rx FIFO by setting the RFEN bit
  - If Rx FIFO is enabled and DMA is required, set DMA bit
  - Enable the abort mechanism by setting the AEN bit
  - Enable the local priority feature by setting the LPRIOEN bit
- Initialize the Control 1 Register (CAN_CTRL1) and optionally the CAN Bit Timing Register (CAN_CBT).
  - Determine the bit timing parameters: PROPSEG, PSEG1, PSEG2, RJW
  - Optionally determine the bit timing parameters: EPROPSEG, EPSEG1, EPSEG2, ERJW
  - Determine the bit rate by programming the PRESDIV field and optionally the EPRESDIV field
  - Determine the internal arbitration mode (LBUF bit)
- Initialize the Message Buffers
  - The Control and Status word of all Message Buffers must be initialized
  - If Rx FIFO was enabled, the ID filter table must be initialized
  - Other entries in each Message Buffer should be initialized as required
- Initialize the Rx Individual Mask Registers (CAN_RXIMRn)
- Set required interrupt mask bits in the CAN_IMASK Registers (for all MB interrupts) and in CAN_CTRL1 / CAN_CTRL2 Registers (for Bus Off and Error interrupts)
- Negate the HALT bit in CAN_MCR

After the last step listed above, FlexCAN attempts to synchronize to the CAN bus.

Chapter 48
De-serial Serial Peripheral Interface (DSPI)

48.1 DSPI chip-specific module information

The device contains seven instances of DSPI:

- DSPI_0
- DSPI_1
- DSPI_2
- DSPI_3
- DSPI_4
- DSPI_M0
- DSPI_M1

DSPI_M0 and DSPI_M1 implement the microsecond bus functionality and support master mode only. DSPI_0, DSPI_1, DSPI_2, DSPI_3 and DSPI_4 are intended for SPI usage and support both master and slave modes.

Note

De-serialization and serial/parallel chaining mode are described and referenced within this chapter; however, these features are not implemented on this chip.

Note

Very strong drive into serial_clock_out pad of DSPI master will affect full-duplex communication. Received data pattern will be corrupted for both master and slave side of DSPI instances.

48.1.1 Number of CTARs

DSPI CTAR registers define different transfer attribute configurations. The DSPI module supports up to eight CTAR registers.

48.1.2 Number of PCS signals

The following table shows the number of peripheral chip select signals available in a DSPI module. CS support is dependent on package size (QFP176/BGA252).

Table 48-1. DSPI PCS signals

DSPI Module	PCS Signals
DSPI_0	PCS0-5
DSPI_1	PCS0-4
DSPI_2	PCS0-3
DSPI_3	PCS0-5
DSPI_4	PCS0-5
DSPI_M0	PCS0-3
DSPI_M1	PCS0-3

48.1.3 IP Instantiation Parameters

The following table shows the full featured DSPI configuration.

Table 48-2. DSPI Module DSPI[4:0]

Feature	Value	Comment
Num_CTAR	8	Number of CTAR Register
TX_FIFO	4	Number of Transmit FIFO registers
RX_FIFO	4	Number of Receive FIFO registers
XSPI	Included	Extended (32-bit) SPI Mode Support
CMD_FIFO	4	Command FIFO depth

Table 48-3. DSPI Module DSPI_M0

Feature	Value	Comment
Num_CTAR	8	Number of CTAR Register
TX_FIFO	4	Number of Transmit FIFO registers
RX_FIFO	4	Number of Receive FIFO registers
XSPI	Included	Extended (32-bit) SPI Mode Support
CMD_FIFO	4	Command FIFO depth
DSI_EXISTS	Included	DSI mode supported.
DSI_64	Included	64 bit DSI Mode Support
TSB_MODE	Included	Timed Serial Bus Mode
ITSB_MODE	Included	Interleaved Timed Serial Bus Mode

Table 48-4. DSPI Module DSPI_M1

Feature	Value	Comment
Num_CTAR	8	Number of CTAR Register
TX_FIFO	4	Number of Transmit FIFO registers
RX_FIFO	4	Number of Receive FIFO registers
XSPI	Included	Extended (32-bit) SPI Mode Support
CMD_FIFO	4	Command FIFO depth
DSI_EXISTS	Included	DSI mode supported.
TSB_MODE	Included	Timed Serial Bus Mode
ITSB_MODE	Included	Interleaved Timed Serial Bus Mode

48.2 Introduction

The deserial serial peripheral interface (DSPI) module provides a synchronous serial bus for communication between an MCU and an external peripheral device. The module supports MCU pin count reduction through serialization and deserialization of MCU internal signals transmitted over the DSPI serial link.

48.2.1 Block Diagram

The block diagram of this module is as follows:

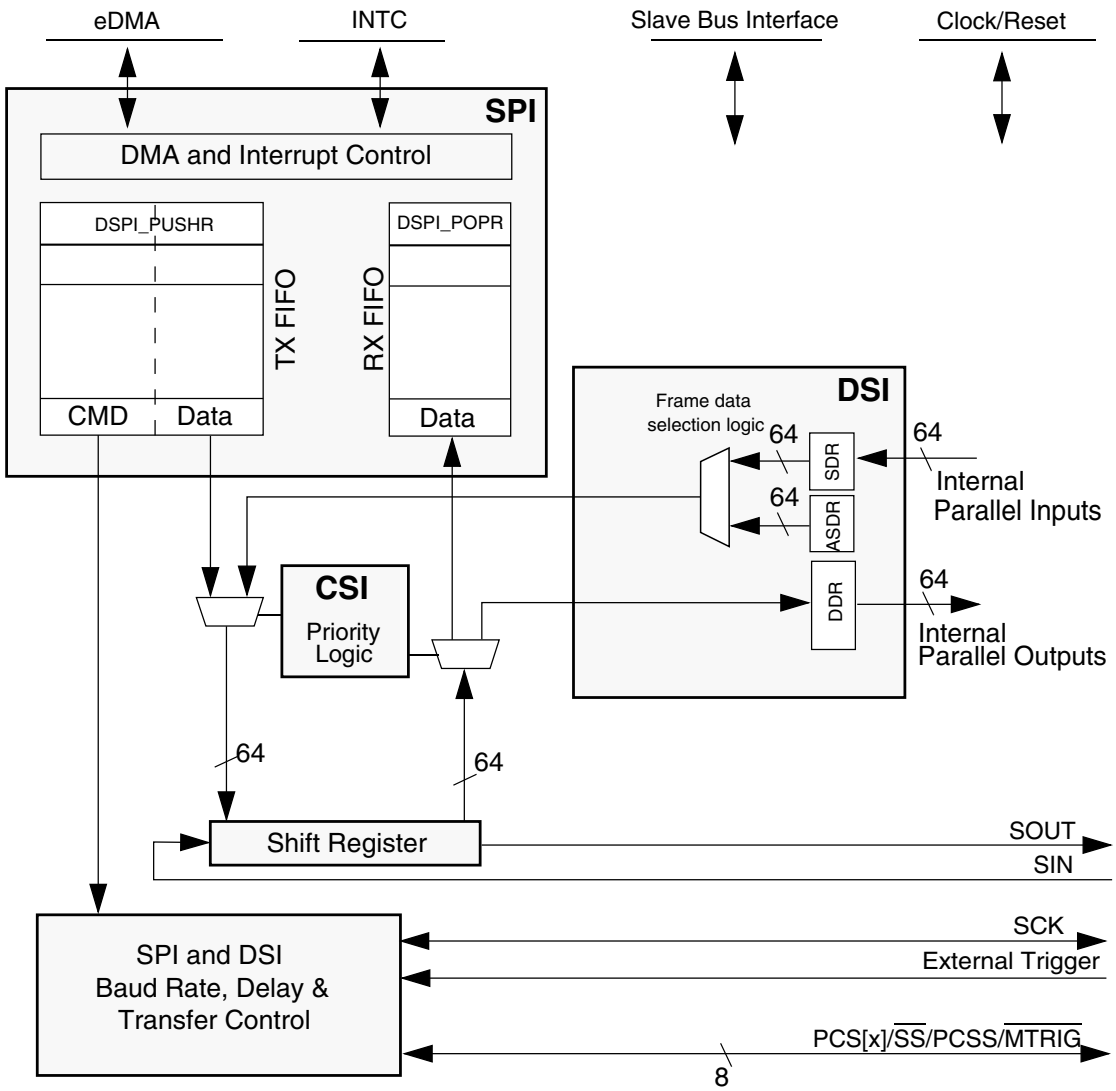

Figure 48-1. DSPI Block Diagram

48.2.2 Features

The module supports the following features:

- Full-duplex, three-wire synchronous transfers
- Master and Slave modes
  - Data streaming operation in Slave mode with continuous slave selection
- Buffered transmit operation using the transmit first in first out (TX FIFO) with depth of four entries

- Buffered receive operation using the receive FIFO (RX FIFO) with depth of four entries
- TX and RX FIFOs can be disabled individually for low-latency updates to SPI queues
- Visibility into TX and RX FIFOs for ease of debugging
- Programmable transfer attributes on a per-frame basis:
  - eight transfer attribute and extended transfer attribute registers
  - Serial clock (SCK) with programmable polarity and phase
  - Various programmable delays
  - Programmable serial frame size of 4–64 bits, expandable by software control
    - SPI frames longer than 32 bits can be supported using the continuous selection format
  - Continuously held chip select capability
  - Parity control
- 6 peripheral chip selects (PCSs), expandable to 64 with external demultiplexer
- Deglitching support for up to 32 PCS with external demultiplexer
- DMA support for adding entries to TX FIFO and removing entries from RX FIFO:
  - TX FIFO is not full (TFFF)
  - RX FIFO is not empty (RFDF)
  - CMD FIFO is not full (CMDFFF)
- Interrupt conditions:
  - End of Queue reached (EOQF)
  - TX FIFO is not full (TFFF)
  - CMD FIFO is not full (CMDFFF)
  - Transfer of current frame complete (TCF)
  - Transfers due from current command frame complete (CMDTCF)
  - Attempt to transmit with an empty Transmit FIFO (TFUF)
  - RX FIFO is not empty (RFDF)

    - Frame received while Receive FIFO is full (RFOF)
    - SPI Parity Error (SPEF)
    - Data present in TX FIFO while CMD FIFO is empty (TFIWF)
- Modified SPI transfer formats for communication with slower peripheral devices
- Power-saving architectural features:
    - Support for Stop mode

The DSPI also supports pin reduction through serialization if enabled for the module.

- Two sources of serialized data:
    - The module memory-mapped register
    - Parallel Input signals
    - Programmable selection of source data on bit basis
- Transfer initiation conditions:
    - Continuous
    - Change in data
- Pin serialization with interleaved SPI frames for control and diagnostics
- Continuous serial communications clock

DSPI supports a combined SPI and DSI modes of operation known as the Combined Serial Interface (CSI). It also supports the downstream Micro Second Channel in the Timed Serial Bus (TSB) configuration or Interleaved Frames Configuration; configurable by software.

Both TSB and Interleaved TSB modes have the following common features::

- Transmission of frames is done at frame boundaries
- Frames from SPI and DSI are identifiable by a bit transmitted at the start of each frame
- Separate interrupts for frame completion from SPI and DSI

48.2.3 SPI Configuration

The SPI configuration allows the module to send and receive serial data. This configuration allows the module to operate as a basic SPI block with internal FIFOs supporting external queue operation. Transmitted data and received data reside in separate FIFOs. The host CPU or a DMA controller read the received data from the Receive FIFO and write transmit data to the Transmit FIFO.

For queued operations, the SPI queues can reside in system RAM, external to the module. Data transfers between the queues and the module FIFOs are accomplished by a DMA controller or host CPU. The following figure shows a system example with DMA, DSPI, and external queues in system RAM.

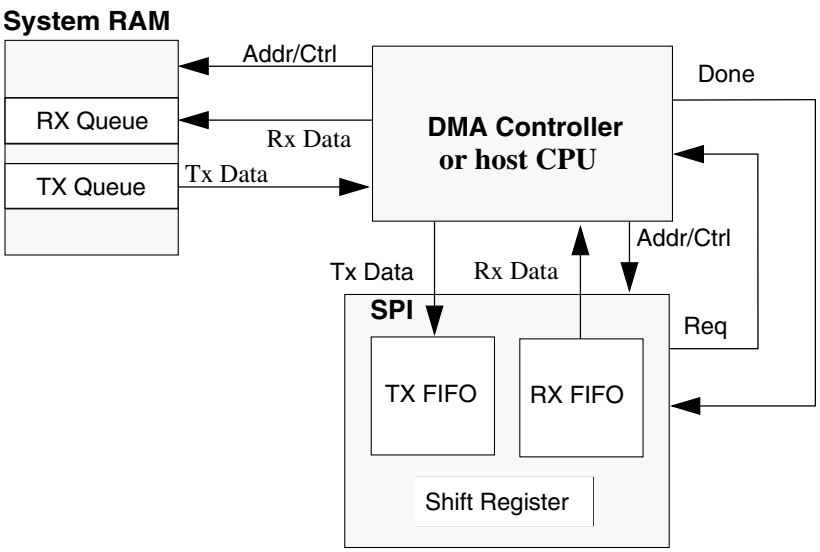

Figure 48-2. SPI with queues and DMA

48.2.4 DSI Configuration

In the DSI configuration the DSPI serializes up to 64 Parallel Input signals or register bits. The DSPI also deserializes the received data to Parallel Output signals or to a memory-mapped register. The data is transferred using a SPI-like protocol.

TSB mode, detailed on Timed Serial Bus (TSB), provides the Micro Second downstream Channel support (MSC), serializing from 4 to 64 Parallel Input signals or register bits.

48.2.5 CSI Configuration

There are three configurations available in this mode.

- The normal CSI configuration is a combination of the SPI and DSI configurations. In this configuration the DSPI interleaves DSI data frames with SPI data frames. Interleaving is done on the frame boundaries.
- In the TSB configuration, transmission of SPI data has higher priority than DSI data.
- In the Interleaved TSB (ITSB) configuration, the frames from SPI and DSI are interleaved without priority. On every trigger, frames from DSI are sent when there are no frames in the SPI or the previous transmission was a frame from SPI. ITSB is detailed in Interleaved TSB (ITSB) Mode.

48.2.6 Modes of Operation

The module supports the following modes of operation that can be divided into two categories:

- Module-specific modes:
  - Master mode
  - Slave mode
  - Module Disable mode
- MCU-specific modes:
  - External Stop mode
  - Debug mode

The module enters module-specific modes when the host writes a module register. The MCU-specific modes are controlled by signals external to the module. The MCU-specific modes are modes that an MCU may enter in parallel to the block-specific modes.

48.2.6.1 Master Mode

Master mode allows the module to initiate and control serial communication. In this mode, the SCK signal and the PCS[*x*] signals are controlled by the module and configured as outputs.

48.2.6.2 Slave Mode

Slave mode allows the module to communicate with SPI/DSI bus masters. In this mode, the module responds to externally controlled serial transfers. The SCK signal and the PCS[0]/$\overline{SS}$ signals are configured as inputs and driven by an SPI bus master.

48.2.6.3 Module Disable Mode

The Module Disable mode can be used for MCU power management. The clock to the non-memory mapped logic in the module can be stopped while in the Module Disable mode.

48.2.6.4 External Stop Mode

External Stop mode is used for MCU power management. The module supports the Peripheral Bus Stop mode mechanism. When a request is made to enter External Stop mode, it acknowledges the request and completes the transfer that is in progress. When the module reaches the frame boundary, it signals that the protocol clock to the module may be shut off.

48.2.6.5 Debug Mode

Debug mode is used for system development and debugging. The MCR[FRZ] bit controls module behavior in the Debug mode:

- If the bit is set, the module stops all serial transfers, when the MCU is in debug mode.
- If the bit is cleared, the MCU debug mode has no effect on the module.

48.3 Module signal descriptions

This section provides description of the module signals.

The following table lists the signals that may connect off chip depending on device implementation.

Table 48-5. Module signal descriptions

Signal	Master Mode	Slave Mode	Port Direction
PCS0/$\overline{SS}$	Peripheral Chip Select 0 output	Slave Select input	I/O

Table continues on the next page...

Table 48-5. Module signal descriptions (continued)

Signal	Master Mode	Slave Mode	Port Direction
PCS[3:1]	Peripheral Chip Select 1 – 3	Unused	O
PCS4/ $\overline{\text{MTRIG}}$	Peripheral Chip Select 4	Master Trigger	O
PCS5/ $\overline{\text{PCSS}}$	Peripheral Chip Select 5 /Peripheral Chip Select Strobe	Unused	O
SIN	Serial Data In	Serial Data In	I
SOUT	Serial Data Out	Serial Data Out	O
SCK	Master mode: Serial Clock (output)	Serial Clock (input)	I/O

48.3.1 PCS0/$\overline{\text{SS}}$ — Peripheral Chip Select/Slave Select

In Master mode, the PCS0 signal is an output that selects which slave device the current transmission is intended for.

In Slave mode, the active low $\overline{\text{SS}}$ signal is an input signal that allows an SPI master to select the module as the target for transmission.

48.3.2 PCS1 – PCS3 — Peripheral Chip Selects 1 – 3

PCS1 – PCS3 are output signals in Master mode.

In Slave mode, these signals are unused.

48.3.3 PCS4/$\overline{\text{MTRIG}}$ — Peripheral Chip Select 4/Master Trigger

In Master mode, PCS4 is an output signal.

In slave mode, the active low $\overline{\text{MTRIG}}$ is an output trigger signal that indicates that a change in data to be serialized has occurred. The $\overline{\text{MTRIG}}$ provides a pulse in DSI Configuration when a change in data to be serialized occurs. The $\overline{\text{MTRIG}}$ pulse is four protocol clock cycles in duration. If the DSPI is in slave mode and the MTO is disabled, the PCS4/$\overline{\text{MTRIG}}$ signal is unused.

48.3.4 PCS5/$\overline{\text{PCSS}}$ — Peripheral Chip Select 5/Peripheral Chip Select Strobe

PCS5 is a Peripheral Chip Select output signal. When the module is in Master mode and the MCR[PCSSE] bit is cleared, this signal selects the slave device the current transfer is intended for.

When the module is in Master mode and the MCR[PCSSE] bit is set, the $\overline{\text{PCSS}}$ signal acts as a strobe to an external peripheral chip select demultiplexer, which decodes the PCS0 – PCS4 signals, preventing glitches on the demultiplexer outputs.

This signal is not used in Slave mode.

48.3.5 SIN — Serial Input

SIN is a serial data input signal.

NOTE

Serial Data Out output buffers are controller through SIUL, and cannot be controller through the module

48.3.6 SOUT — Serial Output

SOUT is a serial data output signal.

NOTE

Serial Data Out output buffers are controller through SIUL, and cannot be controller through the module.

48.3.7 SCK — Serial Clock

SCK is a serial communication clock signal.

In Master mode, the module generates the SCK.

In Slave mode, SCK is an input from an external bus master.

48.4 Memory Map/Register Definition

Register accesses to memory addresses that are reserved or undefined result in a transfer error. Write access to the POPR also results in a transfer error.

DSPI memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	Module Configuration Register (DSPI_MCR)	32	R/W	0000_4001h	48.4.1/1950

48.4.1 Module Configuration Register (DSPI_MCR)

Contains bits to configure various attributes associated with the module operations. The HALT and MDIS bits can be changed at any time, but the effect takes place only on the next frame boundary. Only the HALT and MDIS bits in the MCR can be changed, while the module is in the Running state.

Address: 0h base + 0h offset = 0h

DSPI_MCR field descriptions

Field	Description
0 MSTR	Master/Slave Mode Select Configures the module for either Master mode or Slave mode. 0 The module is in Slave mode. 1 The module is in Master mode.
1 CONT_SCKE	Continuous SCK Enable Enables the Serial Communication Clock (SCK) to run continuously. 0 Continuous SCK disabled. 1 Continuous SCK enabled.
2–3 DCONF	DSPI Configuration Selects among the different configurations of the module. 00 SPI 01 DSI 10 CSI 11 Reserved
4 FRZ	Freeze Enables the DSPI transfers to be stopped on the next frame boundary when the device enters Debug mode. 0 Do not halt serial transfers in Debug mode. 1 Halt serial transfers in Debug mode.
5 MTFE	Modified Timing Format Enable Enables a modified transfer format to be used. 0 Modified SPI transfer format disabled. 1 Modified SPI transfer format enabled.
6 PCSSE	Peripheral Chip Select Strobe Enable Enables the PCS5/ $\overline{\text{PCSS}}$ to operate as a PCS Strobe output signal. 0 PCS5/ $\overline{\text{PCSS}}$ is used as the Peripheral Chip Select[5] signal. 1 PCS5/ $\overline{\text{PCSS}}$ is used as an active-low PCS Strobe signal.
7 ROOE	Receive FIFO Overflow Overwrite Enable In the RX FIFO overflow condition, configures the module to ignore the incoming serial data or overwrite existing data. If the RX FIFO is full and new data is received, the data from the transfer, generating the overflow, is ignored or shifted into the shift register. 0 Incoming data is ignored. 1 Incoming data is shifted into the shift register.
8–9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
10–15 PCSIS	Peripheral Chip Select x Inactive State Determines the inactive state of PCSx.

Table continues on the next page...

DSPI_MCR field descriptions (continued)

Field	Description
	0 The inactive state of PCSx is low. 1 The inactive state of PCSx is high.
16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
17 MDIS	Module Disable Allows the clock to be stopped to the non-memory mapped logic in the module effectively putting it in a software-controlled power-saving state. The reset value of the MDIS bit is parameterized, with a default reset value of 0. When DSPI is used in Slave Mode, it is recommended to leave this bit set to '0', since a slave doesn't have control over master transactions. 0 Enables the module clocks. 1 Allows external logic to disable the module clocks.
18 DIS_TXF	Disable Transmit FIFO When the TX FIFO is disabled, the transmit part of the module operates as a simplified double-buffered SPI. This bit can be written only when the MDIS bit is cleared. 0 TX FIFO is enabled. 1 TX FIFO is disabled.
19 DIS_RXF	Disable Receive FIFO When the RX FIFO is disabled, the receive part of the module operates as a simplified double-buffered SPI. This bit can only be written when the MDIS bit is cleared. 0 RX FIFO is enabled. 1 RX FIFO is disabled.
20 CLR_TXF	Clear TX FIFO Flushes the TX FIFO. Writing a 1 to CLR_TXF clears the TX FIFO Counter. The CLR_TXF bit is always read as zero. 0 Do not clear the TX FIFO counter. 1 Clear the TX FIFO counter.
21 CLR_RXF	Flushes the RX FIFO. Writing a 1 to CLR_RXF clears the RX Counter. The CLR_RXF bit is always read as zero. 0 Do not clear the RX FIFO counter. 1 Clear the RX FIFO counter.
22–23 SMPL_PT	Sample Point Controls when the module master samples SIN in Modified Transfer Format. This field is valid only when CPHA bit in CTARn[CPHA] is 0. 00 0 protocol clocks between SCK edge and SIN sample 01 1 protocol clock between SCK edge and SIN sample 10 2 protocol clocks between SCK edge and SIN sample 11 Reserved
24–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

DSPI_MCR field descriptions (continued)

Field	Description
28 XSPI	Extended SPI Mode This bit enables usage of CTARE (Command and Transfer Attribute Register Extended) Registers. CTARE registers allow the user to send up to 32 bit SPI frames. Command Cycling is also enabled which allows the user to send mutiple Data Frames using a single Command Frame. When MCR[DIS_TXF] is asserted, the Extended SPI Mode cannot be used to transmit SPI frames which are more than 16 bits in size. 0 Normal SPI Mode. Frame size can be up to 16 bits. Command Cycling is not available in this mode. 1 Extended SPI Mode. Up to 32 bit SPI Frames along with Command Cycling is Enabled.
29 FCPCS	Fast Continuous PCS Mode. This bit enables the masking of “After SCK (t_{ASC})” and “PCS to SCK (t_{CSC})” delays when operating in Continuous PCS mode. This masking is not available if Continuous SCK mode is enabled. The individual delay masks are selected via bits MASC and MCSC of the PUSHR register. The firmware should select appropriate masks when providing continuous frames via the PUSHR register. 0 Normal or Slow Continuous PCS mode. Masking of delays is disabled. 1 Fast Continuous PCS mode. Delays masked via control bits in PUSHR register.
30 PES	Parity Error Stop Controls SPI operation when a parity error is detected in a received SPI frame. 0 SPI frame transmission continues. 1 SPI frame transmission stops.
31 HALT	Halt The HALT bit starts and stops DSPI transfers. See Start and Stop of module transfers. 0 Start transfers. 1 Stop transfers.

48.4.2 Transfer Count Register (DSPI_TCR)

TCR contains a counter that indicates the number of SPI transfers made. The transfer counter is intended to assist in queue management. Do not write the TCR when the module is in the Running state.

Address: 0h base + 8h offset = 8h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	SPI_TCNT																0															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DSPI_TCR field descriptions

Field	Description
0–15 SPI_TCNT	SPI Transfer Counter Counts the number of SPI transfers the module makes. The SPI_TCNT field increments every time the last bit of an SPI frame is transmitted. A value written to SPI_TCNT presets the counter to that value. SPI_TCNT is reset to zero at the beginning of the frame when the CTCNT field is set in the executing SPI command. The Transfer Counter wraps around; incrementing the counter past 65535 resets the counter to zero.
16–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

48.4.3 Clock and Transfer Attributes Register (In Master Mode) (DSPI_CTAR*n*)

CTAR registers are used to define different transfer attributes. Do not write to the CTAR registers while the module is in the Running state.

In Master mode, the CTAR registers define combinations of transfer attributes such as frame size, clock phase and polarity, data bit ordering, baud rate, and various delays. In slave mode, a subset of the bitfields in CTAR0 and CTAR1 are used to set the slave transfer attributes.

When the module is configured as an SPI master, the CTAS field in the command portion of the TX FIFO entry selects which of the CTAR registers is used. When the module is configured as an SPI bus slave, the CTAR0 register is used.

When the module is configured as a DSI master, the DSICTAS field in the DSI Configuration Register 0 (DSICR0), selects which of the CTAR register is used. When the module is configured as a DSI bus slave, the CTAR1 register is used.

In CSI Configuration, the transfer attributes are selected based on whether the current frame is SPI data or DSI data. SPI transfers in CSI Configuration follow the protocol described for SPI Configuration, and DSI transfers in CSI Configuration follow the protocol described for DSI Configuration. CSI Configuration is valid only in conjunction with master mode.

TSB mode sets some limitations on transfer attributes:

- Clock phase is forced to be CPHA = 1 and the CPHA bit setting has no effect.
- PCS lines are driven at the driving edge of the SCK clock together with SOUT, so PCS assertion and negation delays control is unavailable and PCSSCK, PASC, CSSCK and ASC fields have no effect.
- Delay after transfer can be set from 1 to 64 serial clocks with help of PDT and DT fields

Address: 0h base + Ch offset + (4d × i), where i=0d to 7d

DSPI_CTAR*n* field descriptions

Field	Description
0 DBR	Double Baud Rate Doubles the effective baud rate of the Serial Communications Clock (SCK). This field is used only in master mode. It effectively halves the Baud Rate division ratio, supporting faster frequencies, and odd division ratios for the Serial Communications Clock (SCK). When the DBR bit is set, the duty cycle of the Serial Communications Clock (SCK) depends on the value in the Baud Rate Prescaler and the Clock Phase bit as listed in the following table. See the BR field description for details on how to compute the baud rate.
1–4 FMSZ	Frame Size The number of bits transferred per frame is equal to the FMSZ field value plus 1. Regardless of the transmission mode, the minimum valid frame size value is 4. There is a constraint on the minimum allowable Frame size, which depends on the Register Read/Write clock to the System Protocol Clock Ratio. The minimum Frame size (FMSZ + 1) is decided by the following equation. Upper Ceiling must be applied for non-integer values.

Table 48-12. DSPI SCK Duty Cycle

DBR	CPHA	PBR	SCK Duty Cycle
0	any	any	50/50
1	0	00	50/50
1	0	01	33/66
1	0	10	40/60
1	0	11	43/57
1	1	00	50/50
1	1	01	66/33
1	1	10	60/40
1	1	11	57/43

0 The baud rate is computed normally with a 50/50 duty cycle.
1 The baud rate is doubled with the duty cycle depending on the Baud Rate Prescaler.

Table continues on the next page...

DSPI_CTAR*n* field descriptions (continued)

Field	Description
	Min. Frame Size = ((4 x f_p) + (3 x f_r)) / (n x f_r) f_p = Protocol Clock Frequency f_r = Bus clock (register interface clock) Frequency n = (PBR x BR) / (1 + DBR) = Multiple of protocol clock required to get Baud (SCK) Clock However, the minimum frame size can never be less than 4. There is no constraint on the maximum programmable frame size. Also note that `fp' can be equal to, less than or greater than `fr' purely based on user requirement. When the DSPI operates in TSB mode, the FMSZ field value plus 1 is equal to the data frame bit number, where control of the PCS assertion switches from the DSICR0 to the DSICR1 register. If TSB Mode is operated when DSI is used in 64 bit mode, then DSICR0[FMSZ4] also comes into picture while switching PCS assertion control.
5 CPOL	Clock Polarity Selects the inactive state of the Serial Communications Clock (SCK). This bit is used in both master and slave mode. For successful communication between serial devices, the devices must have identical clock polarities. When the Continuous Selection Format is selected, switching between clock polarities without stopping the module can cause errors in the transfer due to the peripheral device interpreting the switch of clock polarity as a valid clock edge. 0 The inactive state value of SCK is low. 1 The inactive state value of SCK is high.
6 CPHA	Clock Phase Selects which edge of SCK causes data to change and which edge causes data to be captured. This bit is used in both master and slave mode. For successful communication between serial devices, the devices must have identical clock phase settings. In Continuous SCK mode or TSB mode, the bit value is ignored and the transfers are done as if the CPHA bit is set to 1. 0 Data is captured on the leading edge of SCK and changed on the following edge. 1 Data is changed on the leading edge of SCK and captured on the following edge.
7 LSBFE	LSB First Specifies whether the LSB or MSB of the frame is transferred first. When the DSPI operates in TSB configuration, this bit should be set to be compliant to the MSC specification. 0 Data is transferred MSB first. 1 Data is transferred LSB first.
8–9 PCSSCK	PCS to SCK Delay Prescaler Selects the prescaler value for the delay between assertion of PCS and the first edge of the SCK. See the CSSCK field description for information on how to compute the PCS to SCK Delay. Refer PCS to SCK Delay (t_{CSC}) for more details. In the TSB mode, the PCSSCK field has no effect. 00 PCS to SCK Prescaler value is 1. 01 PCS to SCK Prescaler value is 3. 10 PCS to SCK Prescaler value is 5. 11 PCS to SCK Prescaler value is 7.
10–11 PASC	After SCK Delay Prescaler

Table continues on the next page...

DSPI_CTAR*n* field descriptions (continued)

Field	Description
	Selects the prescaler value for the delay between the last edge of SCK and the negation of PCS. See the ASC field description for information on how to compute the After SCK Delay. In the TSB mode, the PASC field has no effect. Refer After SCK Delay (t_{ASC}) for more details. 00 Delay after Transfer Prescaler value is 1. 01 Delay after Transfer Prescaler value is 3. 10 Delay after Transfer Prescaler value is 5. 11 Delay after Transfer Prescaler value is 7.
12–13 PDT	Delay after Transfer Prescaler Selects the prescaler value for the delay between the negation of the PCS signal at the end of a frame and the assertion of PCS at the beginning of the next frame. The PDT field is only used in master mode. In the TSB mode the PDT field defines two MSB bits of the Delay after Transfer. See the DT field description for details on how to compute the Delay after Transfer. Refer Delay after Transfer (t_{DT}) for more details. 00 Delay after Transfer Prescaler value is 1. 01 Delay after Transfer Prescaler value is 3. 10 Delay after Transfer Prescaler value is 5. 11 Delay after Transfer Prescaler value is 7.
14–15 PBR	Baud Rate Prescaler Selects the prescaler value for the baud rate. This field is used only in master mode. The baud rate is the frequency of the SCK. The protocol clock is divided by the prescaler value before the baud rate selection takes place. See the BR field description for details on how to compute the baud rate. 00 Baud Rate Prescaler value is 2. 01 Baud Rate Prescaler value is 3. 10 Baud Rate Prescaler value is 5. 11 Baud Rate Prescaler value is 7.
16–19 CSSCK	PCS to SCK Delay Scaler Selects the scaler value for the PCS to SCK delay. This field is used only in master mode. In the TSB mode the field has no effect. The PCS to SCK Delay is the delay between the assertion of PCS and the first edge of the SCK. The delay is a multiple of the protocol clock period, and it is computed according to the following equation: $t_{CSC} = (1/f_P) \times PCSSCK \times CSSCK$. The following table lists the delay scaler values.

Table 48-11. Delay Scaler Encoding

Field Value	Delay Scaler Value
0000	2
0001	4
0010	8
0011	16
0100	32
0101	64
0110	128
0111	256

Table continues on the next page...

DSPI_CTAR*n* field descriptions (continued)

Field	Description
	Table 48-11. Delay Scaler Encoding (continued) Field Value / Delay Scaler Value: 1000 – 512 1001 – 1024 1010 – 2048 1011 – 4096 1100 – 8192 1101 – 16384 1110 – 32768 1111 – 65536 Refer PCS to SCK Delay (t_{CSC}) for more details.
20–23 ASC	After SCK Delay Scaler Selects the scaler value for the After SCK Delay. This field is used only in master mode. The After SCK Delay is the delay between the last edge of SCK and the negation of PCS. The delay is a multiple of the protocol clock period, and it is computed according to the following equation: $t_{ASC} = (1/f_P) \times PASC \times ASC$ See Delay Scaler Encoding table in CTARn[CSSCK] bit field description for scaler values. Refer After SCK Delay (t_{ASC}) for more details.
24–27 DT	Delay After Transfer Scaler Selects the Delay after Transfer Scaler. This field is used only in master mode. The Delay after Transfer is the time between the negation of the PCS signal at the end of a frame and the assertion of PCS at the beginning of the next frame. In the Continuous Serial Communications Clock operation, the DT value is fixed to one SCK clock period, The Delay after Transfer is a multiple of the protocol clock period, and it is computed according to the following equation: $t_{DT} = (1/f_P) \times PDT \times DT$ See Delay Scaler Encoding table in CTARn[CSSCK] bit field description for scaler values. In the TSB mode, the Delay after Transfer is equal to a number formed by concatenation of the PDT and DT fields plus 1 of the SCK clock periods. Refer Delay after Transfer (t_{DT}) for more details.
28–31 BR	Baud Rate Scaler Selects the scaler value for the baud rate. This field is used only in master mode. The prescaled protocol clock is divided by the Baud Rate Scaler to generate the frequency of the SCK. The baud rate is computed according to the following equation: SCK baud rate = (f_P /PBR) x [(1+DBR)/BR] The following table lists the baud rate scaler values. **Table 48-10. Baud Rate Scaler** CTARn[BR] / Baud Rate Scaler Value: 0000 – 2

48.4.4 Clock and Transfer Attributes Register (In Slave Mode) (DSPI_CTAR*n*_SLAVE)

When the module is configured as an SPI bus slave, the CTAR0 register is used.

When the module is configured as a DSI master, the DSICTAS field in the DSI Configuration Register 0 (DSICR0), selects which of the CTAR register is used. When the module is configured as a DSI bus slave, the CTAR1 register is used.

Address: 0h base + Ch offset + (4d × i), where i=0d to 1d

DSPI_CTAR*n*_SLAVE field descriptions

Field	Description
0–4 FMSZ	Frame Size The number of bits transfered per frame is equal to the concatenated field {CTARn_SLAVE[FMSZ5], CTARn_SLAVE[FMSZ]} value plus 1. Note that the minimum valid value of frame size is 4.
5 CPOL	Clock Polarity Selects the inactive state of the Serial Communications Clock (SCK). 0 The inactive state value of SCK is low. 1 The inactive state value of SCK is high.
6 CPHA	Clock Phase Selects which edge of SCK causes data to change and which edge causes data to be captured. This bit is used in both master and slave mode. For successful communication between serial devices, the devices must have identical clock phase settings. In Continuous SCK mode or TSB mode , the bit value is ignored and the transfers are done as the CPHA bit is set to 1. 0 Data is captured on the leading edge of SCK and changed on the following edge. 1 Data is changed on the leading edge of SCK and captured on the following edge.
7 PE	Parity Enable Enables parity bit transmission and reception for the frame. 0 No parity bit included/checked. 1 Parity bit is transmitted instead of last data bit in frame, parity checked for received frame.
8 PP	Parity Polarity Controls polarity of the parity bit transmitted and checked. 0 Even Parity: the number of 1 bits in the transmitted frame is even. The SR[SPEF] bit is set if the number of 1 bits is odd in the received frame. 1 Odd Parity: the number of 1 bits in the transmitted frame is odd. The SR[SPEF] bit is set if the number of 1 bits is even in the received frame.
9 FMSZ5	MSB of Frame Size when DSI is used in 64-bit Mode The number of bits transferred per frame is equal to the concatenated field {CTARn_SLAVE[FMSZ[5]], CTARn_SLAVE[FMSZ]} value plus 1.
10–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

48.4.5 Status Register (DSPI_SR)

SR contains status and flag bits. The bits reflect the status of the module and indicate the occurrence of events that can generate interrupt or DMA requests. Software can clear flag bits in the SR by writing a 1 to them. Writing a 0 to a flag bit has no effect. This register may not be writable in Module Disable mode due to the use of power saving mechanisms.

Address: 0h base + 2Ch offset = 2Ch

DSPI_SR field descriptions

Field	Description
0 TCF	Transfer Complete Flag Indicates that all bits in a frame have been shifted out. TCF remains set until it is cleared by writing a 1 to it. 0 Transfer not complete. 1 Transfer complete.

Table continues on the next page...

DSPI_SR field descriptions (continued)

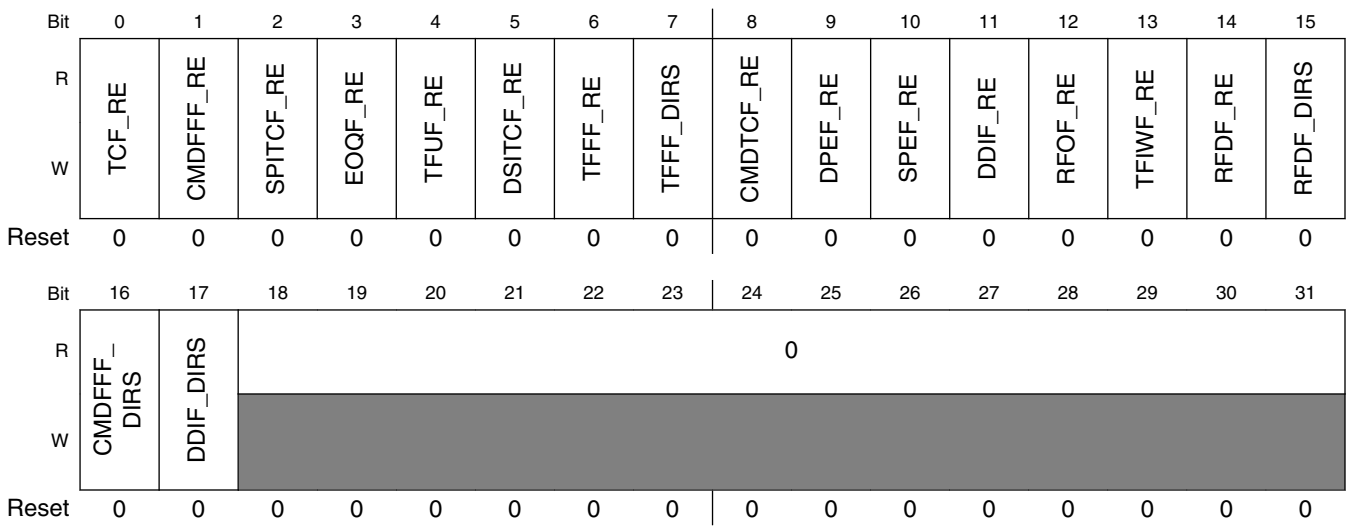
Field	Description
1 TXRXS	TX and RX Status Reflects the run status of the module. 0 Transmit and receive operations are disabled (The module is in Stopped state). 1 Transmit and receive operations are enabled (The module is in Running state).
2 SPITCF	SPI Frame Transfer Complete Flag. This bit functions similar to TCF except that this bit is asserted only on SPI frame transmission completion in CSI Mode. This includes the ITSB Mode and 'TSB in CSI' Mode. This flag will not be asserted when the module is used in SPI or DSI Modes. 0 SPI frame transfer is not complete. 1 SPI frame transfer is complete.
3 EOQF	End of Queue Flag Indicates that the last entry in a queue has been transmitted when the module is in Master mode. The EOQF bit is set when the TX FIFO entry has the EOQ bit set in the command halfword and the end of the transfer is reached. The EOQF bit remains set until cleared by writing a 1 to it. When the EOQF bit is set, the TXRXS bit is automatically cleared. 0 EOQ is not set in the executing command. 1 EOQ is set in the executing SPI command.
4 TFUF	Transmit FIFO Underflow Flag Indicates an underflow condition in the TX FIFO. The transmit underflow condition is detected only for DSPI blocks operating in Slave mode and SPI configuration. TFUF is set when the TX FIFO of the module operating in SPI Slave mode is empty and an external SPI master initiates a transfer. The TFUF bit remains set until cleared by writing 1 to it. 0 No TX FIFO underflow. 1 TX FIFO underflow has occurred.
5 DSITCF	DSI Frame Transfer Complete Flag. This bit functions similar to TCF except that this bit is asserted only on DSI frame transmission completion in CSI Mode. This includes the ITSB Mode and 'TSB in CSI' Mode. This flag will not be asserted when the module is used in SPI or DSI Modes. 0 DSI frame transfer is not complete. 1 DSI frame transfer is complete.
6 TFFF	Transmit FIFO Fill Flag Provides a method for the module to request more entries to be added to the TX FIFO. The TFFF bit is set while the TX FIFO is not full. The TFFF bit can be cleared by writing 1 to it or by acknowledgement from the DMA controller to the TX FIFO full request. 0 TX FIFO is full. 1 TX FIFO is not full.
7 BSYF	Busy Flag. This bit is valid only when DSPI_MCR[XSPI] is enabled. Indicates that the current Command Frame is being used for transmiting multiple data frames. This bit is not set for the last Data Frame of a Cyclic

Table continues on the next page...

DSPI_SR field descriptions (continued)

Field	Description
	command Transfer or when DSPI_CTARE[DTCP] = 1. Refer Command First In First Out (CMD FIFO) Buffering Mechanism for more details. 0 No Cyclic Command Transfer in Progress. 1 Cyclic Command Transfer is in progress. Current Data Frame is not the last data frame for on-going cyclic command transfer..
8 CMDTCF	Command Transfer Complete Flag. Indicates that the last Data frame for the current Cyclic Command has been transmitted. Hence this bit is set only for the last Data Frame of a Cyclic Command Transfer or when DSPI_CTARE[DTCP] = 1. The bit remains set until it is cleared by writing a '1' to it. 0 Data Transfer by current Command not complete. 1 Data Transfer by current Command is complete.
9 DPEF	DSI Parity Error Flag Indicates that a DSI frame with parity error had been received. The bit remains set until it is cleared by writing a 1 to it. 0 No parity error. 1 Parity error has occurred.
10 SPEF	SPI Parity Error Flag Indicates that a SPI frame with parity error had been received. The bit remains set until it is cleared by writing a 1 to it. 0 No parity error. 1 Parity error has occurred.
11 DDIF	DSI Data Received with Active Bits Indicates that a DSI frame had been received with bits selected by DIMR with active polarity, defined by the DPIR register. The bit remains set until it is cleared by writing a 1 to it. 0 No DSI data with active bits was received. 1 DSI data with active bits was received.
12 RFOF	Receive FIFO Overflow Flag Indicates an overflow condition in the RX FIFO. The field is set when the RX FIFO and shift register are full and a transfer is initiated. The bit remains set until it is cleared by writing a 1 to it. 0 No Rx FIFO overflow. 1 Rx FIFO overflow has occurred.
13 TFIWF	Tranmit FIFO Invalid Write Flag Indicates Data Write on TX FIFO while CMD FIFO is empty. Without a Command, the Data entries present in TXFIFO are invalid. This bit remains set until it is cleared by writing a '1' to it. 0 No Invalid Data present in TX FIFO. 1 Invalid Data present in TX FIFO since CMD FIFO is empty.
14 RFDF	Receive FIFO Drain Flag

Table continues on the next page...



DSPI_SR field descriptions (continued)

Field	Description
	Provides a method for the module to request that entries be removed from the RX FIFO. The bit is set while the RX FIFO is not empty. The RFDF bit can be cleared by writing 1 to it or by acknowledgement from the DMA controller when the RX FIFO is empty. 0 RX FIFO is empty. 1 RX FIFO is not empty.
15 CMDFFF	Command FIFO Fill Flag Provides a method for the module to request more entries to be added to the CMD FIFO. The CMDFFF bit is set while the CMD FIFO is not full. The CMDFFF is cleared by writing a '1' to it or by acknowledgement from the DMA controller to the CMD FIFO full request. 0 CMD FIFO is full. 1 CMD FIFO is not full.
16–19 TXCTR	TX FIFO Counter Indicates the number of valid entries in the TX FIFO. The TXCTR is incremented every time the PUSHR is written. The TXCTR is decremented every time an SPI command is executed and the SPI data is transferred to the shift register.
20–23 TXNXTPTR	Transmit Next Pointer Indicates which TX FIFO entry is transmitted during the next transfer. The TXNXTPTR field is updated every time SPI data is transferred from the TX FIFO to the shift register.
24–27 RXCTR	RX FIFO Counter Indicates the number of entries in the RX FIFO. The RXCTR is decremented every time the POPR is read. The RXCTR is incremented every time data is transferred from the shift register to the RX FIFO.
28–31 POPNXTPTR	Pop Next Pointer Contains a pointer to the RX FIFO entry to be returned when the POPR is read. The POPNXTPTR is updated when the POPR is read.

48.4.6 DMA/Interrupt Request Select and Enable Register (DSPI_RSER)

RSER controls DMA and interrupt requests. Do not write to the RSER while the module is in the Running state.

Address: 0h base + 30h offset = 30h

DSPI_RSER field descriptions

Field	Description
0 TCF_RE	Transmission Complete Request Enable Enables TCF flag in the SR to generate an interrupt request. 0 TCF interrupt requests are disabled. 1 TCF interrupt requests are enabled.
1 CMDFFF_RE	Command FIFO Fill Flag Request Enable. Enables the CMDFFF flag in the SR to generate a request. The CMDFFF_DIRS bit selects between generating an interrupt request or a DMA request. 0 CMDFFF interrupts or DMA requests are disabled. 1 CMDFFF interrupts or DMA requests are enabled.
2 SPITCF_RE	SPI Frame Transmission Complete Request Enable. The SPITCF_RE bit enables SPITCF flag in the SR to generate an interrupt request. 0 SPITCF interrupt requests are disabled. 1 SPITCF interrupt requests are enabled.
3 EOQF_RE	Finished Request Enable

Table continues on the next page...

DSPI_RSER field descriptions (continued)

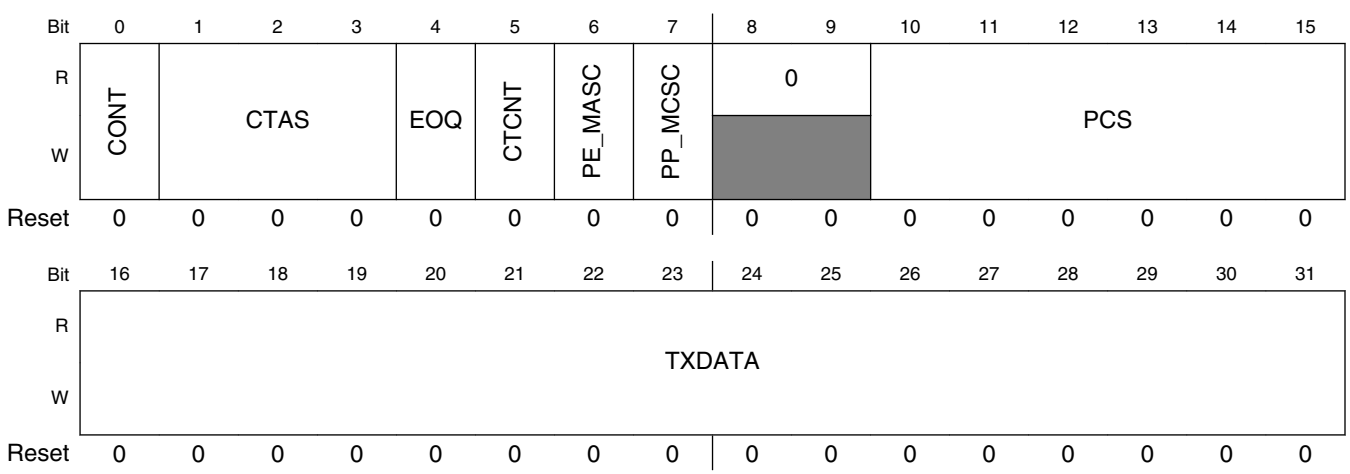
Field	Description
	Enables the EOQF flag in the SR to generate an interrupt request. 0 EOQF interrupt requests are disabled. 1 EOQF interrupt requests are enabled.
4 TFUF_RE	Transmit FIFO Underflow Request Enable Enables the TFUF flag in the SR to generate an interrupt request. 0 TFUF interrupt requests are disabled. 1 TFUF interrupt requests are enabled.
5 DSITCF_RE	DSI Frame Transmission Complete Request Enable. The DSITCF_RE bit enables DSITCF flag in the SR to generate an interrupt request. 0 DSITCF interrupt requests are disabled. 1 DSITCF interrupt requests are enabled.
6 TFFF_RE	Transmit FIFO Fill Request Enable Enables the TFFF flag in the SR to generate a request. The TFFF_DIRS bit selects between generating an interrupt request or a DMA request. 0 TFFF interrupts or DMA requests are disabled. 1 TFFF interrupts or DMA requests are enabled.
7 TFFF_DIRS	Transmit FIFO Fill DMA or Interrupt Request Select Selects between generating a DMA request or an interrupt request. When SR[TFFF] and RSER[TFFF_RE] are set, this field selects between generating an interrupt request or a DMA request. 0 TFFF flag generates interrupt requests. 1 TFFF flag generates DMA requests.
8 CMDTCF_RE	Command Transmission Complete Request Enable. The CMDTCF_RE bit enables CMDTCF flag in the SR to generate an interrupt request. 0 CMDTCF interrupt requests are disabled. 1 CMDTCF interrupt requests are enabled.
9 DPEF_RE	DSI Parity Error Request Enable Enables the DPEF flag in the SR to generate an interrupt request. 0 DPEF interrupt requests are disabled. 1 DPEF interrupt requests are enabled.
10 SPEF_RE	SPI Parity Error Request Enable Enables the SPEF flag in the SR to generate an interrupt request. 0 SPEF interrupt requests are disabled. 1 SPEF interrupt requests are enabled.
11 DDIF_RE	DSI data received with active bits Request Enable Enables the DDIF flag in the SR to generate an interrupt or DMA request.

Table continues on the next page...

DSPI_RSER field descriptions (continued)

Field	Description
	0 DDIF interrupt and DMA requests are disabled. 1 DDIF interrupt and DMA requests are enabled.
12 RFOF_RE	Receive FIFO Overflow Request Enable Enables the RFOF flag in the SR to generate an interrupt request. 0 RFOF interrupt requests are disabled. 1 RFOF interrupt requests are enabled.
13 TFIWF_RE	Transmit FIFO Invalid Write Request Enable. Enables the TFIWF flag in the SR to generate an interrupt request. 0 TFIWF interrupt requests are disabled. 1 TFIWF interrupt requests are enabled.
14 RFDF_RE	Receive FIFO Drain Request Enable Enables the RFDF flag in the SR to generate a request. The RFDF_DIRS bit selects between generating an interrupt request or a DMA request. 0 RFDF interrupt or DMA requests are disabled. 1 RFDF interrupt or DMA requests are enabled.
15 RFDF_DIRS	Receive FIFO Drain DMA or Interrupt Request Select Selects between generating a DMA request or an interrupt request. When the RFDF flag bit in the SR is set, and the RFDF_RE bit in the RSER is set, the RFDF_DIRS bit selects between generating an interrupt request or a DMA request. 0 Interrupt request. 1 DMA request.
16 CMDFFF_DIRS	Command FIFO Fill DMA or Interrupt Request Select Selects between generating a DMA request or an interrupt request. When the CMDFFF flag bit in the SR is set, and the CMDFFF_RE bit in the RSER is set, the CMDFFF_DIRS bit selects between generating an interrupt request or a DMA request. 0 CMDFFF flag generates interrupt requests. 1 CMDFFF flag generates DMA requests.
17 DDIF_DIRS	DSI data received with active bits - DMA or Interrupt Request Select. Selects between generating a DMA request or an interrupt request. When the DDIF flag bit in the SR is set, and the DDIF_RE bit in the RSER is set, the DDIF_DIRS bit selects between generating an interrupt request or a DMA request. 0 Interrupt request. 1 DMA request.
18–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

48.4.7 PUSH TX FIFO Register In Master Mode (DSPI_PUSHR)



PUSHR provides the means to write to the TX FIFO and CMD FIFO . Data written to this register is transferred to the TX FIFO and CMD FIFO. 8- or 16-bit write accesses to the Data Field of PUSHR transfers the 16 bit Data field of PUSHR to the TX FIFO. Write accesses to the Command Field of PUSHR transfers the 16 bit Command Field of PUSHR to the CMD FIFO. The register structure is different in Master and Slave modes. In Master mode, the register provides 16-bit command to the CMD FIFO and 16-bit data to the TX FIFO. In Slave mode, CMD FIFO is unused and hence the 16 bit Command Field of PUSHR is reserved.

Unless Extended SPI Mode is being used, the TX FIFO and CMD FIFO must be filled simultaneously. In other words, write accesses must be given to both Data and Command fields of PUSHR for every PUSHR operation performed when MCR[XSPI] is 0. When Extended SPI Mode is disabled, since both TX FIFO and CMD FIFO are written to and read from simultaneously, they can be thought of as a single 32 bit FIFO. When Extended SPI Mode is enabled, TX FIFO and CMD FIFO can be written independently.

A PUSHR Read Operation returns the topmost TX FIFO and CMD FIFO entries concatenated.

When the module is disabled, any writes to this register will not update the FIFO. Hence any reads performed during Module disable mode will return the last PUSHR write performed when Module was enabled.

Address: 0h base + 34h offset = 34h

DSPI_PUSHR field descriptions

Field	Description
0 CONT	Continuous Peripheral Chip Select Enable

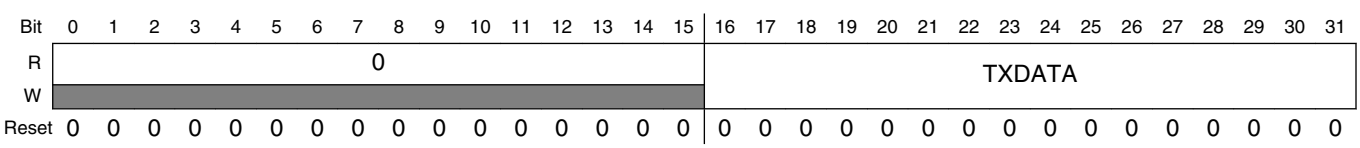
Table continues on the next page...

DSPI_PUSHR field descriptions (continued)

Field	Description
	Selects a continuous selection format. The bit is used in SPI Master mode. The bit enables the selected PCS signals to remain asserted between transfers. 0 Return PCSn signals to their inactive state between transfers. 1 Keep PCSn signals asserted between transfers.
1–3 CTAS	Clock and Transfer Attributes Select Selects which CTAR to use in master mode to specify the transfer attributes for the associated SPI frame. In SPI Slave mode, CTAR0 is used. See Number of CTARs to determine how many CTARs this device has. You should not program a value in this field for a register that is not present. 000 CTAR0 001 CTAR1 010 CTAR2 011 CTAR3 100 CTAR4 101 CTAR5 110 CTAR6 111 CTAR7
4 EOQ	End Of Queue Host software uses this bit to signal to the module that the current SPI transfer is the last in a queue. At the end of the transfer, the EOQF bit in the SR is set. 0 The SPI data is not the last data to transfer. 1 The SPI data is the last data to transfer.
5 CTCNT	Clear Transfer Counter Clears the TCNT field in the TCR register. The TCNT field is cleared before the module starts transmitting the current SPI frame. 0 Do not clear the TCR[TCNT] field. 1 Clear the TCR[TCNT] field.
6 PE_MASC	Parity Enable or Mask T_{ASC} delay in the current frame PE – This bit enables parity bit transmission and parity reception check for the SPI frame. MASC - The current frame has the “after SCK” delay masked if this bit is asserted. See Fast Continuous Selection Format for more details. **NOTE:** This bit is used as Mask T_{ASC} in the Fast Continuous PCS mode when MCR[FCPCS] is set. 0 PE - No parity bit included/checked. MASC - T_{ASC} delay is not masked and the current frame has the after SCK delay. 1 PE - Parity bit is transmitted instead of the last data bit in the frame; parity is checked for the received frame. MASC - T_{ASC} delay is masked in the current frame.
7 PP_MCSC	Parity Polarity or Mask T_{CSC} delay in the next frame PP - It controls the polarity of the parity bit transmitted and checked. MCSC - The next frame has the “PCS to SCK” delay masked if this bit is asserted. See Fast Continuous Selection Format for more details.

Table continues on the next page...

DSPI_PUSHR field descriptions (continued)



Field	Description
	NOTE: This bit is used as Mask T $_{CSC}$ in the Fast Continuous PCS mode when MCR[FCPCS] is set. 0 PP - Even Parity: the number of 1 bits in the transmitted frame is even. The SR[SPEF] bit is set if the number of 1 bits is odd in the received frame. MCSC - T $_{CSC}$ delay is not masked and the next frame has the PCS to SCK delay. 1 PP - Odd Parity: the number of 1 bits in the transmitted frame is odd. The SR[SPEF] bit is set if the number of 1 bits is even in the received frame. MCSC - T $_{CSC}$ delay is masked in the next frame.
8–9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
10–15 PCS	Select which PCS signals are to be asserted for the transfer. See Number of PCS signals for the number of PCS signals used in this MCU. 0 Negate the PCS[x] signal. 1 Assert the PCS[x] signal.
16–31 TXDATA	Transmit Data Holds SPI data to be transferred according to the associated SPI command.

48.4.8 PUSH TX FIFO Register In Slave Mode (DSPI_PUSHR_SLAVE)

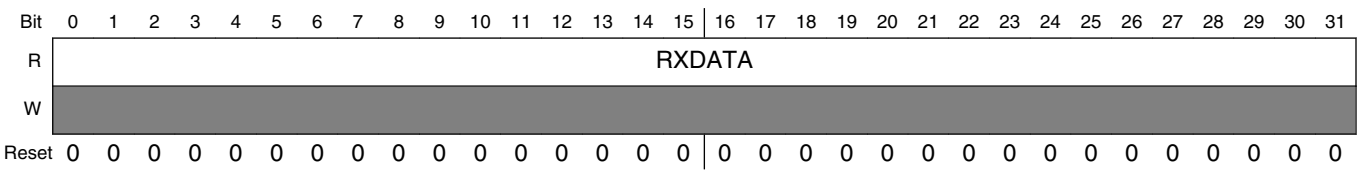
PUSHR provides the means to write to the TX FIFO. Data written to this register is transferred to the TX FIFO. Eight- or sixteen-bit write accesses to the Data Field of PUSHR transfers the 16 bit Data Field of PUSHR to the TX FIFO. The register structure is different in master and slave modes. In master mode the register provides 16-bit command to the CMD FIFO and 16-bit data to the TX FIFO. In slave mode, CMD FIFO is unused and hence the 16 bit Command Field of PUSHR is reserved.

In addition, upto 32 bit SPI frames may be queued for transmission/reception by enabling MCR[XSPI] mode.

Address: 0h base + 34h offset = 34h

DSPI_PUSHR_SLAVE field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 TXDATA	Transmit Data Holds SPI data to be transferred according to the associated SPI command.



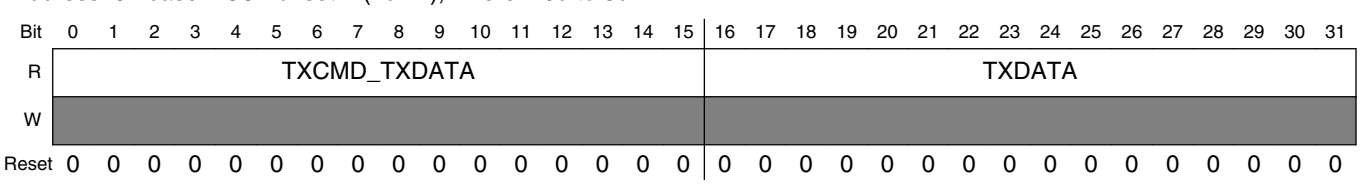
DSPI_PUSHR_SLAVE field descriptions (continued)

Field	Description

48.4.9 POP RX FIFO Register (DSPI_POPR)

POPR is used to read the RX FIFO. Eight- or sixteen-bit read accesses to the POPR have the same effect on the RX FIFO as 32-bit read accesses. A write to this register will generate a Transfer Error.

Address: 0h base + 38h offset = 38h



DSPI_POPR field descriptions

Field	Description
0–31 RXDATA	Received Data Contains the SPI data from the RX FIFO entry to which the Pop Next Data Pointer points.

48.4.10 Transmit FIFO Registers (DSPI_TXFR*n*)

TXFRn registers provide visibility into the TX FIFO for debugging purposes. Each register is an entry in the TX FIFO. The registers are read-only and cannot be modified. Reading the TXFRx registers does not alter the state of the TX FIFO. Reading TXFRn registers is invalid for a D SPI Master when being used in the Extended SPI (XSPI) Mode.

Address: 0h base + 3Ch offset + (4d × i), where i=0d to 3d

DSPI_TXFR*n* field descriptions

Field	Description
0–15 TXCMD_ TXDATA	Transmit Command or Transmit Data In Master mode the TXCMD field contains the command that sets the transfer attributes for the SPI data. In Slave mode, this field is reserved.
16–31 TXDATA	Transmit Data Contains the SPI data to be shifted out.

48.4.11 Receive FIFO Registers (DSPI_RXFR*n*)

RXFRn provide visibility into the RX FIFO for debugging purposes. Each register is an entry in the RX FIFO. The RXFR registers are read-only. Reading the RXFRx registers does not alter the state of the RX FIFO. The field MCR[MDIS] must be 0 when RXFR is read.

Address: 0h base + 7Ch offset + (4d × i), where i=0d to 3d

DSPI_DSICR0 field descriptions

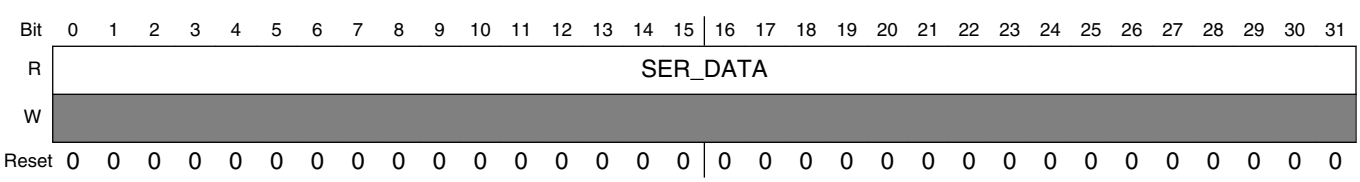
Field	Description
0 MTOE	Multiple Transfer Operation Enable Enables multiple DSPIs to be connected in a parallel or serial configuration. The MTOE and TSB bits should not be set simulteneously. 0 Multiple transfer operation disabled. 1 Multiple transfer operation enabled.
1 FMSZ4	MSB of the frame size in master mode. If the bit is set, 16 is added to the frame size, as defined by the CTARn[FMSZ] field. The CTARx register is selected by the DSICTAS field.
2–7 MTOCNT	Multiple Transfer Operation Count Selects the number of bits to be shifted out during a transfer in Multiple Transfer Operation. The field sets the number of SCK cycles that the bus master must generate to complete the transfer. The number of SCK cycles used is one more than the value in the MTOCNT field. The number of SCK cycles defined by MTOCNT must be equal to or greater than the frame size. When TSBC is set, MTOCNT has no effect.
8 FMSZ5	MSB of the frame size in master mode when DSI is used in 64-bit mode. If the bit is set, 32 is added to the frame size, as defined by the concatenation of {DSICR0[FMSZ[4]] , CTARn[FMSZ]} fields. The CTARn register is selected by the DSICTAS field. Hence the final concatenated frame size using this bit would be {DSICR0[FMSZ[5]], DSICR0[FMSZ[4]] , CTARn[FMSZ]}. This field is only valid when DSICR1[DSI64E] is enabled.

Table continues on the next page...

DSPI_DSICR0 field descriptions (continued)

Field	Description
9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
10 ITSB	Interleaved TSB mode. This bit enables the Interleaved TSB mode of operation. When enabled, there is no priority among frames from the SPI/DSI. DSI frames are always sent when either the previous transmission was a SPI frame or if the TX_FIFO is empty. Frames are transmitted on every trigger whose source is selected by the TRG bit setting. The ITSB mode requires the DSICR0[TSBC] bit to be set and should be written only when MCR[HALT] bit is asserted. If ITSB bit is set without setting DSICR0[TSBC], then the module operates in the Normal Mode depending on MCR[DCONF] bit. See Interleaved TSB (ITSB) Mode for more details. 0 Interleaved mode is disabled. 1 Interleaved mode is enabled.
11 TSBC	Timed Serial Bus Configuration. Enables the Timed Serial Bus Configuration, which allows 64-bit data to be used. It also allows tDT to be programmable. 0 Timed Serial Bus Configuration disabled. 1 Timed Serial Bus Configuration enabled.
12 TXSS	Transmit Data Source Select. Selects the source of data to be serialized. The source can be either data from host software written to the DSI Alternate Serialization Data Register (ASDR0/1) or Parallel Input pin states latched into the DSI Serialization Data Register (SDR0/1). 0 Source of serialized data is the SDR. 1 Source of serialized data is the ASDR.
13–14 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15 CID	Change In Data Transfer Enable Enables a change in serialization data to initiate a DSI frames transfer in DSI and CSI configurations. When the CID bit is set, DSI frames are initiated when the current DSI data differs from the previous DSI data shifted out. **NOTE:** When TRIG[ENABLE] is set, the CID bit is given by TRIG[CID] which overrides DSICR0[CID].
16 DCONT	DSI Continuous Peripheral Chip Select Enable Enables the PCS signals to remain asserted between transfers. The DCONT bit affects the PCS signals only in DSI master mode. When the TSBC bit is set, DCONT has no effect. 0 Return Peripheral Chip Select signals to their inactive state after the transfer is complete. 1 Keep Peripheral Chip Select signals asserted after transfer is complete.
17–19 DSICTAS	DSI Clock and Transfer Attributes Select Selects the CTAR register to use to provide transfer attributes for DSI frames. The DSICTAS field is used in DSI master mode. In DSI slave mode, CTAR1 is always selected.
20 DMS	Data Match Stop If set, stops DSI frame transmissions if DDIF flag is set in the SR register.

Table continues on the next page...



DSPI_DSICR0 field descriptions (continued)

Field	Description
	0 DDIF flag does not have an effect on DSI frame transmissions. 1 DDIF flag stops DSI frame transmissions.
21 PES	Parity Error Stop If set, stops DSI operation if the parity error happened in the received DSI frame. 0 Parity error does not stop DSI frame transmissions. 1 Parity error stops all DSI frame transmissions.
22 PE	Parity Enable Enables parity bit transmission and parity reception check for the DSI frames. 0 No parity bit included/checked. 1 Parity bit is transmitted instead of the last data bit in the frame; parity is checked for the received frame.
23 PP	Parity Polarity Controls the polarity of the parity bit transmitted and checked. 0 Even Parity: the number of 1 bits in the transmitted frame is even. The SR[DPEF] bit is set if in the received frame number of 1 bits is odd. 1 Odd Parity: the number of 1 bits in the transmitted frame is odd. The SR[DPEF] bit is set if in the received frame number of 1 bits is even.
24–31 DPCSx	DSI Peripheral Chip Select 0–7 Selects which of the PCS signals to assert during a DSI master mode transfer. 0 Negate PCS[x]. 1 Assert PCS[x].

48.4.13 DSI Serialization Data Register 0 (DSPI_SDR0)

SDR0 contains the states of the 32 LSB Parallel Input signals. The states of the Parallel Input signals are latched into the SDR0 on the rising edge of every bus clock. The SDR0 is read-only. When the TXSS bit in the DSICR0 is cleared, the data in the SDR0 is used as the source of the DSI frames. When DSICR1[DSI64E] is enabled, SDR1 forms the MSB half and SDR0 forms the LSB half of the 64-bit Serilization Data Register.

Address: 0h base + C0h offset = C0h

DSPI_SDR0 field descriptions

Field	Description
0–31 SER_DATA	Serialized Data Contains the signal states of the 32 LSB Parallel Input signals.

48.4.14 DSI Alternate Serialization Data Register 0 (DSPI_ASDR0)

ASDR0 is used by host software to write the 32 LSB of the data to be serialized. When the TXSS bit in the DSICR0 is set, the data in the ASDR0 is the source of the DSI frames. Writes to the ASDR0 take effect on the next frame boundary. When DSICR1[DSI64E] is enabled, ASDR1 forms the MSB half and ASDR0 forms the LSB half of the 64-bit Alternate Serilization Data Register.

Address: 0h base + C4h offset = C4h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

DSPI_ASDR0 field descriptions

Field	Description
0–31 ASER_DATA	Alternate Serialized Data Holds the alternate 32 LSB of the data to be serialized.

48.4.15 DSI Transmit Comparison Register 0 (DSPI_COMPR0)

COMPR0 holds a copy of the 32 LSB of the last transmitted DSI data. COMPR0 is read-only. DSI data is transferred to this register as it is loaded into the TX Shift Register. When DSICR1[DSI64E] is enabled, COMPR1 forms the MSB half and COMPR0 forms the LSB half of the 64-bit Transmit Comparison Register.

Address: 0h base + C8h offset = C8h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

DSPI_COMPR0 field descriptions

Field	Description
0–31 COMP_DATA	Compare Data Holds the 32 LSB of the last serialized DSI data.

48.4.16 DSI Configuration Register 1 (DSPI_DSICR1)

DSICR1 selects various attributes associated with DSI, TSB (and ITSB) mode. The user must not write to the DSICR1 while the module is in the Running state.

Address: 0h base + D0h offset = D0h

DSPI_DSICR1 field descriptions

Field	Description
0–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2–7 TSBCNT	Timed Serial Bus Operation Count When TSBC is set, TSBCNT defines the length of the data frame. The TSBCNT field valid value can vary from 3 to 63 when DSICR1[DSI64E] is set, otherwise this field can vary from 3 to 31. The TSBCNT field selects the number of data bits to be shifted out during a transfer in TSB mode. The number of data bits in the data frame is one more than the value in the TSBCNT field.
8–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11 CSI_PRTY	CSI Priority This field allows the user to configure the priority of SPI and DSI frames when module is operating in CSI Mode. This is not applicable when DSICR0[ITSB] is enabled. 0 SPI frames has priority over DSI frames. 1 DSI frames have priority over SPI frames.

Table continues on the next page...

DSPI_DSICR1 field descriptions (continued)

Field	Description
12 CSE	Command Select Enable When the DSICR0[ITSB] is set, the CSE bit controls insertion of command selection bit (Logic 1) in the beginning of the SPI (command) frame. 0 No selection bit is inserted in the beginning of the command frame. 1 Command selection bit is inserted at the beginning of the command frame. Total number of bits in the command frame is increased by 1.
13 DSI64E	DSI 64-bit Mode Enable When DSI64E is set, DSI Mode operates in 64-bit configuration allowing serialization and deserialization of Data frames up to 64 bits in size. The Extended Registers DSPI_SDR1, DSPI_ASDR1, DSPI_COMPR1, DSPI_DDR1, DSPI_SSR1, DSPI_DIMR1, DSPI_DPIR1 are only valid when this Mode is enabled. 0 DSI 64-bit Mode Disabled. DSI Mode operates in the default 32 bit configuration. 1 DSI 64-bit Mode Enabled. DSI Mode operates in 64-bit configuration.
14 DSE1	Data Select Enable 1 When the TBSC bit is set, the DSE1 bit controls insertion of the zero bit (Data Select) in the middle of the data frame. The insertion bit position is defined by the FMSZ field of CTARn register, selected by the DSICR0[DSICTAS] field. If DSICR1[DSI64] is enabled, then the insertion bit position is defined by concatenation of {DSICR0[FMSZ4], CTAR[FMSZ]} fields. The TSBCNT field value must be greater than the position of insertion for proper operation of the DSE1 bit. 0 No Zero bit is inserted in the middle of the data frame. 1 Zero bit is inserted at the middle of the data frame. Total number of bits in the data frame is increased by 1.
15 DSE0	Data Select Enable 0 When the TBSC bit is set, the DSE1 bit controls insertion of the zero bit (Data Select) in the beginning of the DSI frame. 0 No Zero bit is inserted in the beginning of the frame. 1 Zero bit is inserted at the beginning of the data frame. Total number of bits in the data frame is increased by 1.
16–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–31 DPCS1_x	DSI Peripheral Chip Select 0–7 These bits define the PCSs to assert for the second part of the DSI frame when operating in TSB (and ITSB) configuration with dual receiver. The DPCS1 bits select which of the PCS signals to assert during the second part of the DSI frame. The DPCS1 bits control the assertions of the PCS signals only in TSB and ITSB mode. 0 Negate PCS[x]. 1 Assert PCS[x].

48.4.17 DSI Serialization Source Select Register 0 (DSPI_SSR0)

SSR0 is used to create a combined frame for transmission that contains bits from ASDR0 and from SDR0. Each bit in the SSR0 register selects a corresponding bit to be serialized. When DSICR0[TXSS] is set, the SSR0 register value has no effect. When DSICR1[DSI64E] is enabled, SSR1 forms the MSB half and SSR0 forms the LSB half of the 64-bit Serilization Source Select Register.

Address: 0h base + D4h offset = D4h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

DSPI_SSR0 field descriptions

Field	Description
0–31 SS	Source Select Select the serialization source for the 32 LSB of the DSI frame. Each SS bit selects data for a corresponded bit in the transmitted frame. 0 The bit in the transmitted frame is taken from the Parallel Input pin. 1 The bit in the transmitted frame is taken from the ASDR0 register

48.4.18 DSI Serialization Data Register 1 (DSPI_SDR1)

SDR1 contains the states of the 32 MSB parallel input signals. The states of these parallel input signals are latched into the SDR1 on the rising edge of every bus clock. The SDR1 is read-only. When the TXSS bit in the DSICR0 is cleared, the data in the SDR1 and SDR0 is used as the source of the DSI frames. The concatenation of {DSPIx_SDR1, DSPIx_SDR0} provides the 64-bit data to be serialized. This register is valid only when DSICR1[DSI64E] is enabled.

Address: 0h base + F0h offset = F0h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

DSPI_SDR1 field descriptions

Field	Description
0–31 SER_DATA	Serialized Data Contains the 32 MSB signal states of the 64 parallel input signals. This field is valid only when DSICR1[DSI64E] is set. The concatenation of {DSPIx_SDR1, DSPIx_SDR0} provides the 64-bit data to be serialized.

48.4.19 DSI Alternate Serialization Data Register 1 (DSPI_ASDR1)

ASDR1 is used by host software to write the 32 MSB of the 64-bit data to be serialized. When the TXSS bit in the DSICR0 is set, the data in the ASDR1 and ASDR0 is the source of the DSI frames. Writes to the ASDR1 take effect on the next frame boundary. The concatenation of {DSPIx_ASDR1, DSPIx_ASDR0} provides the 64-bit alternate serialization data. This register is valid only when DSICR1[DSI64E] is enabled.

Address: 0h base + F4h offset = F4h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

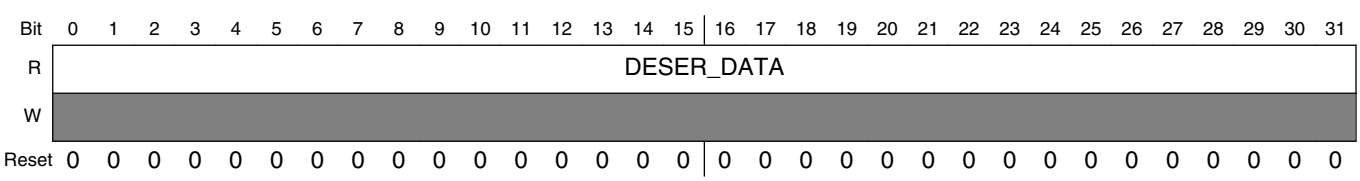
DSPI_ASDR1 field descriptions

Field	Description
0–31 ASER_DATA	Alternate Serialized Data Holds the 32 MSB of the 64-bit alternate data to be serialized. This field is valid only when DSICR1[DSI64E] is set. The concatenation of {DSPIx_ASDR1, DSPIx_ASDR0} provides the 64-bit alternate serialization data.

48.4.20 DSI Transmit Comparison Register 1 (DSPI_COMPR1)

COMPR1 holds a copy of the 32 MSB of the last transmitted 64-bit DSI data. COMPR1 is read-only. Upper 32 bits of the 64-bit DSI data is transferred to this register as it is loaded into the TX Shift Register. The concatenation of {DSPIx_COMPR1, DSPIx_COMPR0} provides the 64-bit transmit comparison data. This register is valid only when DSICR1[DSI64E] is enabled.

Address: 0h base + F8h offset = F8h



DSPI_COMPR1 field descriptions

Field	Description
0–31 COMP_DATA	Compare Data Holds the 32 MSB of the last serialized 64-bit DSI data. This field is valid only when DSICR1[DSI64E] is set. The concatenation of {DSPIx_COMPR1, DSPIx_COMPR0} provides the last serialized 64-bit DSI data.

48.4.21 DSI Deserialization Data Register 1 (DSPI_DDR1)

DDR1 holds the 32 MSB signal states for the 64 Parallel Output signals. The DDR1 is read-only and host software can read data from incoming DSI frames. The concatenation of {DSPIx_DDR1, DSPIx_DDR0} provides the 64-bit Deserialized data. This register is valid only when DSICR1[DSI64E] is enabled.

Address: 0h base + FCh offset = FCh

DSPI_DDR1 field descriptions

Field	Description
0–31 DESER_DATA	Deserialized Data Holds 32 MSB of the deserialized data that is presented as signal states to the 64 Parallel Output signals.This field is valid only when DSICR1[DSI64E] is set. The concatenation of {DSPIx_DDR1, DSPIx_DDR0} provides the 64-bit deserialized data.

48.4.22 DSI Serialization Source Select Register 1 (DSPI_SSR1)

SSR1 is used to create a combined frame for transmission that contains bits from ASDR1 and from SDR1. Each bit in the SSR1 register selects a corresponding bit to be serialized. When DSICR0[TXSS] is set, the SSR1 register value has no effect. The concatenation of {DSPIx_SSR1, DSPIx_SSR0} provides the 64-bit Serialization Source Select Value. This register is valid only when DSICR1[DSI64E] is enabled.

Address: 0h base + 100h offset = 100h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

DSPI_SSR1 field descriptions

Field	Description
0–31 SS	Source Select Select the serialization source for the 32 MSB of the 64-bit DSI frame. Each SS bit selects data for a corresponded bit in the transmitted frame. This field is valid only when DSICR1[DSI64E] is set. The concatenation of {DSPIx_SSR1, DSPIx_SSR0} provides the 64-bit serialization source select value. 0 The bit in the transmitted frame is taken from the Parallel Input pin. 1 The bit in the transmitted frame is taken from the ASDR0/1 register

48.4.23 DSI Deserialized Data Interrupt Mask Register 1 (DSPI_DIMR1)

DIMR1 selects bits from the 32 MSB in the received 64-bit DSI frame to be checked to generate the DDI interrupt. The concatenation of {DSPIx_DIMR1, DSPIx_DIMR0} provides the 64-bit Deserialized Data Interrupt Mask Value. This register is valid only when DSICR1[DSI64E] is enabled.

Address: 0h base + 114h offset = 114h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

DSPI_DIMR1 field descriptions

Field	Description
0–31 MASK	Mask Defines which of the 32 MSB in the received 64-bit deserialization data should be checked to produce the Deserialized Data Interrupt (DDI). 0 The bit in the received DSI frame does not produce a DDI interrupt. 1 The bit in the received DSI frame can produce a DDI interrupt if the data bit matches the configured polarity.

48.4.24 DSI Deserialized Data Polarity Interrupt Register 1 (DSPI_DPIR1)

DPIR1 defines which of the 32 MSB value in the received 64-bit DSI frame generates the DDI interrupt. The concatenation of {DSPIx_DPIR1, DSPIx_DPIR0} provides the 64-bit Deserialized Data Polarity Value. This register is valid only when DSICR1[DSI64E] is enabled.

Address: 0h base + 118h offset = 118h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

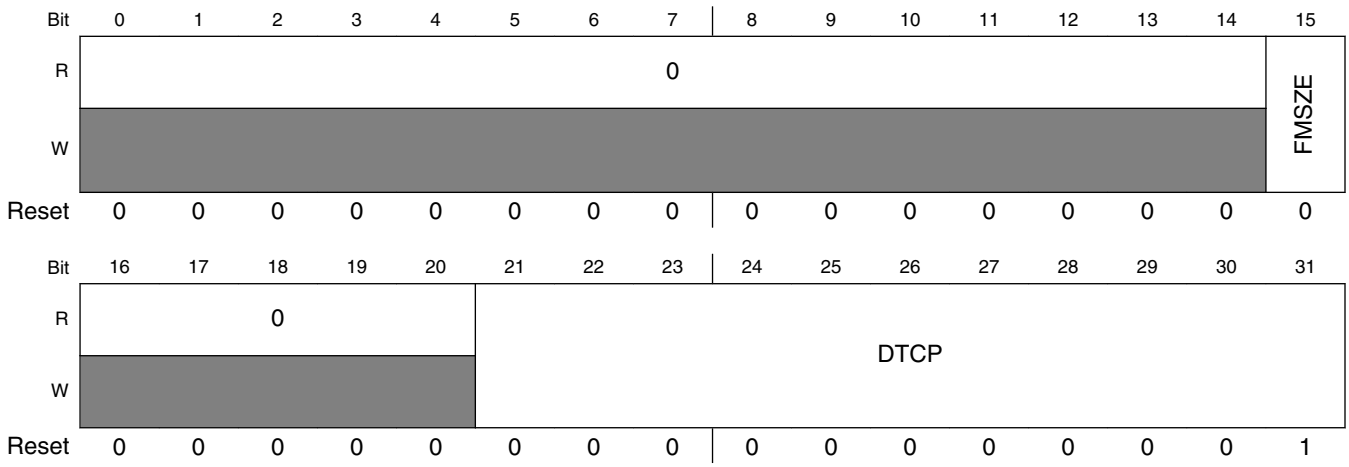
DSPI_DPIR1 field descriptions



Field	Description
0–31 DP	Data Polarity Defines which of the 32 MSB of the received 64-bit deserialization data sets the SR[DDIF] bit. 0 If the received bit is 0, the SR[DDIF] bit is set. 1 If the received bit is 1, the SR[DDIF] bit is set.

48.4.25 Clock and Transfer Attributes Register Extended (DSPI_CTARE*n*)

CTARE registers are used to define the extended transfer attributes for an SPI frame. These registers are valid only when DSPIx_MCR[XSPI] is set.

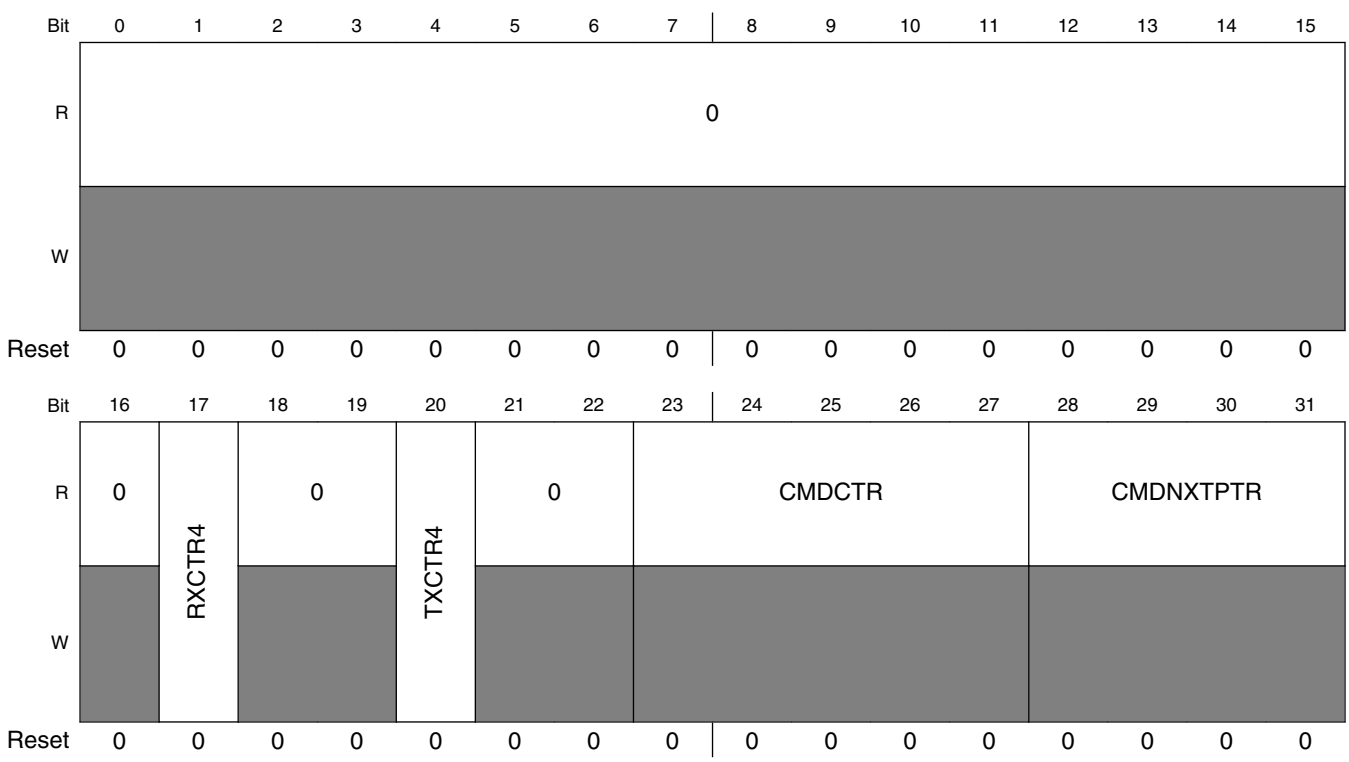
When the module is configured as an SPI master, the CTAS field in CMD FIFO entry selects which of the CTARE registers is used. When the module is configured as an SPI bus slave, the CTARE0 register is used.

Address: 0h base + 11Ch offset + (4d × i), where i=0d to 7d

DSPI_CTARE*n* field descriptions

Field	Description
0–14 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15 FMSZE	Frame Size Extended This field is valid only when DSPIx_MCR[XSPI] is set. This field concatenated with DSPIx_CTAR[FMSZ] defines the Frame size of the SPI frames to be transmitted. Effective frame size would be the concatenation of {DSPIx_CTARE[FMSZE], DSPIx_CTAR[FMSZ]} plus 1.

Table continues on the next page...



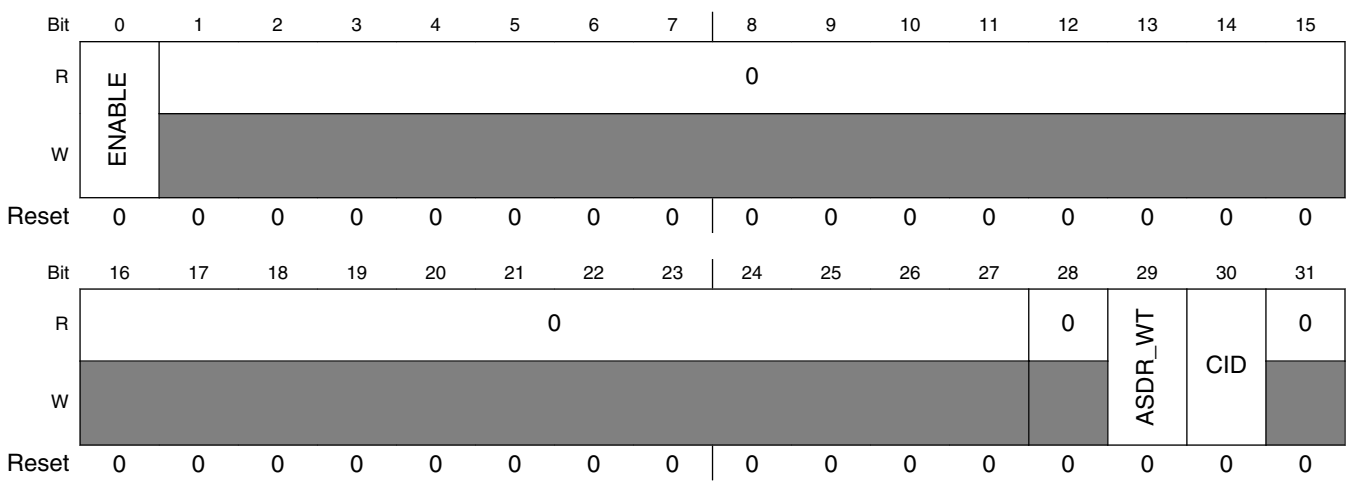
DSPI_CTARE*n* field descriptions (continued)

Field	Description
	0 Default Mode. Up to 16 bit SPI frames can be transfered. 1 Up to 32 bit SPI frames can be transfered. Each Frame transfer will be a result of 2 simulataneous TX FIFO Pop Operation.
16–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21–31 DTCP	Data Transfer Count Preload This field is valid only when DSPIx_MCR[XSPI] is set. This field defines the number of data frames (whose size is defined by CTARE[FMSZE] and CTAR[FMSZ]) to be transmitted using the Command frame which selected this DSPIx_CTARE register. The value 0 is reserved and should not be written in this field. The default value of this field is 1.

48.4.26 Status Register Extended (DSPI_SREX)

The register contains status fields. The fields reflect the status of the module and indicate the occurrence of events. This register is not writable.

Address: 0h base + 13Ch offset = 13Ch



DSPI_SREX field descriptions

Field	Description
0–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
17 RXCTR4	RX FIFO Counter[4] This bit is an extension of SR[RXCTR]. The concatenated field {RXCTR4, RXCTR} indicates the number of entries in the RX FIFO. This field is decremented every time the POPR is read. And this field is incremented every time data is transferred from the shift register to the RX FIFO.
18–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20 TXCTR4	TX FIFO Counter[4] This bit is an extension of SR[TXCTR]. The concatenated field {TXCTR4, TXCTR} indicates the number of valid entries in the TX FIFO. This field is incremented every time the PUSHR is written. And this field is decremented every time an SPI command is executed and the SPI data is transferred to the shift register.
21–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23–27 CMDCTR	CMD FIFO Counter Indicates the number of entries in the CMD FIFO. The CMDCTR is incremented every time the command part of PUSHR is written. The CMDCTR is decremented every time a SPI command is executed (all data frames due to current command frame have been transmitted).
28–31 CMDNXTPTR	Command Next Pointer Indicates which CMD FIFO Entry is used during the next transfer. The CMDNXTPTR field is updated every time SPI data due to current command have been transmitted.

48.4.27 Trigger Register (DSPI_TRIG)

This register provides the user to configure trigger settings for various modes. The trigger settings in this register are activated only if the bit TRIG[ENABLE] is set.

Address: 0h base + 140h offset = 140h

DSPI_TRIG field descriptions

Field	Description
0 ENABLE	Trigger Register Enable This bit is used to enable the TRIG register. 0 TRIG register is disabled. Trigger settings configured in this register have no effect on the module. 1 TRIG register is enabled. Trigger settings configured in this register are valid.
1–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29 ASDR_WT	ASDR Write Trigger Enable Enables the module to initiate a DSI frames transfer on a write operation performed on ASDR0 register. 0 ASDR0 write trigger disabled. 1 ASDR0 write trigger enabled.
30 CID	Change In Data Transfer Enable Enables a change in serialization data to initiate a DSI frames transfer in DSI and CSI configurations. When the CID bit is set, DSI frames are initiated when the current DSI data differs from the previous DSI data shifted out. **NOTE:** When TRIG[ENABLE] is set, the CID bit is given by TRIG[CID] which overrides DSICR0[CID].
31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

48.4.28 Time Slot Length Register (DSPI_TSL)

The TSL register is only valid when DSICR0[ITSB] is enabled and internal triggering mechanism is used. It provides the length of every time slot in terms of baud cycles.

Address: 0h base + 150h offset = 150h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	TS3_LEN							0	TS2_LEN						
W

DSPI_TSL field descriptions

Field	Description
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

DSPI_TSL field descriptions (continued)

Field	Description
1–7 TS3_LEN	Time Slot 3 Length This field provides the length of TS3 in terms of baud cycles. It must be ensured that the programmed value is greater than or equal to the length of the frame to be transmitted during TS3.Time Slot3 Length = TS3_LEN+1.This time slot shall be skipped if programmed to 0.
8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
9–15 TS2_LEN	Time Slot 2 Length This field provides the length of TS2 in terms of baud cycles. It must be ensured that the programmed value is greater than or equal to the length of the frame to be transmitted during TS2.Time Slot 2 Length = TS2_LEN+1.This time slot shall be skipped if programmed to 0.
16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
17–23 TS1_LEN	Time Slot 1 Length This field provides the length of TS1 in terms of baud cycles. Time Slot 1 Length = TS1_LEN+1. Ensure that the programmed value is greater than or equal to the length of the frame to be transmitted during TS1. This time slot shall be skipped if programmed to 0.
24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25–31 TS0_LEN	Time Slot 0 Length This field provides the length of TS0 in terms of baud cycles. Time Slot 0 Length = TS0_LEN+1. Ensure that the programmed value is greater than or equal to the length of the frame to be transmitted during TS0. This time slot shall be skipped if programmed to 0.

48.4.29 Time Slot Configuration Register (DSPI_TS_CONF)

This register provides the basic configuration options available for the triggered implementation of MSC protocol. This register is only valid when DSICR0[ITSB] is enabled. Some configurations in this register check for the validity of command frame. The following conditions must be true for a command frame to be valid : a) The previous transmitted frame should not be a command frame. b) Data required to transmit the command frame should be available.

Address: 0h base + 154h offset = 154h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

48.5 Functional description

The Deserial Serial Peripheral Interface (DSPI) block supports full-duplex, synchronous serial communications between MCUs and peripheral devices. The DSPI can also be used to reduce the number of pins required for I/O by serializing and deserializing up to 64 Parallel Input/Output signals. All communications are done with SPI-like protocol.

The DSPI has the following configurations

- The SPI Configuration in which the module operates as a basic SPI or a queued SPI.
- DSI Configuration in which the DSPI serializes Parallel Input signals or bits from memory mapped register.
- CSI Configuration in which the DSPI combines the functionality of the SPI and DSI configurations.

The DCONF field in the DSPI Module Configuration Register (MCR) determines the module Configuration. See Module Configuration Register (DSPI_MCR) for the DSPI configuration values.

The CTARn registers hold clock and transfer attributes. The SPI configuration allows to select which CTAR to use on a frame by frame basis by setting a field in the SPI command. The Extended SPI Mode (DSPIx_MCR[XSPI]) further allows the usage CTAREn (CTARn Extended) registers which allows the user to send multiple data frames using a single command frame.

The DSI configuration statically selects which CTAR to use. In CSI, Configuration priority logic determines if SPI data or DSI data is transferred and dictates what CTAR register is used for the data transfer. See Clock and Transfer Attributes Register (In

Master Mode) (DSPI_CTAR*n*) for information on the fields of CTAR registers. See Clock and Transfer Attributes Register Extended (DSPI_CTARE*n*) for information on the fields of CTARE registers.

Typical master to slave connections are shown in the following figure. When a data transfer operation is performed, data is serially shifted a predetermined number of bit positions. Because the modules are linked, data is exchanged between the master and the slave. The data that was in the master shift register is now in the shift register of the slave, and vice versa. At the end of a transfer, the Transfer Control Flag(TCF) bit in the Shift Register(SR) is set to indicate a completed frame transfer.

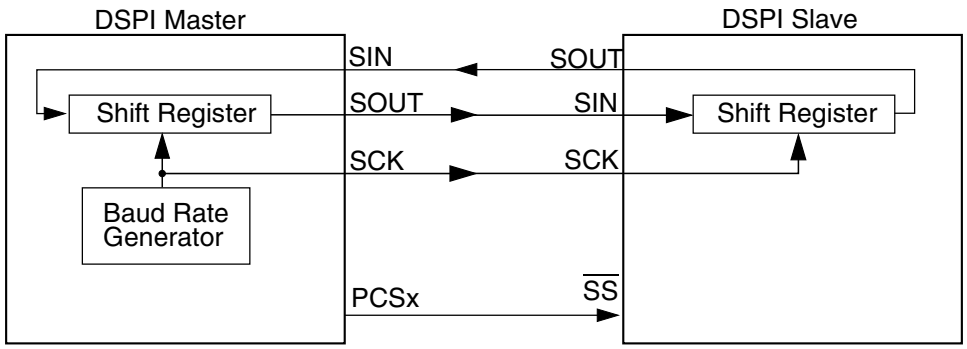

Figure 48-58. SPI and DSI serial protocol overview

Generally, more than one slave device can be connected to the module master. Six Peripheral Chip Select (PCS) signals of the module masters can be used to select which of the slaves to communicate with. Refer to Number of PCS signals for the number of PCS signals used in this MCU.

The three DSPI configurations share transfer protocol and timing properties which are described independently of the configuration in Transfer formats. The transfer rate and delay settings are described in Module baud rate and clock delay generation.

48.5.1 Start and Stop of module transfers

The module has two operating states: Stopped and Running. Both the states are independent of its configuration. The default state of the module is Stopped. In the Stopped state, no serial transfers are initiated in Master mode and no transfers are responded to in Slave mode. The Stopped state is also a safe state for writing the various configuration registers of the module without causing undetermined results. In the Running state serial transfers take place.

The TXRXS bit in the SR indicates the state of module. The bit is set if the module is in Running state.

The module starts or transitions to Running when all of the following conditions are true:

- SR[EOQF] bit is clear
- MCU is not in the Debug mode or the MCR[FRZ] bit is clear
- MCR[HALT] bit is clear

The module stops or transitions from Running to Stopped after the current frame when any one of the following conditions exist:

- SR[EOQF] bit is set
- MCU in the Debug mode and the MCR[FRZ] bit is set
- MCR[HALT] bit is set

State transitions from Running to Stopped occur on the next frame boundary if a transfer is in progress, or immediately if no transfers are in progress.

48.5.2 Serial Peripheral Interface (SPI) configuration

The SPI configuration transfers data serially using a shift register and a selection of programmable transfer attributes. The module is in SPI configuration when the DCONF field in the MCR is 0b00. The SPI frames can be 32 bits long. The host CPU or a DMA controller transfers the SPI data from the external to DSPI RAM queues to a TX FIFO buffer. The received data is stored in entries in the RX FIFO buffer. The host CPU or the DMA controller transfers the received data from the RX FIFO to memory external to the module. The operation of FIFO buffers is described in Transmit First In First Out (TX FIFO) buffering mechanism, Transmit First In First Out (TX FIFO) buffering mechanism, Command First In First Out (CMD FIFO) Buffering Mechanism and Receive First In First Out (RX FIFO) buffering mechanism. The interrupt and DMA request conditions are described in Interrupts/DMA requests.

The SPI configuration supports two block-specific modes—Master mode and Slave mode. In Master mode the module initiates and controls the transfer according to the fields of the executing SPI Command. In Slave mode, the module responds only to transfers initiated by a bus master external to it and the SPI command field space is reserved.

48.5.2.1 Master mode

In SPI Master, mode the module initiates the serial transfers by controlling the SCK and the PCS signals. The executing SPI Command determines which CTARs will be used to set the transfer attributes and which PCS signals to assert. The command field also contains various bits that help with queue management and transfer protocol. See PUSH TX FIFO Register In Master Mode (DSPI_PUSHR) for details on the SPI command fields. The data in the executing TX FIFO entry is loaded into the shift register and shifted out on the Serial Out (SOUT) pin. In SPI Master mode, each SPI frame to be transmitted has a command associated with it, allowing for transfer attribute control on a frame by frame basis. In Extended SPI Master Mode, multiple SPI frames can have a single command associated with them allowing for efficient SPI frame transfers requiring common transfer attributes. In addition, the Extended SPI Mode allows for larger frame sizes of up to 32 bits.

48.5.2.2 Slave mode

In SPI Slave mode the module responds to transfers initiated by an SPI bus master. It does not initiate transfers. Certain transfer attributes such as clock polarity, clock phase, and frame size must be set for successful communication with an SPI master. The SPI Slave mode transfer attributes are set in the CTAR0 and CTARE0. The data is shifted out with MSB first. Shifting out of LSB is not supported in this mode.

48.5.2.3 FIFO disable operation

The FIFO disable mechanisms allow SPI transfers without using the TX FIFO, CMD FIFO or RX FIFO. The module operates as a double-buffered simplified SPI when the FIFOs are disabled. The Transmit and Receive side of the FIFOs are disabled separately; setting the MCR[DIS_TXF] bit disables the TX FIFO and CMD FIFO, and setting the MCR[DIS_RXF] bit disables the RX FIFO.

The FIFO disable mechanisms are transparent to the user and to host software. Transmit data and commands are written to the PUSHR and received data is read from the POPR.

When the TX FIFO is disabled (CMD FIFO is also disabled), the fields SR[TFFF], SR[TFUF], SR[CMDFFF], SREX[CMDCTR] and SR[TXCTR] behave as if there is a one-entry FIFO but the contents of TXFRs, SR[TXNXTPTR] and SREX[CMDNXTPTR] are undefined. Similarly, when the RX FIFO is disabled, the RFDF, RFOF, and RXCTR fields in the SR behave as if there is a one-entry FIFO, but the contents of the RXFR registers and POPNXTPTR are undefined.

48.5.2.4 Transmit First In First Out (TX FIFO) buffering mechanism

The TX FIFO functions as a buffer of SPI data for transmission. The TX FIFO holds four words, each consisting of SPI data. The number of entries in the TX FIFO is device-specific. SPI data is added to the TX FIFO by writing to the Data Field of module PUSH FIFO Register (PUSHR). TX FIFO entries can only be removed from the TX FIFO by being shifted out or by flushing the TX FIFO.

The TX FIFO Counter field (TXCTR) in the module Status Register (SR) indicates the number of valid entries in the TX FIFO. The TXCTR is updated every time a 8- or 16-bit write takes place to the Data Field of PUSHR or SPI data is transferred into the shift register from the TX FIFO.

The TXNXTPTR field indicates the TX FIFO Entry that will be transmitted during the next transfer. The TXFRn Registers are invalid in the Extended SPI Mode, since the TX FIFO and CMD FIFO can be used independently. The TXNXTPTR field is incremented every time SPI data is transferred from the TX FIFO to the shift register. The maximum value of the field is equal to the maximum implemented TXFR number and it rolls over after reaching the maximum.

48.5.2.4.1 Filling the TX FIFO

Host software or other intelligent blocks can add (push) entries to the TX FIFO and CMD FIFO by writing to the PUSHR. When the TX FIFO is not full, the TX FIFO Fill Flag (TFFF) in the SR is set. The TFFF bit is cleared when TX FIFO is full and the DMA controller indicates that a write to PUSHR is complete. Writing a '1' to the TFFF bit also clears it. The TFFF can generate a DMA request or an interrupt request. See Transmit FIFO Fill Interrupt or DMA Request for details.

The module ignores attempts to push data to a full TX FIFO, and the state of the TX FIFO does not change and no error condition is indicated.

48.5.2.4.2 Draining the TX FIFO

The TX FIFO entries are removed (drained) by shifting SPI data out through the shift register. Entries are transferred from the TX FIFO to the shift register and shifted out as long as there are valid entries in the TX FIFO. Every time an entry is transferred from the TX FIFO to the shift register, the TX FIFO Counter decrements by one. When Extended SPI Mode (DSPIx_MCR[XSPI]) is enabled, if the frame size of SPI Data to be transmitted is more than 16 bits, then it causes two Data entries to be popped from TX FIFO simultaneously which are transferred to the shift register. The first of the two popped entries forms the 16 least significant bits of the SPI frame to be transmitted. Such

an operation also causes TX FIFO Counter to decrement by two. At the end of a transfer, the TCF bit in the SR is set to indicate the completion of a transfer. The TX FIFO is flushed by writing a '1' to the CLR_TXF bit in MCR.

If an external bus master initiates a transfer with a module slave while the slave's TX FIFO is empty, the Transmit FIFO Underflow Flag (TFUF) in the slave's SR is set. See Transmit FIFO Underflow Interrupt Request for details.

48.5.2.5 Command First In First Out (CMD FIFO) Buffering Mechanism

The CMD FIFO functions as a buffer of SPI command used for SPI data transmission. When Extended SPI Mode (DSPIx_MCR[XSPI]) is disabled, the TX FIFO and CMD FIFO must be filled together, i.e. write enables should be given for both the Data and Command fields while performing a PUSHR operation. When Extended SPI Mode (DSPIx_MCR[XSPI]) is enabled, the TX FIFO and CMD FIFO can be filled independently.

The CMD FIFO holds 4 words, each representing SPI command fields. The number of entries in the CMD FIFO is device-specific. SPI Command is added to the CMD FIFO by writing to the command field of DSPI PUSH FIFO Register (PUSHR). CMD FIFO entries can only be removed from the CMD FIFO by being shifted out (to help transmit SPI data) or by flushing the CMD FIFO.

When Extended SPI Mode (DSPIx_MCR[XSPI]) is disabled, every CMDFIFO entry has a corresponding single TXFIFO entry attached to it since both these FIFO's are filled simultaneously.

When Extended SPI Mode (DSPIx_MCR[XSPI]) is enabled, every CMDFIFO entry can have multiple TXFIFO entries attached to it. Thus a single CMD FIFO entry can be used to transmit multiple TX FIFO entries. The CTARE[DTCP] field decides the number of SPI Data Frames having frame size as {FMSZE, FMSZ} to be transmitted using the current Command Entry. The CTAR/CTARE registers pointed by the CTAS field in the Command frame gives FMSZ and FMSZE fields respectively. The time for which a command entry is in use is known as a Command Cycle. The Busy Flag SR[BSYF] is asserted for the duration of the Command Cycle except for the last SPI frame in the Command Cycle.

The CMD FIFO Counter field (CMDCTR) in the DSPI Status Register (SR) indicates the number of valid entries in the CMD FIFO. The CMDCTR field is updated every time a 8- or 16-bit write takes place on the lower half of DSPI_PUSHR or SPI data is transferred into the shift register from the TX FIFO.

The TXFRn Registers are invalid in the Extended SPI Mode, since the TX FIFO and CMD FIFO can be used independently. The CMDNXTPTR field indicates which CMD FIFO Entry will be used during the next command cycle. The CMDNXTPTR field is incremented every time the last SPI data in the command cycle is transferred from the TX FIFO to the shift register and it rolls over after reaching the maximum.

48.5.2.6 Receive First In First Out (RX FIFO) buffering mechanism

The RX FIFO functions as a buffer for data received on the SIN pin. The RX FIFO holds four received SPI data frames. The number of entries in the RX FIFO is device-specific. SPI data is added to the RX FIFO at the completion of a transfer when the received data in the shift register is transferred into the RX FIFO. SPI data are removed (popped) from the RX FIFO by reading the module POP RX FIFO Register (POPR). RX FIFO entries can only be removed from the RX FIFO by reading the POPR or by flushing the RX FIFO.

The RX FIFO Counter field (RXCTR) in the module's Status Register (SR) indicates the number of valid entries in the RX FIFO. The RXCTR is updated every time the POPR is read or SPI data is copied from the shift register to the RX FIFO.

The POPNXTPTR field in the SR points to the RX FIFO entry that is returned when the POPR is read. The POPNXTPTR contains the positive offset from RXFR0 in a number of 32-bit registers. For example, POPNXTPTR equal to two means that the RXFR2 contains the received SPI data that will be returned when the POPR is read. The POPNXTPTR field is incremented every time the POPR is read. The maximum value of the field is equal to the maximum implemented RXFR number and it rolls over after reaching the maximum.

48.5.2.6.1 Filling the RX FIFO

The RX FIFO is filled with the received SPI data from the shift register. While the RX FIFO is not full, SPI frames from the shift register are transferred to the RX FIFO. Every time an SPI frame is transferred to the RX FIFO, the RX FIFO Counter is incremented by one.

If the RX FIFO and shift register are full and a transfer is initiated, the RFOF bit in the SR is set indicating an overflow condition. Depending on the state of the ROOE bit in the MCR, the data from the transfer that generated the overflow is either ignored or shifted in to the shift register. If the ROOE bit is set, the incoming data is shifted in to the shift register. If the ROOE bit is cleared, the incoming data is ignored.

48.5.2.6.2 Draining the RX FIFO

Host CPU or a DMA can remove (pop) entries from the RX FIFO by reading the module POP RX FIFO Register (POPR). A read of the POPR decrements the RX FIFO Counter by one. Attempts to pop data from an empty RX FIFO are ignored and the RX FIFO Counter remains unchanged. The data, read from the empty RX FIFO, is undetermined.

When the RX FIFO is not empty, the RX FIFO Drain Flag (RFDF) in the SR is set. The RFDF bit is cleared when the RX_FIFO is empty and the DMA controller indicates that a read from POPR is complete or by writing a 1 to it.

48.5.3 Deserial Serial Interface (DSI) Configuration

The DSI Configuration supports pin count reduction by serializing Parallel Input signals or register bits and shifting them out in a SPI-like protocol. The timing and transfer protocol is described in Transfer formats. The received serial frames are converted to a parallel form (deserialized) and placed on the Parallel Output signals or in the DSPI_DDR register. The various features of the DSI Configuration are set in DSPI DSI Configuration Registers (DSPI_DSICR0/1).

The DSI frames can be from 4 to 32 bits. This can go up to 64 bits when DSICR1[DSI64E] is enabled. With Multiple Transfer Operation (MTO) the DSPI supports serial chaining of DSPI blocks within the device to create DSI frames up to 64 bits, consisting of concatenated bits from multiple DSPIs. The DSPI also supports parallel chaining allowing several DSPIs and off-chip SPI devices to share the same Serial Communications Clock (SCK) and Peripheral Chip Select (PCS) signals. See Multiple Transfer Operation (MTO) for details on the serial and parallel chaining support.

Multiple Transfer Operation (MTO) and DSICR1[DSI64E] are not supported together and cannot be enabled simultaneously.

48.5.3.1 DSI Master Mode

In DSI master mode the DSPI initiates and controls the DSI transfers. The DSI master has eight different conditions that can initiate a transfer:

- Continuous
- Change in data
- Trigger signal

- ASDR write
- Trigger signal combined with a change in data
- Trigger signal combined with ASDR write
- Change in data combined with ASDR write
- Trigger signal combined with change in data combined with ASDR write

These transfer initiation conditions are described in DSI Transfer Initiation Control. Transfer attributes are set during initialization. The DSICTAS field in the DSPI_DSICR0 determines which of the DSPI_CTAR registers will control the transfer attributes.

48.5.3.2 Slave Mode

In DSI slave mode the DSPI responds to transfers initiated by a SPI or DSI bus master. In this mode the DSPI does not initiate DSI transfers. Certain transfer attributes such as clock polarity and phase must be set for successful communication with a DSI master. The DSI slave mode transfer attributes are set in the DSPI_CTAR1. The data is shifted out with MSB first.

If the CID bit in the DSPI_DSICR0 is set and the data in DSPI_COMPR0/1 differs from the selected source of the serialized data, the slave DSPI will assert the $\overline{\text{MTRIG}}$ signal. Also, if TRIG[ASDR_WT] is set and an ASDR0 write is detected, the slave DSPI will assert the $\overline{\text{MTRIG}}$ signal. These features are included to support chaining of several DSPI. Details about the $\overline{\text{MTRIG}}$ signal is found in Multiple Transfer Operation (MTO).

48.5.3.3 DSI Serialization

In the DSI Configuration, upto 64 bits can be serialized using two different sources. The TXSS bit in the DSPI_DSICR0 selects between the DSPI DSI Serialization Data Register (DSPI_SDR0/1) and the DSPI DSI Alternate Serialization Data Register (DSPI_ASDR0/1) as the source of the serialized data. The DSPI_SDR0 holds the latest 32 Parallel Input signal values which is sampled at every rising edge of the bus clock. When DSICR1[DSI64E] is enabled, 64-bit DSI Frames are supported and hence DSPI_SDR1 holds upto 32 most significant parallel input signal values which is sampled at every rising edge of the bus clock. The DSPI_ASDR0/1 register is written by host software and used as an alternate source of serialized data. (DSPI_ASDR1 is only usable when DSICR1[DSI64E] is enabled).

The DSPI has to sample the inputs (from SDR0/1 or ASDR0/1) before it transmits a DSI frame. Due to the asynchronous clocking structure within DSPI, the sampled data (from SDR0/1 or ASDR0/1) must be synchronized into the Protocol Domain before being loaded into the Shift Register for transmission.

To prevent Clock Domain Crossing issues, inputs from SDR0/1 or ASDR0/1 should not change while they are being sampled into the Protocol Domain. This is ensured in the following manner for the ASDR0 inputs. The initial write performed on ASDR0 register will cause the 32-bit ASDR0 input to be latched into a temporary register which is then locked (further latching is prevented) until this data gets synchronized into the Protocol Domain. Once synchronized, the lock is removed and the next ASDR0 write will again trigger this process. If there was a write performed on ASDR0 while the lock was asserted, this will be would be taken into consideration as soon as the previous synchronization process completes and lock gets de-asserted. In case multiple writes were performed on ASDR0 when lock was asserted, only the latest value will be considered for synchronization once the lock gets de-asserted. This process is true for ASDR1 register as well.

The entire process explained above is also true for the SDR0 and SDR1 inputs, the only difference being that SDR0/1 inputs are delayed internally by a single Bus clock (register interface clock) to detect a change in the parallel input pins.

Once the synchronization process for a particular De-serial input begins, it takes up to 5 Bus clock (register interface clock) periods and 5 Protocol clock periods before the synchronization process for the next De-serial input can begin. Hence the writes performed on ASDR0/1 and SDR0/1 are constrained with this timing.

Note

The Parallel Input pin state, to be transmitted, should be selected by TXSS or DSPI_SSR0/1 register and the frame size should be higher than the bit position in the preselected frame.

DSPI_SSR0/1 register provides additional way to create the frame for transmission. Each bit from this register is OR'd with the TXSS bit and controls individual transmitted bit source. This way, the transmitted frame can have any combination of the DSPI_SDR0/1 and DSPI_ASDR0/1 bits. This feature allows control SPI based devices, requiring control and data fields in the frame. Control field may come from DSPI_ASDR0/1 register, set by the device's CPU, while data field can be generated by device peripheral modules, like PWM timers.

A copy of the last DSI frame shifted out of the Shift Register is stored in the DSPI DSI Transmit Comparison Registers (DSPI_COMPR0/1). This register provides added visibility for debugging and it serves as a reference for transfer initiation control. The following figure shows the DSI Serialization logic.

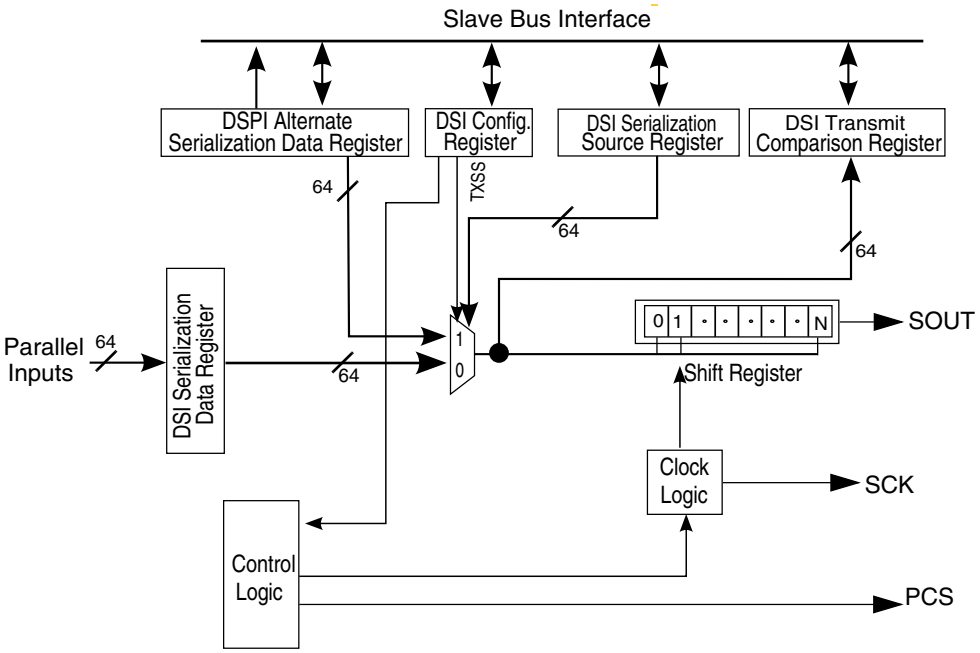

Figure 48-59. DSI Serialization Diagram

48.5.3.4 DSI Transfer Initiation Control

Data transfers for a DSPI in DSI configuration are initiated by a condition. The transfer initiation conditions are selected by the TRRE and CID bits in the DSPI_DSICR0.

NOTE

By default, the TRRE and CID bits are programmed using DSICR0[TRRE] and DSICR0[CID]. When TRIG[ENABLE] is set, the TRRE and CID bits are given by TRIG[TRRE] and TRIG[CID] respectively and the bits DSICR0[TRRE], DSICR0[CID] have no effect.

The following table lists the transfer initiation conditions.

Table 48-89. DSI Data Transfer Initiation Control

TRRE	CID	ASDR_WT	Transfer Initiation Control
0	0	0	Continuous
0	0	1	ASDR Write
0	1	0	Change in Data
0	1	1	Change in Data or ASDR Write
1	0	0	Triggered
1	0	1	Triggered or ASDR Write
1	1	0	Triggered or Change in Data

Table continues on the next page...

Table 48-89. DSI Data Transfer Initiation Control (continued)

TRRE	CID	ASDR_WT	Transfer Initiation Control
1	1	1	Triggered or Change in Data or ASDR Write

48.5.3.4.1 Continuous Control

For Continuous Control a new DSI frame shifts out when the previous transfer cycle has completed and the Delay after Transfer (t_{DT}) has elapsed. This has no effect when DSPI is in Slave Mode.

48.5.3.4.2 ASDR Write Control

For ASDR Write Control, a DSI frame shifts out whenever a write operation to ASDR0 is detected. For ASDR_WT to have any affect, TRIG[ASDR_WT] bit must be set. Note that ASDR0 write operations will not generate ASDR write triggers when the module is in STOPPED state, including when MCR[HALT] is asserted.

NOTE

If a DSI frame > 32 bits needs to be transmitted, the user must update ASDR1 before updating ASDR0.

48.5.3.4.3 Change In Data Control

For Change in Data Control a transfer is initiated when the data to be serialized has changed since the transfer of the last DSI frame. A copy of the previously transferred DSI data is stored in DSPI_COMPR0/1. When the data, selected for the transfer from the DSPI_SDR0/1 and DSPI_ASDR0/1 registers is different from the data in the DSPI_COMPR0/1 a new DSI frame is transmitted. The $\overline{\text{MTRIG}}$ output signal is asserted every time a change in data is detected.

NOTE

It is not advisable to configure a DSPI Slave with the combination DSICR0[DCONT] = 1, DSICR0[CID] = 1 ; since the following statement then holds true.

Once slave select is asserted, there is a very small window (of up to 3 module clocks) after every SOF (Start of Frame) during which if a write on ASDR/SDR registers occur, the next frame to be transmitted would be loaded into the shift register.

However, it is not feasible that such a write is initiated and completed within this short span of time; hence the data transmitted by DSPI slave would lag by one data frame.

48.5.3.4.4 Change In Data or ASDR Write Control

For Change in Data or ASDR Write Control, initiation of a transfer is controlled by the detection of a change in data to be serialized or whenever a write operation to ASDR0 is detected.

NOTE

For any DSI transfer initiation combination where TRIG[ASDR_WT] and DSICR0[HT] are both enabled, it is possible that the ASDR0 write operation causes a Change of DSI Data. This special condition results in transmission of a single DSI frame even though 2 separate triggers were generated.

48.5.4 Combined Serial Interface (CSI) Configuration

The CSI Configuration of the DSPI is used to support SPI and DSI functions on a frame by frame basis. CSI Configuration allows interleaving of DSI data frames from the parallel input signals with SPI data frames from the TX FIFO. The data returned from the bus slave is either used to drive the Parallel Output signals or it is stored in the RX FIFO. The CSI Configuration allows serialized data and configuration or diagnostic data to be transferred to a slave device using only one serial link. The DSPI is in CSI Configuration when the DCONF field in the DSPI_MCR is 0b10. The following figure shows an example of how a DSPI can be used with a deserializing peripheral that supports SPI control for control and diagnostic frames.

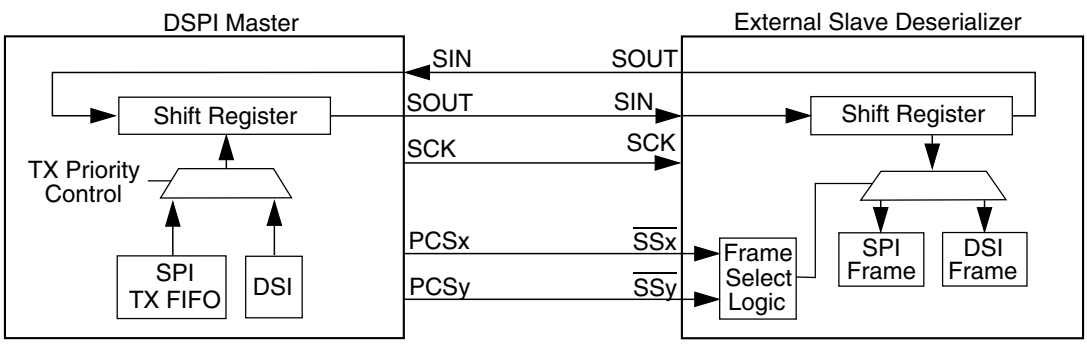

Figure 48-60. Example of System using DSPI in CSI Configuration

In CSI Configuration the DSPI transfers DSI data based on DSI Transfer Initiation Control.

When DSICR1[PRTY] is set to zero and there are SPI commands in the TX FIFO, the SPI frames have priority over the DSI frames. When the TX FIFO or CMD FIFO is empty, DSI transfer resumes.

When DSICR1[PRTY] bit is set, the DSI frames have priority over SPI frames. Thus, only when the DSI frame initiation requests have been catered to, will the SPI frames be transmitted, if available.

NOTE

The following combination is not a legal scenario and should be avoided - DSICR1[PRTY] = 1, DSICR1[TRRE] = 0 and DSICR1[CID] = 0, since such a configuration prevents SPI frames from ever getting transmitted.

Two peripheral chip select signals indicate whether DSI data or SPI data is transmitted. The user must configure the DSPI so that the two CTAR registers associated with DSI data and SPI data assert different peripheral chip select signals denoted in the figure as PCSx and PCSy. The CSI Configuration is only supported in master mode.

Data returned from the external slave while a DSI frame is transferred is placed on the Parallel Output signals. Data returned from the external slave while a SPI frame is transferred is moved to the RX FIFO. The TX FIFO, CMD FIFO and RX FIFO are fully functional in CSI mode.

48.5.4.1 CSI Serialization

Serialization in the CSI configuration is similar to serialization in DSI Configuration. The transfer attributes for SPI frames are determined by the DSPI_CTAR register selected by the CTAS field in the SPI command halfword. The transfer attributes for the DSI frames are determined by the DSPI_CTAR register selected by the DSICTAS field in the DSPI_DSICR0.

The Parallel Inputs signal states are latched into the DSPI DSI Serialization Data Register (DSPI_SDR0/1) and serialized based on the transfer initiation control settings in the DSPI_DSICR0. When SPI frames are written to the TX FIFO (and when CMD FIFO is not empty) they have priority over DSI data from the DSPI_SDR and are transferred at the next frame boundary. A copy of the most recently transferred DSI frame is stored in the DSPI_COMPR0/1. The Transfer Priority Logic selects the source of the serialized data and asserts the appropriate PCS signal.

Separate frame completion interrupts are available to indicate frame transmission completion from SPI and DSI frames.

48.5.4.2 CSI Deserialization

The deserialized frames in CSI Configuration goes into the DSPI_DDR0/1 or the RX FIFO based on the transfer priority logic. When DSI frames are transferred the returned frames are deserialized and latched into the DSPI_DDR0/1. When SPI frames are transferred the returned frames are deserialized and written to the RX FIFO.

48.5.5 Module baud rate and clock delay generation

The SCK frequency and the delay values for serial transfer are generated by dividing the protocol clock frequency by a prescaler and a scaler with the option for doubling the baud rate. The following figure shows conceptually how the SCK signal is generated.

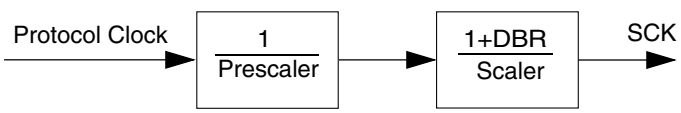

Figure 48-61. Communications clock prescalers and scalers

48.5.5.1 Baud rate generator

The baud rate is the frequency of the SCK. The protocol clock is divided by a prescaler (PBR) and scaler (BR) to produce SCK with the possibility of halving the scaler division. The DBR, PBR, and BR fields in the CTARs select the frequency of SCK by the formula in the BR field description. The following table shows an example of how to compute the baud rate.

Table 48-90. Baud rate computation example

f_P	PBR	Prescaler	BR	Scaler	DBR	Baud rate
100 MHz	0b00	2	0b0000	2	0	25 Mb/s
20 MHz	0b00	2	0b0000	2	1	10 Mb/s

NOTE

The clock frequencies mentioned in the preceding table are given as an example. Refer to the clocking chapter for the frequency used to drive this module in the device.

48.5.5.2 PCS to SCK Delay (t_{CSC})

The PCS to SCK delay is the length of time from assertion of the PCS signal to the first SCK edge. See Figure 48-63 for an illustration of the PCS to SCK delay. The PCSSCK and CSSCK fields in the CTAR*x* registers select the PCS to SCK delay by the formula in the CSSCK field description. The following table shows an example of how to compute the PCS to SCK delay.

Table 48-91. PCS to SCK delay computation example

f_P	PCSSCK	Prescaler	CSSCK	Scaler	PCS to SCK Delay
100 MHz	0b01	3	0b0100	32	0.96 µs

PCSCSK and CSSCK fields have no effect in TSB configuration.

NOTE

The clock frequency mentioned in the preceding table is given as an example. Refer to the clocking chapter for the frequency used to drive this module in the device.

48.5.5.3 After SCK Delay (t_{ASC})

The After SCK Delay is the length of time between the last edge of SCK and the negation of PCS. See Figure 48-63 and Figure 48-64 for illustrations of the After SCK delay. The PASC and ASC fields in the CTAR*x* registers select the After SCK Delay by the formula in the ASC field description. The following table shows an example of how to compute the After SCK delay.

Table 48-92. After SCK Delay computation example

f_P	PASC	Prescaler	ASC	Scaler	After SCK Delay
100 MHz	0b01	3	0b0100	32	0.96 µs

PCASC and ASC fields have no effect in TSB configuration.

NOTE

The clock frequency mentioned in the preceding table is given as an example. Refer to the clocking chapter for the frequency used to drive this module in the device.

48.5.5.4 Delay after Transfer (t_{DT})

The Delay after Transfer is the minimum time between negation of the PCS signal for a frame and the assertion of the PCS signal for the next frame. See Figure 48-63 for an illustration of the Delay after Transfer. The PDT and DT fields in the CTAR*x* registers select the Delay after Transfer by the formula in the DT field description. The following table shows an example of how to compute the Delay after Transfer.

Table 48-93. Delay after Transfer computation example

f_P	PDT	Prescaler	DT	Scaler	Delay after Transfer
100 MHz	0b01	3	0b1110	32768	0.98 ms

NOTE

The clock frequency mentioned in the preceding table is given as an example. Refer to the clocking chapter for the frequency used to drive this module in the device.

When in Non-Continuous Clock mode the t_{DT} delay is configured according to the equation specified in the CTAR[DT] field description. When in Continuous Clock mode and TSB is not enabled, the delay is fixed at 1 SCK period.

In TSB mode the Delay after Transfer is equal to a number formed by concatenation of PDT and DT fields plus 1 of the SCK clock periods. See detailed information on Timed Serial Bus (TSB)".

48.5.5.5 Peripheral Chip Select Strobe Enable ($\overline{\text{PCSS}}$)

The $\overline{\text{PCSS}}$ signal provides a delay to allow the PCS signals to settle after a transition occurs thereby avoiding glitches. When the Module is in Master mode and the PCSSE bit is set in the MCR, $\overline{\text{PCSS}}$ provides a signal for an external demultiplexer to decode the PCS[0] – PCS[4] signals into as many as 128 glitch-free PCS signals. The following figure shows the timing of the $\overline{\text{PCSS}}$ signal relative to PCS signals.

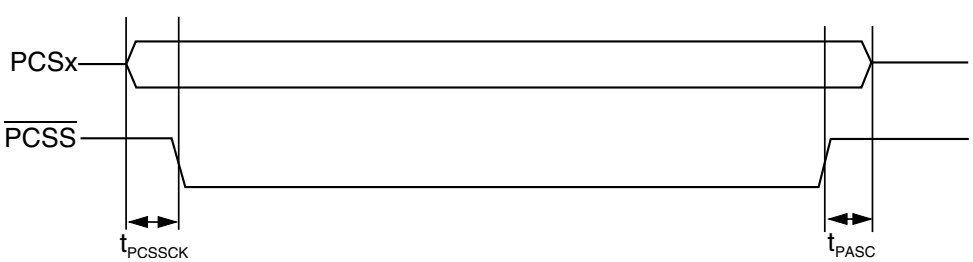

Figure 48-62. Peripheral Chip Select Strobe timing

The delay between the assertion of the PCS signals and the assertion of $\overline{\text{PCSS}}$ is selected by the PCSSCK field in the CTAR based on the following formula:

$$t_{\text{PCSSCK}} = \frac{1}{f_{\text{P}}} \times \text{PCSSCK}$$

At the end of the transfer, the delay between $\overline{\text{PCSS}}$ negation and PCS negation is selected by the PASC field in the CTAR based on the following formula:

$$t_{\text{PASC}} = \frac{1}{f_{\text{P}}} \times \text{PASC}$$

The following table shows an example of how to compute the t_{pcssck} delay.

Table 48-94. Peripheral Chip Select Strobe Assert computation example

f_P	PCSSCK	Prescaler	Delay before Transfer
100 MHz	0b11	7	70.0 ns

The following table shows an example of how to compute the t_{pasc} delay.

Table 48-95. Peripheral Chip Select Strobe Negate computation example

f_P	PASC	Prescaler	Delay after Transfer
100 MHz	0b11	7	70.0 ns

The $\overline{\text{PCSS}}$ signal is not supported when Continuous Serial Communication SCK or TSB mode is enabled.

NOTE

The clock frequency mentioned in the preceding tables is given as an example. Refer to the clocking chapter for the frequency used to drive this module in the device.

48.5.6 Transfer formats

The SPI serial communication is controlled by the Serial Communications Clock (SCK) signal and the PCS signals. The SCK signal provided by the master device synchronizes shifting and sampling of the data on the SIN and SOUT pins. The PCS signals serve as enable signals for the slave devices.

In Master mode, the CPOL and CPHA bits in the Clock and Transfer Attributes Registers (CTARn) select the polarity and phase of the serial clock, SCK.

- CPOL - Selects the idle state polarity of the SCK
- CPHA - Selects if the data on SOUT is valid before or on the first SCK edge

Even though the bus slave does not control the SCK signal, in Slave mode the values of CPOL and CPHA must be identical to the master device settings to ensure proper transmission. In SPI Slave mode, only CTAR0 is used. In DSI slave mode, only CTAR1 is used.

The module supports four different transfer formats:

- Classic SPI with CPHA=0
- Classic SPI with CPHA=1
- Modified Transfer Format with CPHA = 0
- Modified Transfer Format with CPHA = 1

A modified transfer format is supported to allow for high-speed communication with peripherals that require longer setup times. The module can sample the incoming data later than halfway through the cycle to give the peripheral more setup time. The MTFE bit in the MCR selects between Classic SPI Format and Modified Transfer Format.

In the SPI and DSI configurations, the module provides the option of keeping the PCS signals asserted between frames. See Continuous Selection Format for details.

48.5.6.1 Classic SPI Transfer Format (CPHA = 0)

The transfer format shown in following figure is used to communicate with peripheral SPI slave devices where the first data bit is available on the first clock edge. In this format, the master and slave sample their SIN pins on the odd-numbered SCK edges and change the data on their SOUT pins on the even-numbered SCK edges.

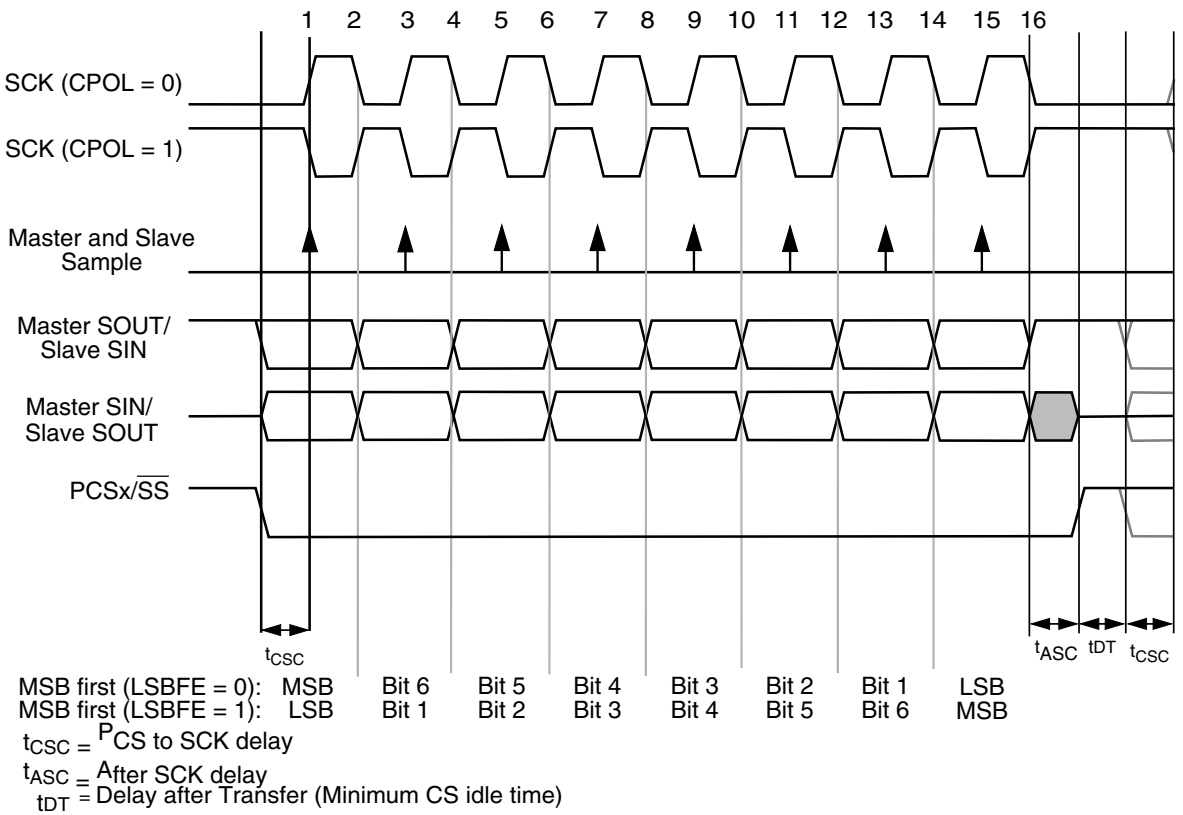

Figure 48-63. Module transfer timing diagram (MTFE=0, CPHA=0, FMSZ=8)

The master initiates the transfer by placing its first data bit on the SOUT pin and asserting the appropriate peripheral chip select signals to the slave device. The slave responds by placing its first data bit on its SOUT pin. After the t_{ASC} delay elapses, the master outputs the first edge of SCK. The master and slave devices use this edge to sample the first input data bit on their serial data input signals. At the second edge of the SCK, the master and slave devices place their second data bit on their serial data output signals. For the rest of the frame the master and the slave sample their SIN pins on the odd-numbered clock edges and changes the data on their SOUT pins on the even-numbered clock edges. After the last clock edge occurs, a delay of t_{ASC} is inserted before the master negates the PCS signals. A delay of t_{DT} is inserted before a new frame transfer can be initiated by the master.

48.5.6.2 Classic SPI Transfer Format (CPHA = 1)

This transfer format shown in the following figure is used to communicate with peripheral SPI slave devices that require the first SCK edge before the first data bit becomes available on the slave SOUT pin. In this format, the master and slave devices change the data on their SOUT pins on the odd-numbered SCK edges and sample the data on their SIN pins on the even-numbered SCK edges.

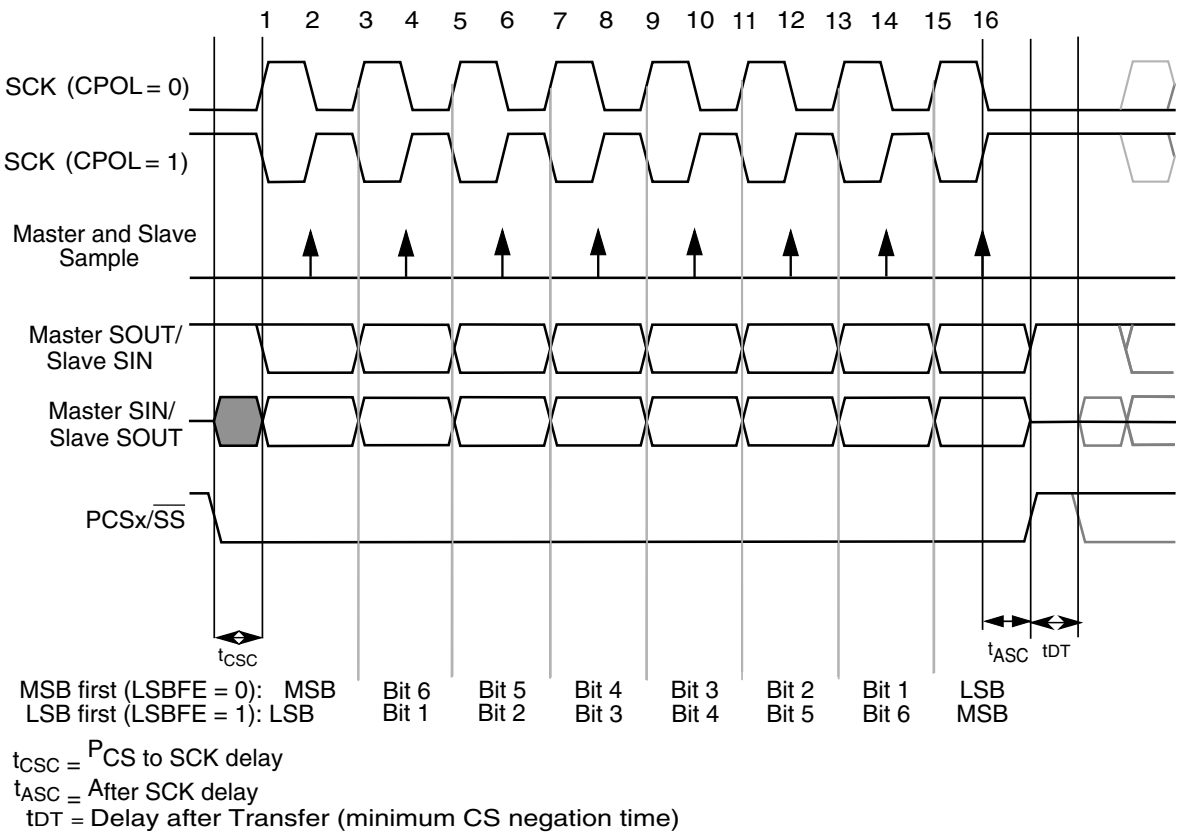

Figure 48-64. Module transfer timing diagram (MTFE=0, CPHA=1, FMSZ=8)

The master initiates the transfer by asserting the PCS signal to the slave. After the t_{CSC} delay has elapsed, the master generates the first SCK edge and at the same time places valid data on the master SOUT pin. The slave responds to the first SCK edge by placing its first data bit on its slave SOUT pin.

At the second edge of the SCK the master and slave sample their SIN pins. For the rest of the frame the master and the slave change the data on their SOUT pins on the odd-numbered clock edges and sample their SIN pins on the even-numbered clock edges. After the last clock edge occurs, a delay of t_{ASC} is inserted before the master negates the PCS signal. A delay of t_{DT} is inserted before a new frame transfer can be initiated by the master.

48.5.6.3 Modified SPI/DSI Transfer Format (MTFE = 1, CPHA = 0)

In this Modified Transfer Format both the master and the slave sample later in the SCK period than in Classic SPI mode to allow the logic to tolerate more delays in device pads and board traces. These delays become a more significant fraction of the SCK period as the SCK period decreases with increasing baud rates.

The master and the slave place data on the SOUT pins at the assertion of the PCS signal. After the PCS to SCK delay has elapsed the first SCK edge is generated. The slave samples the master SOUT signal on every odd numbered SCK edge. The DSPI in the slave mode when the MTFE bit is set also places new data on the slave SOUT on every odd numbered clock edge. Regular external slave, configured with CPHA=0 format drives its SOUT output at every even numbered SCK clock edge.

The DSPI master places its second data bit on the SOUT line one protocol clock after odd numbered SCK edge if the protocol clock frequency to SCK frequency ratio is higher than three. If this ratio is below four the master changes SOUT at odd numbered SCK edge. The point where the master samples the SIN is selected by the DSPI_MCR[SMPL_PT] field. The master sample point can be delayed by one or two protocol clock cycles. The SMPL_PT field should be set to 0 if the protocol to SCK frequency ratio is less than 4. However if this ratio is less than 4, the actual sample point is delayed by one protocol clock cycle automatically by the design.

The following timing diagrams illustrate the DSPI operation with MTFE=1. Timing delays shown are:

- T_{csc} - PCS to SCK assertion delay
- T_{acs} - After SCK PCS negation delay
- T_{su_ms} - master SIN setup time
- T_{hd_ms} - master SIN hold time
- T_{vd_sl} - slave data output valid time, time between slave data output SCK driving edge and data becomes valid.
- T_{su_sl} - data setup time on slave data input
- T_{hd_sl} - data hold time on slave data input
- T_{sys} - protocol clock period.

The following figure shows the modified transfer format for CPHA = 0 and Fsys/Fsck = 4. Only the condition where CPOL = 0 is illustrated. Solid triangles show the data sampling clock edges. The two possible slave behavior are shown.

- Signal, marked "SOUT of Ext Slave", presents regular SPI slave serial output.
- Signal, marked "SOUT of DSPI Slave", presents DSPI in the slave mode with MTFE bit set.

Other MTFE = 1 diagrams show DSPI SIN input as being driven by a regular external SPI slave, configured according DSPI master CPHA programming.

Note

In the following diagrams, f_{sys} represents the protocol clock frequency from which the Baud frequency f_{sck} is derived.

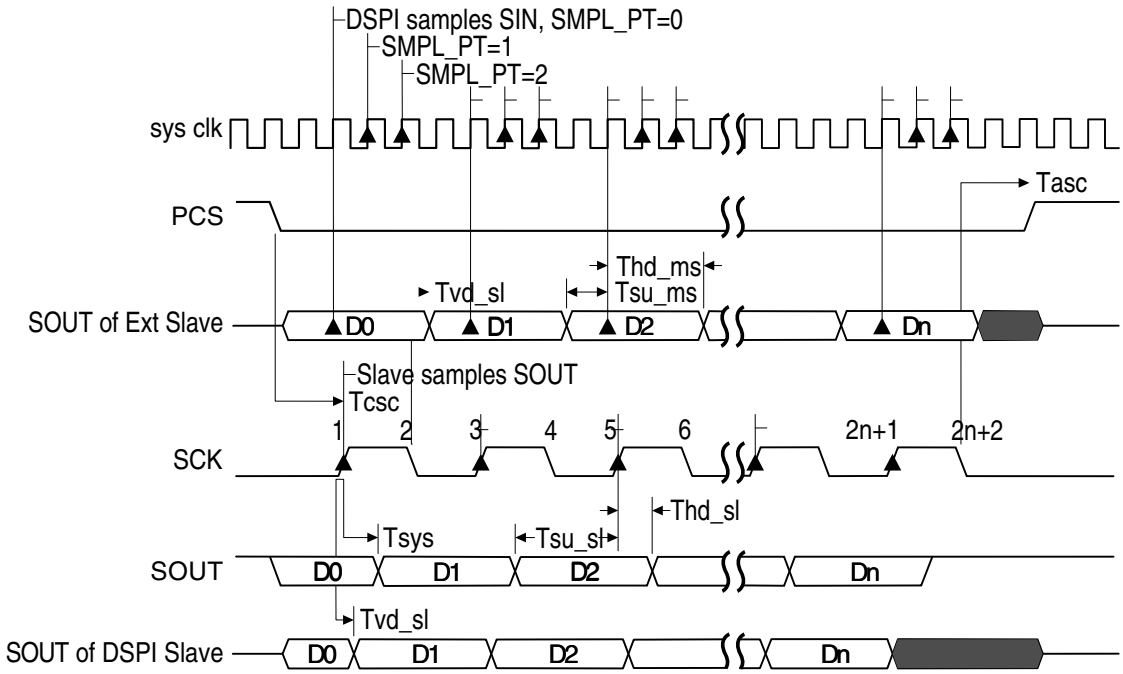

Figure 48-65. DSPI Modified Transfer Format (MTFE=1, CPHA=0, $f_{sck} = f_{sys}/4$)

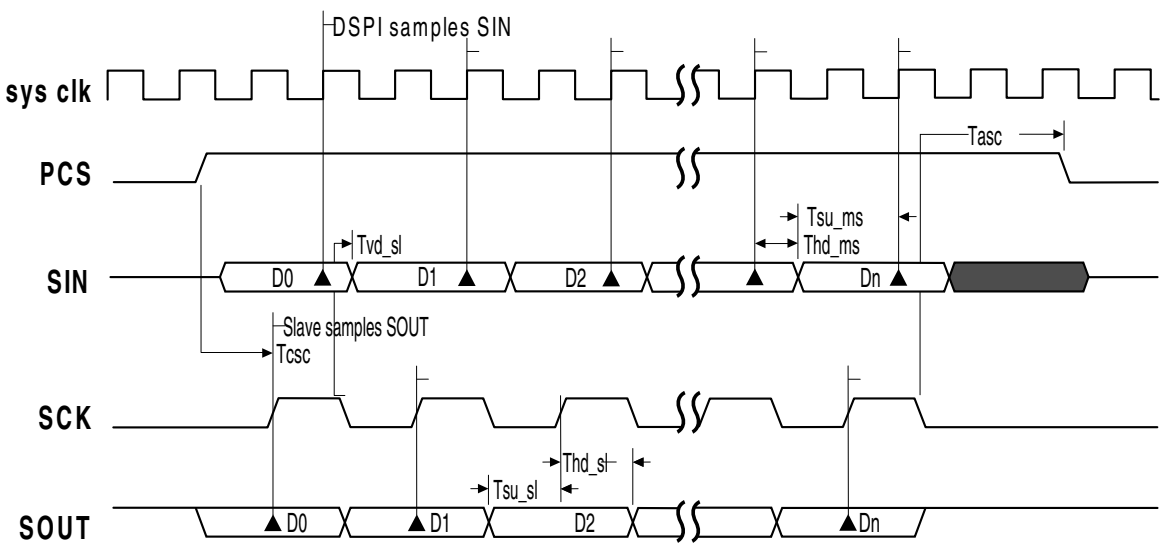

Figure 48-66. DSPI Modified Transfer Format (MTFE=1, CPHA=0, $f_{sck} = f_{sys}/2$)

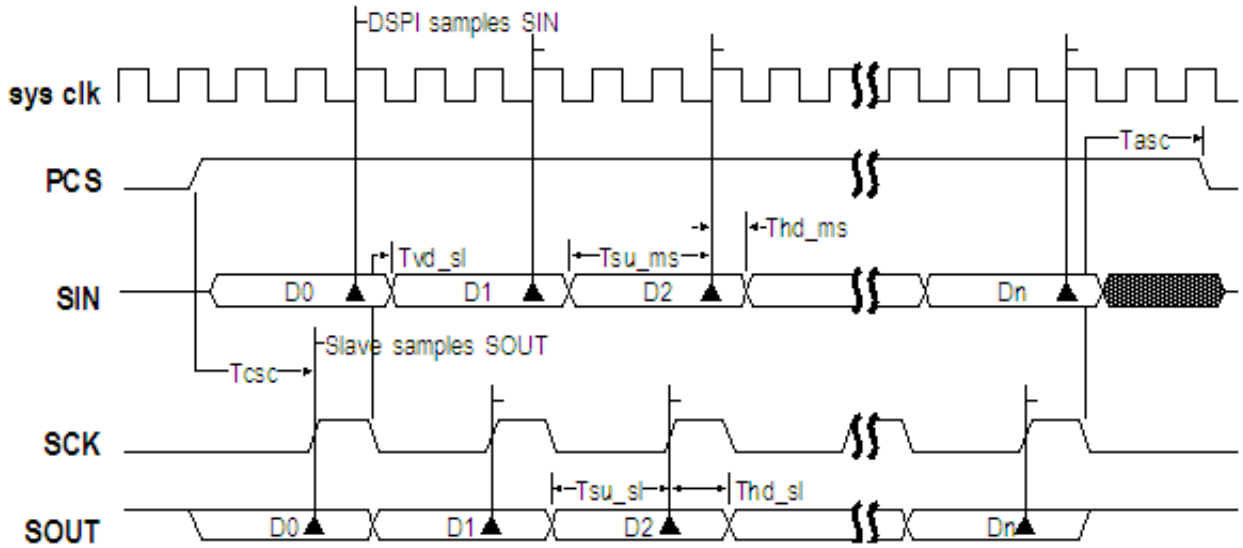

Figure 48-67. DSPI Modified Transfer Format (MTFE=1, CPHA=0, $f_{sck} = f_{sys}/3$)

48.5.6.4 Modified SPI/DSI Transfer Format (MTFE = 1, CPHA = 1)

The following figures show the Modified Transfer Format for CPHA = 1. Only the condition, where CPOL = 0 is shown. At the start of a transfer the DSPI asserts the PCS signal to the slave device. After the PCS to SCK delay has elapsed the master and the slave put data on their SOUT pins at the first edge of SCK. The slave samples the master SOUT signal on the even numbered edges of SCK. The master samples the slave SOUT signal on the odd numbered SCK edges starting with the third SCK edge. The slave samples the last bit on the last edge of the SCK. The master samples the last slave SOUT bit one half SCK cycle after the last edge of SCK. No clock edge will be visible on the master SCK pin during the sampling of the last bit. **The SCK to PCS delay and the After SCK delay must be greater or equal to half of the SCK period.**

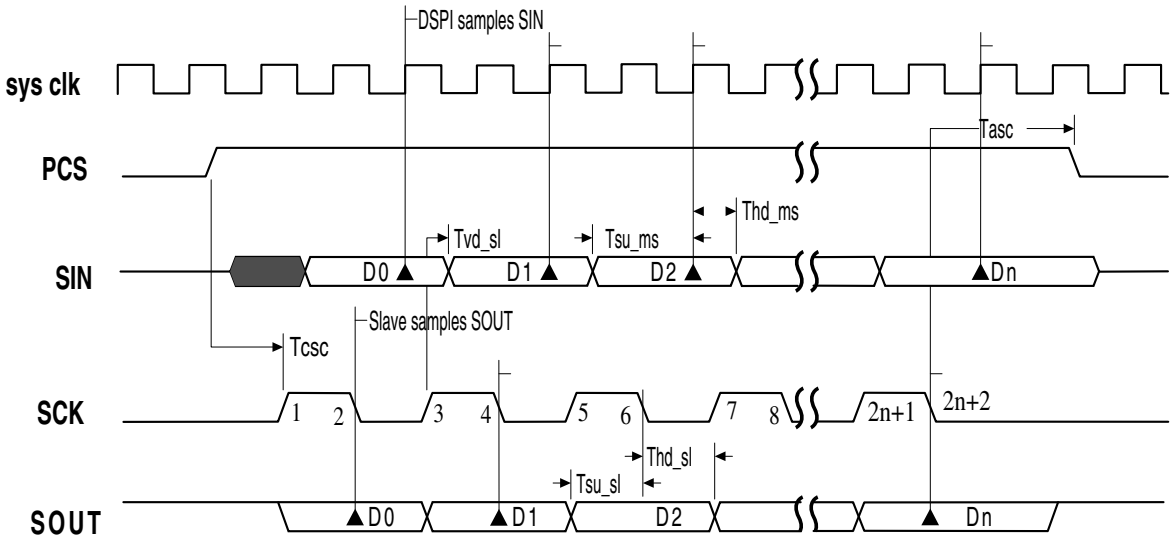

Figure 48-68. DSPI Modified Transfer Format (MTFE=1, CPHA=1, $f_{sck} = f_{sys}/2$)

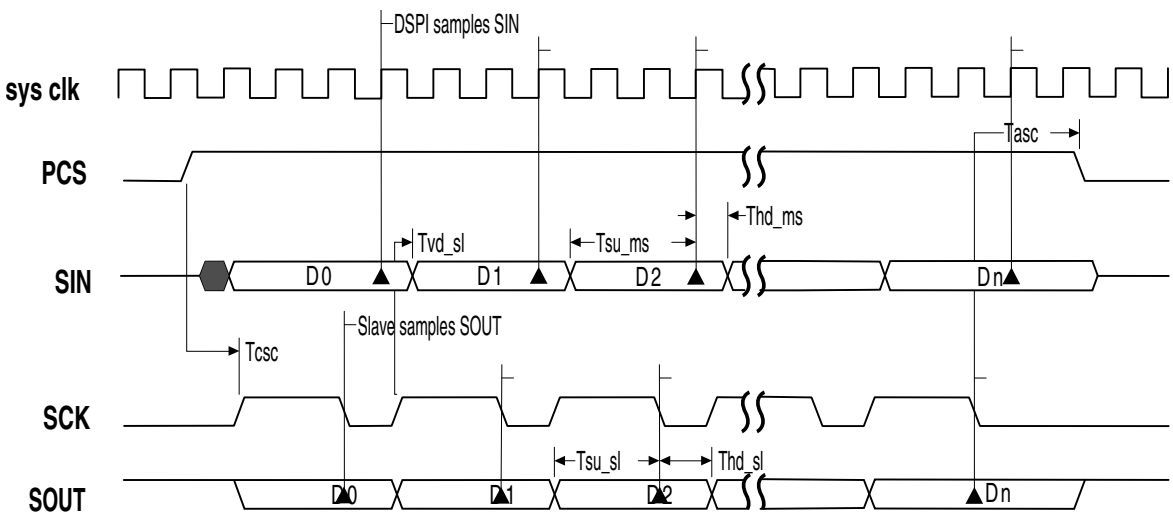

Figure 48-69. DSPI Modified Transfer Format (MTFE=1, CPHA=1, $f_{sck} = f_{sys}/3$)

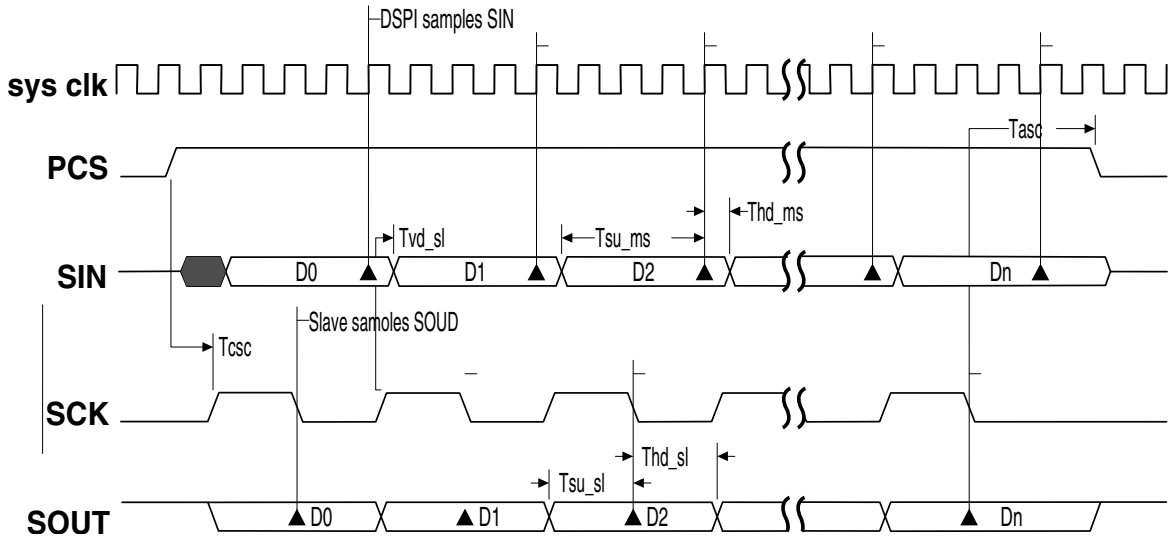

Figure 48-70. DSPI Modified Transfer Format (MTFE=1, CPHA=1, $f_{sck} = f_{sys}/4$)

48.5.6.5 Continuous Selection Format

Some peripherals must be deselected between every transfer. Other peripherals must remain selected between several sequential serial transfers. The Continuous Selection Format provides the flexibility to handle both the following cases. The Continuous Selection Format is enabled for the SPI configuration by setting the CONT bit in the SPI command. Continuous Selection is enabled for the DSI Configuration by setting the DCONT bit in the DSICR0. The behavior of the PCS signals in the two configurations is identical so only SPI configuration will be described.

When the CONT bit = 0, the module drives the asserted Chip Select signals to their idle states in between frames. The idle states of the Chip Select signals are selected by the PCSISn bits in the MCR. The following timing diagram is for two four-bit transfers with CPHA = 1 and CONT = 0.

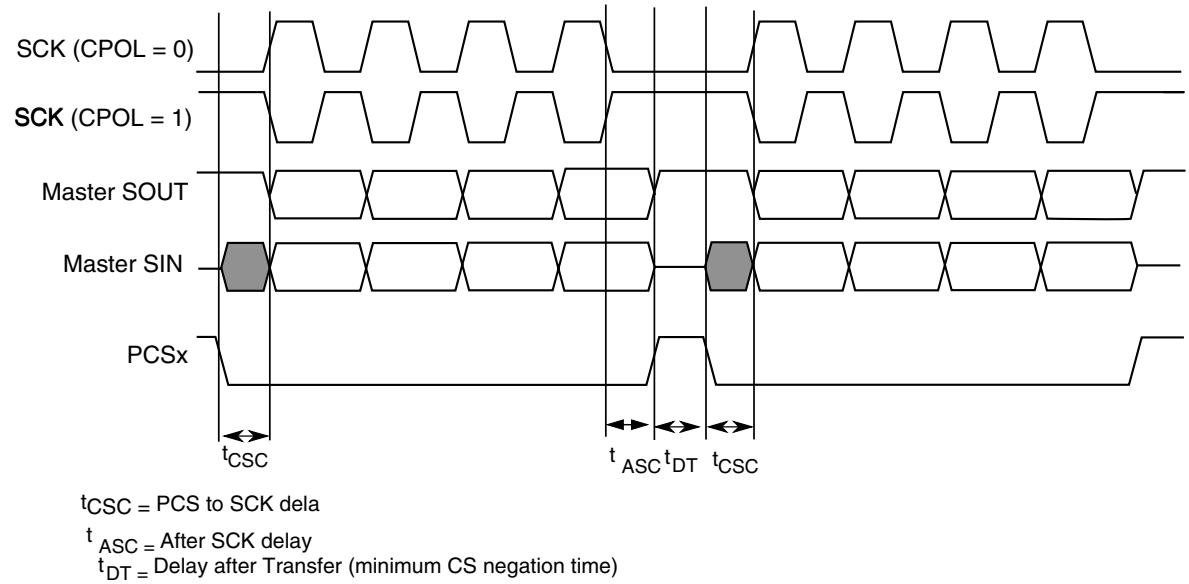

Figure 48-71. Example of non-continuous format (CPHA=1, CONT=0)

When the CONT bit = 1, the PCS signal remains asserted for the duration of the two transfers. The Delay between Transfers (t_{DT}) is not inserted between the transfers. The following figure shows the timing diagram for two four-bit transfers with CPHA = 1 and CONT = 1.

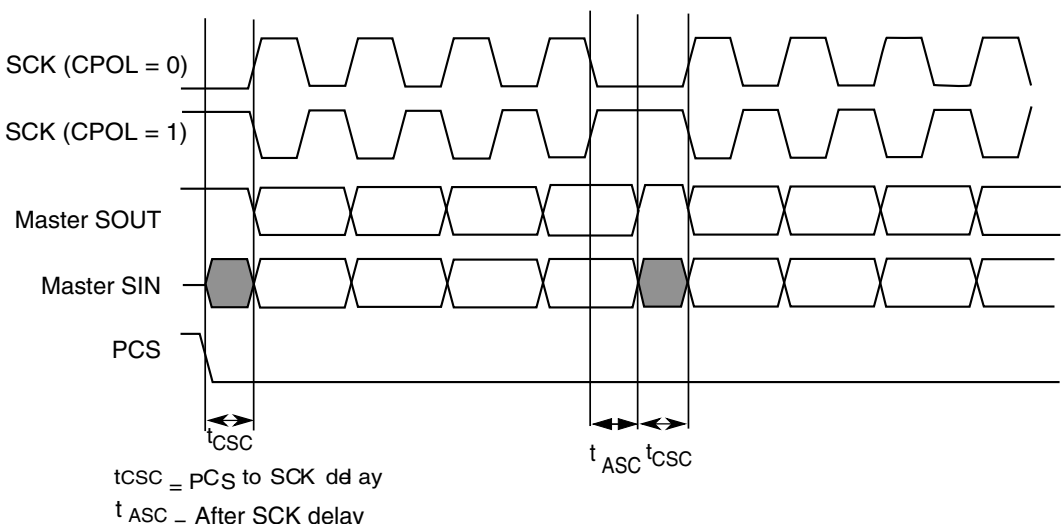

Figure 48-72. Example of continuous transfer (CPHA=1, CONT=1)

When using the module with continuous selection follow these rules:

- All transmit commands must have the same PCSn bits programming.
- The CTARs, selected by transmit commands, must be programmed with the same transfer attributes. Only FMSZ field can be programmed differently in these CTARs.

- When transmitting multiple frames in this mode, the user software must ensure that the last frame has the PUSHR[CONT] bit deasserted in Master mode and the user software must provide sufficient frames in the TX_FIFO to be sent out in Slave mode and the master deasserts the PCSn at end of transmission of the last frame.
- The PUSHR[CONT] / DSICR0[DCONT] bits must be deasserted before asserting MCR[HALT] bit in master mode. This will make sure that the PCSn signals are deasserted. Asserting MCR[HALT] bit during continuous transfer will cause the PCSn signals to remain asserted and hence Slave Device cannot transition from Running to Stopped state.

NOTE

User must fill the TX FIFO with the number of entries that will be concatenated together under one PCS assertion for both master and slave before the TX FIFO becomes empty.

When operating in Slave mode, ensure that when the last entry in the TX FIFO is completely transmitted, that is, the corresponding TCF flag is asserted and TXFIFO is empty, the slave is deselected for any further serial communication; otherwise, an underflow error occurs.

48.5.6.6 Fast Continuous Selection Format

The Fast Continuous Selection Format functions similar to Continuous Selection Format except that the inter command delays, t_{ASC} and t_{CSC}, can be masked out and are not inserted by the hardware.

NOTE

The Fast Continuous Selection Format is available in the SPI configuration only and when Continuous Serial Communication Clock mode is disabled. Masking of delays is not allowed in DSI and CSI configurations or if the transfer is non-continuous.

The Fast Continuous Selection Format is enabled by writing ‘1’ into FCPCS bit of the MCR register. When this bit is asserted, MASC and MCSC bits of the PUSHR register perform the function of mask bits for the transmit frame. These bits individually mask the t_{ASC} and t_{CSC} delays as programmed by the user software. A normal Continuous Selection Format has these two delays for each frame that is transmitted with the CONT

bit asserted. In order to avoid these delays and to speed up the transfer process, the software can simply mask these delays while programming the command in the PUSHR register.

While masking the delays, the software must follow the following masking rules, else correct operation is not guaranteed.

- MASC bit masks the “After SCK” delay for the current frame.
- MCSC bit masks the “PCS to SCK” delay for the next frame.
- “After SCK” (t_{ASC}) delay must not be masked when the current frame is the last frame in the continuous selection format.
- The “PCS to SCK” delay for the first frame in the continuous selection format cannot be masked.
- Masking of only t_{ASC} is not allowed. If t_{ASC} is masked then t_{CSC} must be masked too.
- Masking of both t_{ASC} and t_{CSC} delays is allowed. In this case, the delay between two frames is equal to half the baud rate set by the user software.
- Masking of only t_{CSC} is allowed. In this case, the delay between two frames is equal to the t_{ASC} time and thus the user software must ensure that the t_{ASC} time is greater than the baud rate.
- The user software must not mask these delays if the continuous selection format is not used and MCR[FCPCS] is asserted.
- Rules applicable to the Continuous Selection Format are applicable here too.

The following figure shows the timing for a Fast Continuous Selection Format transfer. Here seven frames are transferred with both t_{ASC} and t_{CSC} delays masked except for the last frame that terminated the transfer. The last frame has t_{ASC} delay at its end.

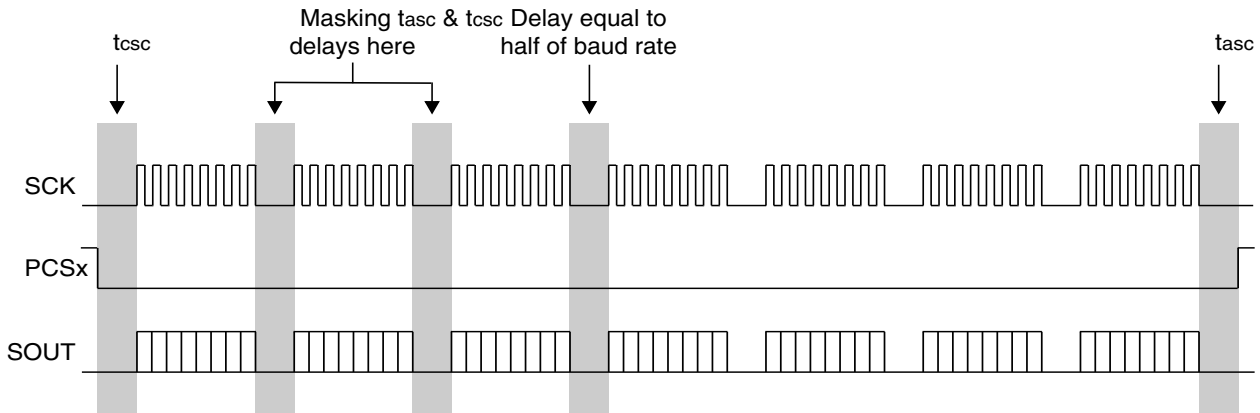

Figure 48-73. Example of Fast Continuous Selection Format

In case any chip select is to be changed, then the fast continuous selection format should be terminated and then the chips selects should change and appropriate delays must be introduced.

48.5.7 Continuous Serial Communications Clock

The module provides the option of generating a Continuous SCK signal for slave peripherals that require a continuous clock.

Continuous SCK is enabled by setting the CONT_SCKE bit in the MCR. Enabling this bit generates the Continuous SCK regardless of the MCR[HALT] bit status. Continuous SCK is valid in all configurations.

Continuous SCK is only supported for CPHA=1. Clearing CPHA is ignored if the CONT_SCKE bit is set. Continuous SCK is supported for Modified Transfer Format.

Clock and transfer attributes for the Continuous SCK mode are set according to the following rules:

- When the module is in SPI configuration, CTAR0 is used initially. At the start of each SPI frame transfer, the CTAR specified by the CTAS for the frame is used.
- When the module is in DSI configuration, the CTAR specified by the DSICTAS field is used at all times.
- When the module is in CSI configuration, the CTAR selected by the DSICTAS field is used initially.

- At the start of a SPI frame transfer, the CTAR specified by the CTAS value for the frame is used.
- At the start of a DSI frame transfer, the CTAR specified by the DSICTAS field is used.

- In all configurations, the currently selected CTAR remains in use until the start of a frame with a different CTAR specified, or the Continuous SCK mode is terminated.

It is recommended to keep the baud rate the same while using the Continuous SCK. Switching clock polarity between frames while using Continuous SCK can cause errors in the transfer. Continuous SCK operation is not guaranteed if the module is put into the External Stop mode or Module Disable mode.

Enabling Continuous SCK disables the PCS to SCK delay and the Delay after Transfer (t_{DT}) is fixed to one SCK cycle. When TSB configuration is enabled the t_{DT} is programmable from 1 to 64 SCK cycles. The following figure is the timing diagram for Continuous SCK format with Continuous Selection disabled.

NOTE

In Continuous SCK mode, for the SPI transfer CTAR0 should always be used, and the TX FIFO must be cleared using the MCR[CLR_TXF] field before initiating transfer.

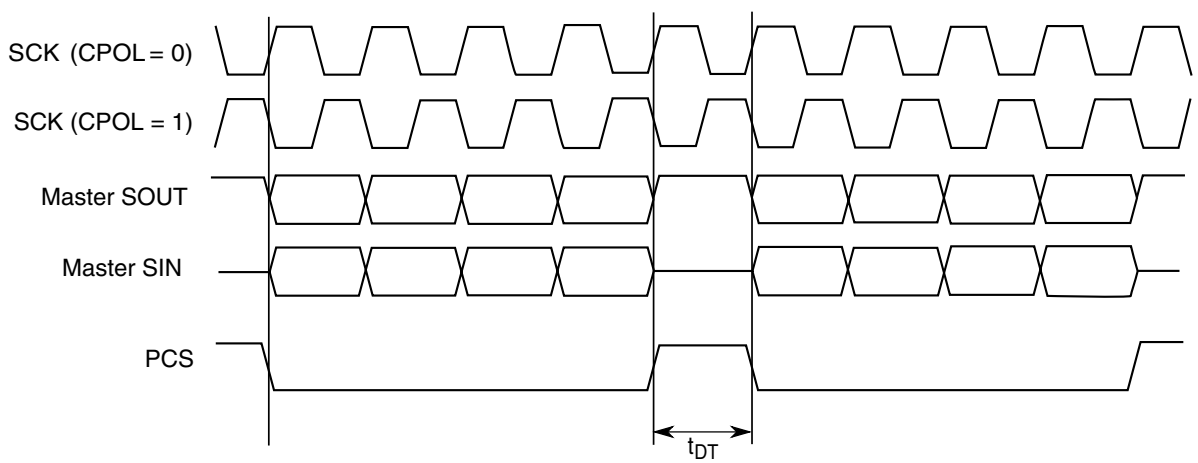

Figure 48-74. Continuous SCK Timing Diagram (CONT=0)

If the CONT bit in the TX FIFO entry is set or the DCONT in the DSICR0 is set, PCS remains asserted between the transfers. Under certain conditions, SCK can continue with PCS asserted, but with no data being shifted out of SOUT, that is, SOUT pulled high. This can cause the slave to receive incorrect data. Those conditions include:

- Continuous SCK with CONT bit set, but no data in the TX FIFO.

- Continuous SCK with CONT bit set and entering Stopped state (refer to Start and Stop of module transfers).
- Continuous SCK with CONT bit set and entering Stop mode or Module Disable mode.

The following figure shows timing diagram for Continuous SCK format with Continuous Selection enabled.

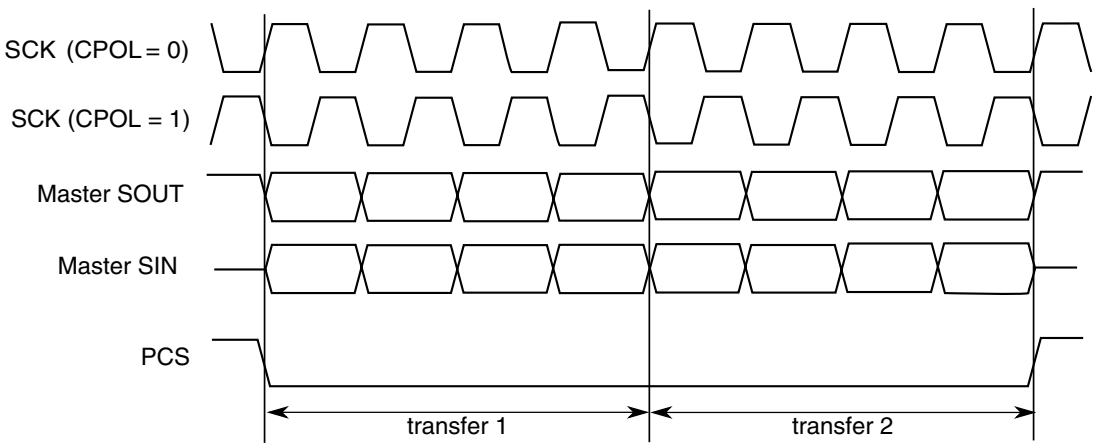

Figure 48-75. Continuous SCK timing diagram (CONT=1)

48.5.8 Slave Mode Operation Constraints

Slave mode logic shift register is buffered. This allows data streaming operation, when the DSPI is permanently selected and data is shifted in with a constant rate.

The transmit data is transferred at second SCK clock edge of the each frame to the shift register if the $\overline{SS}$ signal is asserted and any time when transmit data is ready and $\overline{SS}$ signal is negated.

Received data is transferred to the receive buffer at last SCK edge of each frame, defined by frame size programmed to the CTAR0/1 register. Then the data from the buffer is transferred to the RXFIFO or DDR register.

If the $\overline{SS}$ negates before that last SCK edge, the data from shift register is lost.

48.5.9 Timed Serial Bus (TSB)

The DSPI can be programmed in Timed Serial Bus configuration by setting the TSBC bit in the DSPI_DSICR0 register. See DSPI DSI Configuration Register 0 (DSPI_DSICR0) for details.

TSB configuration provides the Micro Second Channel (MSC) downstream channel support.

The MSC upstream channel is not supported by the DSPI, but can be supported by any available Serial Communication Controller (SCI or UART) in the chip.

The DSI Continuous Frame Selection Format is not supported by the TSB Mode (DSICR0[DCONT] bit cannot not be asserted).

To work in TSB mode the DSPI must be in master mode and in DSI (DCONF = 0b01) or CSI (DCONF = 0b10) configuration. Both Continuous and Non Continuous Serial Communication Clock (controlled by the DSPI_MCR[CONT_SCKE] bit) are supported in the TSB mode.

The following figure shows the signals used in the TSB interface.

In the TSB configuration the DSPI is able to send from 4 to 66 bits MSC data frames (4 to 64 serialized data bits and up to 2 Data Selection zero bits). The serialized data bits source can be either:

- the DSPI DSI Alternate Serialization Data Register (DSPI_ASDR0/1), written by the host software,
- Parallel Input pin states latched into the DSPI DSI Serialization Data Register (DSPI_SDR0/1).

DSPI_DSICR0 TXSS bit or DSPI_SSR0/1 register bits define the source of the data.

The Least Significant Bits of the DSPI_ASDR0 or DSPI_SDR0 registers are selected to be serialized if the data frame is set to less than 32 bits.

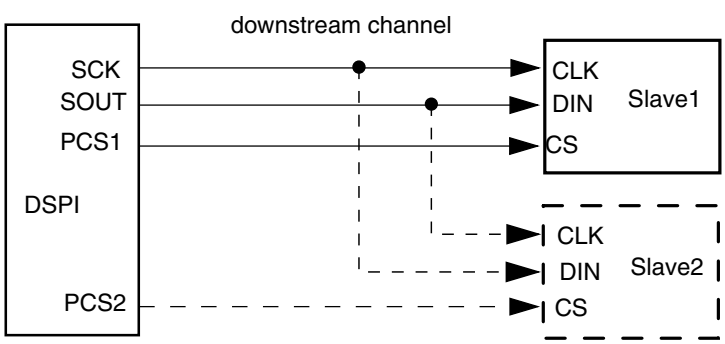

Figure 48-76. DSPI usage in the TSB Configuration

The PCS signals are driven together with SOUT. The t_{CSC} and t_{ASC} delays are not available. Delay after Transfer (DT) is set in SCK clock periods as a binary number formed by concatenation of the DSPI_CTARn PDT and DT fields plus one, allowing to set DT from 1 to 64 serial clock periods. DT field provides least significant bits and PDT field provides most significant bits of the Delay after Transfer.

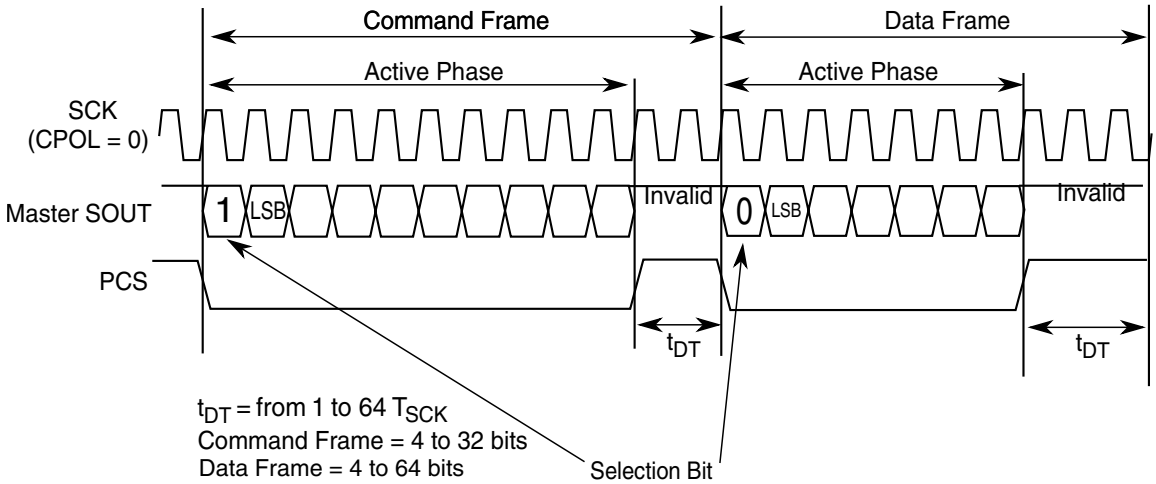

Figure 48-77. TSB Downstream Frames

Above figure shows the two types of MSC downstream frames - command frame, and data frame.

The first transmitted bit, called the selection bit, determines the frame type:

- The selection bit "0" indicates a data frame
- The selection bit "1" indicates a command frame

Data frame may contain up to 2 selection bits to support two external slave devices, (so called dual receiver configuration) or no selection bits at all.

The command frame can be written by software, through SPI TX FIFO, using one or two FIFO entries with help of the CONT bit or MCR[XSPI]. The data frame consists of up to 64 bits from the SDR0/1 or ASDR0/1 registers and up to two selection bits (0). Number of data bits in the data frame is defined by the DSCICR1[TSBCNT] field.

The selection bit of the MSC command frames (1) can be implemented by software.

The selection bits in the data frames are enabled by DSPI_DSICR1 DSE0 and DSE1 bits. Each DSEn bit set increases the data frame size by one bit.

To comply with MSC specification, set DSPI_CTARn[LSBFE] to transmit least significant bit first.

Regardless the LSBFE bit setting, the Data Frame Selection Bits, if enabled, are always transmitted first, before corresponded data sub frames.

48.5.9.1 MSC Dual Receiver Support with PCS Switch Over

When in TSB mode it is possible to switch the set of PCS signals that are driven during the first part of the frame to a different set of PCS signals during the second part of the frame. The bit, at which this switch over occurs, is defined by FMSZ field of the DSPI_CTARn register, selected by DSICTAS field of the DSICR0 register. If DSICR1[DSI64E] is enabled, then the bit at which the PCS switch occurs, is defined by the concatenation of {DSICR0[FMSZ4], CTAR[FMSZ]} fields.

Number of the bits, not including the Data Selection Bit, in the first part of the frame is equal to value of the FMSZ field plus one. (This value changes to {FMSZ4,FMSZ} plus one, when DSICR1[DSI64E] is enabled). During this part of the frame the PCS signal levels are controlled by DSPI_DSICR0 DPCSn bits, after that by DSPI_DSICR1 DPCS1_n bits.

The PCS switch over occurs at driving edge of the SCK clock output.

The second Data Selection Bit is inserted after the PCS switch over if enabled.

Data Frame with PCS switch over is shown in the following figure.

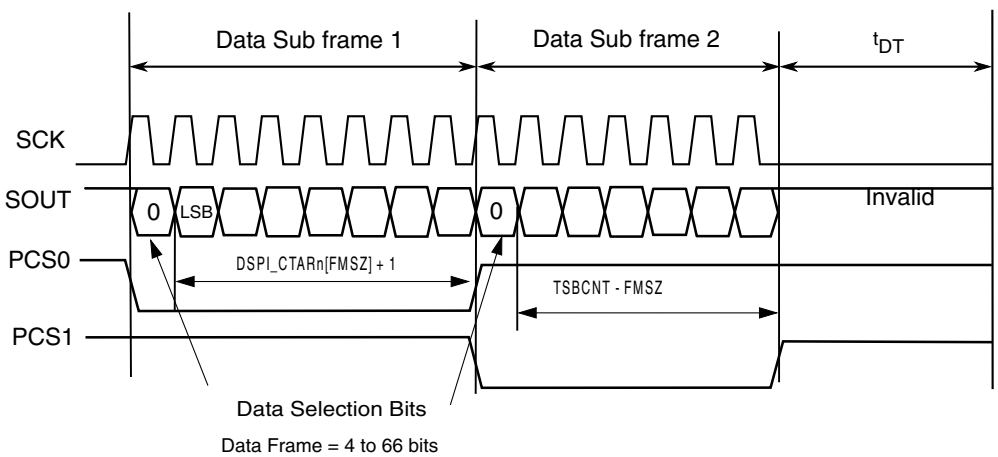

Figure 48-78. TSB Data Frame Format for MSC Dual Receiver Operation

48.5.10 Interleaved TSB (ITSB) Mode

This mode is similar to the TSB mode in some aspects except for the differences mentioned in the table below. The major difference is that the ITSB mode is highly generic in its approach to be compliant with the Downstream operation of the Microsecond Channel Protocol. It includes a triggered time-slot based system with user configurable options for the frames to be transmitted in each time slot. (The time period between any two triggers is known as a time-slot).

The DSPI can be programmed to the ITSB Mode by asserting DSICR0[TSBC], DSICR0[ITSB]. To work in ITSB Mode, the DSPI must be in Master Mode and MCR[DCONF] must be set to CSI mode. (DCONF = 0b01). Both continuous and non-continuous clock serial communication clock (MCR[CONT_SCKE] are supported in this mode. MSC dual receiver support with PCS switchover is also supported in ITSB mode. See MSC Dual Receiver Support with PCS Switch Over for more details.

There are three types of frames which can be transmitted in a time slot i.e. Data Frame, Command Frame and Passive (Idle) frame. Similar to the TSB Mode, SPI frames are used for MSC Command frames, while DSI frames are used for MSC Data frames. A Passive Frame is an Idle frame in which no chip selects are asserted and no data is transmitted. The frame transmission is broadly governed by the following rules:

- Transmission of frames is done on trigger pulses that can be generated internal to the DSPI. The internal trigger is periodic with a period of 4. Thus there are 4 time-slots which appear periodically in the ITSB mode. The frame rules to be followed during each of the 4 time-slots can be programmed via TS_CONF[TSn] fields. The length of each time slot can be programmed via TSL[TSx_LEN] fields. The minimum length of a time slot is governed by the following formulae :
  - Minimum Length for Time slot X = Frame size of the frame to be transmitted in Time slot X + no. of selection bits, if any + 2 (Inherent time(Delay) changed by baud rate(Fp/n)).
  - The above constraint is only true for Data and Command frames. Passive frames do not have a minimum trigger length constraint. The user software shall configure the trigger lengths and trigger source.
- If the previously transmitted frame was a Command (SPI) frame or the TX_FIFO (or CMD FIFO) is empty, the non-passive frame transmitted on a subsequent trigger will not be a command frame.
- If the previously transmitted frame was not a Command (SPI) frame and the TX_FIFO (and CMD FIFO) have sufficient data to allow a SPI frame transmission, the frame transmitted on subsequent trigger can be a Command (SPI) frame.
- A Dual Receiver Frame (DRF) is a single Data (DSI) Frame which is split and transmitted to two different receivers (via occurrence of PCS switchover at the split) - the former part being called DRF1 and the latter part as DRF2 (Dual Receiver Frames 1 & 2). Using TS_CONF[TSn] fields, a time-slot can be programmed to transmit a sole DRF1 or a DRF2 frame. A sole DRF1 frame followed by any other frame is a valid scenario. A DRF2 frame programmed for a time slot is only valid if the immediate previous time-slot was DRF1 - an invalid DRF2 frame, if programmed results in the transmission of a Passive frame (PF).

This mode does not change the way DSI and SPI frame transmissions are done except that ITSB mode interleaves the source (SPI or DSI) with a configurable set of rules based on triggered time-slot system. All features of SPI and DSI mode can be used except for the Continuous Frame Selection format (PUSHR[CONT] and DSICR0[DCONT] bits should not be asserted).

MCR[MTFE] should be set to 0 during ITSB Mode of operation, since MicroSecond Channel upstream operation is not supported.

The following table lists the differences between the TSB and ITSB modes:

Table 48-96. Differences between TSB and ITSB modes

TSB Mode	ITSB Mode
Priority available to frames from SPI. Back to back SPI frames are sent out.	No priority. Messages are interleaved such that there are no back-to-back SPI frames
Selection Bit inserted for DSI frames only. Selection bit for SPI frames is inserted by software.	Selection bit for both DSI and SPI frames inserted automatically. Encoding of selection bit same as TSB mode (0 = DSI; 1 = SPI).
No triggered transmission.	Triggered time-slot based transmission (that is frames are transmitted continuously on every trigger).
Gap between frames is configurable. Time between frames is t_{DT} which is configurable from 1 to 64 baud rate clock cycles.	Gap between frames is configurable and can be introduced in any of the two ways - By programming a Passive Frame or by increasing the length of a time-slot. Time t_{DT} is not used in this mode as it can be made part of the trigger period (as passive time).

In both TSB & ITSB mode, separate frame completion interrupts will be available to indicate frame transmission completion from SPI & DSI frames.

The ITSB mode is suitable to implement the Downstream Channel for the MSC Bus because of the above features.

48.5.10.1 Configuring DSPI for ITSB mode

The following steps give the recommended way to initialize the DSPI for the ITSB mode of operation:

- The DSPI should be put in HALT mode (by asserting the MCR[HALT] bit) before programming the registers.
- Set the DSICR0[TSBC] and DSICR0[ITSB] bits. The DSICR0[TRRE] and DSICR0[CID] bits should be cleared. DSICR0[DCONT] and PUSHR[CONT] should not be used in ITSB mode. The bit MCR[MTFE] should be cleared as

Upstream operation is not supported in ITSB Mode. If DSICR0[ITSB] bit is set without setting DSICR0[TSBC], then the DSPI operates in the Normal Mode depending on MCR[DCONF] bit.

- Configure the Time Slot Length's via TSL register and the frame rules for each time slot via TS_CONF register.
- Based on trigger source requirements, set the values in the DSICR0[TRG] bit.
- Enable frame completion interrupts for either any frame completion (TCF) or separate frame complete (DSITCF and SPITCF) as required by application.
- When remainder configuration of DSPI is complete, clear the MCR[HALT] bit to allow DSPI to start operations.

Once configured and DSPI is brought out of HALT, the ITSB mode shall start sequencing the frames from either DSI or SPI as per the rules mentioned in Interleaved TSB (ITSB) Mode.

48.5.10.2 Variable Length Time Slots

In the Interleaved TSB Mode, the TSL[TSx_LEN] registers are used to configure the time slot length's as required by the application. There are up to 4 time slots named TS0, TS1, TS2 and TS3 respectively, which repeat periodically. To achieve a periodicity less than 4, any time slot length can be programmed as 0 (which eliminates this time slot). The following figures illustrate this concept.

In the figure below, the fields TSL[TSx_LEN] are programmed to be non-zero for x = 0,1,2,3. Hence, the time slots repeat after every 4 trigger pulses as shown.

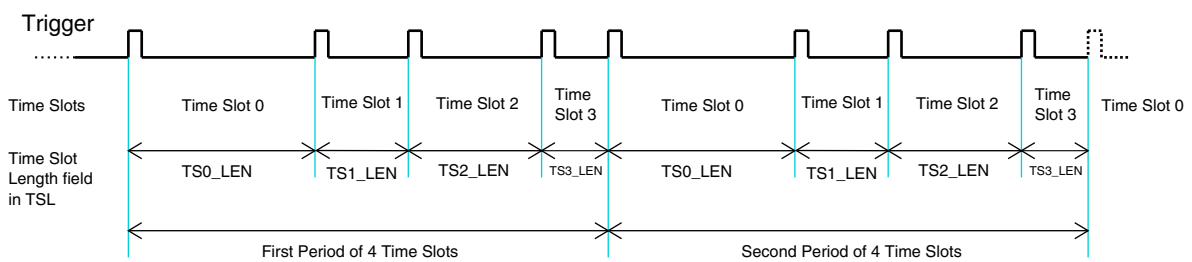

Figure 48-79. Periodic Time Slots with period = 4

In the figure below, the fields TSL[TSx_LEN] are programmed to be non-zero for x = 0,1,2, while TSL[TS3_LEN] = 0. Hence, the time slots repeat after every 3 trigger pulses as shown.

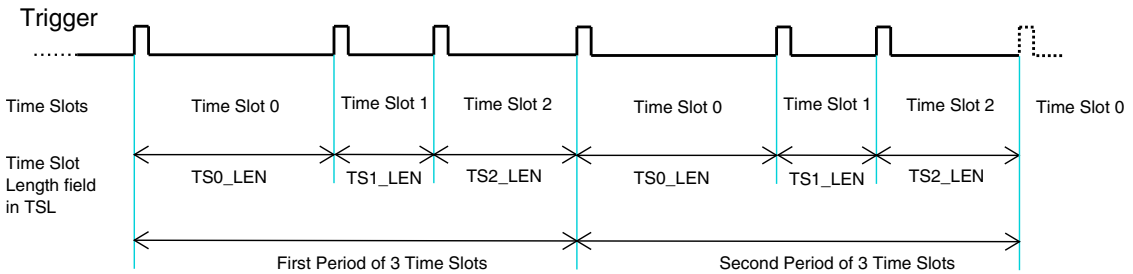

Figure 48-80. Periodic Time Slots with period = 3

The following figure shows time slots with periodicity of 1. Here the fields TSL[TSx_LEN] are programmed to zero for x = 1,2 and 3 while TSL[TS0_LEN] is non-zero. Hence, the time slots repeat after every trigger as shown.

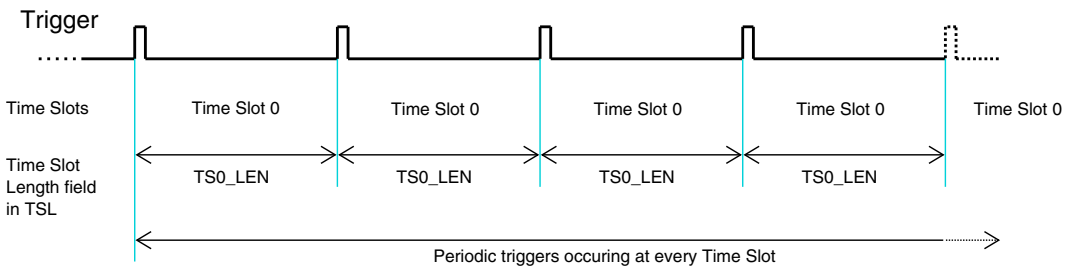

Figure 48-81. Periodic Time Slots with period = 1

Similarly, any TSL[TSx_LEN] can be made 0 to vary periodicity of time slots, but it is an illegal scenario to have all TSL[TSx_LEN] fields as 0.

NOTE

If external triggering mechanism is enabled (DSICR[TRG] is set), then it must be ensured that the minimum distance between two trigger pulses is at least 5P, where P is the protocol clock period.

When internal triggering mechanism is enabled (DSICR[TRG] is zero), the minimum value which can be programmed in the field TSL[TSx_LEN] is given by L = F + 1 + m; where F is the frame size of the frame programmed to be transmitted for the time slot TSx. The variable 'm' equals 1 when maximum baud rate is programmed (i.e. SCK = protocol clock frequency/ 2) and 0 otherwise.

48.5.10.3 Using ITSB mode for MSC Downstream Channel

MSC Downstream Channel uses three types of frames: command frames, data frames and passive frames. The Downstream operation of these frames require:

- Data frames can be sent back to back.
- Back to back command frames are not a legal scenario.
- Passive frames are used when no activity is desired for any time slot. In a passive frame, chip selects are de-asserted, and no SCK or data is transmitted. For this reason Command Frames cannot be separated by Passive frames as it would still be an illegal scenario.
- In dual MSC ASIC, some bits of the data frame goes to first ASIC and remainder bits to second ASIC. The first part is referred to as DRF1 (Dual Receiver Frame 1) and the second part as DRF2 (Dual Receiver Frame 2).
- A DRF2 programmed for a time slot is only valid if the immediately preceding time slot was DRF1. If DRF2 is valid, it would be transmitted seamlessly after DRF1 without waiting for the trigger pulse for the time slot of DRF2. For that reason, the TSL[TSx_LEN] for DRF1 must be programmed to the minimum possible value. If DRF2 is not valid, a Passive Frame is transmitted instead.

The ITSB mode can help implement the MSC Downstream Channel by allowing the command frames to be sent via the SPI interface and data frames to be sent via the DSI interface. Once the DSPI has been configured to work in ITSB mode (See Configuring DSPI for ITSB mode), the user software can program the DSI and SPI sides to send data and command frames respectively. The programming of frames for transmission via DSI or SPI is same as explained in Combined Serial Interface (CSI) Configuration.

The following figure shows a sample MSC Downstream transmission for the ITSB mode with the following configuration:

- All TSL[LEN] are programmed to be non-zero. Note that the length between triggers are not drawn to scale in the figure. The lengths of all 4 time slots shown are unequal.
- Data and Command selection bits are enabled, i.e. DSICR1[DSE0] and DSICR1[CSE] are set.
- TS_CONF[TS0] = CMD_SRDF
- TS_CONF[TS1] = CMD_SRDF
- TS_CONF[TS2] = CMD_PF
- TS_CONF[TS3] = CMD_SRDF
- PCS0 is used for Data Frames while PCS1 is used for Command Frames. Both chip select's are active low.

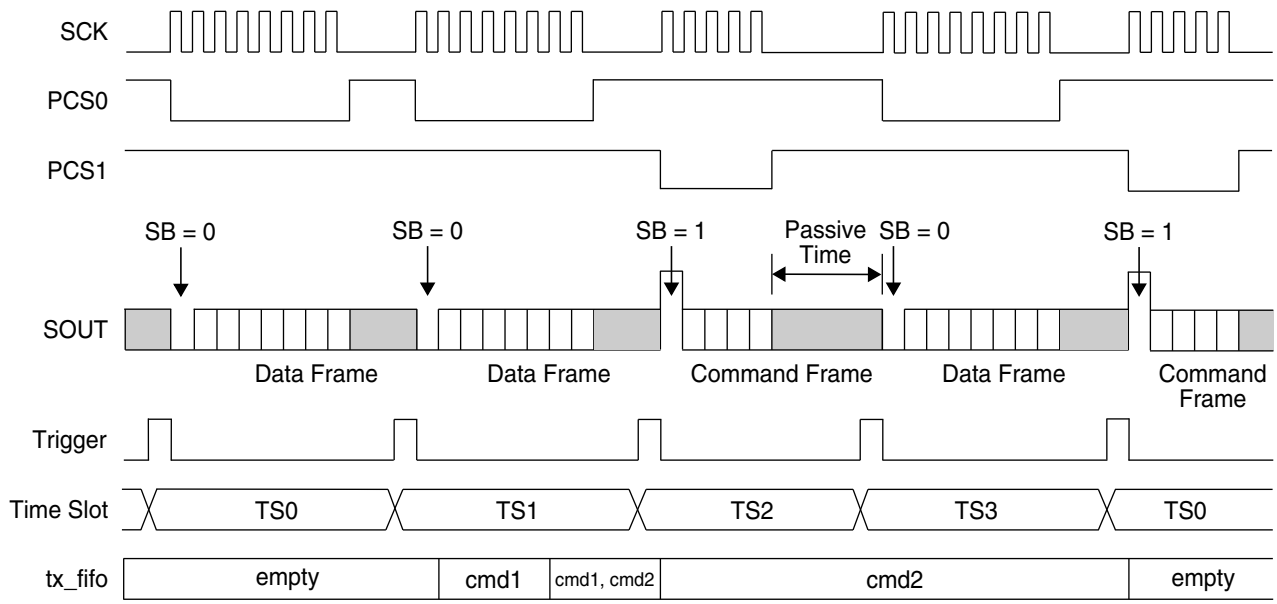

Figure 48-82. Sample MSC Downstream transmission using ITSB mode

Brief description of operation includes:

- At the first trigger, TS0 is initiated. The frame rule for TS0 is configured as CMD_SRDF (Command if valid, else Single Receiver Data Frame). Since there is no data present in the TXFIFO, a valid command frame is not available to be transmitted. Hence a single receiver data frame is transmitted instead.
- The second trigger initiates TS1. Again a single receiver data frame is transmitted since the frame rule for TS1 is programmed to CMD_SRDF and a command frame is not valid as there is no data present in the TXFIFO when TS1 is initiated.
- During TS1, two frames are pushed into the TX_FIFO.
- At third trigger, TS2 is initiated , the frame rule for which is programmed to CMD_PF (Command if valid. else Passive Frame). A Command frame is transmitted as the TX_FIFO is not empty.
    - Since the frame size of the command frame is less than the trigger length for TS2, no transmission happens till next trigger. This is marked as the “Passive Time”. Such passive time exists in all frames after frame transmission completes and until next trigger pulse is detected.
- For TS3, the frame rule programmed is CMD_SRDF. Since the previous transmission was a command frame, a single receiver data frame is transmitted during TS3.

- The time slot TS0 repeats, and this time a command frame is transmitted during TS0 since the Command Frame is eligible to be transmitted.
- At sixth trigger (not shown), TS1 occurs and the process continues.

The figure below shows another sample MSC Downstream transmission for the ITSB mode with the following configuration:

- All TSL[LEN] are programmed to be non-zero. Note that the length between triggers are not drawn to scale in the figure. The lengths of all 4 time slots shown are unequal.
- Data and Command selection bits are enabled, i.e. DSICR1[DSE0] and DSICR1[CSE] are set.
- TS_CONF[TS0] = CMD_DRF1
- TS_CONF[TS1] = DRF2
- TS_CONF[TS2] = CMD_DRF1
- TS_CONF[TS3] = CMD_DRF2
- PCS0 is used for DRF1 while PCS1 is used for DRF2 or Command Frames. Both chip select's are active low.

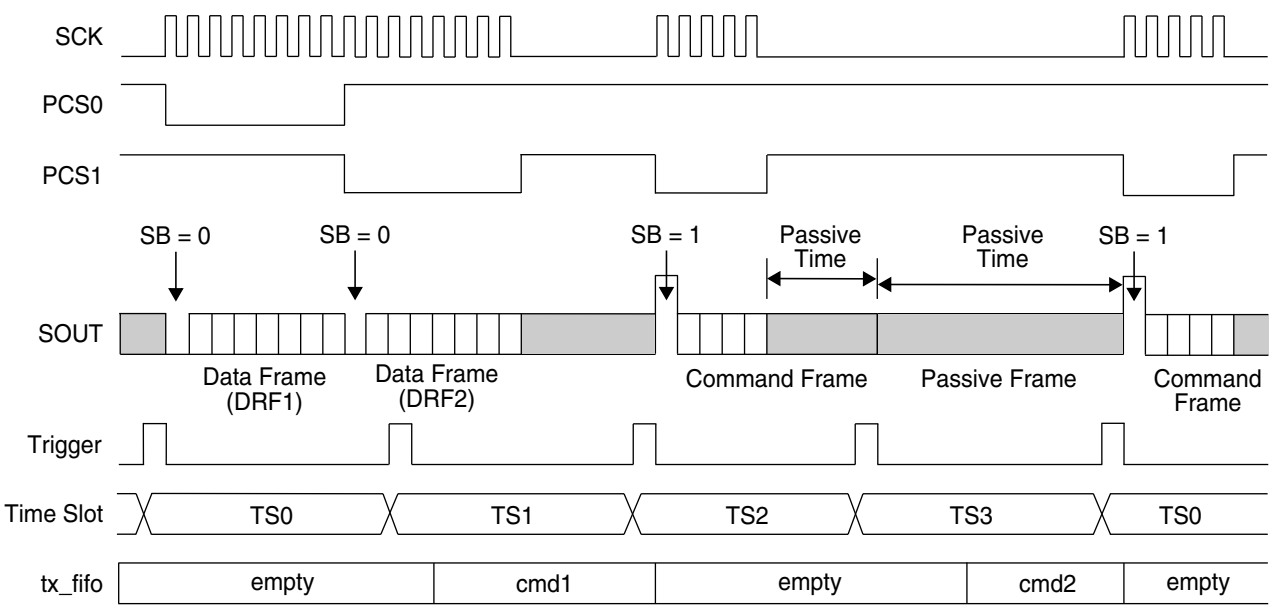

Figure 48-83. Sample MSC Downstream transmission using ITSB mode

Brief description of operation includes:

- At the first trigger, TS0 is initiated. The frame rule for TS0 is configured as CMD_DRF1 (Command if valid, else Dual Receiver Frame 1). Since there is no data present in the TXFIFO, a valid command frame is not available to be transmitted. Hence DRF1 is selected for transmission. Now it is checked if the next trigger is DRF2 which is true and hence DRF1 and DRF2 are transmitted back-to-back seamlessly with the PCS switch-over occurring in between. Note that this happens independent of the next trigger. If the next trigger were configured to CMD_DRF2 instead, then at the current trigger, the validity of CMD is checked to confirm the presence of DRF2 for next trigger. If presence of DRF2 is confirmed for next trigger, it is transmitted along with DRF1 seamlessly as shown here, otherwise only DRF1 would be transmitted in the current trigger and the CMD frame would be transmitted in the next trigger.
- During TS1, one frame is pushed into the TX_FIFO.
- Since DRF2 is transmitted immediately after DRF1, the occurrence second trigger does not cause any operation. Hence it must be ensured by the user that Trigger Length of TS0 must be programmed to minimum possible value - during which DRF1 can be successfully transmitted. This ensures that trigger for TS1 occurs sometime after the switch-over and not after DRF2 has been transmitted.
- The third trigger initiates TS2, the frame rule for which is configured as CMD_DRF1. A Command frame is transmitted as the data required to transmit a command frame is available (TX_FIFO and CMD_FIFO is not empty) and the previous transmitted frame was not a command frame.
- The fourth trigger initiates TS3, the frame rule for which is configured as CMD_DRF1. Since a CMD frame isn't available and DRF2 is not valid (since DRF1 wasn't transmitted in the previous trigger), a passive frame is transmitted instead.
- The time slot TS0 repeats, and this time a command frame is transmitted during TS0 since the Command Frame is eligible to be transmitted.
- At sixth trigger (not shown), TS1 occurs and the process continues.

NOTE

For a command/data frame to be transmitted on a trigger, they should be available some time before the occurrence of the trigger. A DSI frame must be updated/present "X" time units before the occurrence of the trigger for the time slot in which this data is to be transmitted. This is true for all DSI frames and also implies that when DRF1 and DRF2 are positioned to be

transmitted seamlessly, both DRF1 and DRF2 frames must be available 'X' time units before occurrence of trigger pulse for the time slot of DRF1 itself.

Similarly, a command frame must be available "Y" time units before the occurrence of the trigger for the time slot in which this data is to be transmitted.

Here X = 2R + 1P and Y = 1R + 3P; where R = register clock period, P = protocol clock period.

48.5.11 Parity Generation and Check

The module can generate and check parity in the serial frame. The parity bit replaces the last transmitted bit in the frame. The parity is calculated for all transmitted data bits in frame, not including the last data bit that would be transmitted. The parity generation/ control is done on frame basis. The registers field setting frame size defines the total number of bits in the frame, including the parity bit. Thus, to transmit/receive the same number of data bits with parity check, increase the frame size by one versus the same data size frame without the parity check.

Parity can be selected as odd or even. Parity Errors in the received frame set Parity Error flags in the Status register. The Parity Error Interrupt Requests are generated if enabled. The module can be programmed to stop SPI or/and DSI frame transmission in case of a frame reception with parity error.

48.5.11.1 Parity for SPI Frames

When the module is in the master mode the parity generation is controlled by PE and PP bits of the CMD FIFO entries (PUSHR). Setting the PE bit enables parity generation for transmitted SPI frames and parity check for received frames. PP bit defines polarity of the parity bit.

When continuous PCS selection is used to transmit SPI data, two parity generation scenarios are available:

- Generate/check parity for the whole frame
- Generate/check parity for each sub-frame separately.

To generate/check parity for the whole frame set PE bit only in the last command/TX FIFO entry, forming this frame (with the PUSHR register).

To generate/check parity for each sub-frame set PE bit in each command/TX FIFO entry, forming this frame.

If the parity error occurs for received SPI frame, the SR[SPEF] bit is set. If MCR[PES] bit is set, the module stops SPI frames transmission. To resume SPI operation clear the SR[SPEF] or the MCR[PES] bits.

In slave mode the parity is controlled by the PE and PP bits of the CTAR0 register similar to the master mode parity generation without continuous PCS selection.

48.5.11.2 Parity for DSI Frames

When DSPI is in Master Mode, parity generation is controlled by PE and PP bits of the DSPI_DSICR0 register similar to the SPI frames. The parity is calculated and checked for each DSI frame. DSPI_DSICR0[DCONT] bit has no effect on parity generation. In slave mode the parity is controlled by the PE and PP bits of the CTAR1 register.

If the parity error occurs for received DSI frame, the DSPI_SR[DPEF] bit is set. If DSPI_DSICR0[PES] bit is set, the DSPI stops DSI frames transmission. To resume DSI operation clear the DSPI_SR[DPEF] or the DSPI_DSICR0[PES] bits.

48.5.12 Interrupts/DMA requests

The module has several conditions that can generate only interrupt requests and two conditions that can generate interrupt or DMA requests. The following table lists these conditions.

Table 48-97. Interrupt and DMA request conditions

Condition	Flag	Interrupt	DMA
End of Queue (EOQ)	EOQF	Yes	-
TX FIFO Fill	TFFF	Yes	Yes
CMD FIFO Fill	CMDFFF	Yes	Yes
TX FIFO Invalid Write	TFIWF	Yes	-
Transfer Complete	TCF	Yes	-
CMD Transfer Complete	CMDTCF	Yes	-
SPI Transfer Complete	SPITCF	Yes	-
DSI Transfer Complete	DSITCF	Yes	-
TX FIFO Underflow	TFUF	Yes	-
RX FIFO Drain	RFDF	Yes	Yes
RX FIFO Overflow	RFOF	Yes	-
SPI Parity Error	SPEF	Yes	-

Table continues on the next page...

Table 48-97. Interrupt and DMA request conditions (continued)

Condition	Flag	Interrupt	DMA
DSI Parity Error	DPEF	Yes	-
DSI Deserialized Data Match	DDIF	Yes	Yes

Each condition has a flag bit in the module Status Register (SR) and a Request Enable bit in the DMA/Interrupt Request Select and Enable Register (RSER). Certain flags (as shown in above table) generate interrupt requests or DMA requests depending on configuration of RSER register.

The module also provides a global interrupt request line, which is asserted when any of individual interrupt requests lines is asserted.

48.5.12.1 End of Queue Interrupt Request

The End of Queue Request indicates that the end of a transmit queue is reached. The End of Queue Request is generated when the EOQ bit in the executing SPI command is set and the EOQF_RE bit in the RSER is set.

When MCR[XSPI] is enabled and the EOQ bit in the executing SPI command is set, the End of Queue Request will only be generated once the last bit of the last Data frame in the Command Cycle has been transmitted.

NOTE

When MCR[XSPI] is disabled, this interrupt request is generated when the last bit of the SPI frame with EOQ bit set is transmitted.

48.5.12.2 Transmit FIFO Fill Interrupt or DMA Request

The Transmit FIFO Fill Request indicates that the TX FIFO is not full. The Transmit FIFO Fill Request is generated when the number of entries in the TX FIFO is less than the maximum number of possible entries, and the TFFF_RE bit in the RSER is set. The TFFF_DIRS bit in the RSER selects whether a DMA request or an interrupt request is generated.

NOTE

TFFF flag clears automatically when DMA is used to fill TX FIFO.

To clear TFFF when not using DMA, follow these steps for every PUSH performed using CPU to fill TX FIFO:

1. Wait until TFFF = 1.
2. Write data to PUSHR using CPU.
3. Clear TFFF by writing a 1 to its location. If TX FIFO is not full, this flag will not clear.

48.5.12.3 Command FIFO Fill Interrupt or DMA Request

The Command FIFO Fill Request indicates that the CMD FIFO is not full. The Command FIFO Fill Request is generated when the number of entries in the CMD FIFO is less than the maximum number of possible entries, and the CMDFFF_RE bit in the RSER is set. The CMDFFF_DIRS bit in the RSER selects whether a DMA request or an interrupt request is generated.

This Request is useful when MCR[XSPI] is enabled, since TX FIFO and CMD FIFO can be filled independently. If MCR[XSPI] is disabled, then 'TX FIFO Fill Interrupt or DMA Request' will suffice to fill both FIFO's since both FIFO's must be filled simultaneously.

NOTE

CMDFFF flag clears automatically when DMA is used to fill CMDFIFO.

To clear CMDFFF when not using DMA, follow these steps for every PUSH performed using CPU to fill CMDFIFO:

1. Wait until CMDFFF = 1
2. Write data to PUSHR using CPU.
3. Clear CMDFFF by writing a 1 to its location. If CMD FIFO is not full, this flag will not clear.

48.5.12.4 Transmit FIFO Invalid Write Interrupt Request

The Transmit FIFO Invalid Write Request is valid only when MCR[XSPI] is enabled. This Request indicates that Data exists in the TX FIFO while the CMD FIFO is empty. Since no Command Fields are associated with the Data present in TX FIFO, this data is considered invalid until a Command Entry becomes available. The Transmit FIFO Invalid Write Request is generated for the above condition when TFIWF_RE bit is set in the RSER.

48.5.12.5 Transfer Complete Interrupt Request

The Transfer Complete Request indicates the end of the transfer of a serial frame. The Transfer Complete Request is generated at the end of each frame transfer when the TCF_RE bit is set in the RSER.

48.5.12.6 Command Transfer Complete Interrupt Request

The Command Transfer Complete Request indicates the end of transfer of the last SPI frame in a Command Cycle. The Transfer Complete Request is generated for the above condition when the CMDTCF_RE bit is set in the RSER.

48.5.12.7 SPI Transfer Complete Interrupt Request

The SPI Transfer Complete Request indicates the end of transfer of an SPI frame in any Transmission Mode which uses DSPI in CSI Mode. The SPI Transfer Complete Request is generated when SR[SPITCF] flag asserts and SPITCF_RE bit is set in the RSER.

48.5.12.8 DSI Transfer Complete Interrupt Request

The DSI Transfer Complete Request indicates the end of transfer of a DSI frame in any Transmission Mode which uses DSPI in CSI Mode. The DSI Transfer Complete Request is generated when SR[DSITCF] flag asserts and DSITCF_RE bit is set in the RSER.

48.5.12.9 Transmit FIFO Underflow Interrupt Request

The Transmit FIFO Underflow Request indicates that an underflow condition in the TX FIFO has occurred. The transmit underflow condition is detected only for the module operating in Slave mode and SPI configuration. The TFUF bit is set when the TX FIFO of a DSPI is empty, and a transfer is initiated from an external SPI master. If the TFUF bit is set while the TFUF_RE bit in the RSER is set, an interrupt request is generated.

48.5.12.10 Receive FIFO Drain Interrupt or DMA Request

The Receive FIFO Drain Request indicates that the RX FIFO is not empty. The Receive FIFO Drain Request is generated when the number of entries in the RX FIFO is not zero, and the RFDF_RE bit in the RSER is set. The RFDF_DIRS bit in the RSER selects whether a DMA request or an interrupt request is generated.

48.5.12.11 Receive FIFO Overflow Interrupt Request

The Receive FIFO Overflow Request indicates that an overflow condition in the RX FIFO has occurred. A Receive FIFO Overflow request is generated when RX FIFO and shift register are full and a transfer is initiated. The RFOF_RE bit in the RSER must be set for the interrupt request to be generated.

Depending on the state of the ROOE bit in the MCR, the data from the transfer that generated the overflow is either ignored or shifted in to the shift register. If the ROOE bit is set, the incoming data is shifted in to the shift register. If the ROOE bit is cleared, the incoming data is ignored.

48.5.12.12 SPI Frame Parity Error Interrupt Request

The SPI Frame Parity Error Flag indicates that a SPI frame with parity error had been received. The SPEF_RE bit in the RSER must be set for the interrupt request to be generated.

48.5.12.13 DSI Frame Parity Error Interrupt Request

The DSI Frame Parity Error Flag indicates that a DSI frame with parity error has been received. The DPEF_RE bit in the DSPI_RSER must be set for the interrupt request to be generated.

48.5.12.14 Deserialized Data Match Interrupt or DMA Request

The Deserialized Data Match Flag (DDIF) indicates that a DSI frame matches DSPI_DPIR0/1 data, masked with DSPI_DIMR0/1, had been received. This Request is generated if DDIF_RE bit in the DSPI_RSER is set. The DDIF_DIRS bit in the RSER selects whether a DMA request or an interrupt request is generated.

48.5.13 Power saving features

The module supports following power-saving strategies:

- External Stop mode
- Module Disable mode – Clock gating of non-memory mapped logic

48.5.13.1 Stop mode (External Stop mode)

The DSPI supports the Stop mode protocol. When a request is made to enter External Stop mode, the DSPI block acknowledges the request. If a serial transfer is in progress, the DSPI waits until it reaches the frame boundary before it is ready to have its clocks shut off. While the clocks are shut off, the DSPI memory-mapped logic is not accessible. This also puts the DSPI in STOPPED state. The SR[TXRXS] bit is cleared to indicate STOPPED state. The states of the interrupt and DMA request signals cannot be changed while in External Stop mode.

48.5.13.2 Module Disable mode

Module Disable mode is a block-specific mode that the module can enter to save power. Host CPU can initiate the Module Disable mode by setting the MDIS bit in the MCR. The Module Disable mode can also be initiated by hardware.

When the MDIS bit is set, the module negates Clock Enable signal at the next frame boundary. Once the Clock Enable signal is negated, it is said to have entered Module Disable Mode. This also puts the module in STOPPED state. The SR[TXRXS] bit is cleared to indicate STOPPED state.If implemented, the Clock Enable signal can stop the clock to the non-memory mapped logic. When Clock Enable is negated, the module is in a dormant state, but the memory mapped registers are still accessible. Certain read or write operations have a different effect when the module is in the Module Disable mode. Reading the RX FIFO Pop Register does not change the state of the RX FIFO. Similarly, writing to the PUSHR Register does not change the state of the TX FIFO or CMD FIFO. Clearing either of the FIFOs has no effect in the Module Disable mode. Changes to the DIS_TXF and DIS_RXF fields of the MCR have no effect in the Module Disable mode. In the Module Disable mode, all status bits and register flags in the module return the correct values when read, but writing to them has no effect. Writing to the TCR during Module Disable mode has no effect. Interrupt and DMA request signals cannot be cleared while in the Module Disable mode.

48.6 Initialization/application information

This section describes how to initialize the module.

48.6.1 How to manage queues

The queues are not part of the module, but it includes features in support of queue management. Queues are primarily supported in SPI configuration.

1. When module executes last command word from a queue, the EOQ bit in the command word is set to indicate it that this is the last entry in the queue.
2. At the end of the transfer, corresponding to the command word with EOQ set is sampled, the EOQ flag (EOQF) in the SR is set.
3. The setting of the EOQF flag disables serial transmission and reception of data, putting the module in the Stopped state. The TXRXS bit is cleared to indicate the Stopped state.
4. The DMA can continue to fill TX FIFO until it is full or step 5 occurs.
5. Disable DMA transfers by disabling the DMA enable request for the DMA channel assigned to TX FIFO (and CMD FIFO) and RX FIFO. This is done by clearing the corresponding DMA enable request bits in the DMA Controller.
6. Ensure all received data in RX FIFO has been transferred to memory receive queue by reading the RXCNT in SR or by checking RFDF in the SR after each read operation of the POPR.
7. Modify DMA descriptor of TX and RX channels for new queues
8. Flush TX FIFO (and CMD FIFO) by writing a 1 to the CLR_TXF bit in the MCR. Flush RX FIFO by writing a '1' to the CLR_RXF bit in the MCR.
9. Clear transfer count either by setting CTCNT bit in the command word of the first entry in the new queue or via CPU writing directly to SPI_TCNT field in the TCR.
10. Enable DMA channel by enabling the DMA enable request for the DMA channel assigned to the module TX FIFO,(and CMD FIFO) and RX FIFO by setting the corresponding DMA set enable request bit.
11. Enable serial transmission and serial reception of data by clearing the EOQF bit.

48.6.2 Switching Master and Slave mode

When changing modes in the module, follow the steps below to guarantee proper operation.

1. Halt it by setting MCR[HALT].
2. Clear the transmit and receive FIFOs by writing a 1 to the CLR_TXF and CLR_RXF bits in MCR.
3. Set the appropriate mode in MCR[MSTR] and enable it by clearing MCR[HALT].

48.6.3 Initializing Module in Master/Slave Modes

Once the appropriate mode in MCR[MSTR] is configured, the module is enabled by clearing MCR[HALT]. It should be ensured that module Slave is enabled before enabling it's Master. This ensures the Slave is ready to be communicated with, before Master initializes communication.

48.6.4 Baud rate settings

The following table shows the baud rate that is generated based on the combination of the baud rate prescaler PBR and the baud rate scaler BR in the CTARs. The values calculated assume a 100 MHz protocol frequency and the double baud rate DBR bit is cleared.

Table 48-98. Baud rate values (bps)

		Baud rate divider prescaler values			
		2	3	5	7
Baud Rate Scaler Values	2	25.0M	16.7M	10.0M	7.14M
	4	12.5M	8.33M	5.00M	3.57M
	6	8.33M	5.56M	3.33M	2.38M
	8	6.25M	4.17M	2.50M	1.79M
	16	3.12M	2.08M	1.25M	893k
	32	1.56M	1.04M	625k	446k
	64	781k	521k	312k	223k
	128	391k	260k	156k	112k
	256	195k	130k	78.1k	55.8k
	512	97.7k	65.1k	39.1k	27.9k
	1024	48.8k	32.6k	19.5k	14.0k
	2048	24.4k	16.3k	9.77k	6.98k
	4096	12.2k	8.14k	4.88k	3.49k
	8192	6.10k	4.07k	2.44k	1.74k
	16384	3.05k	2.04k	1.22k	872
	32768	1.53k	1.02k	610	436

48.6.5 Delay settings

The following table shows the values for the Delay after Transfer (t_{DT}) and CS to SCK Delay (T_{CSC}) that can be generated based on the prescaler values and the scaler values set in the CTARs. The values calculated assume a 100 MHz protocol frequency.

NOTE

The clock frequency mentioned above is given as an example in this chapter. See the clocking chapter for the frequency used to drive this module in the device.

This table does not apply for TSB Continuous mode.

Table 48-99. Delay values

		Delay prescaler values			
		1	3	5	7
Delay scaler values	2	20.0 ns	60.0 ns	100.0 ns	140.0 ns
	4	40.0 ns	120.0 ns	200.0 ns	280.0 ns
	8	80.0 ns	240.0 ns	400.0 ns	560.0 ns
	16	160.0 ns	480.0 ns	800.0 ns	1.1 µs
	32	320.0 ns	960.0 ns	1.6 µs	2.2 µs
	64	640.0 ns	1.9 µs	3.2 µs	4.5 µs
	128	1.3 µs	3.8 µs	6.4 µs	9.0 µs
	256	2.6 µs	7.7 µs	12.8 µs	17.9 µs
	512	5.1 µs	15.4 µs	25.6 µs	35.8 µs
	1024	10.2 µs	30.7 µs	51.2 µs	71.7 µs
	2048	20.5 µs	61.4 µs	102.4 µs	143.4 µs
	4096	41.0 µs	122.9 µs	204.8 µs	286.7 µs
	8192	81.9 µs	245.8 µs	409.6 µs	573.4 µs
	16384	163.8 µs	491.5 µs	819.2 µs	1.1 ms
	32768	327.7 µs	983.0 µs	1.6 ms	2.3 ms
	65536	655.4 µs	2.0 ms	3.3 ms	4.6 ms

48.6.6 Calculation of FIFO pointer addresses

Complete visibility of the TX, CMD and RX FIFO contents is available through the FIFO registers, and valid entries can be identified through a memory-mapped pointer and counter for each FIFO. The pointer to the first-in entry in each FIFO is memory mapped. For the TX FIFO the first-in pointer is the Transmit Next Pointer (TXNXTPTR). For the CMD FIFO the first-in pointer is the Command Next Pointer (CMDNXTPTR). For the RX FIFO the first-in pointer is the Pop Next Pointer (POPNXTPTR). The following figure illustrates the concept of first-in and last-in FIFO entries along with the FIFO Counter. The TX FIFO is chosen for the illustration, but the concepts carry over to the CMD FIFO and RX FIFO. See Transmit First In First Out (TX FIFO) buffering mechanism, Command First In First Out (CMD FIFO) Buffering Mechanism and Receive First In First Out (RX FIFO) buffering mechanism for details on the FIFO operation.

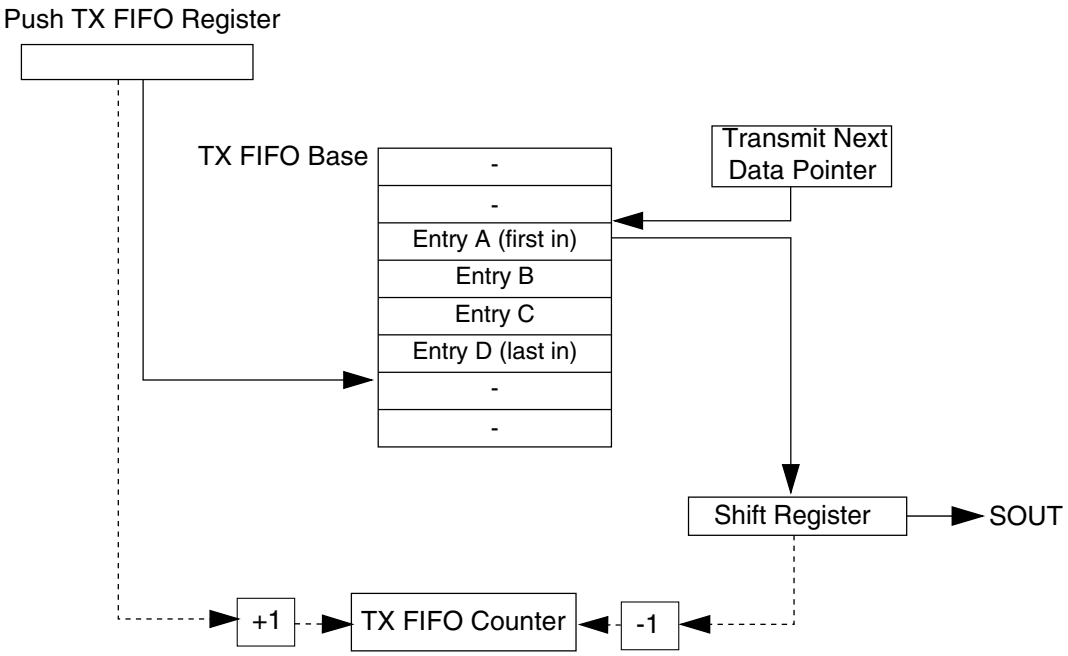

Figure 48-84. TX FIFO pointers and counter

48.6.6.1 Address Calculation for the First-in Entry and Last-in Entry in the TX FIFO

The memory address of the first-in entry in the TX FIFO is computed by the following equation:

$$\text{First-in EntryAddress} = \text{TXFIFOBase} + \left(4 \times \text{TXNXTPTR}\right)$$

The memory address of the last-in entry in the TX FIFO is computed by the following equation:

$$\text{Last-inEntryaddress} = \text{TXFIFOBase} + 4 \times \left(\text{TXCTR} + \text{TXNXTPTR} - 1\right) \text{mod} \left(\text{TXFIFOdepth}\right)$$

TX FIFO Base - Base address of TX FIFO
TXCTR - TX FIFO Counter
TXNXTPTR - Transmit Next Pointer
TX FIFO Depth - Transmit FIFO depth, implementation specific

48.6.6.2 Address Calculation for the First-in Entry and Last-in Entry in the CMD FIFO

The memory address of the first-in entry in the CMD FIFO is computed by the following equation:

$$\text{First-in EntryAddress} = \text{TXFIFOBase} + (4 \times \text{TXNXTPTR})$$

The memory address of the last-in entry in the CMD FIFO is computed by the following equation:

$$\text{Last-inEntryaddress} = \text{TXFIFOBase} + 4 \times (\text{TXCTR} + \text{TXNXTPTR} - 1) \bmod (\text{TXFIFOdepth})$$

CMD FIFO Base - Base address of CMD FIFO
CMDCTR - CMD FIFO Counter
CMDNXTPTR - Command Next Pointer
CMD FIFO Depth - Command FIFO depth, implementation specific

48.6.6.3 Address Calculation for the First-in Entry and Last-in Entry in the RX FIFO

The memory address of the first-in entry in the RX FIFO is computed by the following equation:

$$\text{First-in EntryAddress} = \text{RX FIFOBase} + (4 \times \text{POPNXTPTR})$$

The memory address of the last-in entry in the RX FIFO is computed by the following equation:

$$\text{Last-inEntryaddress} = \text{RX FIFO Base} + 4 \times (\text{RXCTR} + \text{POPNXTPTR} - 1) \bmod (\text{RXFIFOdepth})$$

RX FIFO Base - Base address of RX FIFO
RXCTR - RX FIFO counter
POPNXTPTR - Pop Next Pointer
RX FIFO Depth - Receive FIFO depth, implementation specific

Chapter 49
Zipwire

49.1 Introduction

Zipwire is a group of modules that allow one MCU to have a fast, low pin count, serial communication link directly into the memory mapped peripherals and/or memories of another MCU or a smart ASIC. Zipwire is implemented in hardware so there is no CPU load for the intitiator or target nodes.

Zipwire supports 8-bit, 16-bit or 32-bit reads and writes to any 32-bit address at the target node.

Zipwire architecture is fully pipelined and support multiple outstanding commands to allow maximum use of the serial link bandwidth.

The serial link runs at 320 Mbaud using LVDS physical layer. One LVDS pair for Tx and another pair for Rx, with a separate 20 MHz reference clock. Five pins in total.

Zipwire also supports a streaming mode for the transfer of large blocks of data.

In streaming mode Zipwire has a transfer rate of approximately 32 MB/second. For single random access 32-bit read from any 32-bit address location, the latency is approximately 1 µs.

49.2 Block Diagram

Figure 49-1 shows two MCUs with Zipwire connected using a five wire interface. Both MCUs support Target and Initiator modes of Zipwire. The SIPI Bus Master Interface is used for all Target mode transactions. The SIPI Register Interface is used for all Initiator Transactions and initial setup. The LFAST Register Interface is used for Initial Setup.

The diagram shows the LFAST reference clock coming from MCU B clock system. The Ref_Clock can come from either MCU. It is user configurable, but it must be the same clock that drives both LFAST modules.

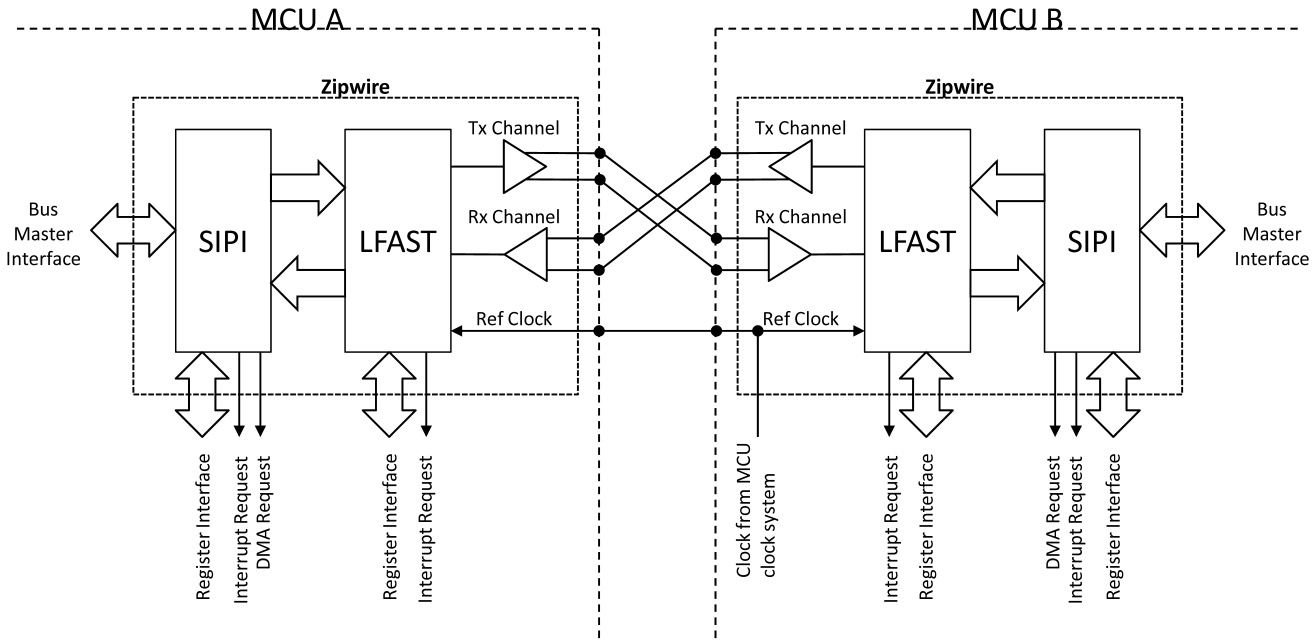

Figure 49-1. Zipwire block diagram

49.3 Architecture

Zipwire is composed of several modules and system resources.

The physical layer is LVDS with 1.2 V common mode voltage and 200mV swing. The LVDS pads are shared with other IO and GPIO.

The transport layer is a protocol called LFAST. LFAST is an asynchronous prototcol, using a non-return to zero encoding. The protocol starts with a fixed 16-bit sync frame to allow the receiver to detect the optimal point to sample the inconing data. Followed by an 8-bit header that defines the channel number and the size of the payload. Finally, the payload, which can be between 8 and 288 bits.

The application layer protocol is called Serial Inter Processor Interface (SIPI) and runs on top of LFAST and is fully encapsulated within the LFAST payload. SIPI uses four fixed sizes of LFAST payload:

- 32-bit
- 64-bit

- 96-bit
- 288-bit

The SIPI protocol implements a suite of commands initiated my one MCU, for reading and writing any 32-bit address location in another connected MCU. The SIPI protocol allows either or both MCUs to initiate commands. The protocol also supports interrupt requests from one MCU to the other.

The SIPI protocol is implemented fully in hardware in a module called SIPI. The module implements both the initiator part of the protocol and the recipient part of the protocol. The module implements four SIPI Initiator channels that can run independently of each other and can run simultaneously. The SIPI module is a bus master on the low speed crossbar. As the target MCU for a command from the inititating MCU, SIPI can perform read and write accesses to any address location within the target MCU. The software running on the local MCU, should configure the system MPU to allow/deny memory accesses to MCU memory and resources as required.

The initiator part of the module is connected to the DMA controller and is able to generate DMA requests as a command is completed. This allows a series of read or write commands to be queued in the Inititator MCU and executed by the DMA and SIPI module without CPU intervention at either Initiator or Target MCU.

49.4 LFAST Clocking

The LFAST implementation includes a dedicated PLL for multiplying a low speed clock source up to 320 MHz for the transmission and reception of data. The high speed asynchronous nature of LFAST, requires that both the local node and remote node, operate from the same, stable, low jitter clock sources. This common low speed clock is referred to a the Reference Clock.

The MCU includes clock multiplexing to allow the source of the LFAST reference clock to come from one of three sources via a programmable clock divider:

- Crystal oscillator
- Output of PLL0
- External pin

The most expedient source for the reference clock is the 20 MHz crystal oscillator on one MCU. This 20 MHz clock can be used as the LFAST Reference clock for the local LFAST. This same 20 MHz clock must be exported from the local MCU to the remote MCU, to be used as the LFAST reference at the remote MCU.

The 20 MHz clock may be used in the following ways:

- Shared between the MCUs using a dedicated reference clock pin on each MCU
- Divided by 2 and shared as a 10 MHz reference
- Shared as the fundamental clock for the MCU system clock and the LFAST reference clock

The LFAST PLL for generating the 320 MHz clock, is shared between LFAST for SIPI.

49.5 Zipwire interconnections

LFAST has the following connections:

- Tx and Rx connections to the pads via the SIUL and the MSCR registers.
- Peripheral Bridge interface (PBRIDGE) — Allows software to read and write configuration registers.
- Tx Data Port/Rx Data Port — Directly connected to the SIPI module. Allows received data to be efficiently transfered to SIPI and transmit data to be transfered from SIPI.
- Interrupt Request connections — Allows the module to flag to the CPU when it requires servicing.

SIPI has the following connections:

- Peripheral Bridge interface (PBRIDGE) — Allows software to read and write configuration registers and SIPI Interface Registers.
- DMA connections — Allows SIPI command sequences to be queues and initiated without CPU intervention.
- Crossbar master port — Allows SIPI to execute requested commands to read and write MCU address space.
- Tx Data Port/Rx Data Port — Directly connected to the LFAST module. Allows received data to be efficiently transfered from LFAST and transmit data to be transfered to LFAST.
- Interrupt Request connections — Allows the module to flag to the CPU when it requires servicing.

49.6 Zipwire performance

Two aspects of performance are considered:

- Bandwidth — The rate at which data can be read or written between two nodes. It assumes that read or write commands from the Inititator node, can be sent continuously at the highest speed the Target node can consume those commands.
- Latency — The time from the Initiator node sending a read or write command to the Initiator node receiving back the read data or write acknowledge.

49.6.1 Read performance

A Zipwire read operation consists of three stages:

- Inititator sends SIPI Read command to Target.
- Target parses the received command and runs a master bus cycle to read the data.
- Target sends the SIPI Read response back to the Initiator.

A SIPI Read command consists of:

- 16-bit header
- 32-bit read address
- 16-bit CRC
- 64 bits total

A SIPI Read response consists of:

- 16-bit header
- 32-bit read data
- 16-bit CRC
- 64 bits total

The SIPI message is encapsulated in an LFAST frame where the LFAST payload is the size of the SIPI message.

The LFAST frame consists of:

- 16-bit synchronisation header
- 8-bit header
- 64-bit payload
- 1-bit stop bit
- 89 bits total

LFAST Baud rate is 320 Mbaud which yields a bit time of 3.13 nS

Therefore, an 89-bit LFAST transmission of a SIPI 64-bit Read command or 64-bit Read response takes 278 nS

The SIPI module takes thirteen system clock cycles to parse a command and create a Read response, plus the time to run the master bus cycle. The time to run the master bus cycle will vary depending on the memory being read.

Assumptions:

- Average of 6 × slow crossbar cycles to read different memories.
- Slow crossbar clocked at 100 MHz
- SIPI clocked at 50 MHz

Therefore, time for SIPI to read an address location is:

- (13 x 50MHz clocks) + (6 x 100MHz clocks) = 320nS

49.6.1.1 Read bandwidth

The Zipwire target node has a three message deep receive FIFO and a three message deep transmit FIFO. So, the Target node can simulataneously be receiving a command, processing a command, and sending the Read response.

The time to transmit a command or response is less than the time to process the command. Therefore, the bandwidth is limited by the time to process the message.

Read Bandwidth = four bytes in 320 nS = 12.5 MB/second

49.6.1.2 Read latency

The latency is the time taken to send a Read command, process the command, and send a Read response.

Read Latency = 278 nS + 320 nS + 278 nS = 876 nS

49.6.2 Write performance

A Zipwire write operation consists of three stages:

- Inititator sends SIPI Write command to Target.
- Target parses the received command and runs a master bus cycle to write the data.
- Target sends the SIPI Write response back to the Initiator.

A SIPI Write command consists of:

- 16-bit header
- 32-bit write address
- 32-bit write data
- 16-bit CRC
- 96 bits total

A SIPI Write acknowledge consists of:

- 16-bit header
- 16-bit CRC
- 32 bits total

The SIPI message is encapsulated in an LFAST frame where the LFAST payload is the size of the SIPI message.

The LFAST frame consists of:

- 16-bit synchronisation header
- 8-bit header
- 96-bit payload (command) or 32 bit (acknowledge)

- 1-bit stop bit
- 121 bits total (command) or 57 bits (acknowledge)

LFAST Baud rate is 320 Mbaud which yields a bit time of 3.13 nS

Therefore, the time for an LFAST transmission is:

- 121-bit LFAST transmission of a SIPI 96-bit Write Command takes 378 nS
- 57-bit LFAST transmission of a SIPI 32-bit Write Acknowledge takes 178 nS

The SIPI module takes thirteen system clock cycles to parse a command and create a Write response, plus the time to run the master bus cycle. The time to run the master bus cycle will vary depending on the memory being written.

Assumptions:

- Average of 5 × slow crossbar cycles to write different memories.
- Slow crossbar clocked at 100 MHz
- SIPI clocked at 50 MHz

Therefore, the time for SIPI to write an address location is:

- (13 × 50 MHz clocks) + (5 × 100 MHz clocks) = 320 nS

49.6.2.1 Write bandwidth

The Zipwire target node has a three message deep receive FIFO and a three message deep transmit FIFO. So, the Target node can simulataneously be receiving a command, processing a command, and sending the Write Acknowledge response.

The time to transmit the command is longer than the time to process the command, or the time to transmit the Write Acknowledge. Therefore, the bandwidth is limited by the time to transmit the command.

Write Bandwidth = four bytes in 378 nS = 10.6 MB/second

49.6.2.2 Write latency

The latency is the time taken to send a Write command, process the command, and send a Write Acknowledge.

Write Latency = 378 nS + 310 nS + 178 nS = 866 nS

49.7 LFAST/SIPI configuration

This section summarizes the module configuration in the controller.

The SIPI and LFAST are connected to one another and appear as a single unit called Zipwire. The LFAST portion of the two modules allows for high speed inter-device communications. The SIPI allows memory to be shared between devices which have SIPI and LFAST communication modules.

The LFAST can operate in either slave or master mode configurations. The node running in master mode controls the serial link, but SIPI, in both master and slave modes, can act as both initiator and target for SIPI commands simultaneously. Please see the SIPI and LFAST chapters for detailed information on module configuration and functionality.

The SIPI CHIP ID = 0980_501Dh.

Chapter 50
Serial Interprocessor Interface (SIPI)

50.1 Introduction

The Serial Interprocessor Interface (SIPI) is an application layer protocol which runs on top of the LFAST (LVDS Fast Asynchronous Serial Transmission) module. It is used by the local device to access the shared memory of a remote device. SIPI defines point-to-point full duplex communication between two devices, where LFAST works as a physical medium of communication between both the devices.

50.1.1 Scalability

The SIPI protocol is designed to provide a sophisticated, high bandwidth, multimaster, multi-channel memory interface between 2 devices using few interconnecting signals. But the protocol is designed in such a way that a subset of the protocol can be implemented, where die area is more important than features.

Main scalable features:

- Number of concurrent channels:
  - Full Implementation = 4
  - Minimum Implementation = 1
- Full implementation has a node both as Initiator and Target of commands. Minimum implementation either Initiator or Target.
- Full Implementation includes a block transfer feature, but this feature is optional.

The rest of this section describes a full implementation of SIPI which includes:

- Advanced High-Performance Bus (AHB-Lite) master interface

- Direct Memory Access (DMA) interface
- LFAST Tx/Rx (transmit/receive) interfaces along with Peripheral Bus Interface (IPS)

50.2 Overview

An instance of SIPI can act as initiator, or target or both. SIPI can access the shared memory directly through its AHB master interface or through its DMA interface. DMA interface is used when the node acts as an initiator while the AHB Master interface will be used when the node acts as target. SIPI has four channels, with one channel (Channel 2) having data streaming capability. Payload width for channel 0, 1 and 3 is 32 bits, and for channel 2 data widths can be 32 bits, or 256 bits when streaming. Any of these channels can be used for DMA access or bus interface access depending on the setting of the SIPI_CCR*n*. CRC encoder calculates the CRC on the command frame. Then the SIPI initiator appends the CRC to the end of the frame before transmission.

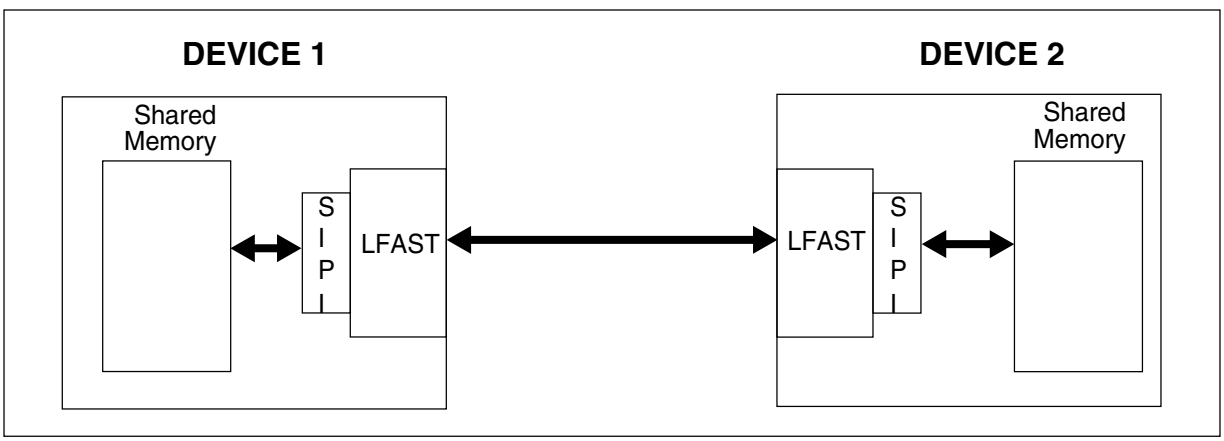

Figure 50-1. Interprocessor communication diagram

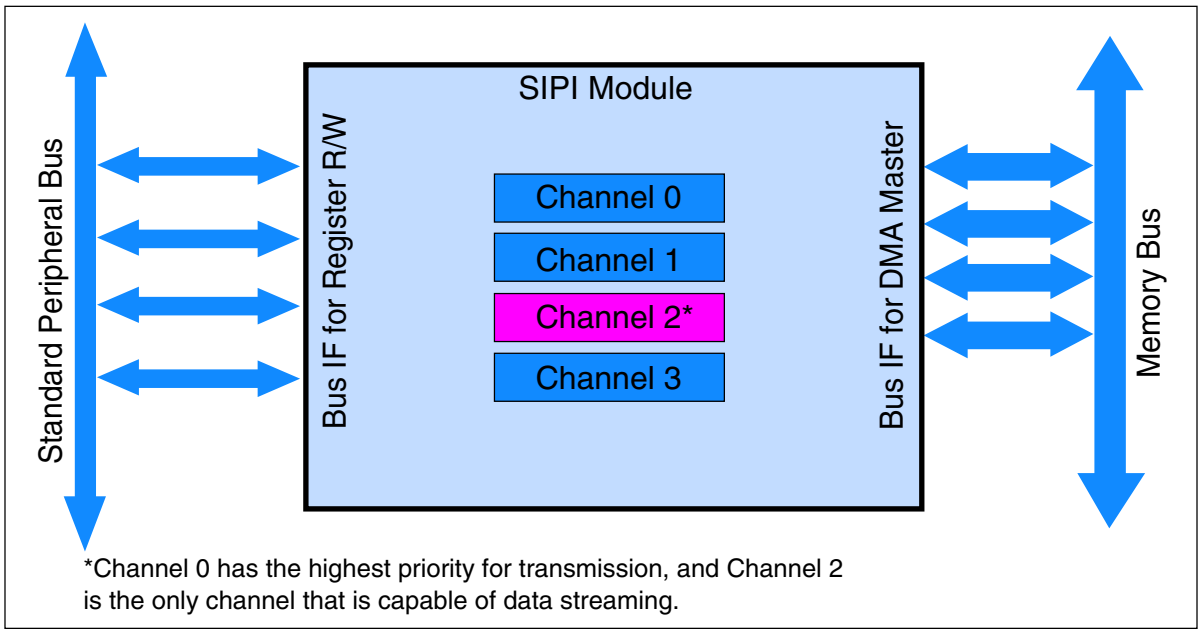

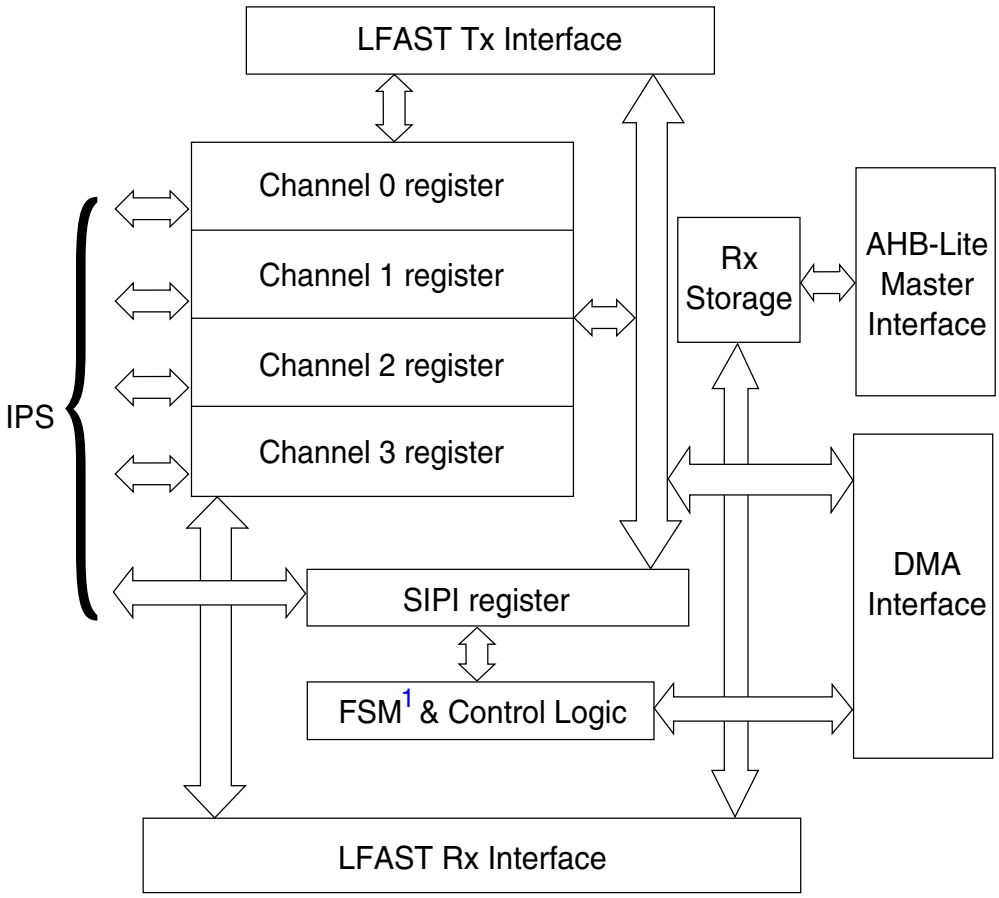

Figure 50-2. SIPI module

50.3 SIPI block diagram

1 Finite State Machine

Figure 50-3. SIPI block diagram

50.4 Feature description

This section describes the features of the SIPI module.

50.4.1 Main features

- Point-to-point communication between two devices
- Full duplex communication
- Four channels, including one channel with data streaming capability

- Configurable DMA access for each channel
- CRC protection mechanism
- Timeout protection mechanism
- Fixed priority channel selection
- Data size up to 256 bits on streaming channel
- Common tag pool for assigning sequential transfer IDs to every new transfer
- AHB master interface which is used by target node to access shared memory
- Target node contains a set of nine 32-bit internal registers to store commands
- Up to two outstanding requests are supported at initiator

50.4.2 Standard features

- IPS bus interface (PBRIDGE)
- SPP DMA2x bus interface
- AHB Master Interface
- LFAST Tx/Rx interfaces
- Cyclic Redundancy Check error detection (CRC16)

50.5 SIPI operation from reset

When the SIPI module exits reset, it is operational and target mode is enabled without the need to configure the control registers.

50.6 Functional description

50.6.1 External signals

The SIPI has no chip external signals.

50.6.2 Frame format

All frames have the same general format:

- 16 bit header
- Address, Address and Data, or nothing
- 16-bit CRC

There are 2 main groups of command; read and write. Within those 2 groups are three read/write formats:

- 32-bit
- 16-bit
- 8-bit

Each command generates one of three different responses:

- Read data
- Write acknowledge
- Error

There is one additional command that requests the module ID from the Target node. The ID is a unique 32-bit ID that is specific to a particular device. It is normally the same as the JTAG ID. The sections below illustrate the four different frame formats that are used to implement all the commands and responses.

The number of frames depends on the data buffers (associated with every channel), the frame data is stored in data buffers at the initiator. Address and data are both transmitted in the same order in which they are stored.

50.6.2.1 Register read request

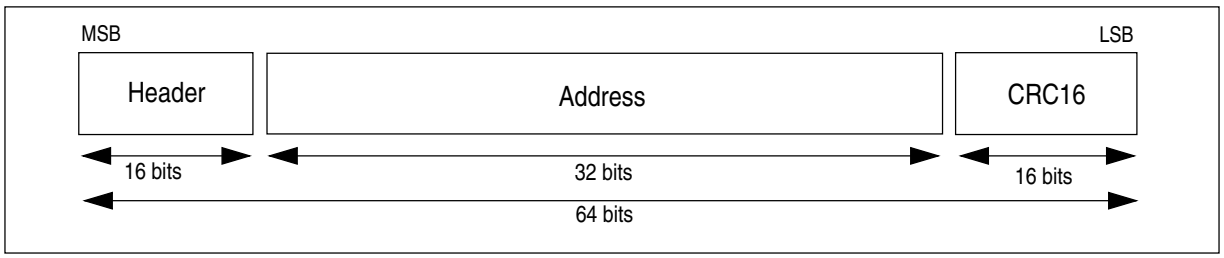

Figure 50-4. SIPI register read request

50.6.2.2 Register read response, ID request response

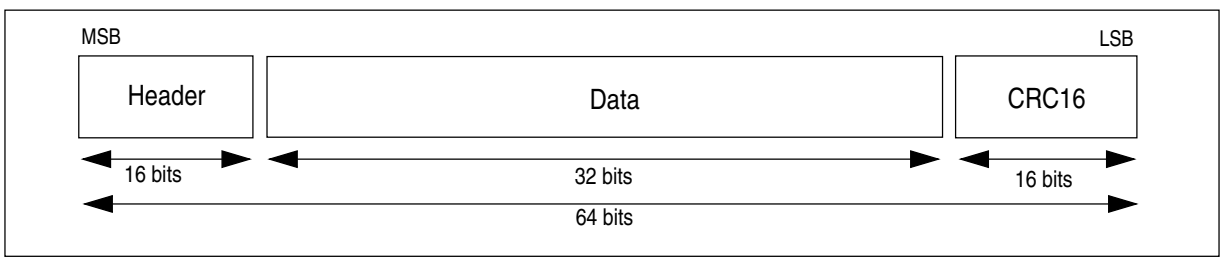

Figure 50-5. SIPI read response

50.6.2.3 Register write request

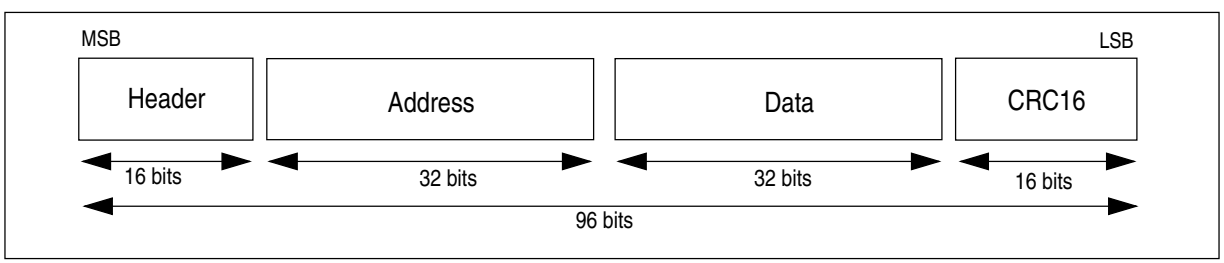

Figure 50-6. SIPI register write request

50.6.2.4 Trigger transfer, ID transfer, write acknowledge and streaming write acknowledge

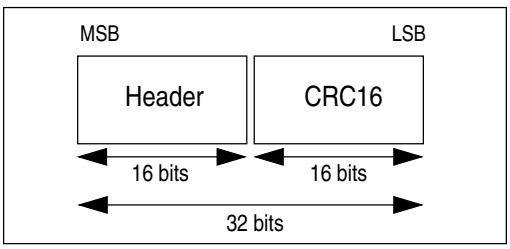

Figure 50-7. SIPI write acknowledge

50.6.2.5 Streaming write request

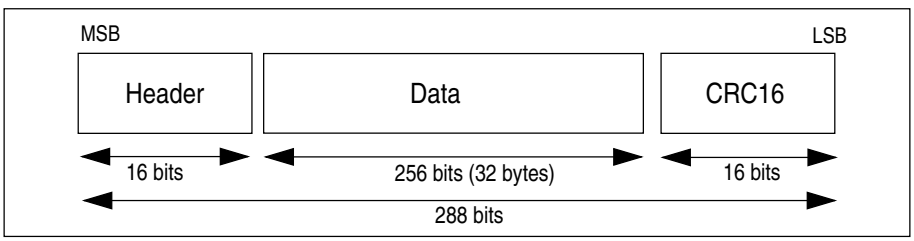

Figure 50-8. Streaming write request format

NOTE

Direct write operations are used to set the streaming address.

Streaming data write is performed using the format shown in Figure 50-8.

50.6.2.6 Header field

Header field contains 16 bits of configuration information. MSB will be transmitted first.

50.6.2.6.1 SIPI header coding

Figure 50-9, Table 50-1, Figure 50-10, and Table 50-2 show how the SIPI header bits are coded.

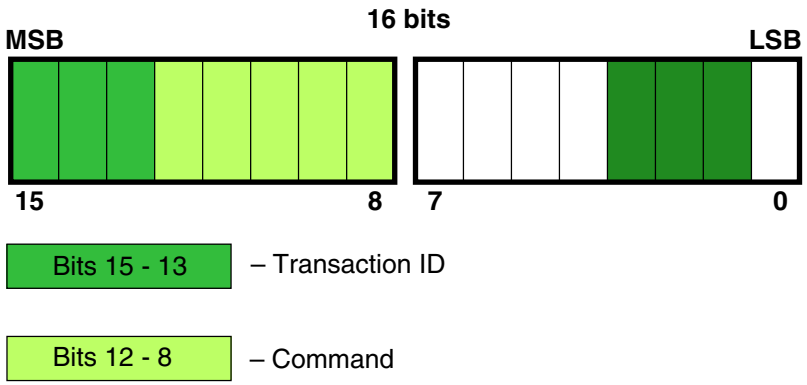

Figure 50-9. SIPI header coding

Table 50-1 shows the command coding for the bits[12:8] of the header.

Table 50-1. SIPI header command coding

b[12:8] (hex)	Command	Payload Size
00	Read 8 bits	64
01	Read 16 bits	64
02	Read 32 Bits	64
03	Reserved	—

Figure 50-10 shows the channel number field in the header and Table 50-2 shows the channel number coding.

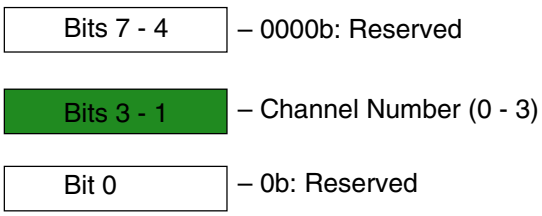

Figure 50-10. SIPI header channel field

Table 50-2. SIPI header channel number coding

SIPI channel name	Channel number coding in header(s)		Comment
	SIPI channel coding select field (SIPI_MCR[CHNSB])		
	Code table I (SIPI_MCR[CHNSB] = 1)	Code table II (SIPI_MCR[CHNSB] = 0)	
0 (Channel A)	000b	100b	In use
1 (Channel B)	001b	101b	In use
2 (Channel C)	010b	110b	In use
3 (Channel D)	011b	111b	In use
4 (Channel E)	100b	000b	Reserved
5 (Channel F)	101b	001b	Reserved
6 (Channel G)	110b	010b	Reserved
7 (Channel H)	111b	011b	Reserved

50.6.2.7 Address field

The address field is 32 bits wide with the MSB transmitted first.

50.6.2.8 Payload field

Table 50-3 shows the payload sizes of LFAST frames.

Table 50-3. Payload size of LFAST channel frame

LFAST Code	SIPI Code	LFAST Payload Size (bits)	LFAST Payload Size (bytes)
000b	—	8	1
001b	—	32	4
010b	010b	64	8
011b	011b	96	12
100b	100b	128	16

Table continues on the next page...

Table 50-3. Payload size of LFAST channel frame (continued)

LFAST Code	SIPI Code	LFAST Payload Size (bits)	LFAST Payload Size (bytes)
101b	101b	256	32
110b	110b	512	64
111b	111b	288	36

Table 50-4 shows the converted coding of LFAST for a given SIPI code.

Table 50-4. Converted coding of LFAST channel code for SIPI headers

LFAST Code	SIPI Code	Channel (hex)[1]
0100b	100b	A
0101b	101b	B
0110b	110b	C
0111b	111b	D
1000b	000b	E (not used by SIPI)
1001b	001b	F (not used by SIPI)
1010b	010b	G (not used by SIPI)
1011b	011b	H (not used by SIPI)

1. SIPI channel 0 sends all commands on LFAST channel A, commands received on LFAST channel A, are processed and the response sent back on LFAST channel A.
SIPI channel 1 sends all commands on LFAST channel B, commands received on LFAST channel B, are processed and the response sent back on LFAST channel B.
SIPI channel 2 sends all commands on LFAST channel C, commands received on LFAST channel C, are processed and the response sent back on LFAST channel C.
SIPI channel 3 sends all commands on LFAST channel D, commands received on LFAST channel D, are processed and the response sent back on LFAST channel D.

50.6.2.9 CRC field

CRC field is 16 bits wide with calculation always enabled using CRC-16-CCITT syndrome (x16 + x12 + x5 + 1). MSB is sent first in the data stream.

50.6.2.9.1 CRC field examples

50.6.2.9.1.1 Example 1 – 32 bit write on channel 1 with ID1

- Header = 260Ah
- Address = 1122_3344h
- Data = CCDD_EEFFh
- CRC = BF7Dh

50.6.2.9.1.2 Example 2 – 32 bit read on channel 2 with ID2

- Header = 420Ch
- Address = 89AB_CDEFh
- CRC = 6B80h

50.6.2.9.1.3 Example 3 – Event command on channel 3 with ID3

- Header = 6C0Eh
- CRC = B286h

50.7 Transfer types

This section describes the available transfer types of the SIPI module. The SIPI frame is inserted inside the payload of the LFAST frame as shown in the figures of the following examples.

50.7.1 Read transfer

A Read transfer can be of two types:

- Read Request Transfer (at initiator node)
- Read Response Transfer (at target node)

50.7.1.1 Register read request transfer

If there is a read request transfer, the initiator node will send header, address and CRC bits as shown in Figure 50-11.

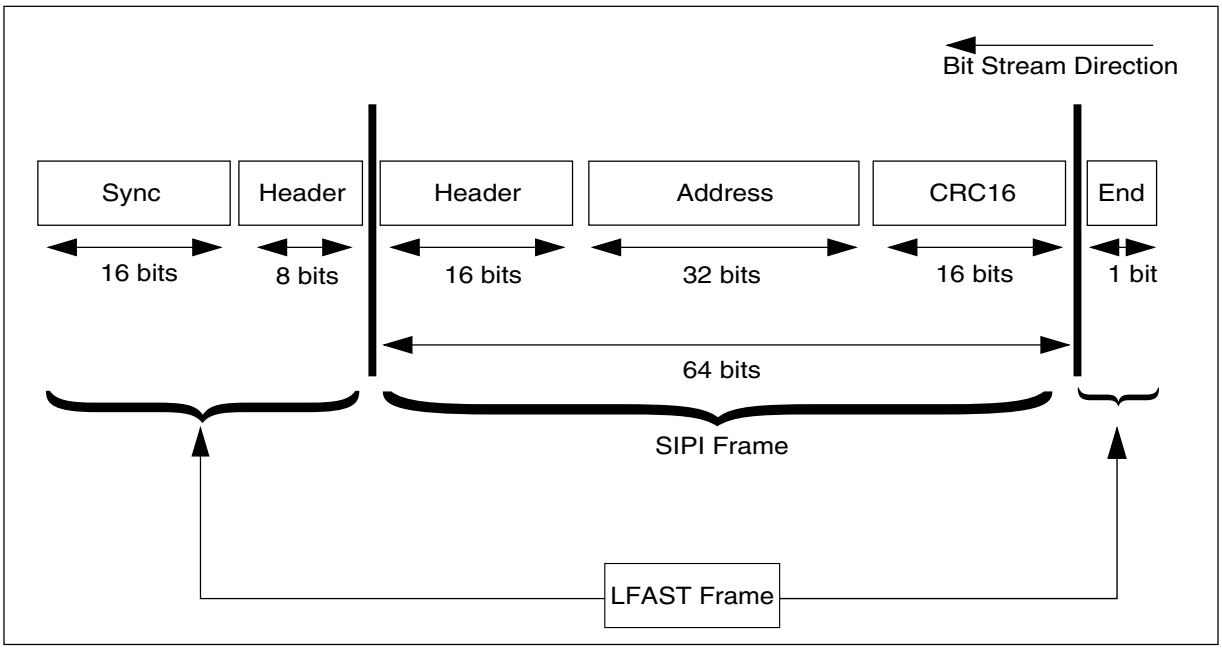

Figure 50-11. Read request transfer

50.7.2 Register read answer transfer

In response to a read request by the initiator node, the target node will send header, payload and CRC16. Data transfer could be in 8-bit, 16-bit or 32-bit modes (see Figure 50-12). In the case of 8-bit or 16-bit modes, copies of the SIPI data is sent in the payload (see Figure 50-13).

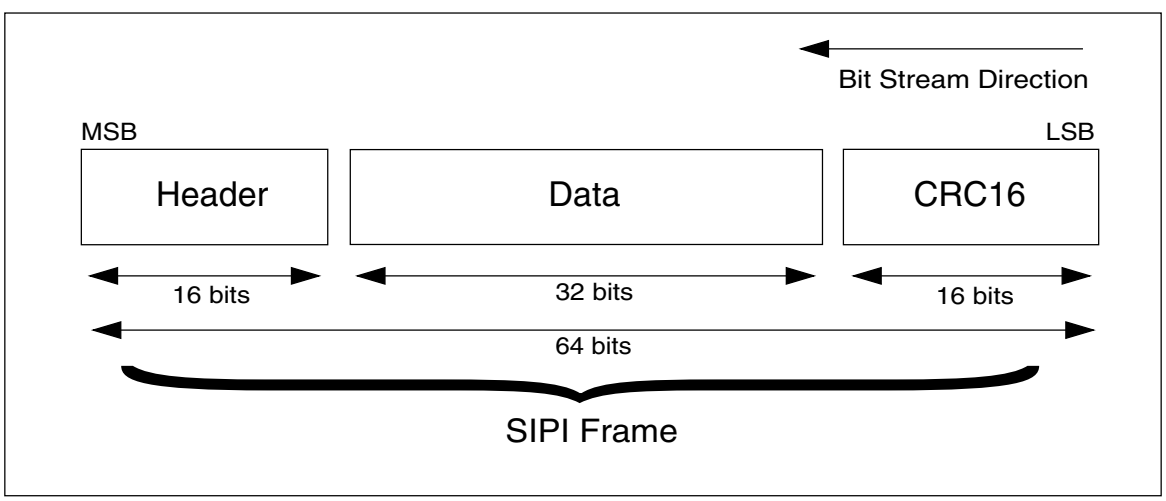

Figure 50-12. Read answer transfer

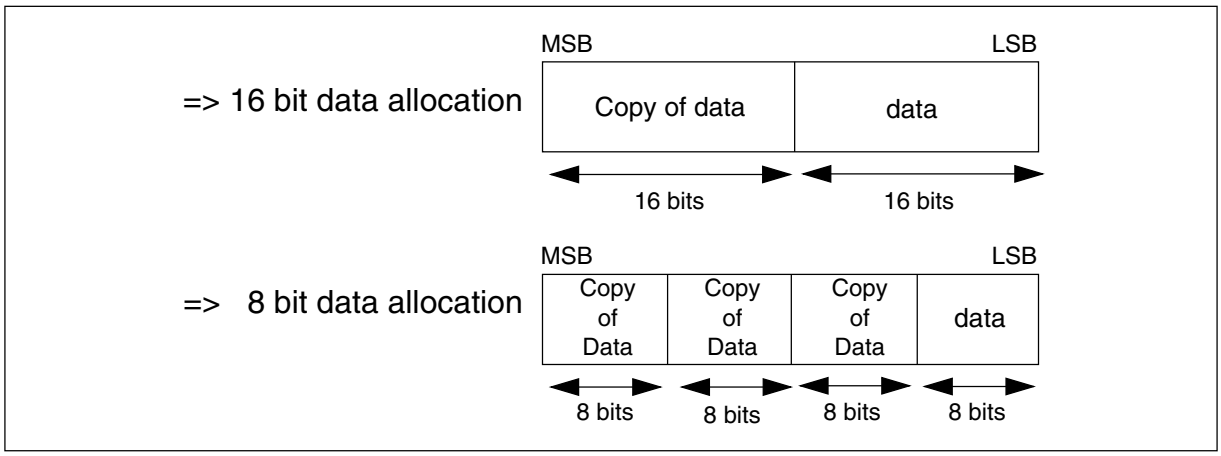

Figure 50-13. Data allocation

Note

- For an 8-bit transfer, address bits [31:2] are used as address and bits [1:0] are used as byte enables.
  - Bits[1:0]:
    - 00 - byte 3 enabled (MSB)
    - 01 - byte 2 enabled
    - 10 - byte 1 enabled
    - 11 - byte 0 enabled (LSB)
- For a 16-bit transfer, address bits [31:1] are used as address and bit [0] is used as halfword enable.
  - Bit[0]:
    - 0 - halfword 1 enabled (MSB)
    - 1 - halfword 0 enabled (LSB)

50.7.3 Register Write transfer

Register Write transfer can be of two types:

- Normal write transfer - channels 0, 1, 2 and 3
- Streaming data transfer - channel 2 only

A Register Write transfer can be done through Normal Write transfer on channels 0, 1, 2 and 3 (see Normal write transfer) as shown in Figure 50-14.

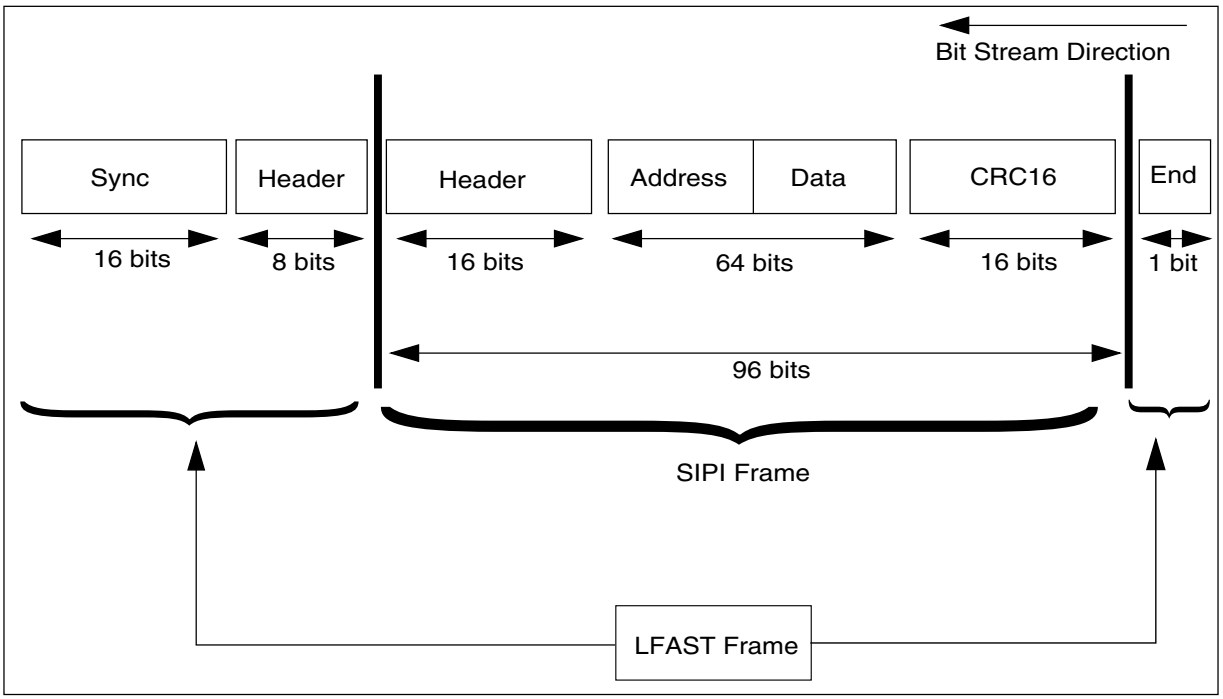

Figure 50-14. Register write transfer (showing LFAST frame encapsulation)

50.7.3.1 Normal write transfer

A normal write transfer contains header, address, data (32-bit) and CRC as shown in Figure 50-15.

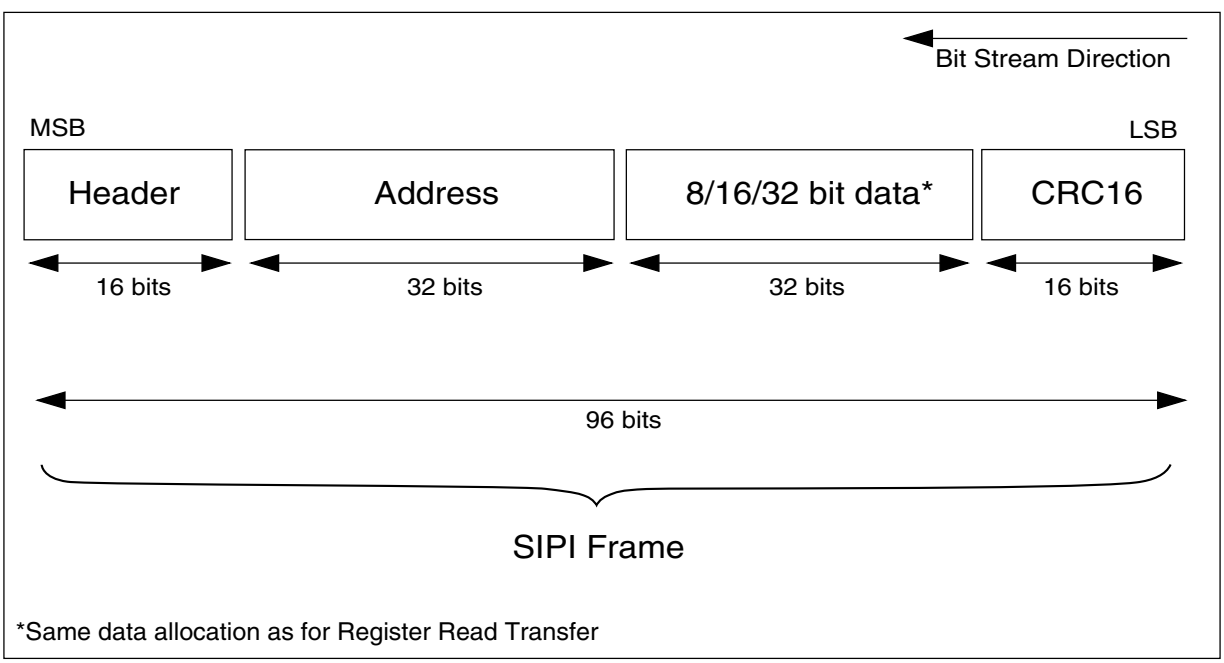

Figure 50-15. Write transfer (LFAST frame encapsulation is not shown)

Note

- For an 8-bit transfer, address bits [31:2] are used as address and bits [1:0] are used as byte enables.
  - Bits[1:0]:
    - 00 - byte 3 enabled (MSB)
    - 01 - byte 2 enabled
    - 10 - byte 1 enabled
    - 11 - byte 0 enabled (LSB)
- For a 16-bit transfer, address bits [31:1] are used as address and bit [0] is used as half word enable.
  - Bit[0]:
    - 0 - half-word 1 enabled (MSB)
    - 1 - half-word 0 enabled (LSB)

50.7.3.2 Streaming write transfer

Streaming write transfer has 256 bits of payload.

50.7.3.2.1 Streaming write transfer with address

Setting the address is performed using a direct write transfer. The SIPI Maximum Count Register (SIPI_MAXCR) and SIPI Address Reload Register (SIPI_ARR) are written before the SIPI Address Count Register (SIPI_ACR). This is to avoid unwanted behavior of the SIPI attempting to access non-shared memory. This is only true for the very first streaming command, subsequent streaming command(s) may not need to write the SIPI_MAXCR and SIPI_ARR (see SIPI Max Count Register (SIPI_MAXCR), SIPI Address Count Register (SIPI_ACR) and SIPI Address Reload Register (SIPI_ARR)).

50.7.3.2.2 Streaming transfer with data

Figure 50-16 shows the packet structure of the streaming transfer containing data.

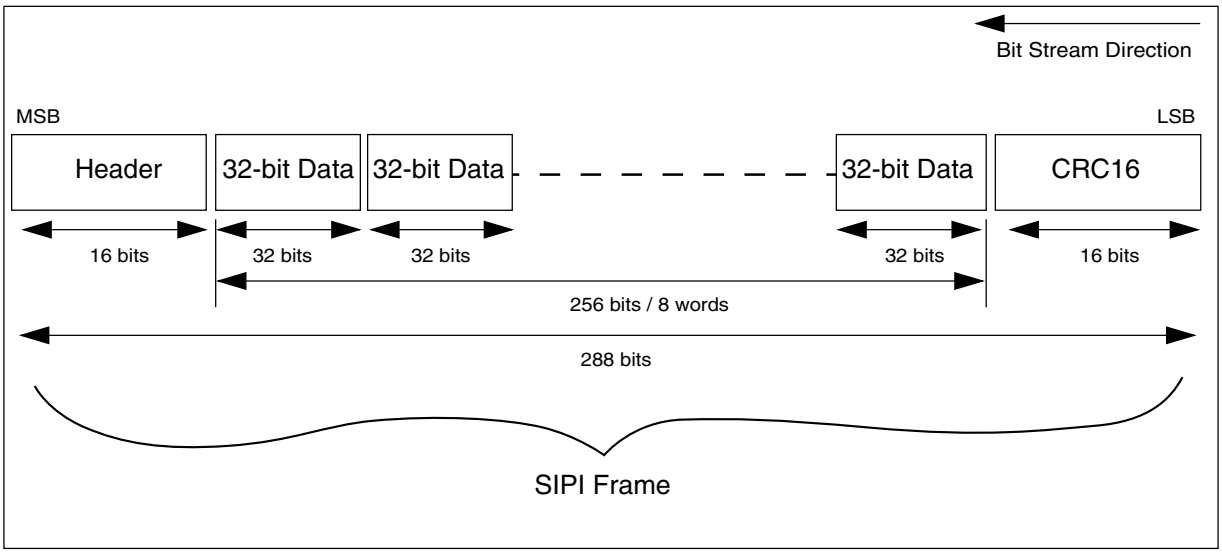

Figure 50-16. Streaming transfer with data

50.7.4 Write Acknowledge transfer

A Write Acknowledge transfer contains only header and CRC bits (see Write Aknowledge transfer. The CRC bits are calculated on the header field.

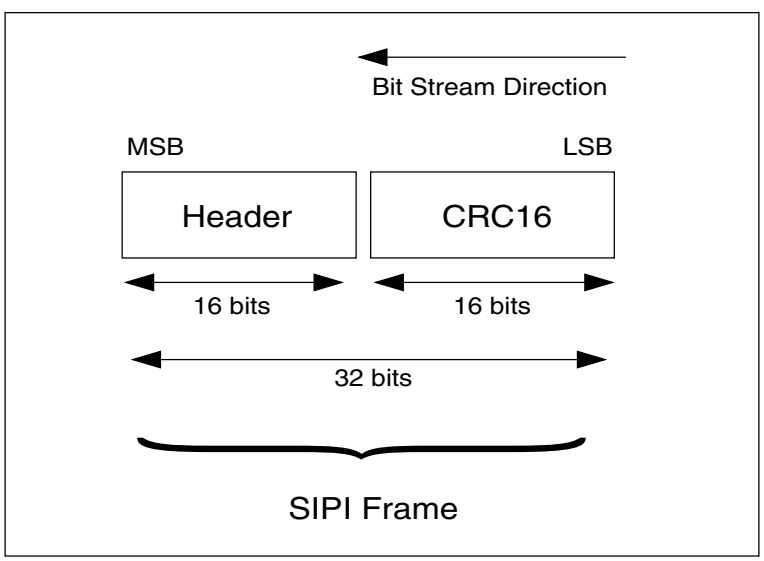

Figure 50-17. Write Aknowledge transfer (LFAST encapsulation is not shown)

50.7.5 ID request response

50.7.5.1 ID request transfer

An ID request is transmitted by the initiator node as shown in Figure 50-18.

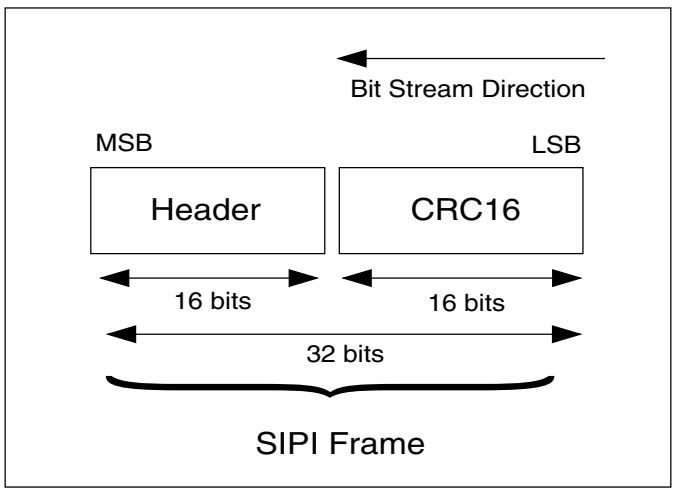

Figure 50-18. ID request transfer (LFAST encapsulation is not shown)

50.7.5.2 ID request response transfer

An ID request response is transmitted by the target node as shown in Figure 50-19.

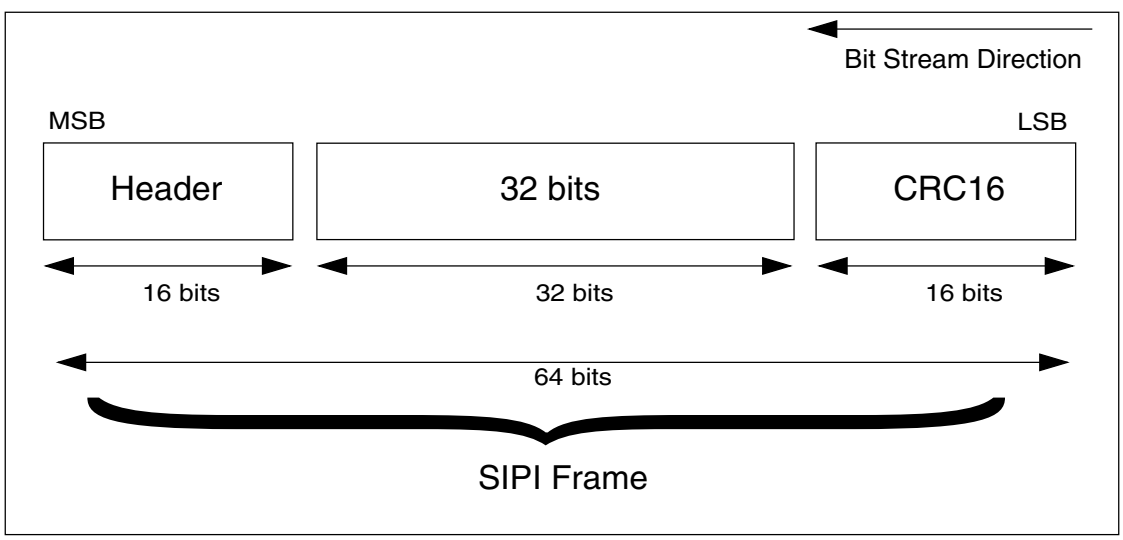

Figure 50-19. ID request response transfer

Note

The ID request response contains the value of the CHIP ID in place of data.

50.8 Transfer API and flow charts

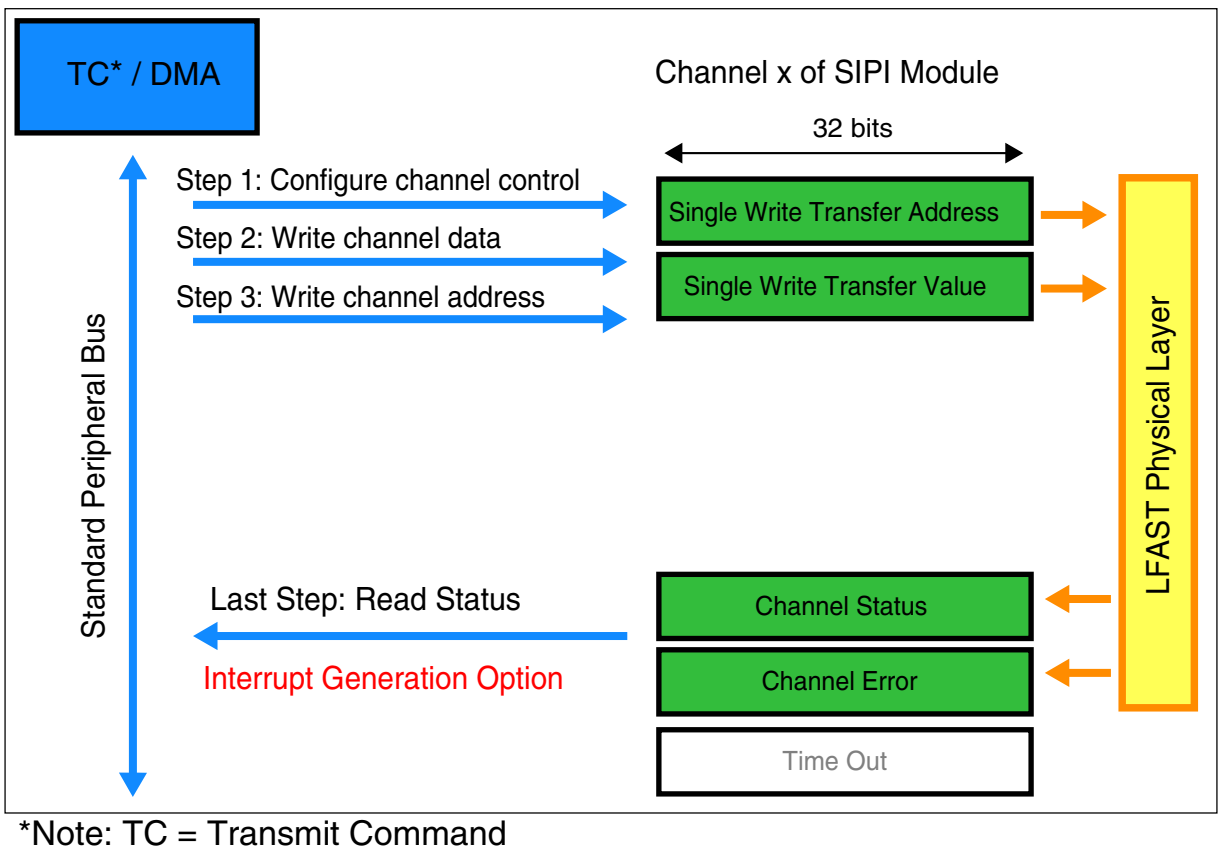

Figure 50-20. SIPI single register write API

Implement the following steps to generate a single Write Transfer Request (Figure 50-20):

1. Configure data and SIPI_CCR*n* at the initiator node.
2. Configure SIPI_CAR*n* at the initiator node.

   As soon as the channel address register (SIPI_CAR*n*) is written and if CCR*n*[CHEN] = 1, the initiator SIPI will calculate the CRC on header, address and data field and will start transmitting data to LFAST.
3. Software polls the status register bits (SIPI_CSR*n*) to determine when the request completes, SIPI_CSR*n*[ACKR] = 1. An interrupt will be generated if the corresponding SIPI_CIR*n*[ACKIE] = 1.

On a single Write transfer request reception (Figure 50-21):

1. Target node will place the address, data and control information on its AHB master interface.
2. When the process in completed, the target node will generate an acknowledge frame and send it back to the LFAST.

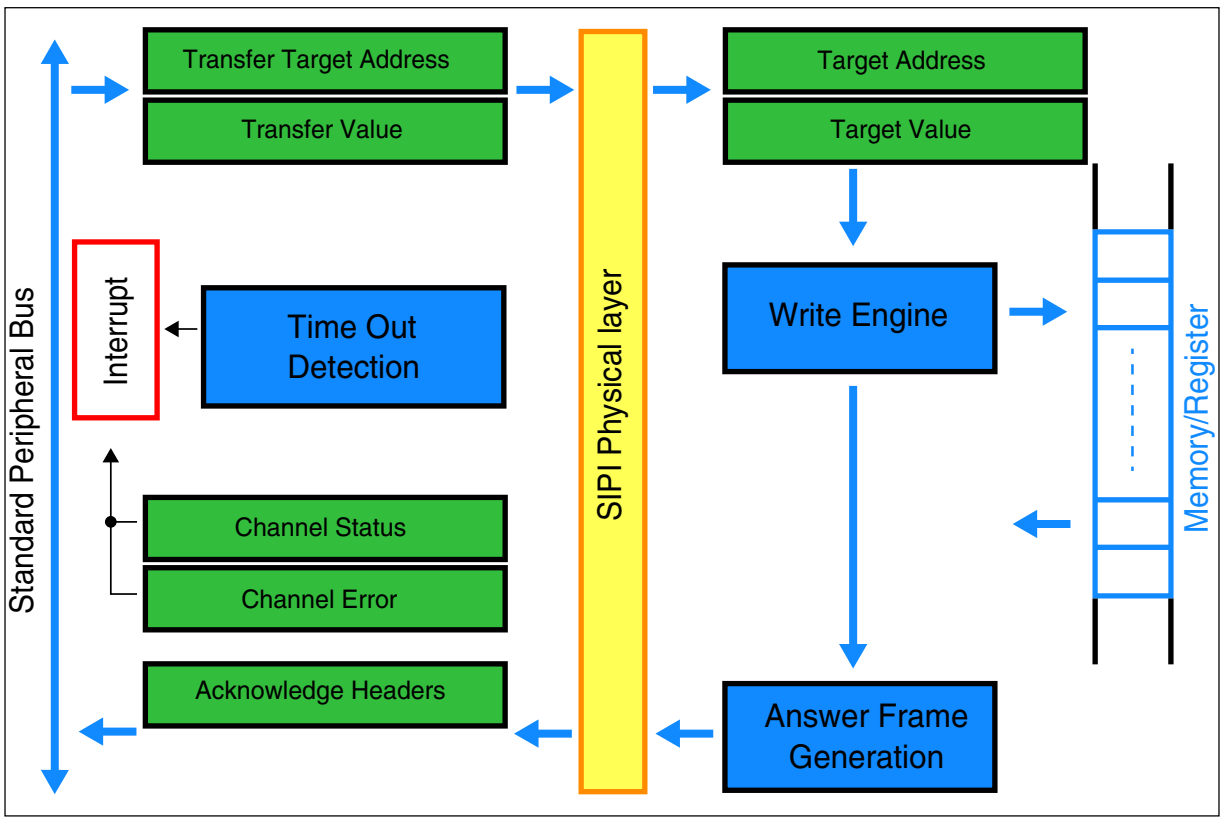

Figure 50-21. SIPI Single Register Write API – Flow Chart

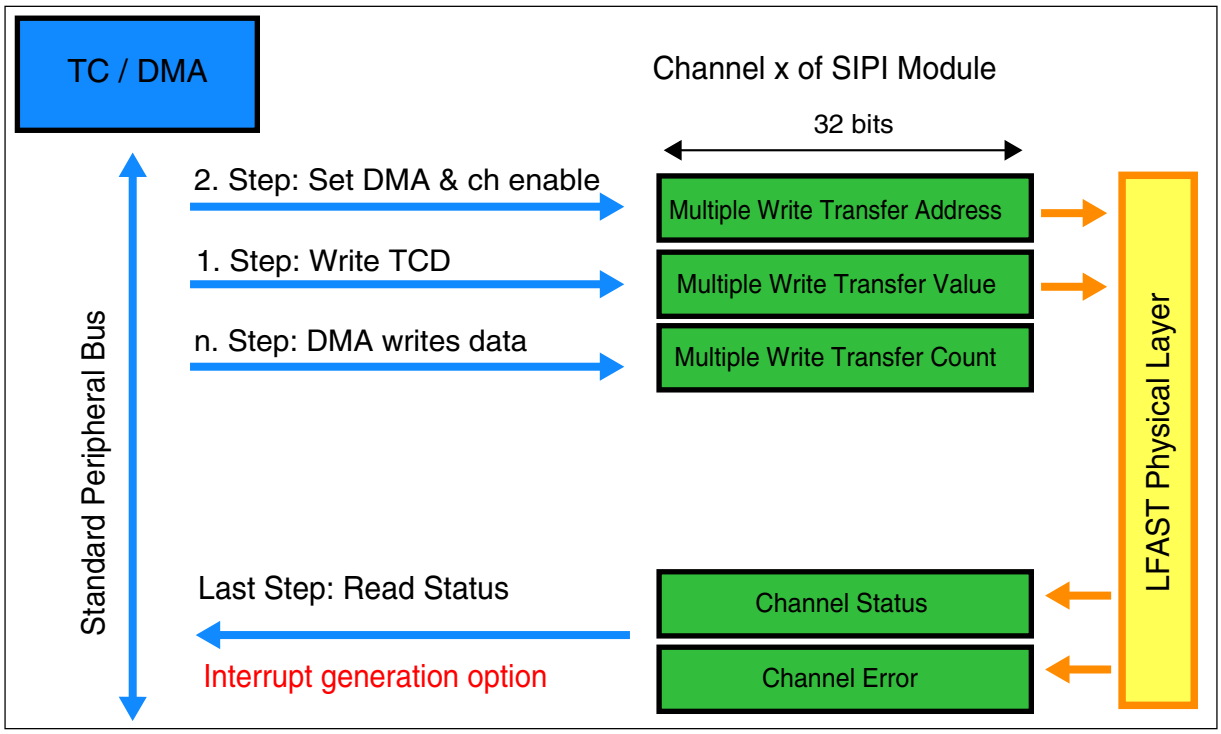

Figure 50-22. SIPI Multiple Register Write API

For multiple write transfer request generation (Figure 50-22):

1. Software will configure the Transfer Control Descriptor (TCD) of the DMA.
2. Software will write SIPI_CCR*n*[CHEN] = 1 and SIPI_CCR*n*[DAN] = 1.
3. SIPI will start copying data into the SIPI_CDR*n* through its DMA interface, depending on the transfer count and data registers size. SIPI_CDR2_0 should be written with the MSB.
4. When the copying process is completer, initiator SIPI will calculate CRC on header, address and data field and start transmitting data to LFAST.
5. Software should poll the SIPI_CSR*n* status register bits to determine if the request has completed. If SIPI_CSR*n*[ACKR] = 1, an interrupt will be generated (if the corresponding SIPI_CIR*n*[ACKIE] = 1).
6. If SIPI_CCR*n*[DEN] = 1, the SIPI request will transfer to the DMA controller. If not, the state machine go idle.
7. Steps 4–7 will be repeated.

On Multiple Write transfer request reception (Figure 50-22):

1. Target node will place the address, data and control information on its AHB Master Interface.
2. When the process in completed, target node will generate an acknowledge frame and send it back to the LFAST.

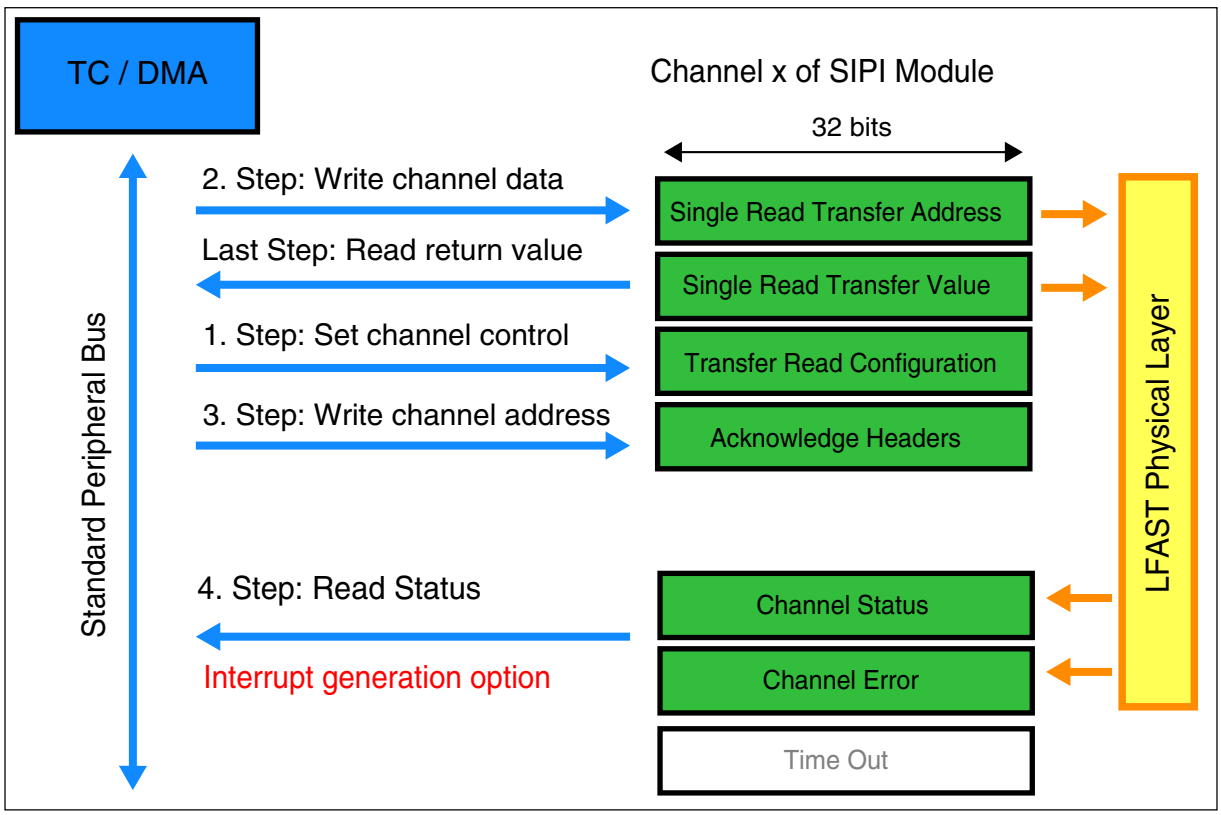

Figure 50-23. SIPI Single Register Read API

For Single Read Transfer Request generation (Figure 50-23):

1. Software/DMA will configure SIPI_CCR*n* and SIPI_CDR*n*, with the last step by writing CAR*n*.
2. As soon as SIPI_CAR is written, the initiator SIPI will calculate CRC of the header and address fields and start transmitting data to the LFAST.
3. Software should poll CSR*n* to determine when the request has completed. If SIPI_CSR*n*[RAR] = 1, an interrupt will be generated (if SIPI_CIR*n*[RAIE] = 1). If SIPI_CSR*n*[RAR] does not set then SIPI_ERR[TOE*n*] = 1 which indicates a timeout has occured.
4. If SIPI_CSR*n*[RAR] = 1 then software can read the data register, or can other necessary action if SIPI_CSR*n*[RAR] = 0.

On Single Read transfer request reception (Figure 50-23):

1. Target node will place the address and control information on its AHB Master Interface.
2. When the process in completed, target node will send read response back to LFAST.

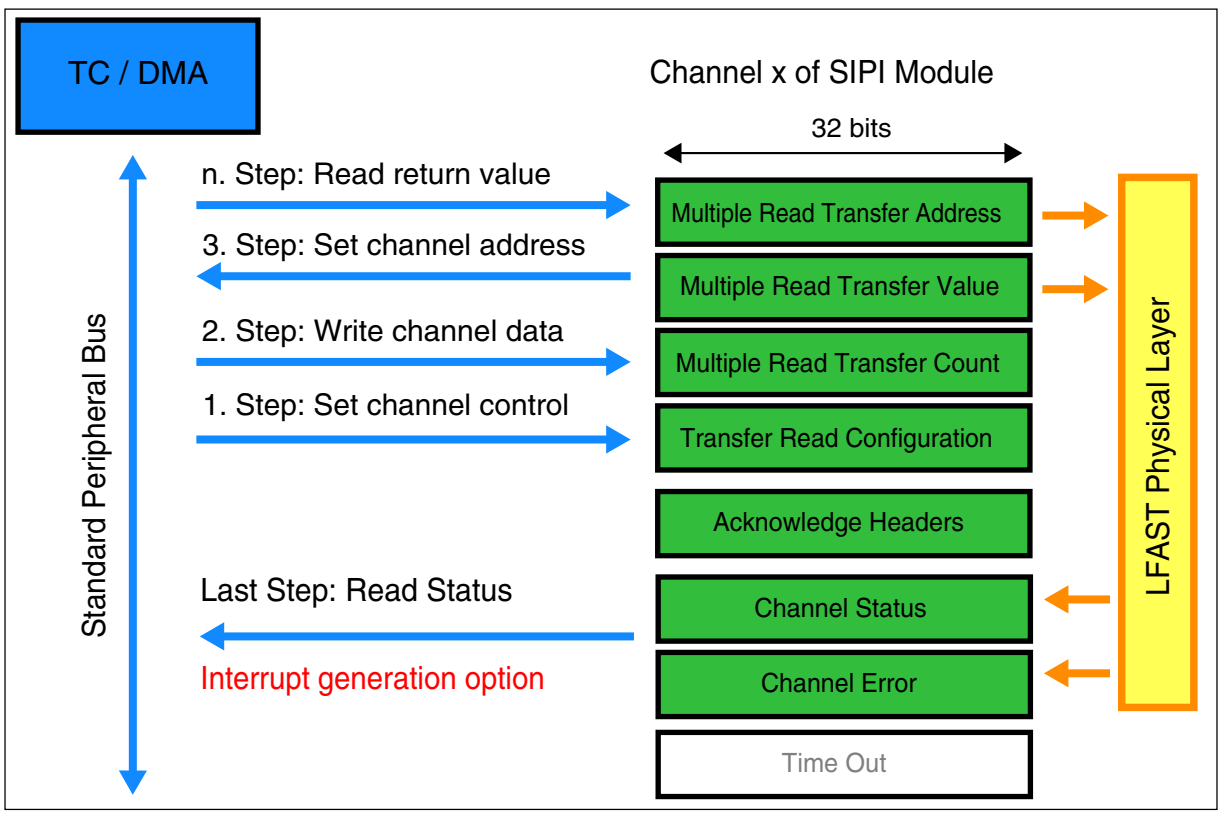

Figure 50-24. SIPI multiple register read API

For multiple read transfer request generation (Figure 50-24):

1. Software/DMA will configure SIPI_CCR*n* and SIPI_CDR*n*, with the last step by writing SIPI_CAR*n*.
2. As soon as channel address register is written, initiator SIPI will calculate CRC on the header and address fields, then starts transmitting data to the LFAST.
3. Software should poll SIPI_CSR*n* to determine when the request has completed. If SIPI_CSR*n*[RAR] = 1 and SIPI_CIR*n*[RAIE] = 1 an interrupt will be generated. If SIPI_CSR*n*[RAR] does not set, then SIPI_ERR[TOE*n*] = 1 which indicates a timeout.
4. Steps 2–3 will be repeated for multiple requests.

On Multiple Read transfer request reception (Figure 50-24):

1. Target node then will start reading data through its AHB interface.
2. When the transfer is completed/all data registers are full, it will calculate CRC and send the response frame back to LFAST.

Figure 50-25, Figure 50-26, Figure 50-27 and Figure 50-28 show the SIPI data streaming of data.

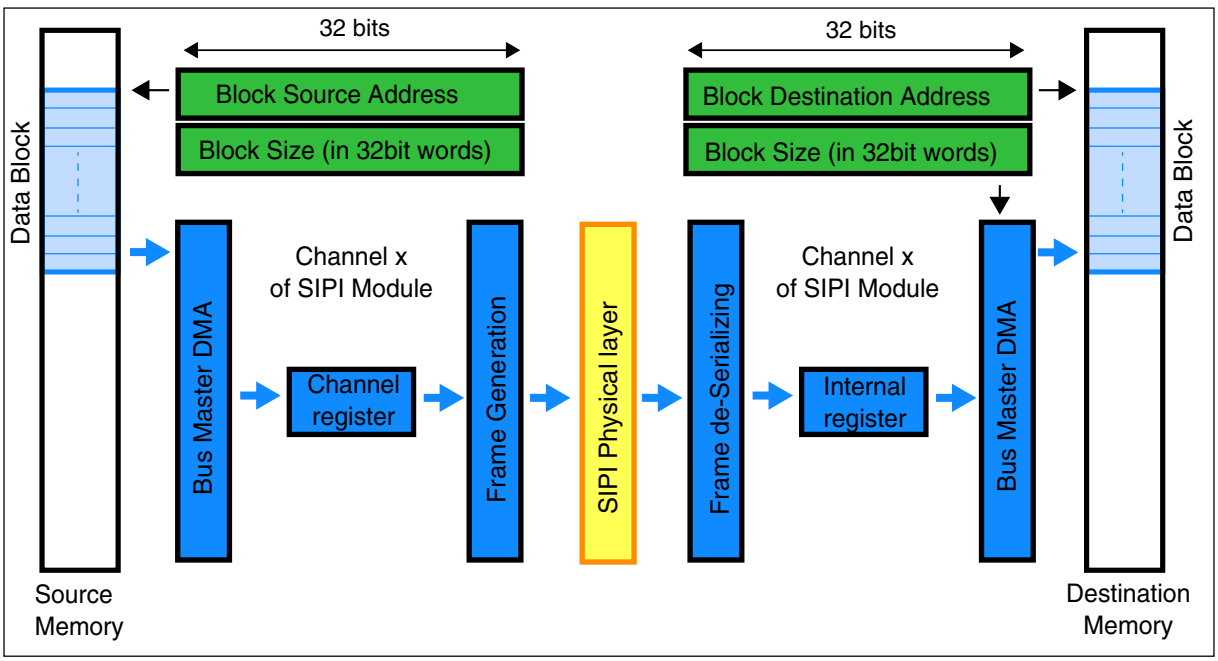

Figure 50-25. SIPI data stream model

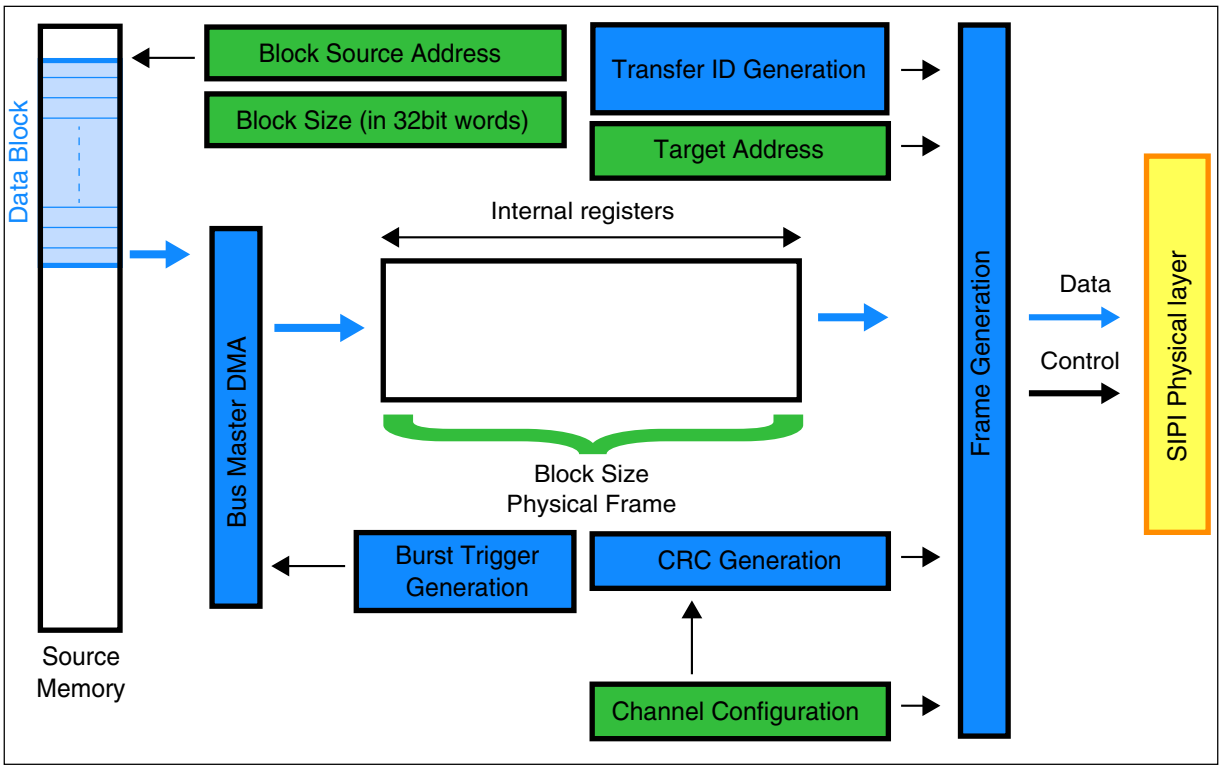

Figure 50-26. SIPI data stream model - Initiator

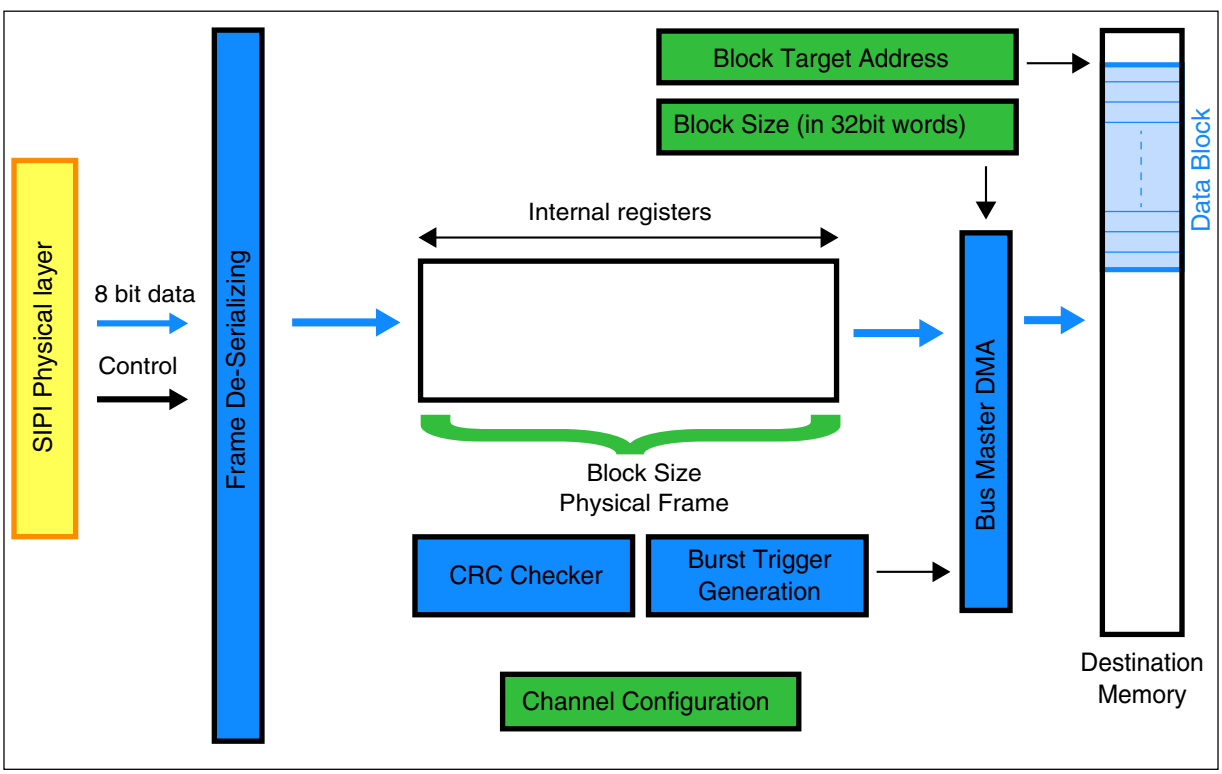

Figure 50-27. SIPI data stream model - Target

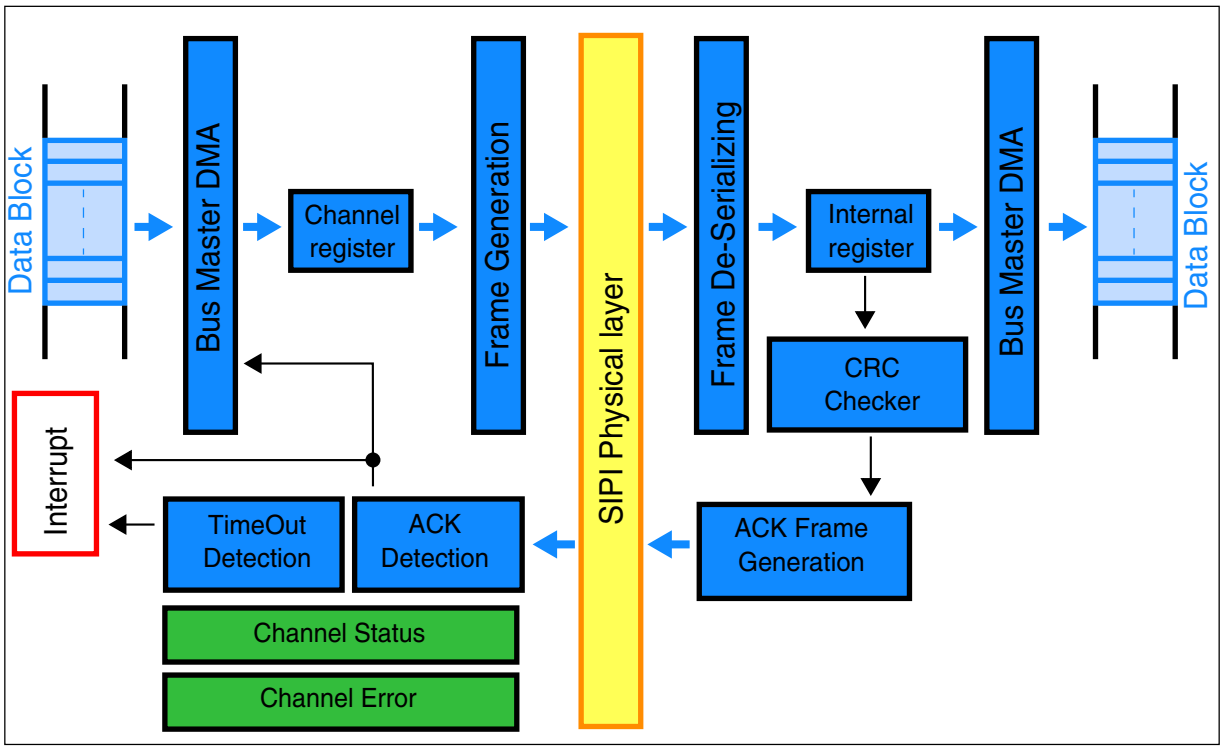

Figure 50-28. SIPI data stream with acknowledge trigger

50.9 DMA programming sequence

The DMA programming sequence is as follows:

1. Software configures TCD (DMA data).
2. DMA transfers from RAM to SIPI registers.
3. SIPI starts transferring the data through LFAST Tx ports.
4. If an acknowledge or fault response is received, SIPI will repeat the process. If any error response is received, SIPI will move to an idle state. An interrupt will be flagged by SIPI, and software will take control of the SIPI.
5. If SIPI has received a read response, and error flags are not set on the LFAST Rx port, SIPI will assert ipd_request. In case of error, move to Step 8.
6. As soon as ipd_request is asserted, DMA transfer starts between the SIPI registers and RAM.
7. If DMA transfer minor loop/major loop is complete, and the request is negated, ipd_request is negated.
8. If an error occurs:

- The SIPI generates an interrupt
- Software takes control of the SIPI

9. Steps 5 – 8 are repeated until the transfer is finished.

50.10 Modes of operation

SIPI has three operating modes:

- Initialization
- Normal
- Module Disable

After hardware reset the SIPI is in module disable mode, which helps reduce power consumption.

50.10.1 Initialization mode

To enter Initialization mode software writes SIPI_MCR[INIT]=1 SIPI_MCR[MOEN] must be set before attempting to write SIPI_MCR[INIT]). To exit Initialization mode software writes SIPI_MCR[INIT]=0 (see SIPI Module Configuration Register (SIPI_MCR)).

All message transfers are stopped when in Initialization mode. If software invokes Initialization mode when a bus transfer is in progress, the transfer will be aborted immediately even if the transfer has not completed.

Note

It is recommended that software checks the state of SIPI (SIPI_MCR[MOEN]) before setting SIPI_MCR[INIT].

50.10.2 Normal mode

Once software has completed initialization of SIPI (SIPI_MCR[INIT]=1), it can enter Normal mode by writing SIPI_MCR[INIT]=0. SIPI needs to be in Normal mode for all data transfers (see SIPI Module Configuration Register (SIPI_MCR)).

Note

SIPI must be enabled before a attempting to write SIPI_MCR[INIT] (SIPI_MCR[MOEN]=1).

50.10.3 Module Disable (MD)

MD mode in the SIPI is used to help reduce power consumption. By default, SIPI is in Disable mode, SIPI_MCR[MOEN]=0, and is exited by writing SIPI_MCR[MOEN]=1 (see SIPI Module Configuration Register (SIPI_MCR)). All the activities on the SIPI Tx and Rx ports are immediately stopped in Module Disable mode.

50.11 Errors

This section describes the potential errors that can occur during SIPI operation.

50.11.1 Timeout error

A timeout error is generated at the initiator node when the acknowledge/response is not received within the time configured in the corresponding CTOR*n*[TOR] field setting (see SIPI Channel Timeout Register 0 (SIPI_CTOR0), SIPI Channel Timeout Register 1 (SIPI_CTOR1), SIPI Channel Timeout Register 2 (SIPI_CTOR2) and SIPI Channel Timeout Register 3 (SIPI_CTOR3)). A timeout error is indicated when ERR[TOE*n*]=1 (see SIPI Error Register (SIPI_ERR)).

Note

SIPI should not drop the response even after a timeout occurs. Software will poll both error and status flags after the transfer to see if there was a timeout error. If there was a timeout error the response received may then be discarded.

50.11.2 CRC error

A CRC error is generated at the target nodes when the CRC received with the frame does not match the calculated CRC, and the SR[GCRCE] is set (see SIPI Status Register (SIPI_SR)). An interrupt will be asserted if MCR[CRCIE]=1 (see SIPI Module Configuration Register (SIPI_MCR)).

Note

The target node will not send an acknowledge to the initiator node when a CRC error is generated. An interrupt will be generated on the target side if the corresponding interrupt

enable bit is set. The initiator node will detect a timeout and take necessary action.

50.11.3 Maximum count reached error

The maximum count reached error is only generated at the target node. It is generated when the value of the SIPI_ACR is equal to the SIPI_MAXCR (see SIPI Max Count Register (SIPI_MAXCR) and SIPI Address Count Register (SIPI_ACR)). When the maximum count is reached, SIPI_SR[MCR] = 1 (see SIPI Status Register (SIPI_SR)). An interrupt will be generated if SIPI_MCR[MCRIE] = 1 (see SIPI Module Configuration Register (SIPI_MCR)).

50.11.4 Transaction ID error

The Transaction ID (TID) error is always generated at the initiator node only. It is generated when header bits 15–13 do not match SIPI_CSR*n*[TID] (transaction ID bits, see SIPI Channel Status Register 0 (SIPI_CSR0), SIPI Channel Status Register 1 (SIPI_CSR1), SIPI Channel Status Register 2 (SIPI_CSR2), and SIPI Channel Status Register 3 (SIPI_CSR3)). SIPI_CSR*n*[TIDE] = 1 when a TID error is detected, and an interrupt will be generated if SIPI_CIR*n*[TIDIE] = 1 (see SIPI Channel Interrupt Register 0 (SIPI_CIR0), SIPI Channel Interrupt Register 1 (SIPI_CIR1), SIPI Channel Interrupt Register 2 (SIPI_CIR2), and SIPI Channel Interrupt Register 3 (SIPI_CIR3)).

50.11.5 Acknowledge error

An incorrect acknowledge is received only from the initiator. When the acknowledge received is incorrect, SIPI_ERR[ACKR*n*] will be set (see SIPI Error Register (SIPI_ERR)). An interrupt will be generated if SIPI_CIR*n*[WAIE]=1 (see SIPI Channel Interrupt Register 0 (SIPI_CIR0), SIPI Channel Interrupt Register 1 (SIPI_CIR1), SIPI Channel Interrupt Register 2 (SIPI_CIR2), and SIPI Channel Interrupt Register 3 (SIPI_CIR3)).

50.12 CRC calculation

Example: If header is AABBh, address is 1122_3344h and data is CCDD_EEFFh. Then CRC calculation will take place as follows:

1) The CRC seed is initialized by FFFF_FFFFh.

2) All the data will be mirrored before sending to CRC engine (for example, MSB will be sent as LSB).

3) So the header will be sent as DD55_0000h.

4) Address will be sent as 22CC_4488h.

5) Data will be sent as FF77_BB33h.

50.13 Interrupt logic

A description of the interrupt logic can be found in the following figure.

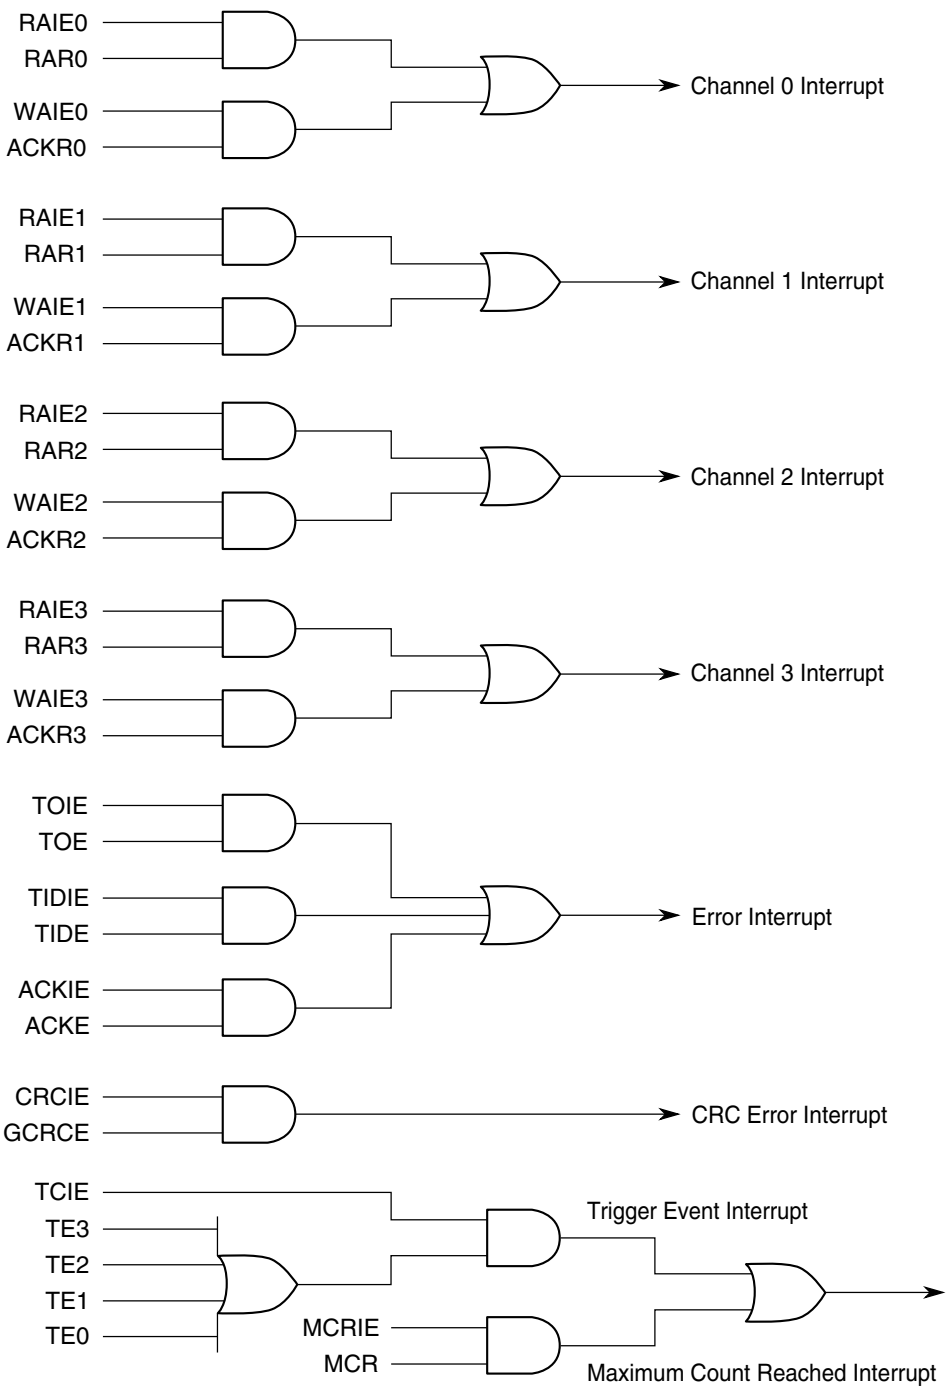

Figure 50-29. Interrupt description

50.14 SIPI control and status overview

The diagram below shows the relationship between transfers and the SIPI control and status registers.

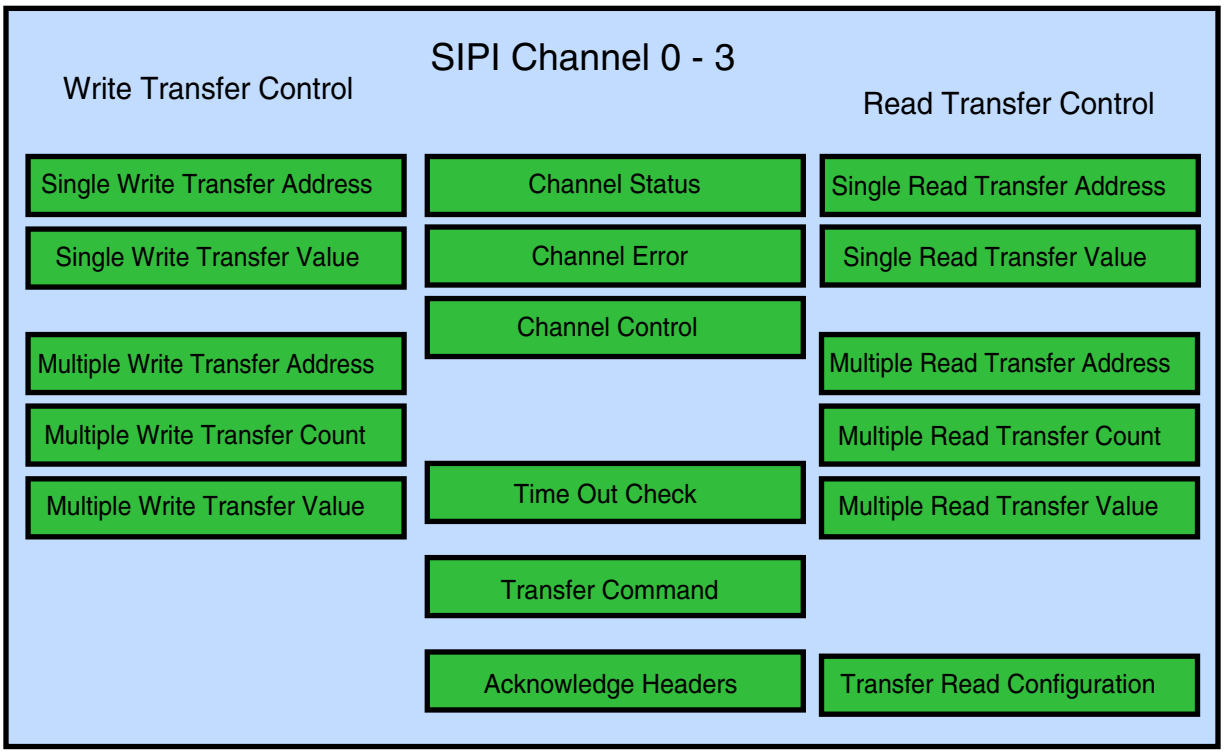

Figure 50-30. SIPI control and status overview – Register transfer

50.15 Memory map and register definition

SIPI memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page

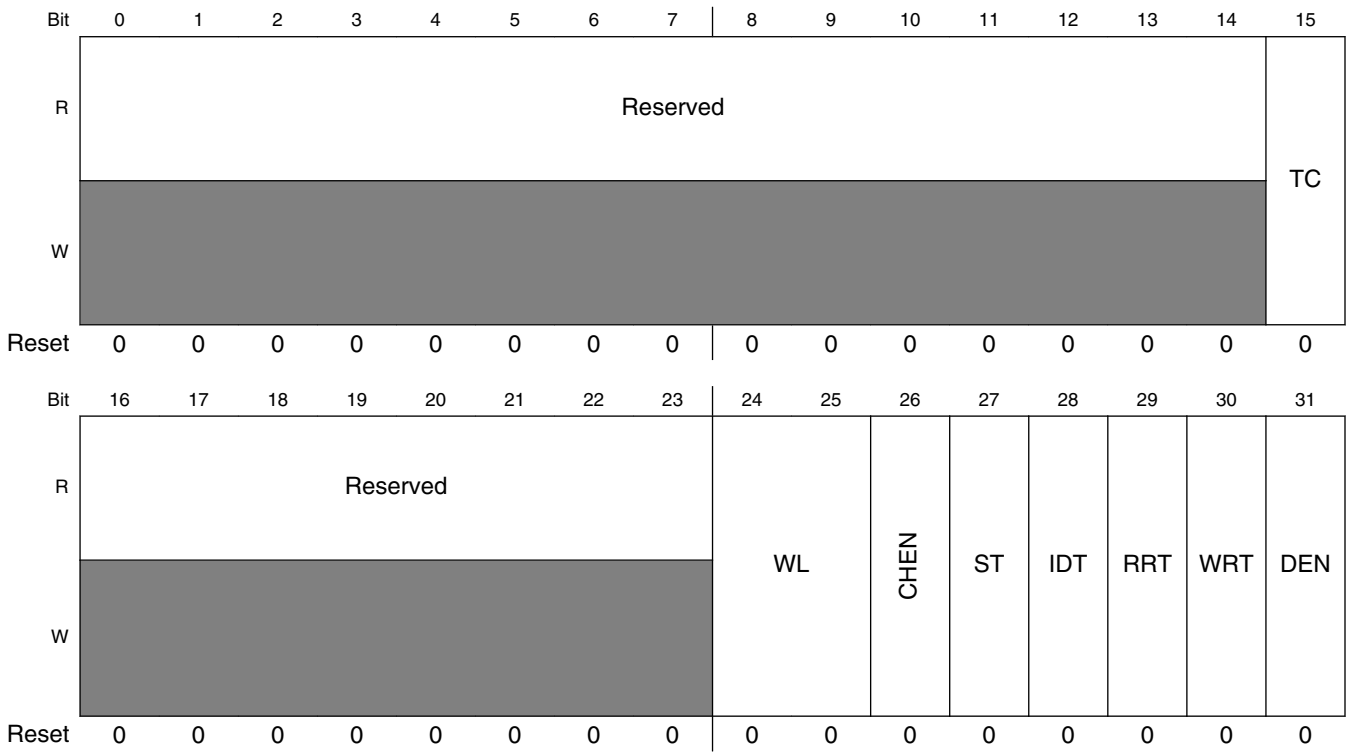
50.15.1 SIPI Channel Control Register 0 (SIPI_CCR0)

NOTE

Back to back transactions are not supported on a single channel (for example, if the channel busy bit, SIPI_CSR0[CB] = 1, is configured for a channel, it cannot be triggered for another transfer until the data buffers are empty and the channel is free, SIPI_CSR0[CB] = 0).



PRIORITY SCHEDULING: The channel whose SIPI_CAR*n* is written first will gain access first irrespective of its priority at the start of the transfer. As more transfers are requested, priority will be resolved as per the priority scheme (for example, channel 0 – channel 1 – channel 2 – channel 3). Scheduling will occur each time the LFAST is not ready to receive data and no channel is pending for data transmission. The reason for the scheduling is that a common CRC module is shared by all channels. If the LFAST is ready to receive data during the entire process, it will happen only in the beginning and later on priority will be resolved as per the priority scheme.

NOTE

This register is only writable in Initialization mode (SIPI_MCR[INIT] = 1), except for command bits (for example, TC, WL, ST, IDT, RRT and WRT). Also, the command bits can be written only when the corresponding Channel busy bit is not asserted (SIPI_CSR*n*[CB] = 1 (see SIPI Channel Status Register 0 (SIPI_CSR0)). Software will need to poll the respective channel busy bits before attempting to change the command type.

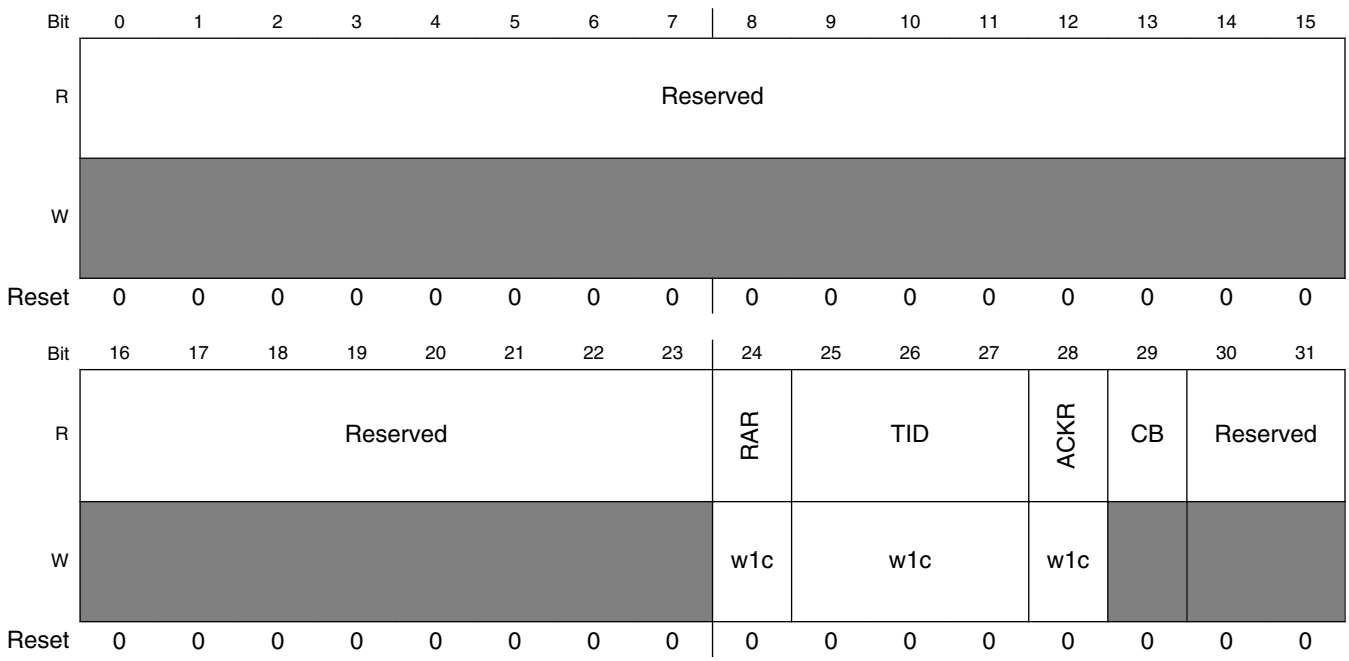
Only one channel at a time can transmit. Therefore, only one channel can remain busy. Maximum time allowed to transmit a full command is nine clock cycles. The Command type of a channel can only be changed when it is no longer busy. Also, to send a command, we need to write to the corresponding SIPI_CAR*n* (see SIPI Channel Address Register 0 (SIPI_CAR0)).

Address: 0h base + 0h offset = 0h

SIPI_CCR0 field descriptions

Field	Description
0–14 Reserved	This field is reserved.
15 TC	Send Trigger Command. A Trigger Command requires that only this bit to be set by software, the trigger does not depend on settings in SIPI_CAR0. 0 Trigger command not sent 1 Trigger command sent
16–23 Reserved	This field is reserved.
24–25 WL	Word Length Transfer. For Streaming write, WL bits should be written 10. 00 8-bit 01 16-bit 10 32-bit 11 not used
26 CHEN	Channel Enable. If all channel enables are simultaneously written to enable the channels, channel 0 will be given the highest priority for transmission. For channels, the lowest channel number is given highest priority.

Table continues on the next page...



SIPI_CCR0 field descriptions (continued)

Field	Description
	0 Channel is disabled 1 Channel is enabled
27 ST	Streaming Transfer. This bit is hard-coded to 0. It can only be written for channel 2 (SIPI_CCR2). This bit can only be written when the corresponding SIPI_CCR*n*[WRT] = 1. **NOTE:** Only transfers with channel 2 can write 1 to this bit. All other channels force SIPI_CCR*n*[ST] = 0. The SIPI_CCR2[WRT] and SIPI_CCR2[ST] bits must be set for streaming. 0 Streaming transfer is disabled 1 Streaming transfer is enabled
28 IDT	ID Read Request Transfer. This request returns the value of the CHIP ID. **NOTE:** The order of priority for writing to IDT, WRT and RRT must be in this order: 1. IDT 2. RRT 3. WRT 0 ID read request not sent 1 ID read request sent
29 RRT	Read Request Transfer. **NOTE:** The order of priority for writing to IDT, WRT and RRT must be in this order: 1. IDT 2. RRT 3. WRT 0 Read request will not be sent 1 Read request transfer by the initiator. This bit can not be written if SIPI_CCR0[IDT] = 1.
30 WRT	Write Request Transfer. **NOTE:** The order of priority for writing to IDT, WRT and RRT must be in this order: 1. IDT 2. RRT 3. WRT 0 No write request will be sent 1 Write request transfer by the initiator. This bit can not be written if SIPI_CCR0[IDT] = 1 or SIPI_CCR0[RRT] = 1.
31 DEN	DMA Enable. When enabling DMA mode, this bit should be set by software. It will then be cleared by hardware after one major loop has completed. 0 Channel will be used for bus interface access. 1 Channel will be used for DMA access

50.15.2 SIPI Channel Status Register 0 (SIPI_CSR0)

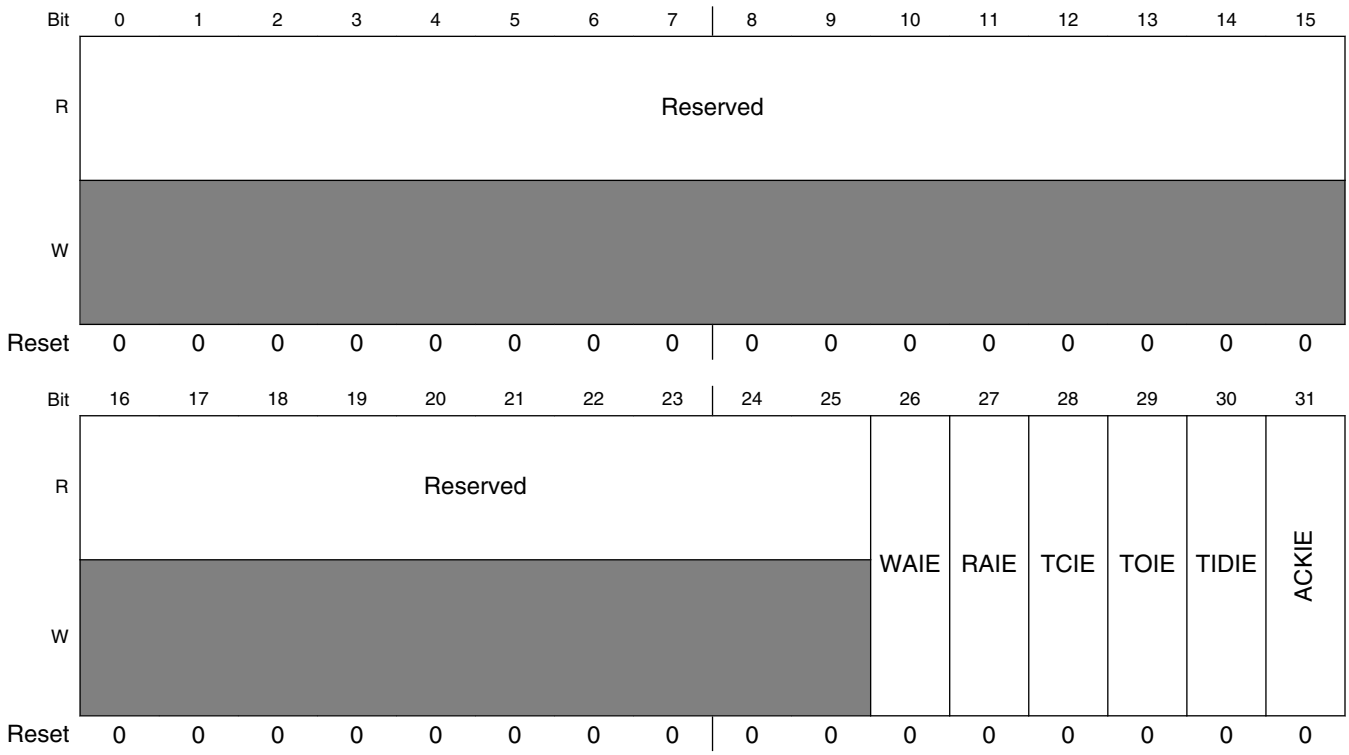
CSR0 contains the status bits for the current transfer.

Address: 0h base + 4h offset = 4h

SIPI_CSR0 field descriptions

Field	Description
0–23 Reserved	This field is reserved.
24 RAR	Read Answer Reception. 0 Read answer not received 1 Read answer received
25–27 TID	Transaction ID of transmitted frame. Transaction ID is a random number associated with every Tx frame to match the received response/ack with the command.
28 ACKR	Acknowledge Received. 0 Acknowledge not received 1 Acknowledge received
29 CB	Channel Busy. Indicates channel 0 status. 0 Channel 0 free 1 Channel 0 busy

Table continues on the next page...



SIPI_CSR0 field descriptions (continued)

Field	Description
30–31 Reserved	This field is reserved.

50.15.3 SIPI Channel Interrupt Register 0 (SIPI_CIR0)

SIPI_CIR0 contains the interrupt enable bits for channel 0.

Address: 0h base + Ch offset = Ch

SIPI_CIR0 field descriptions

Field	Description
0–25 Reserved	This field is reserved.
26 WAIE	Write Acknowledge Interrupt Enable. 0 Interrupt is disabled 1 Interrupt is enabled
27 RAIE	Read Answer Interrupt Enable. 0 Interrupt is disabled 1 Interrupt is enabled

Table continues on the next page...

SIPI_CIR0 field descriptions (continued)

Field	Description
28 TCIE	Trigger Command Interrupt Enable. 0 Interrupt is disabled 1 Interrupt is enabled
29 TOIE	Timeout Error Interrupt Enabled. 0 Interrupt is disabled 1 Interrupt is enabled
30 TIDIE	Transaction ID Error Interrupt Enable. 0 Interrupt is disabled 1 Interrupt is enabled
31 ACKIE	Acknowledge Error Interrupt Enable. 0 Interrupt is disabled 1 Interrupt is enabled

50.15.4 SIPI Channel Timeout Register 0 (SIPI_CTOR0)

SIPI_CTOR0 contains the timeout value for Tx requests.

Address: 0h base + 10h offset = 10h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	Reserved																								TOR							
W

SIPI_CAR0 field descriptions

Field	Description
0–31 CAR	These bits contain the address of the target node.

50.15.7 SIPI Channel Data Register 0 (SIPI_CDR0)

SIPI_CDR0 contains the data to be transmitted, and can be written anytime by software or the DMA. The data can be written in 8, 16 or 32 bit formats.

Address: 0h base + 1Ch offset = 1Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	CDR																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SIPI_CDR0 field descriptions

Field	Description
0–31 CDR	Data register bits. Contains the data that will be transmitted, or received.

50.15.8 SIPI Channel Control Register 1 (SIPI_CCR1)

NOTE

Back to back transactions are not supported on a single channel (for example, if the channel busy bit, SIPI_CSR1[CB] = 1, is configured for a channel, it cannot be triggered for another transfer until the data buffers are empty and the channel is free, SIPI_CSR1[CB] = 0).

PRIORITY SCHEDULING: The channel whose SIPI_CAR*n* is written first will gain access first irrespective of its priority at the start of the transfer. As more transfers are requested, priority will be resolved as per the priority scheme (for example, channel 0 – channel 1 – channel 2 – channel 3). Scheduling will occur each time the LFAST is not ready to receive data and no channel is pending for data transmission. The reason for the scheduling is that a common CRC module is shared by all channels. If the LFAST is ready to receive data during the entire process, it will happen only in the beginning and later on priority will be resolved as per the priority scheme.

NOTE

This register is only writable in Initialization mode (SIPI_MCR[INIT] = 1), except for command bits (for example, TC, WL, ST, IDT, RRT and WRT). Also, the command bits can be written only when the corresponding Channel busy bit is not asserted (SIPI_CSR*n*[CB] = 1 (see SIPI Channel Status Register 1 (SIPI_CSR1)). Software will need to poll the respective channel busy bits before attempting to change the command type.

Only one channel at a time can transmit. Therefore, only one channel can remain busy. Maximum time allowed to transmit a full command is nine clock cycles. The Command type of a channel can only be changed when it is no longer busy. Also, to send a command, we need to write to the corresponding SIPI_CAR*n* (see SIPI Channel Address Register 1 (SIPI_CAR1)).

SIPI_CDR1 field descriptions

Field	Description
0–31 CDR	Data register bits. Contains the data that will be transmitted, or received.

50.15.15 SIPI Channel Control Register 2 (SIPI_CCR2)

NOTE

Back to back transactions are not supported on a single channel (for example, if the channel busy bit, SIPI_CSR2[CB] = 1, is configured for a channel, it cannot be triggered for another transfer until the data buffers are empty and the channel is free, SIPI_CSR2[CB] = 0).

PRIORITY SCHEDULING: The channel whose SIPI_CAR*n* is written first will gain access first irrespective of its priority at the start of the transfer. As more transfers are requested, priority will be resolved as per the priority scheme (for example, channel 0 – channel 1 – channel 2 – channel 3). Scheduling will occur each time the LFAST is not ready to receive data and no channel is pending for data transmission. The reason for the scheduling is that a common CRC module is shared by all channels. If the LFAST is ready to receive data during the entire process, it will happen only in the beginning and later on priority will be resolved as per the priority scheme.

NOTE

This register is only writable in Initialization mode (SIPI_MCR[INIT] = 1), except for command bits (for example, TC, WL, ST, IDT, RRT and WRT). Also, the command bits can be written only when the corresponding Channel busy bit is not asserted (SIPI_CSR*n*[CB] = 1 (see SIPI Channel Status Register 2 (SIPI_CSR2)). Software will need to poll the respective channel busy bits before attempting to change the command type.

Only one channel at a time can transmit. Therefore, only one channel can remain busy. Maximum time allowed to transmit a full command is nine clock cycles. The Command type of a channel can only be changed when it is no longer busy. Also, to send a command, we need to write to the corresponding SIPI_CAR*n* (see SIPI Channel Address Register 2 (SIPI_CAR2)).

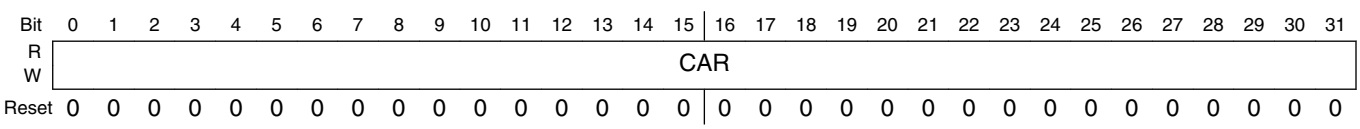
SIPI_CTOR2 field descriptions

Field	Description
0–23 Reserved	This field is reserved.
24–31 TOR	Timeout counter runs on the prescaled peripheral clock. Prescaler is defined by SIPI_MCR[PRSCLR]. **NOTE:** Field can only be written during Initialization mode (SIPI_MCR[INIT] = 1).

50.15.19 SIPI Channel CRC Register 2 (SIPI_CCRC2)

SIPI_CCRC*n* is a read only which returns the CRC calculated value on the header, address and data bits.

Address: 0h base + 54h offset = 54h



SIPI_CCRC2 field descriptions

Field	Description
0–15 CRCI	Reflects received CRC value at initiator
16–31 CRCT	Reflects received CRC value at target

50.15.20 SIPI Channel Address Register 2 (SIPI_CAR2)

SIPI_CAR2 is the address target for data transmission. For streaming operations this register is the start address.

Address: 0h base + 58h offset = 58h

SIPI_CAR2 field descriptions

Field	Description
0–31 CAR	These bits contain the address of the target node.

50.15.21 SIPI Channel Data Register 2 (SIPI_CDR2_*n*)

SIPI_CDR2_*n*contains the data to be transmitted, and can be written anytime by software or the DMA. The data can be written in 8, 16 or 32 bit formats.

Address: 0h base + 5Ch offset + (4d × i), where i=0d to 7d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	CDR2																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SIPI_CDR2_*n* field descriptions

Field	Description
0–31 CDR2	Data register bits. Contains the data that will be transmitted, or received.

50.15.22 SIPI Channel Control Register 3 (SIPI_CCR3)

NOTE

Back to back transactions are not supported on a single channel (for example, if the channel busy bit, SIPI_CSR3[CB] = 1, is configured for a channel, it cannot be triggered for another transfer until the data buffers are empty and the channel is free, SIPI_CSR3[CB] = 0).

PRIORITY SCHEDULING: The channel whose SIPI_CAR*n* is written first will gain access first irrespective of its priority at the start of the transfer. As more transfers are requested, priority will be resolved as per the priority scheme (for example, channel 0 – channel 1 – channel 2 – channel 3). Scheduling will occur each time the LFAST is not ready to receive data and no channel is pending for data transmission. The reason for the scheduling is that a common CRC module is shared by all channels. If the LFAST is ready to receive data during the entire process, it will happen only in the beginning and later on priority will be resolved as per the priority scheme.

NOTE

This register is only writable in Initialization mode (SIPI_MCR[INIT] = 1), except for command bits (for example, TC, WL, ST, IDT, RRT and WRT). Also, the command bits can be written only when the corresponding Channel busy bit is not asserted (SIPI_CSR*n*[CB] = 1 (see SIPI Channel Status Register 3 (SIPI_CSR3)). Software will need to poll the respective channel busy bits before attempting to change the command type.

Only one channel at a time can transmit. Therefore, only one channel can remain busy. Maximum time allowed to transmit a full command is nine clock cycles. The Command type of a channel can only be changed when it is no longer busy. Also, to send a command, we need to write to the corresponding SIPI_CAR*n* (see SIPI Channel Address Register 3 (SIPI_CAR3)).

Address: 0h base + 7Ch offset = 7Ch

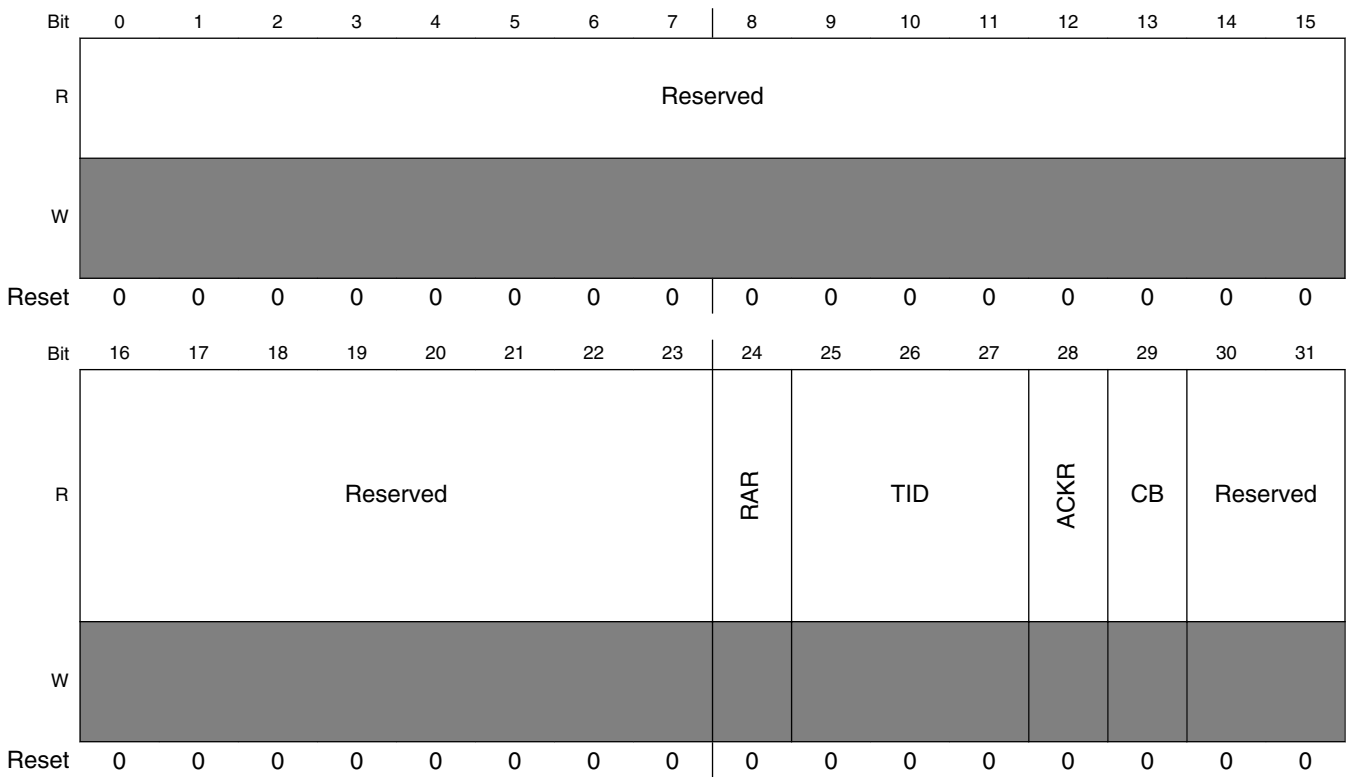
SIPI_CCR3 field descriptions

Field	Description
0–14 Reserved	This field is reserved.
15 TC	Send Trigger Command. A Trigger Command requires that only this bit to be set by software, the trigger does not depend on settings in SIPI_CAR3. 0 Trigger command not sent 1 Trigger command sent
16–23 Reserved	This field is reserved.
24–25 WL	Word Length Transfer. For Streaming write WL bits should be written 10. 00 8-bit 01 16-bit 10 32-bit 11 not used
26 CHEN	Channel Enable. If all channel enables are simultaneously written to enable the channels, channel 0 will be given the highest priority for transmission. For channels, the lowest channel number is given highest priority. 0 Channel is disabled 1 Channel is enabled
27 ST	Streaming Transfer. This bit is hard-coded to 0. It can only be written for channel 2 (SIPI_CCR2). This bit can only be written when the corresponding SIPI_CCR*n*[WRT] = 1. **NOTE:** Only transfers with channel 2 can write 1 to this bit. All other channels force SIPI_CCR*n*[ST] = 0. The SIPI_CCR2[WRT] and SIPI_CCR2[ST] bits must be set for streaming. 0 Streaming transfer is disabled 1 Streaming transfer is enabled
28 IDT	ID Read Request Transfer. This request returns the value of the CHIP ID. **NOTE:** The order of priority for writing to IDT, WRT and RRT must be in this order: 1. IDT 2. RRT 3. WRT 0 ID read request not sent 1 ID read request sent
29 RRT	Read Request Transfer. **NOTE:** The order of priority for writing to IDT, WRT and RRT must be in this order: 1. IDT 2. RRT

Table continues on the next page...



SIPI_CCR3 field descriptions (continued)

Field	Description
	3. WRT 0 Read request will not be sent 1 Read request transfer by the initiator. This bit can not be written if SIPI_CCR3[IDT] = 1.
30 WRT	Write Request Transfer. **NOTE:** The order of priority for writing to IDT, WRT and RRT must be in this order: 1. IDT 2. RRT 3. WRT 0 No write request will be sent 1 Write request transfer by the initiator. This bit can not be written if SIPI_CCR3[IDT] = 1 or SIPI_CCR3[RRT] = 1.
31 DEN	DMA Enable. When enabling DMA mode, this bit should be set by software. It will then be cleared by hardware after one major loop has completed. 0 Channel will be used for bus interface access. 1 Channel will be used for DMA access

50.15.23 SIPI Channel Status Register 3 (SIPI_CSR3)

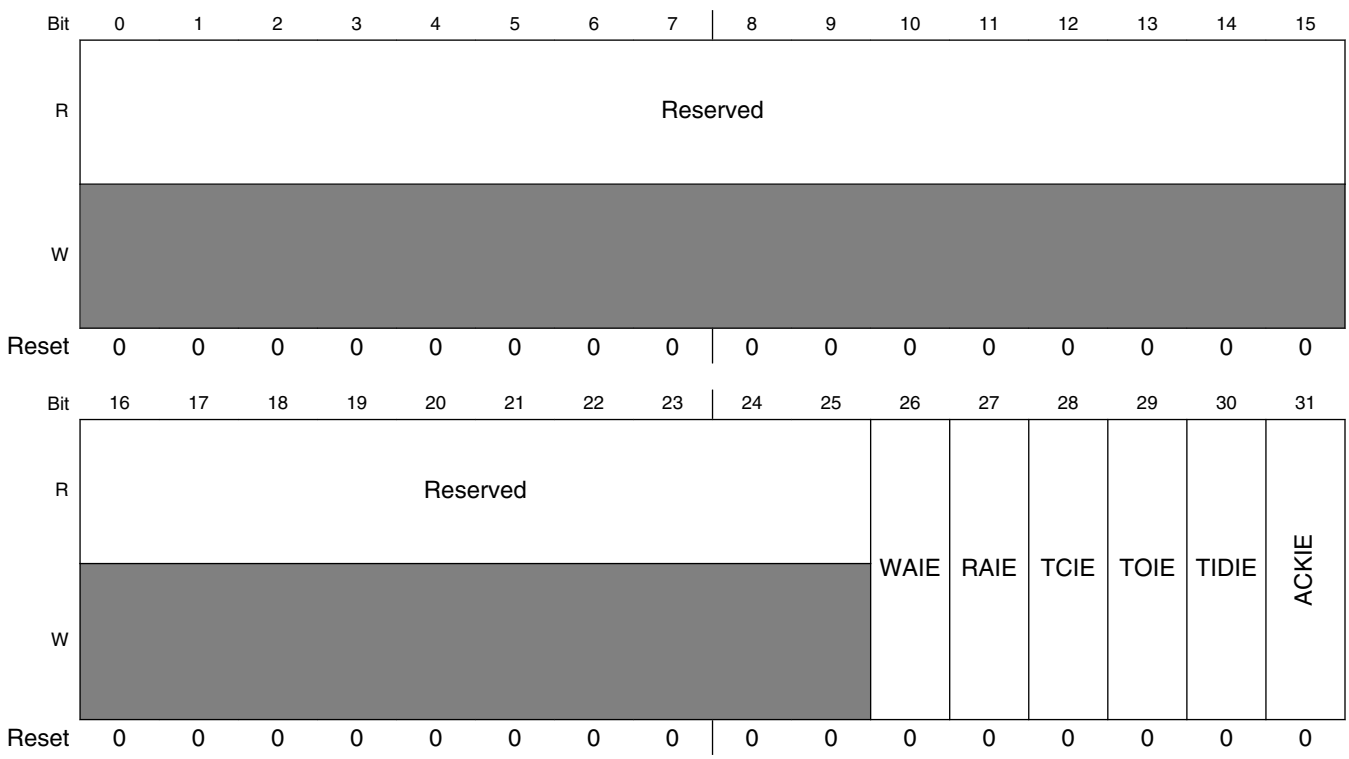
SIPI_CSR3 contains the status bits for the current transfer.

Address: 0h base + 80h offset = 80h

SIPI_CSR3 field descriptions

Field	Description
0–23 Reserved	This field is reserved.
24 RAR	Read Answer Reception. 0 Read answer not received 1 Read answer received
25–27 TID	Transaction ID of transmitted frame. Transaction ID is a random number associated with every Tx frame to match the received response/ack with the command.
28 ACKR	Acknowledge Received. 0 Acknowledge not received 1 Acknowledge received

Table continues on the next page...



SIPI_CSR3 field descriptions (continued)

Field	Description
29 CB	Channel Busy. Indicates channel 3 status. 0 Channel 3 free 1 Channel 3 busy
30–31 Reserved	This field is reserved.

50.15.24 SIPI Channel Interrupt Register 3 (SIPI_CIR3)

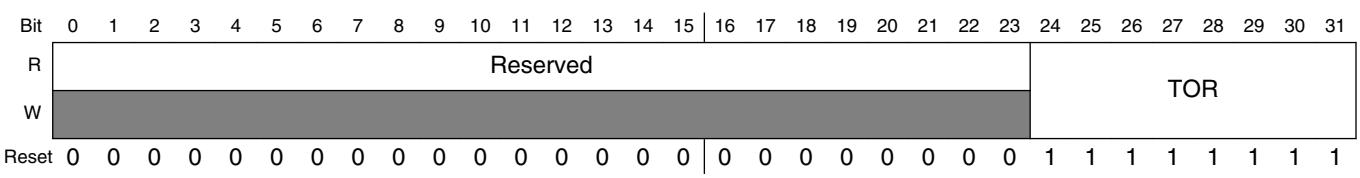
SIPI_CIR3 contains the interrupt enable bits for channel 3.

Address: 0h base + 88h offset = 88h

SIPI_CIR3 field descriptions

Field	Description
0–25 Reserved	This field is reserved.
26 WAIE	Write Acknowledge Interrupt Enable.

Table continues on the next page...



SIPI_CIR3 field descriptions (continued)

Field	Description
	0 Interrupt is disabled 1 Interrupt is enabled
27 RAIE	Read Answer Interrupt Enable. 0 Interrupt is disabled 1 Interrupt is enabled
28 TCIE	Trigger Command Interrupt Enable. 0 Interrupt is disabled 1 Interrupt is enabled
29 TOIE	Timeout Error Interrupt Enabled. 0 Interrupt is disabled 1 Interrupt is enabled
30 TIDIE	Transaction ID Error Interrupt Enable. 0 Interrupt is disabled 1 Interrupt is enabled
31 ACKIE	Acknowledge Error Interrupt Enable. 0 Interrupt is disabled 1 Interrupt is enabled

50.15.25 SIPI Channel Timeout Register 3 (SIPI_CTOR3)

SIPI_CTOR3 contains the timeout value for Tx requests.

Address: 0h base + 8Ch offset = 8Ch

SIPI_CTOR3 field descriptions

Field	Description
0–23 Reserved	This field is reserved.
24–31 TOR	Timeout value for transmitted requests. Timeout counter runs on the prescaled peripheral clock. Prescaler is defined by SIPI_MCR[PRSCLR]. **NOTE:** Field can only be written during Initialization mode (SIPI_MCR[INIT] = 1).

50.15.26 SIPI Channel CRC Register 3 (SIPI_CCRC3)

SIPI_CCRC*n* is a read only which returns the CRC calculated value on the header, address and data bits.

Address: 0h base + 90h offset = 90h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

SIPI_CAR3 field descriptions

Field	Description
0–31 CAR	These bits contain the address of the target node.

50.15.28 SIPI Channel Data Register 3 (SIPI_CDR3)

SIPI_CDR3 contains the data to be transmitted, and can be written anytime by software or the DMA. The data can be written in 8, 16 or 32 bit formats.

Address: 0h base + 98h offset = 98h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

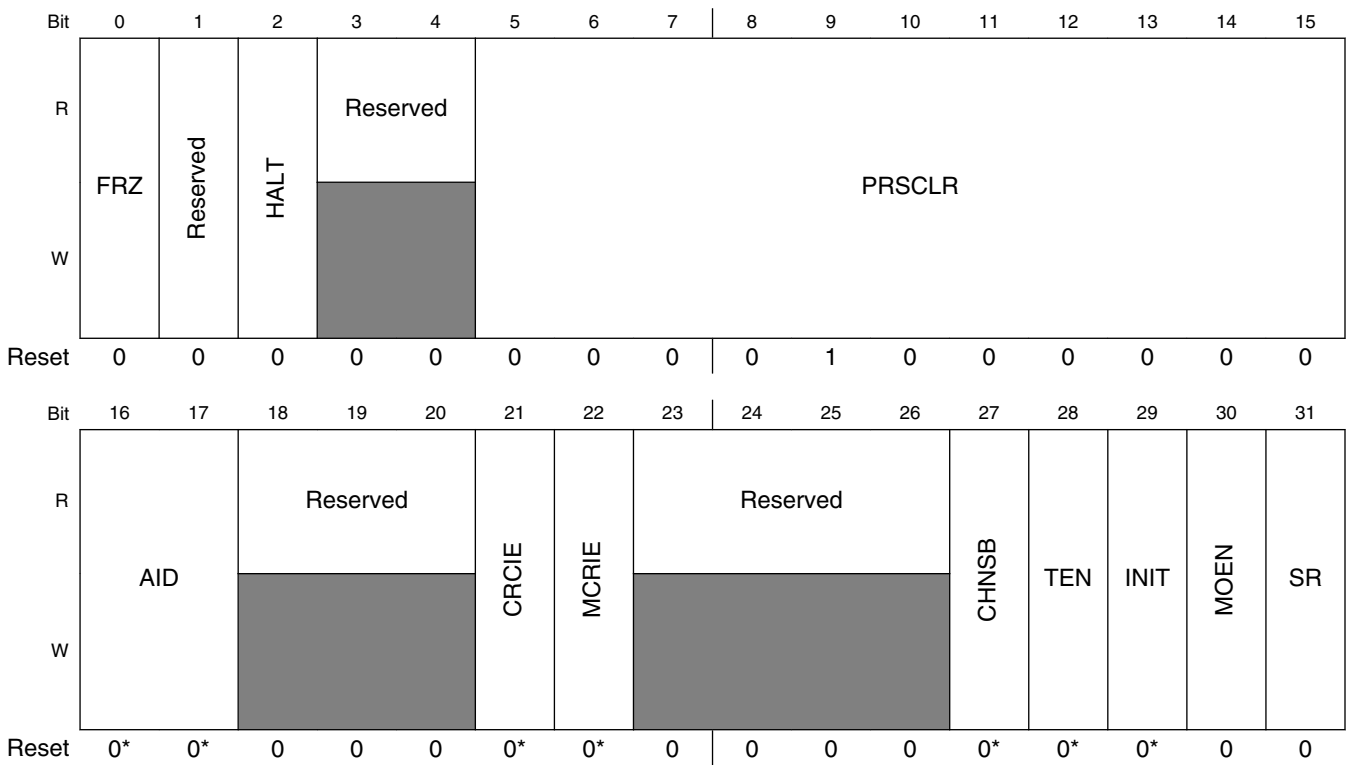
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0



SIPI_CDR3 field descriptions

Field	Description
0–31 CDR	Data register bits. Contains the data that will be transmitted, or received.

50.15.29 SIPI Module Configuration Register (SIPI_MCR)

The SIPI_MCR is a global 32-bit configuration register.

Address: 0h base + 9Ch offset = 9Ch

* Notes:
- INIT field: Can only be written when SIPI_MCR[MOEN] = 1.
- TEN field: Can only be written when SIPI_MCR[MOEN] = 1.
- CHNSB field: Can be written only once after reset.
- MCRIE field: Can only be written when SIPI_MCR[MOEN] = 1.
- CRCIE field: Can only be written when SIPI_MCR[MOEN] = 1.
- AID field: Can be written in initialization mode only (SIPI_MCR[INIT] = 1).

SIPI_MCR field descriptions

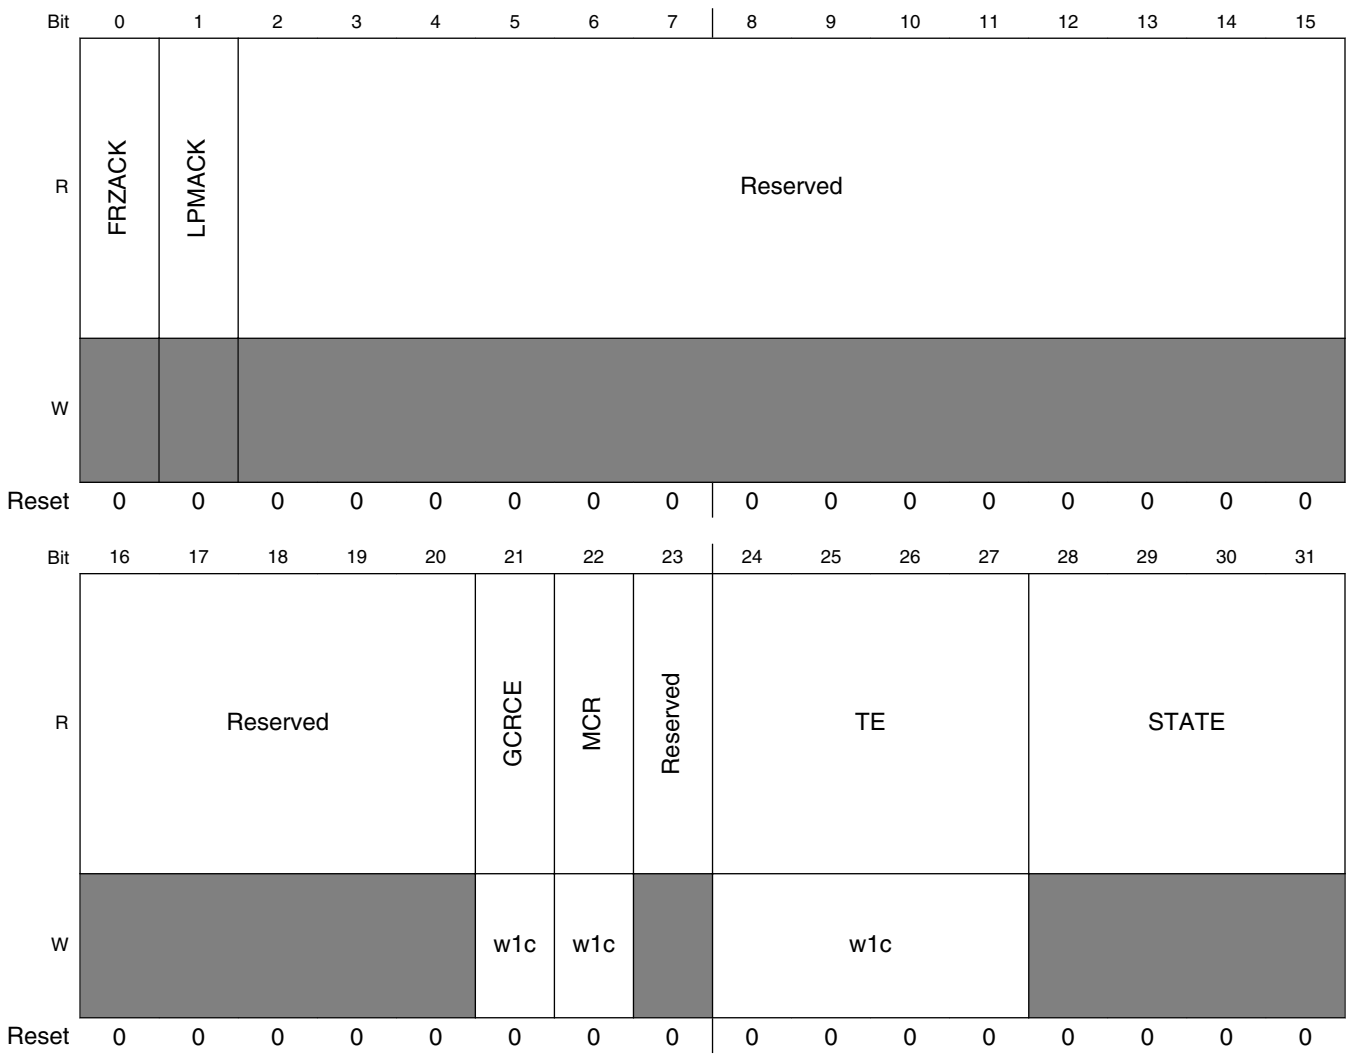
Field	Description
0 FRZ	Freeze Enable The FRZ bit specifies the SIPI behavior when Debug mode is requested at the MCU level. When FRZ is asserted, the SIPI is enabled to enter Freeze mode. Negation of this bit field causes SIPI to exit Freeze mode. **NOTE:** Can only be written when SIPI_MCR[MOEN] = 1.

Table continues on the next page...

SIPI_MCR field descriptions (continued)

Field	Description
	0 Not enabled to enter Freeze mode 1 Enabled to enter Freeze mode
1 Reserved	This field is reserved. **Important:** Always write the default value to this field.
2 HALT	Halt Mode Enable Assertion of this bit puts SIPI into Freeze mode. No Rx or Tx is performed in the SIPI until this bit is cleared. If this bit is enabled in during Tx or Rx communications, the current activity will finish, then the SIPI will enter Freeze mode. **NOTE:** Can only be written when SIPI_MCR[MOEN] = 1. 0 No Freeze mode request 1 Enters Freeze mode if FRZ bit is asserted.
3–4 Reserved	This field is reserved.
5–15 PRSCLR	Timeout counter prescaler The timeout counter runs on the prescaled system clock. Default value is 64 (040h). The allowed programmable values are (all other values are ignored): 040h 64 (default) 080h 128 100h 256 200h 512 400h 1024 **NOTE:** This field should be programmed by software during initialization mode, SIPI_MCR[INIT] = 1. Writes during other times are ignored. **NOTE:** Writes to SIPI_MCR[PRSCLR] can only be accomplished with 16-bit or 32-bit writes.
16–17 AID	Address Increment/Decrement These bits define the type of address change at the target node. **NOTE:** This bits should be programmed by software in initialization mode, SIPI_MCR[INIT] = 1. Writes during other times are ignored. 00 no change. address stays same 01 address increments by 4 10 address decrements by 4 11 not used
18–20 Reserved	This field is reserved.
21 CRCIE	CRC Error Interrupt Enable 0 Interrupt is disabled 1 Interrupt is enabled
22 MCRIE	Max Count Reached Interrupt Enable

Table continues on the next page...



SIPI_MCR field descriptions (continued)

Field	Description
	0 Interrupt is disabled 1 Interrupt is enabled
23–26 Reserved	This field is reserved.
27 CHNSB	Channel coding select bit. 0 Code Table II (see Table 50-2) 1 Code Table I (see Table 50-2)
28 TEN	Target Enable Setting this bit enables the target functionality at SIPI. This bit can be read or written anytime. This bit is automatically negated by hardware when target detects an error in "streaming without ACK" mode. This bit has to be enabled for the transmission operations also.
29 INIT	Initialization Mode Setting this bit puts the module in initialization mode. This bit should be cleared by software. Most register bits are configured using this bit. The SIPI_MCR[MOEN] bit needs to be set first, and then the INIT bit can be set and both bits can't be enabled together. 0 Normal Mode 1 Initialization Mode
30 MOEN	Module Enable This bit should be set or cleared by software. When this bit is negated, all SIPI operations are immediately stopped.
31 SR	Soft Reset Setting this bit clears all status and error registers, and FSMs are moved to idle state. This bit is automatically cleared by hardware once the reset operation is complete.

50.15.30 SIPI Status Register (SIPI_SR)

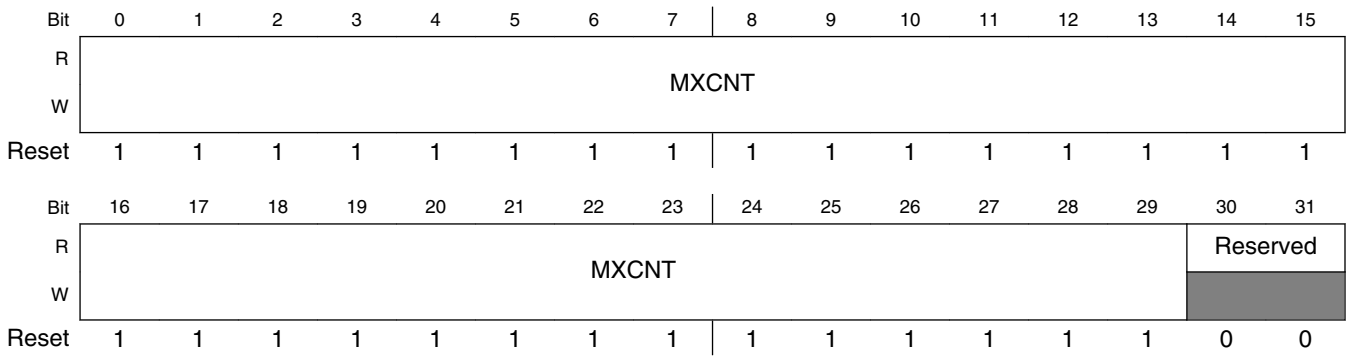
The SIPI_SR is the global status register of SIPI.

Address: 0h base + A0h offset = A0h

SIPI_SR field descriptions

Field	Description
0 FRZACK	Freeze Mode Acknowledge. This read-only bit indicates that SIPI is in Freeze mode. The Freeze mode request cannot be granted until current transmission or reception processes have finished. The software can poll the FRZACK bit to find when the SIPI has actually entered Freeze mode. If Freeze mode is requested while SIPI is in any of the low power modes, then the FRZACK bit will only be set when the low power mode is exited.

Table continues on the next page...



SIPI_SR field descriptions (continued)

Field	Description
	0 SIPI not in Freeze mode 1 SIPI in Freeze mode
1 LPMACK	Low Power Mode Acknowledge. This read-only bit indicates that SIPI is in Disable Mode. Disable mode can not be entered until all current transmission or reception processes have finished. The CPU can poll the LPMACK bit to know when SIPI has actually entered low power mode. 0 SIPI is not in low power mode 1 SIPI is in Disable Mode.
2–20 Reserved	This field is reserved.
21 GCRCE	Global CRC Error Bit. 0 No CRC error 1 CRC error occurred
22 MCR	Maximum Count Reached. This bit will be set whenever SIPI_ACR[ADCNT] = SIPI_MAXCR[MXCNT]. An interrupt will be generated when this bit is set only if SIPI_MCR[MCRIE] = 1. This it should be cleared by software.
23 Reserved	This field is reserved.
24–27 TE	Trigger Event on Respective Channels. This field enables interrupts for target nodes. xxx1 TE0 = 1 - Channel 0 trigger event xx1x TE1 = 1 - Channel 1 trigger event x1xx TE2 = 1 - Channel 2 trigger event 1xxx TE3 = 1 - Channel 3 trigger event
28–31 STATE	These bits reflect the transmit state machine status. They can be polled for determination of state machine status. 0000 IDLE 0001 HEADER_AND_ADDRESS_FIELD 0010 HEADER_AND_DATA_FIELD 0011 HEADER_AND_CRC_FIELD 0100 ADDRESS_AND_CRC_FIELD 0101 ADDRESS_AND_DATA_FIELD 0110 DATA_AND_CRC_FIELD 0111 DATA_FIELD

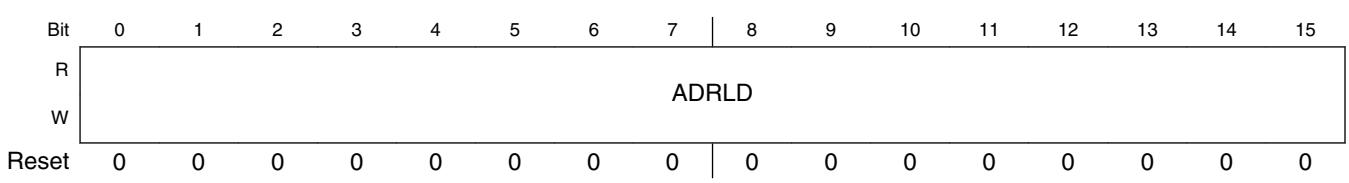
50.15.31 SIPI Max Count Register (SIPI_MAXCR)

SIPI_MAXCR contains the maximum address count value at target node. It is programmed via direct write request through the initiator. This register can be read or written by software anytime.

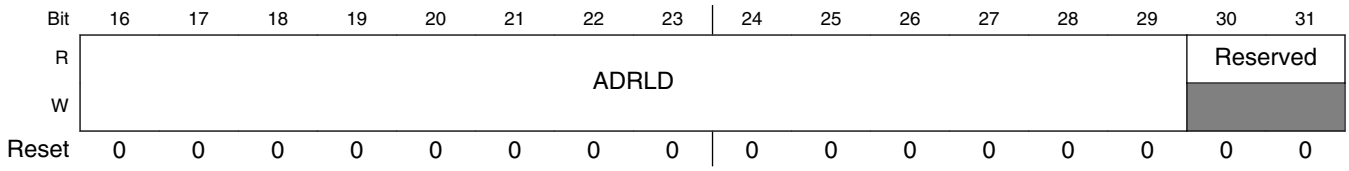
Address: 0h base + A4h offset = A4h

SIPI_MAXCR field descriptions

Field	Description
0–29 MXCNT	This field contains the maximum address count value at the target node. It should be programmed via direct write request through the initiator.
30–31 Reserved	This field is reserved.



50.15.32 SIPI Address Reload Register (SIPI_ARR)



The SIPI_ARR contains the reload value for the address counter at the target node. It should be configured by direct write request from the initiator.

NOTE

This register is writeable only when SIPI_MCR[INIT] = 1.

Address: 0h base + A8h offset = A8h

SIPI_ARR field descriptions

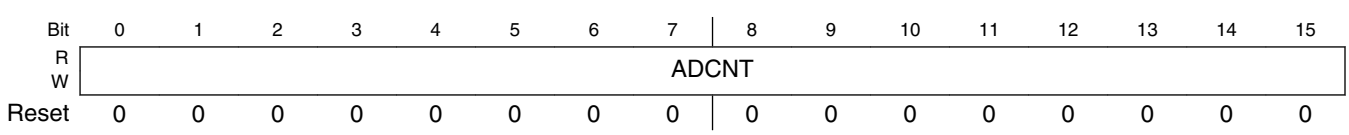
Field	Description
0–29 ADRLD	ADRLD contains the reload value for the address counter at the target node. It should be configured by direct write request from the initiator.
30–31 Reserved	This field is reserved.

50.15.33 SIPI Address Count Register (SIPI_ACR)

This register reflects the count value of address counter at target node. It should be configured by direct write request from initiator. This register can be read/written by software anytime.

NOTE

SIPI_ARR, SIPI_ACR and SIPI_MAXCR will be configured by direct write operation through the initiator.



NOTE

When a streaming write command is received, the target will start the write operation from the address present in SIPI_ACR (address count register).

NOTE

After each 32-bit write has completed, SIPI_ACR[ADCNT] is compared against SIPI_MAXCR[MXCNT]. If they are equal, SIPI_ACR[ADCNT] is loaded with the value stored in SIPI_ARR[ADRLD]. If they are not equal, the SIPI_ACR[ADCNT] will increment by 4, decrement by 4 or remain the same (depending on configuration). In both cases, the SIPI_ACR[ADCNT] will contain the address at which the next streaming write will occur.

Address: 0h base + ACh offset = ACh

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	ADCNT														Reserved	
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SIPI_ACR field descriptions

Field	Description
0–29 ADCNT	Feflects the count value of address counter at target node. It should be configured by direct write request from the initiator. This register can be read/written by software anytime. At the end of the streaming operation, SIPI_ACR will point to the next address to be written.
30–31 Reserved	This field is reserved.

50.15.34 SIPI Error Register (SIPI_ERR)

This register contains the error bits for the last transaction(s) for all the channels. Communication errors are generated only for out of range address accesses, areas that are read only and where accesses do not lead to generation of transfer errors. Also, writing to read only registers will not generate errors.

Address: 0h base + B0h offset = B0h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Field	Description
30 TIDE0	Transaction ID Error for Channel 0. 0 Received transaction ID matched with the stored ID 1 Received transaction ID didn't match with the stored ID
31 ACKE0	Acknowledge Error for Channel 0. 0 Acknowledge received is correct. 1 Acknowledge received is not correct.

Chapter 51
LVDS Fast Asynchronous Serial Transmission (LFAST) – Interprocessor Communications

51.1 Introduction

This chapter describes the specifications of the LFAST module, which implements the LVDS Fast Asynchronous Serial Transmission (LFAST) module. LFAST is used in dual mode (software configurable master/slave operation) for interprocessor communications.

51.2 Block diagram

The following figure depicts LFAST interaction with other modules on the device.

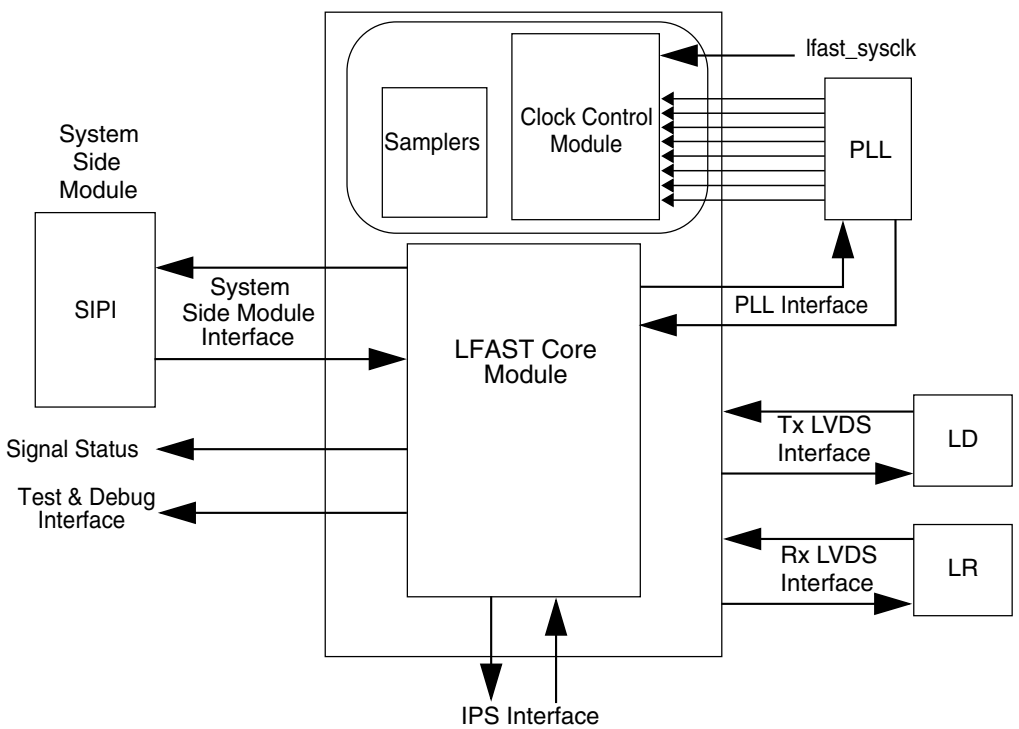

Figure 51-1. LFAST block diagram

51.3 External signals

LFAST is a five pin interface with the following signals :

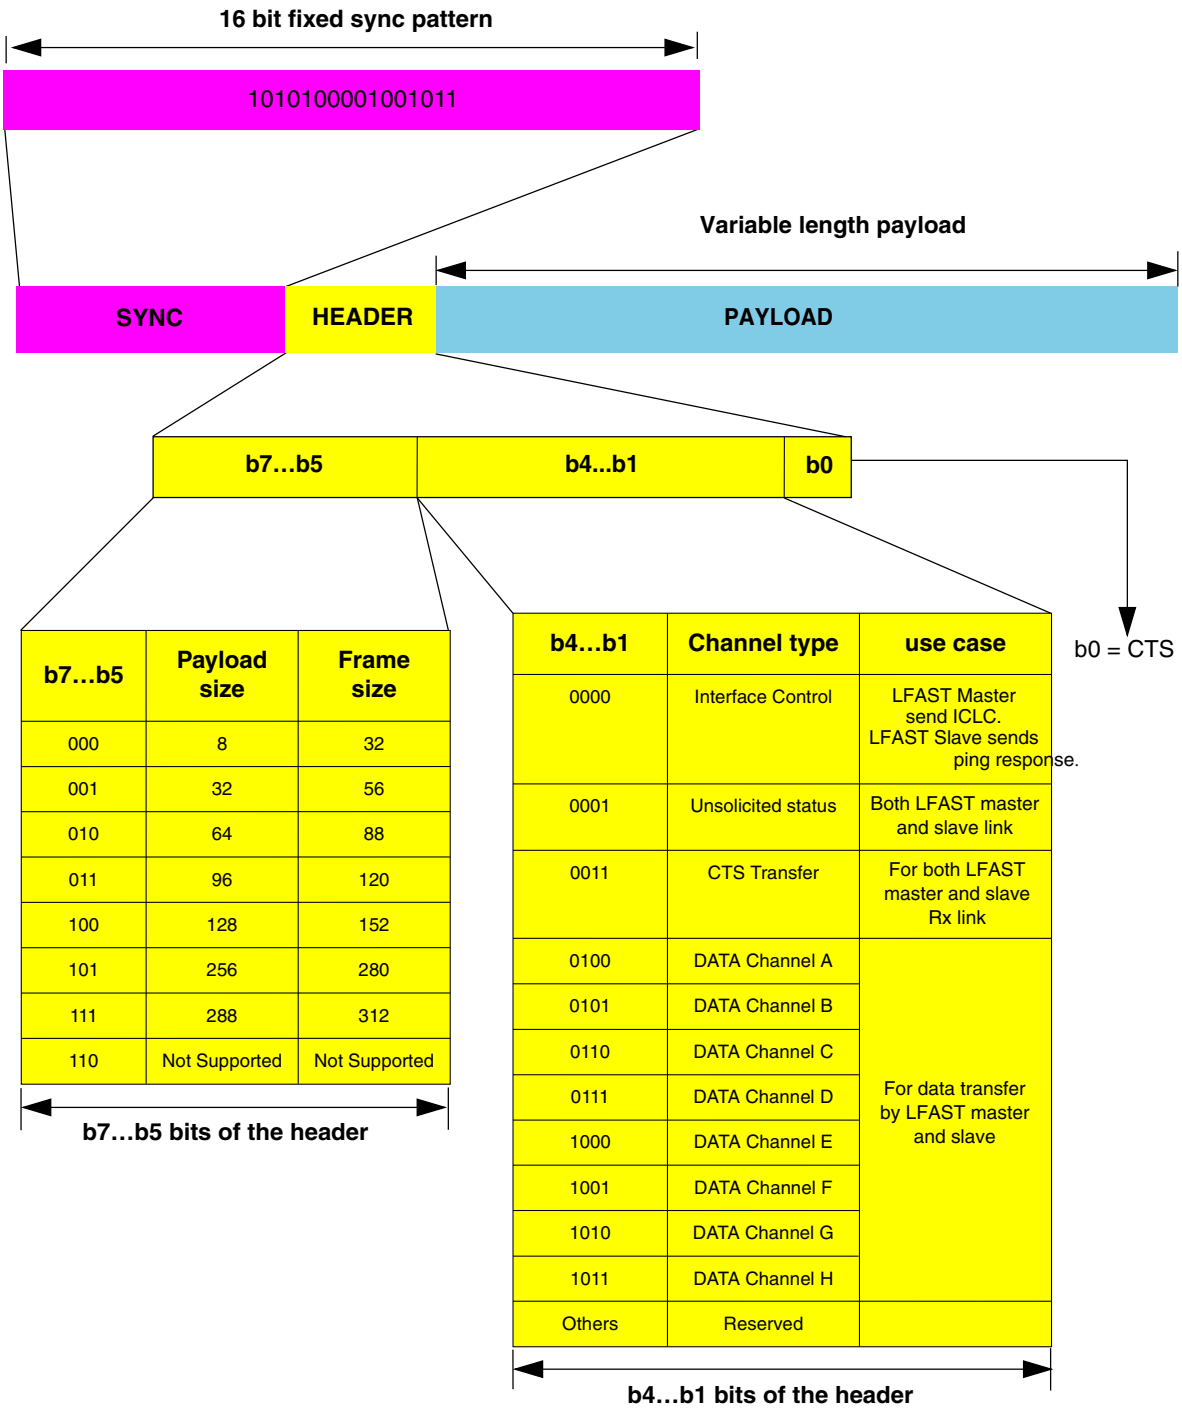
- lfast_sysclk
  - Reference clock of the LFAST master and slave
- txdatap/txdatan
  - Differential transmit (Tx) interface pair
- rxdatap/rxdatan
  - Differential receive (Rx) interface pair

LFAST interface is an asynchronous high speed LVDS interface.

51.3.1 LFAST operating data rates

The change of data rate is controlled by the LFAST master by issuing appropriate Interface Control Logical Channel (ICLC) packets to the LFAST slave. Henceforth, the data rate 6.5 Mbps/5 Mbps (lfast_sysclk ÷ 4 or lfast_sysclk ÷ 2) is referred to as low data rate, and the high data rate is in the Data Sheet.

51.4 LFAST frame structure



A LFAST frame is made up of three fields:

- Sync pattern
- Header
- Payload

Sync pattern and header fields are of fixed length.

Sync pattern is used to synchronize incoming data stream in LFAST module.

Header field of the frame distinguishes various types of data and control transferred and also contains information about the length of the payload. The payload field is the actual data that is transferred across the channel. See Figure 51-2 for details of the LFAST frame.

b7…b5	Payload size	Frame size
000	8	32
001	32	56
010	64	88
011	96	120
100	128	152
101	256	280
111	288	312
110	Not Supported	Not Supported

b4…b1	Channel type	use case
0000	Interface Control	LFAST Master send ICLC. LFAST Slave sends ping response.
0001	Unsolicited status	Both LFAST master and slave link
0011	CTS Transfer	For both LFAST master and slave Rx link
0100	DATA Channel A	For data transfer by LFAST master and slave
0101	DATA Channel B	
0110	DATA Channel C	
0111	DATA Channel D	
1000	DATA Channel E	
1001	DATA Channel F	
1010	DATA Channel G	
1011	DATA Channel H	
Others	Reserved	

Figure 51-2. LFAST frame structure

The same protocol is used on both transmit and receive interfaces for communications of data, control and status information. A synchronization pattern (16 bits) and header (8 bits) are present in every frame.

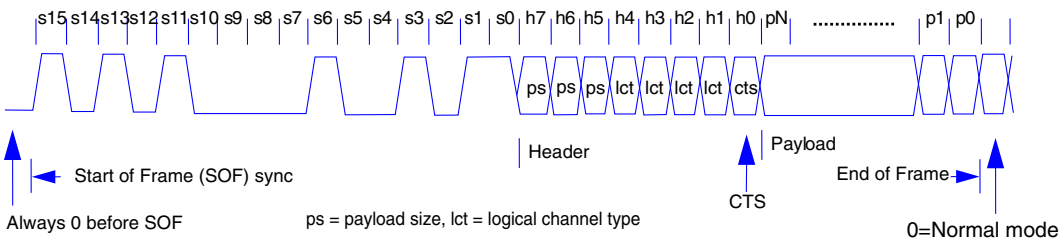


Figure 51-3. Serial frame structure

The frame structure is shown in Figure 51-3 and consists of the following:

- **16-bit synchronization pattern:** Used for clock synchronization and pattern recognition. The frame synchronization code at the start of every frame is a unique reserved word that is used to identify whether the data received is the start of the frame and for synchronization (clock phase extraction) with the stream data. A synchronous sequence is used to give a high quality auto correlation. The LFAST 16-bit synchronization sequence = 1010_1000_0100_1011b = A84Bh.
- **Header - 3 MSB (b7 - b5):** Defines the payload size as shown in Table 51-1 :

Table 51-1. Header payload sizes

b7-b5(bin)	Payload Size	Frame Size
000	8	32
001	32	56
010	64	88
011	96	120
100	128	152
101	256	280
110	—	—
111	288	312

- **Header - (b4 - b1):** Defines the logical channel types, which indicate the type of payload that the frame carries. How the payload field of a frame is used for any other logical channel type is system side module specific except in the case of the interface control logical channel type and clear to send (CTS) frame.
- **Header - (b0):** CTS on the both LFAST master and slave devices.

- **Payload:** Content dependent upon frame type.
- **Bit after frame:** This bit determines entry into Sleep mode (1 = Sleep mode, 0 = normal mode)

51.5 Features

- Supports dual mode (register configurable Master/Slave).
- Supports asynchronous data transfer up to the maximum data rate shown in the product Data Sheet.
- Transmits and receives data, CTS, ICLC and unsolicited frames.
- Receives ICLC frames
- Provision of five interrupts for Tx and Rx channels.
- Supports processor controlled transfer of ICLC frame with 8-bit payload size to implement the data rate changes and test modes.
- Supports LFAST defined CTS controlled data transfer. No dependency between data transmission and reception unless CTS mode is enabled.
- Supports flow control using sliding window protocol.
- Provides configurable frame length for data frame with variable payload sizes of 32, 64, 96, 128, 256 or 288 bits.
- Provides transmit of data frame length with 96 bits of payload size and reception of data frame with 128 bits of payload size.
- Provides configurable frame length for unsolicited frame with variable payload sizes of 8, 32, 64, 96, 128, 256 or 288 bits.
- Supports PLL configuration (for example, feedback loop divider, etc.) through registers.
- Supports LVDS configuration through registers.
- Supports multiple loopback modes for checking the physical interface.
- Supports automatic ping response generation in slave mode.
- Supports for detection of unsupported channel number and unsupported payload size.

51.6 Memory map and register definition

All registers are 32 bits wide.

NOTE

Read/Write accesses to all unimplemented registers and write accesses to Read only register will return a Transfer Error.

LFAST memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	LFAST Mode Configuration Register (LFAST_MCR)	32	R/W	See section	51.6.1/2140

51.6.1 LFAST Mode Configuration Register (LFAST_MCR)

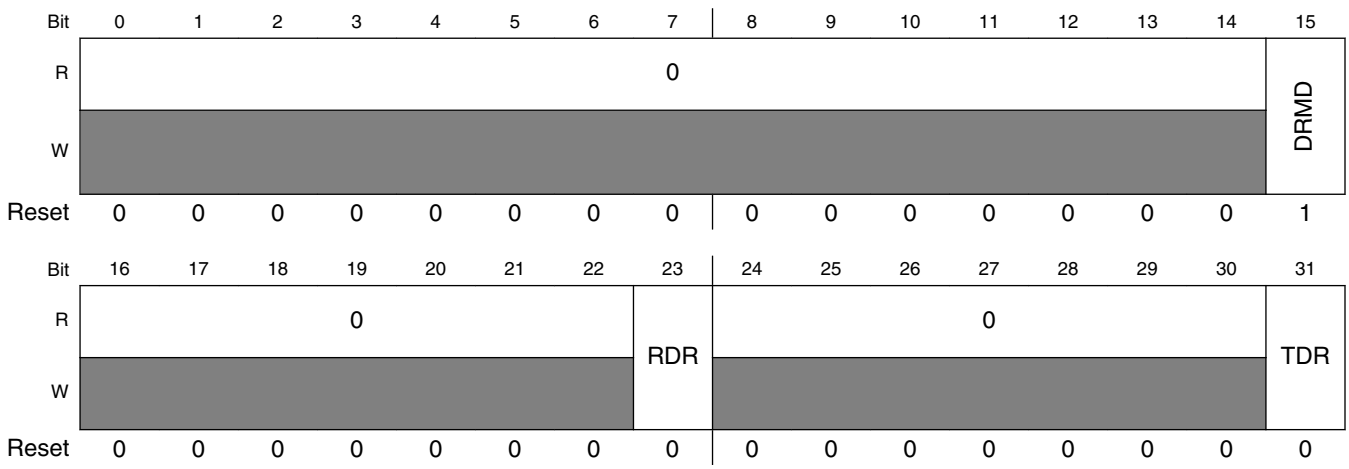
Address: 0h base + 0h offset = 0h

* Notes:
- DRFRST field: Set by user software and then cleared by system hardware.
- CTSEN field: Only writable when MCR[DRFEN] = 0.
- MSEN field: Writable only once after the asynchronous reset.

LFAST_MCR field descriptions

Field	Description
0 MSEN	LFAST Master or Slave mode Enable. This bit selects either the LFAST master or slave functionality. 0 Enable the modules LFAST Slave functionality only. 1 Enable the modules LFAST Master functionality only.
1–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 IPGDBG	Control bit to enable support for IPG Debug mode. This mode is indicated by assertion of IPG debug mode signal. 0 IPG debug mode enable signal will be ignored. 1 IPG debug mode enable signal will not be ignored.
8–14 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15 LSSEL	Selects the fraction of sysclk in Low Speed Select mode (see Slow speed clock for details). 0 Low Speed Mode in which the lfast_sysclk input is used to generate 4 phases of lfast_sysclk/2. 1 Low Speed Mode in which the lfast_sysclk input is used to generate 4 phases of lfast_sysclk/4.
16 DRFEN	LFAST Enable. This bit enables/disables the reception and transfer of LFAST device. 0 LFAST is immediately disabled. All current/pending requests are terminated and the Tx and Rx data FIFOs are flushed. If this bit is cleared in the middle of a transmit/receive operation, then that operation is terminated immediately and nothing is transmitted/received further. All the programmable

Table continues on the next page...



LFAST_MCR field descriptions (continued)

Field	Description
	registers retain their values and status registers are cleared to their reset values. Registers read/write operations can be performed through the IPS Bus. 1 LFAST is Enabled.
17 RXEN	LFAST Receiver Enable. This bit controls the reception of the frames and decoding on the LFAST device. This bit also disables the Rx LVDS Line Receiver (LR). 0 Receiver Interface is disabled. If this bit is cleared during a data transfer, the current frame is received and then the Rx block is disabled. After the Rx block is disabled, all new frames from LFAST peer device are ignored. System Side Module Rx interface isn't disabled by this bit. 1 Receiver Interface is Enabled.
18 TXEN	LFAST Transmitter Enable. This bit controls the transmission of frames from the LFAST device and disables the Tx LVDS LD. This bit can also be modified by LFAST slave H/W on reception of an ICLC command frame. This field can only be written in dual mode (LFAST_GSR[DUALMD] = 1). 0 LFAST transmitter Interface is disabled. No new request is accepted but ongoing request is served. 1 LFAST transmitter Interface is enabled. New requests are accepted.
19–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 TXARBD	Tx Arbiter Disable. This bit enables/disables the Tx block arbiter. Current frame transfer is completed, but new frame requests are ignored. 0 Enable Tx arbiter and framer. When enabled it takes all the frame request and services based on priority. 1 Disable Tx arbiter and framer. All frame requests are ignored.
28 CTSEN	CTS Enable. This bit defines the Push-Pull mode of the LFAST devices receiver. This bit is used to enable/disable CTS mode of the Tx block. This bit is only writable when MCR[DRFEN] = 0. 0 CTS mode is disabled. Indicates that the device is in Push mode. The CTS bit of frames transmitted is 1. The CTS bit doesn't represent the status of Rx FIFO. 1 CTS mode is enabled. The CTS bit of all transmit frames is set when the Rx FIFO empty space is on or above higher threshold, and cleared when the Rx FIFO empty space is on or below lower threshold.
29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30 DRFRST	LFAST Soft Reset. This bit is automatically cleared after Reset.. 0 No Soft Reset 1 Soft Reset to LFAST is asserted. When set it causes a reset of the LFAST module; all the registers will be reset to their default values and all the FIFOs will be flushed.
31 DATAEN	DATA Frame Enable. This bit enables/disables the transmission and reception of data frames between the LFAST master and slave devices. 0 Data frame transmission and reception is disabled. Tx data frame requests are ignored by the transmitter. Frame with LCT of data frame is ignored by the receiver. 1 Data frame transmission and reception is enabled. Tx data frame requests are serviced by the transmitter. Frame with LCT of data frame is received and placed into the Rx data FIFO.

51.6.2 LFAST Speed Control Register (LFAST_SCR)

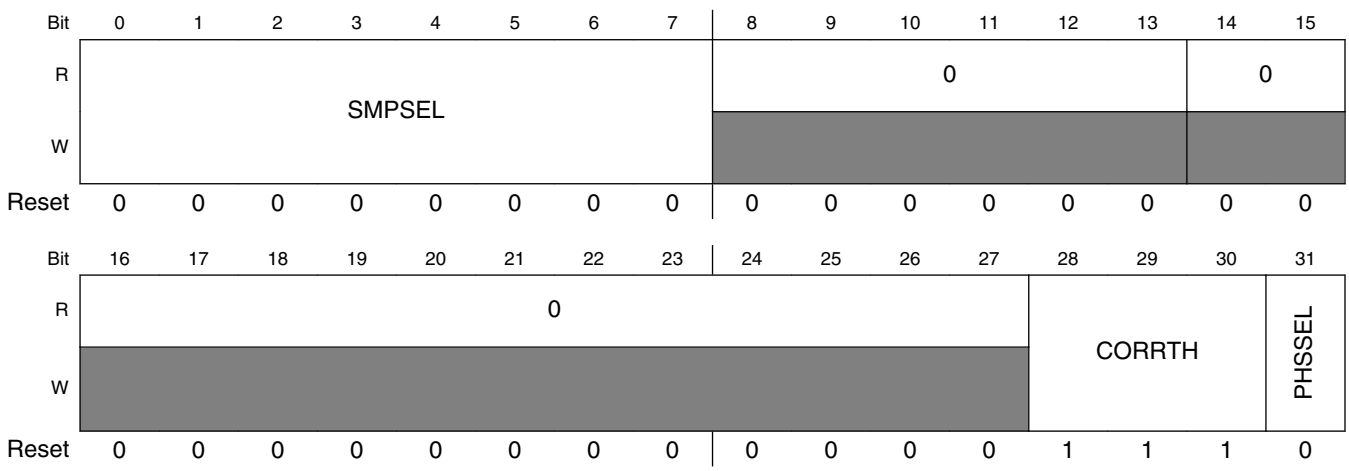
The SCR is used to configure the Rx and Tx data rate of the LFAST.

Address: 0h base + 4h offset = 4h

LFAST_SCR field descriptions

Field	Description
0–14 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15 DRMD	Data Rate Controller mode. Defines the mode setting for LFAST slave device by S/W or LFAST master. 0 S/W controls the Data Rate controller mode. In LFAST Slave the ICLC frames for rate change have no affect on the Data rate. 1 In LFAST Slave the reception of ICLC frame for rate change sets appropriate speed mode. In LFAST Master the SCR[DRMD] should be 0.
16–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23 RDR	Receiver Data Rate. This bit defines the receiver data rate. For LFAST Master: • S/W should program this bit only after transmission of an ICLC frame changing the speed mode of the slaves Tx interface. For LFAST Slave: • When SCR[DRMD] = 1, the H/W programs this bit on reception of ICLC frame for changing speed mode of Slaves Rx interface. • The S/W can program this bit when SCR[DRMD] = 0. • This bit is cleared on MCR[DRFEN] negation. 0 Data rate of Rx block is low speed. 1 Data rate of Rx block is high speed.

Table continues on the next page...



LFAST_SCR field descriptions (continued)

Field	Description
24–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 TDR	Transmit Data Rate. This bit defines the transmitter data rate. For LFAST Master: • S/W should program this bit only after transmission of an ICLC frame changing the speed mode of the slaves Rx interface. For LFAST Slave: • When SCR[DRMD] = 1, the H/W programs this bit on reception of ICLC frame for changing speed mode of Slaves Tx interface. • The S/W can program this bit when SCR[DRMD] = 0. • This bit is cleared on MCR[DRFEN] negation. 0 Data rate of Tx block is low speed. 1 Data rate of Tx block is high speed.

51.6.3 LFAST Correlator Control Register (LFAST_COCR)

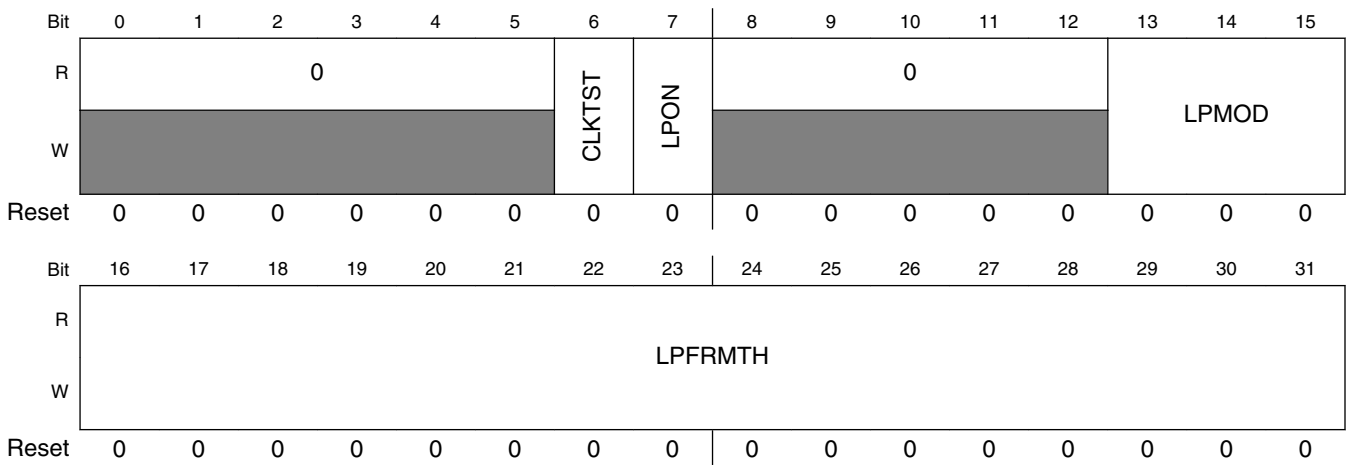
The COCR is used to select the sampler data path and the number of bits of correlation to be used.

Address: 0h base + 8h offset = 8h

LFAST_COCR field descriptions

Field	Description
0–7 SMPSEL	Sampler Data Path Selector (overrides the correlator selection). Defines the sampler data path to be activated at all the times. All the bits should be 0 (00h) for Sampler Data Path to be selected by the correlator. In Low Speed mode only Sampler Data Paths 0-3 are valid. This field can only be written when MCR[RXEN] = 0.

Table continues on the next page...



LFAST_COCR field descriptions (continued)

Field	Description
	00h Sampler Data Path selected by correlator 01h Sampler Data Path 0 selected 02h Sampler Data Path 1 selected 04h Sampler Data Path 2 selected 08h Sampler Data Path 3 selected 10h Sampler Data Path 4 selected 20h Sampler Data Path 5 selected 40h Sampler Data Path 6 selected others Sampler Data Path 7 selected
8–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28–30 CORRTH	Correlator threshold level. Defines the correlation threshold level. This field can only be written when MCR[RXEN] = 0. 000 9 Bits of correlation 001 10 Bits of correlation ... 110 15 Bits of correlation 111 16 Bits of correlation
31 PHSSEL	Polyphase 8 or 4 phase selection. Defines the number of phases for the polyphase generator used. This bit is ignored in low speed mode since only 4 Phases are used in low speed mode. In High Speed mode phase 0, 2, 4 and 6 are used when 4 phase mode is selected. This field can only be written when MCR[RXEN] = 0 0 8 phases 1 4 phases

51.6.4 LFAST Test Mode Control Register (LFAST_TMCR)

The TMCR enables and configures the LFAST clock test and loopback modes.

Address: 0h base + Ch offset = Ch

LFAST_TMCR field descriptions

Field	Description
0–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6 CLKTST	Clock Test mode. S/W can define when the clock test mode is enabled. This bit can also be set and cleared by LFAST slave H/W on reception of an ICLC command. 1 Clock Test mode enabled 0 Clock Test mode disabled
7 LPON	Loopback mode Logic Enable. S/W can define when the loopback logic is enabled. This bit can also be written by LFAST slave H/W on reception of an ICLC command. 1 Loopback mode is enabled 0 Loopback mode is disabled
8–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13–15 LPMOD	Loopback mode. Defines the type of loopback mode enabled. This field can only be written when TMCR[LPON] = 0. 000 Rx loopback 001 Rx LVDS loopback 010 Tx loopback without automatic frame generation 011 Tx loopback with automatic frame generation 100 Tx LVDS loopback (external) with automatic frame generation 101 Reserved

Table continues on the next page...

LFAST_TMCR field descriptions (continued)

Field	Description
	110 Reserved 111 Reserved
16–31 LPFRMTH	Loopback check mode valid pass frames threshold value. Defines the number of frames to verify before setting GCR[LPFPDV] when running in Automatic Loopback Frame mode. The loopback frame is considered pass when the payload is CBh, header is 13h and sync is valid. This mode is valid only when TMCR[LPMOD] = 011b or TMCR[LPMOD] = 100b. This field can only be written when TMCR[LPON] = 0. 0000h Reserved.(Not to be used) 0001h Check 1 frame have correct sync, header and payload. ... FFFEh Check 65534 frames have correct sync, header and payload. FFFFh Check 65535 frames have correct sync, header and payload.

51.6.5 LFAST Auto Loopback Control Register (LFAST_ALCR)

Address: 0h base + 10h offset = 10h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

LFAST_SLCR field descriptions

Field	Description
0–7 HSCNT	High Speed Sleep mode Exit Time. Defines 1/4 of the number of the high speed clock cycle wait after the negation of the LVDS LD sleep signal, and before the start of new frame. This wait is the summation of settling time of the Line Driver (LD) after negation of its sleep signal, and the wakeup time of the LR of the peer LFAST. This field can only be written when MCR[DRFEN] = 0. 00h 0 cycle 01h 1 cycle ...

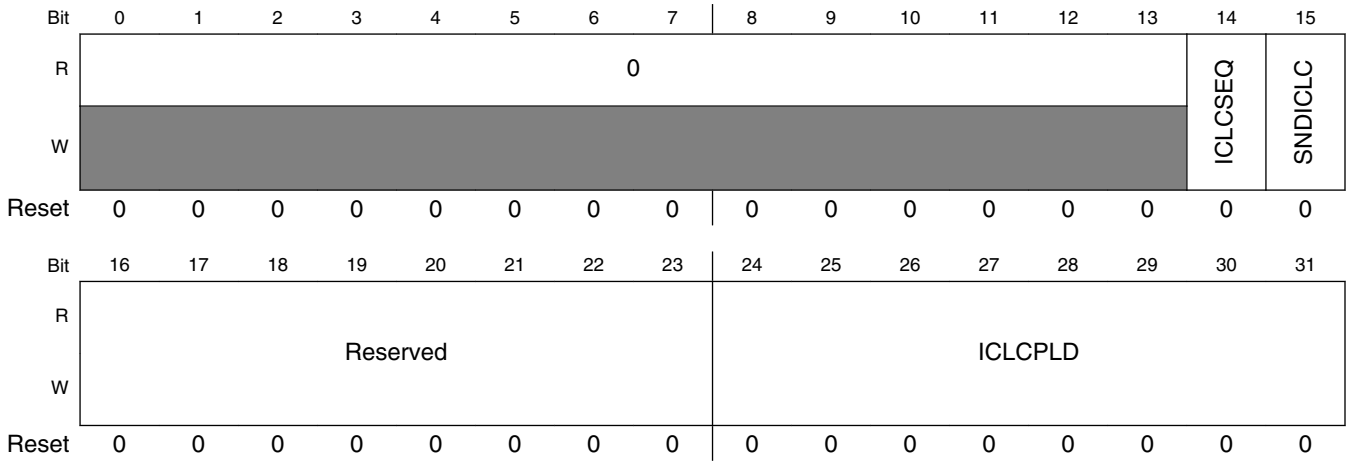

Table continues on the next page...

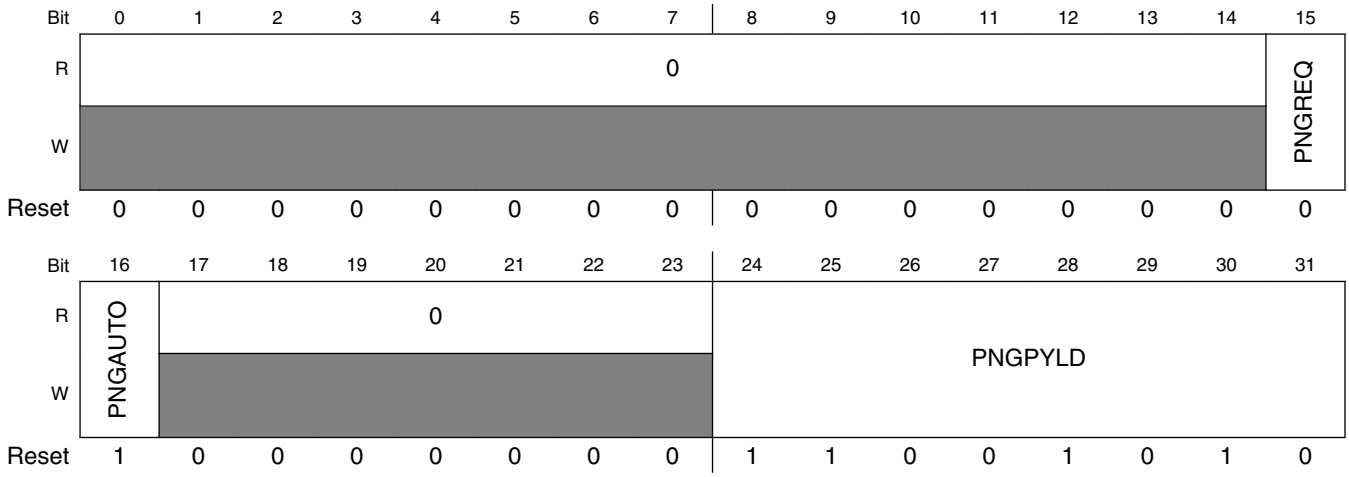
LFAST_SLCR field descriptions (continued)

Field	Description
	12h 18 cycles (200 ns + 8 cycles of High speed clock) ... FEh 254 cycles FFh 255 cycles
8–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12–15 LSCNT	Low Speed Sleep mode Exit Time. Defines 1/4 of the number of Low speed clock cycle wait after the negation of LVDS LD sleep signal, and before the start of new frame. This wait is the summation of settling time of LD after negation of LVDS LD sleep signal, and the wakeup time of the LR of the peer LFAST. This field can only be written when MCR[DRFEN] = 0. 0h 0 cycle 1h 1 cycle (200ns + 1 cycle of Low speed clock) ... Eh 14 cycles Fh 15 cycles
16–23 HWKCNT	Wake Up time for the LD. Defines the 1/4 of the number of High speed clock cycles used during the wakeup of the LD from shutdown mode. This is time required by the LD to move from moving from Shutdown to Normal State in High speed mode. This field can only be written when MCR[DRFEN] = 0. 00h 0 cycles 01h 1 cycle ... 5Fh 95 cycles (1.18 µs) ... FFh 255 cycles Maximum
24–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28–31 LWKCNT	Wake Up time for the LD. Defines the 1/4 of the number Low speed clock used during the wakeup of the LD from shutdown mode. This is time required by the LD to move from Shutdown to Normal State in Low speed mode. This field can only be written when MCR[DRFEN] = 0. 0h 0 cycle 1h 1 cycle 2h 2 cycles (1.18 µs) ... Eh 14 cycles Fh 15 cycles

51.6.8 LFAST ICLC Control Register (LFAST_ICR)

Address: 0h base + 1Ch offset = 1Ch

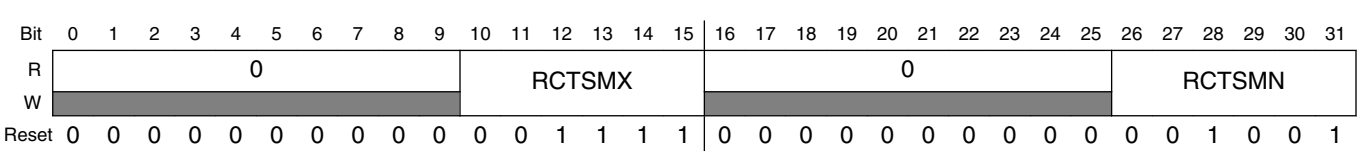


LFAST_ICR field descriptions

Field	Description
0–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14 ICLCSEQ	ICLC enabled. This bit should be set whenever the S/W is performing a series of ICLC frame transfers. This bit ensures only ICLC frame transmission request is serviced, other pending frames request are ignored. 0 Single ICLC frame transfer. 1 S/W is performing ICLC frame transfers. Only the ICLC frames will be scheduled during this period. All the other frames will be scheduled only after ICR[ICLCSEQ] = 0.
15 SNDICLC	ICLC frame request. This bit is set to initiate the transfer of ICLC frame by LFAST master. This bit should be set (ICR[SNDICLC] = 1) after writing the required ICLC payload to be transmitted in the ICLCPLD field of the register. This bit is self clearing, which will be cleared when ICLC frame transfer is complete. Set by user software and cleared by system hardware. 0 No Valid ICLC frame for transfer. 1 Valid ICLC frame for transfer.
16–23 Reserved	This field is reserved.
24–31 ICLCPLD	ICLC Payload. This field is used to program the payload of the ICLC frame to be transmitted. New ICLC payload should be set when ICR[SNDICLC] = 0. This field can only be written when ICR[SNDICLC] = 0 (see Table 51-53 for supported ICLC payloads).

51.6.9 LFAST Ping Control Register (LFAST_PICR)

Address: 0h base + 20h offset = 20h

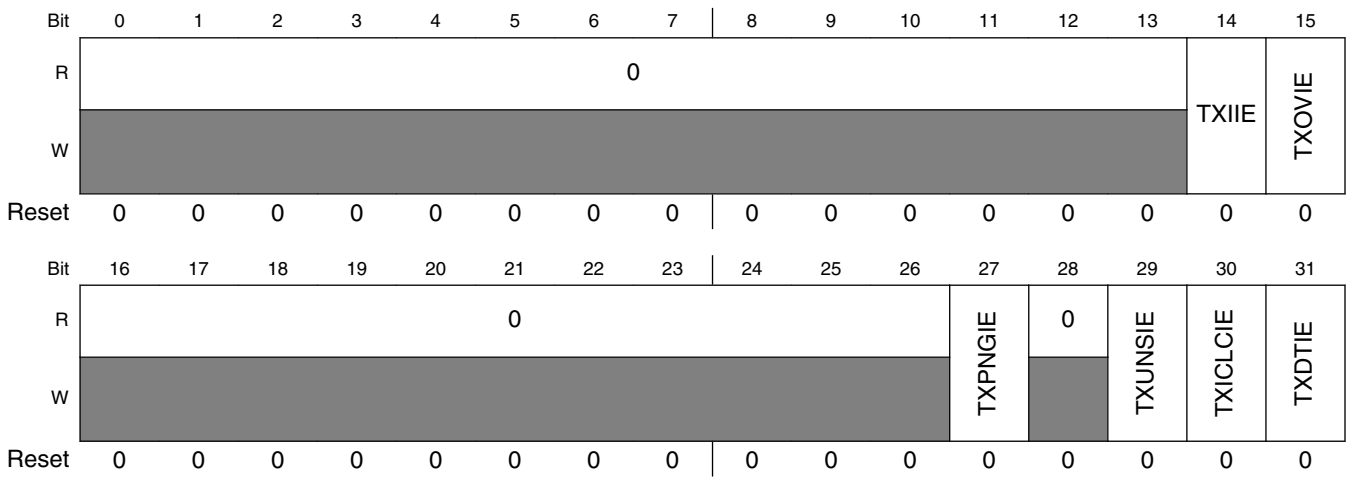


LFAST_PICR field descriptions

Field	Description
0–14 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15 PNGREQ	Ping Response Frame Request. This bit is set to initiate the transfer of Ping response frame. Cleared after transmission of Ping response frame. Set by user software and cleared by system hardware. 1 Ping response frame transmission request is queued 0 No pending Ping response frame transmission request
16 PNGAUTO	Ping Response Enable. Defines when ping response should be automatically sent on reception of Ping ICLC frame from LFAST master. This field can only be written when MCR[DRFEN] = 0. 0 Ping response should not be automatically sent. 1 Ping response should be automatically sent.
17–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–31 PNGPYLD	LFAST Slave: Defines the LFAST slaves ping reply frame payload content. This field can only be written when MCR[DRFEN] = 0. LFAST Master: Defines the expected payload of ping response frame. Used for comparison with ping frame received.

51.6.10 LFAST Rx FIFO CTS Control Register (LFAST_RFCR)

Address: 0h base + 2Ch offset = 2Ch



LFAST_RFCR field descriptions

Field	Description
0–9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
10–15 RCTSMX	Rx FIFO Maximum Threshold. Defines the condition for CTS bit of frames to be negated. This field can only be written when LFAST_MCR[DRFEN] = 0.
16–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26–31 RCTSMN	Rx FIFO Minimum Threshold. Defines the condition for CTS bit of frames to be set. This field can only be written when LFAST_MCR[DRFEN] = 0.

51.6.11 LFAST Tx Interrupt Enable Register (LFAST_TIER)

Address: 0h base + 30h offset = 30h

LFAST_TIER field descriptions

Field	Description
0–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14 TXIIE	Tx Data Interface Not Enabled - (Mask) Enables or disables the interrupt. Tx Data Interface not enabled and a frame is ready to be transmitted 0 Interrupt is disabled 1 Interrupt is enabled
15 TXOVIE	Transmit Data FIFO Overflow Interrupt Enable. 0 Interrupt is disabled 1 Interrupt is enabled
16–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 TXPNGIE	Ping Response Frame Transmitted Interrupt Enable.

Table continues on the next page...

LFAST_TIER field descriptions (continued)

Field	Description
	0 Interrupt is disabled 1 Interrupt is enabled
28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29 TXUNSIE	Unsolicited Frame transmitted Interrupt Enable 0 Interrupt is disabled 1 Interrupt is enabled
30 TXICLCIE	ICLC Frame transmitted Interrupt Enable 0 Interrupt is disabled 1 Interrupt is enabled
31 TXDTIE	Data Frame transmitted Interrupt Enable 0 Interrupt is disabled 1 Interrupt is enabled

51.6.12 LFAST Rx Interrupt Enable Register (LFAST_RIER)

Address: 0h base + 34h offset = 34h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0								RXUOIE	RXMNIE	RXMXIE	RXUFIE	RXOFIE	RXSZIE	RXICIE	RXLCEIE
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0												RXCTSIE	RXDIE	RXUNSIE	0
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

LFAST_RIER field descriptions

Field	Description
0–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8 RXUOIE	Unsolicited frame register overflow. Indicates existing unsolicited frame hasn't been read and a new unsolicited frame has arrived. 0 Interrupt is disabled 1 Interrupt is enabled

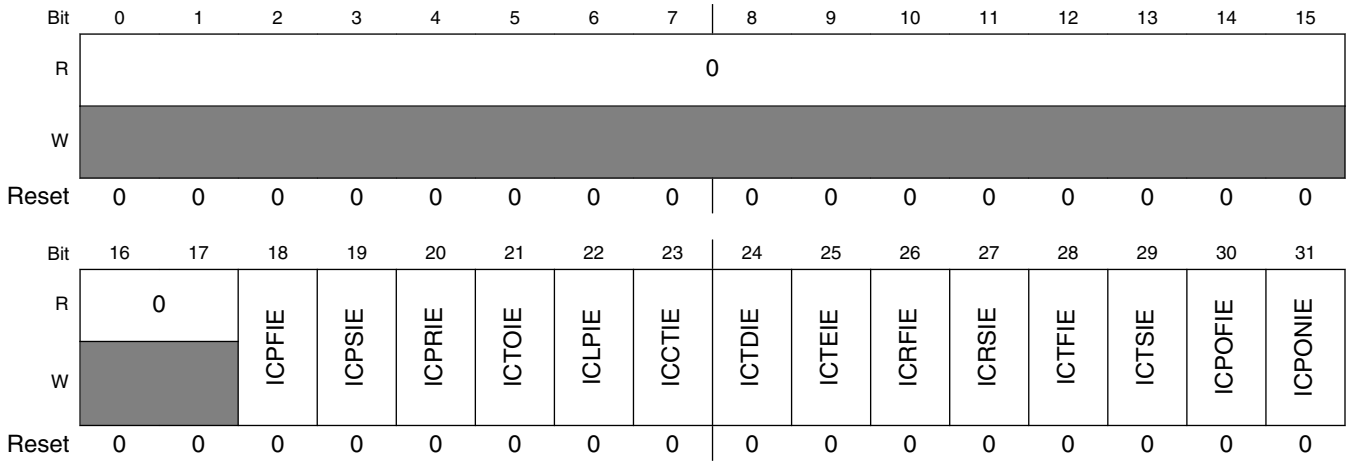


Table continues on the next page...

LFAST_RIER field descriptions (continued)

Field	Description
9 RXMNIE	Rx Data FIFO Min Threshold reached 0 Interrupt is disabled 1 Interrupt is enabled
10 RXMXIE	Rx Data FIFO Max Threshold reached 0 Interrupt is disabled 1 Interrupt is enabled
11 RXUFIE	Rx Data FIFO Underflow 0 Interrupt is disabled 1 Interrupt is enabled
12 RXOFIE	Rx Data FIFO Overflow 0 Interrupt is disabled 1 Interrupt is enabled
13 RXSZIE	Frame with unsupported frame size received. Valid frame sizes are defined in Table 51-57 0 Interrupt is disabled 1 Interrupt is enabled
14 RXICIE	Invalid ICLC code Received 0 Interrupt is disabled 1 Interrupt is enabled
15 RXLCEIE	Invalid Logical Channel Type 0 Interrupt is disabled 1 Interrupt is enabled
16–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28 RXCTSIE	Frame with CTS bit Low Received 0 Interrupt is disabled 1 Interrupt is enabled
29 RXDIE	Data frame received 0 Interrupt is disabled 1 Interrupt is enabled
30 RXUNSIE	Unsolicited Frame received 0 Interrupt is disabled 1 Interrupt is enabled
31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

51.6.13 LFAST Rx ICLC Interrupt Enable Register (LFAST_RIIER)

Address: 0h base + 38h offset = 38h

LFAST_RIIER field descriptions

Field	Description
0–17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
18 ICPFIE	Ping Frame Response failed 0 Interrupt is disabled 1 Interrupt is enabled
19 ICPSIE	Ping Frame Response successful 0 Interrupt is disabled 1 Interrupt is enabled
20 ICPRIE	ICLC frame for Ping Frame Request received 0 Interrupt is disabled 1 Interrupt is enabled
21 ICTOIE	ICLC frame for Test mode off received 0 Interrupt is disabled 1 Interrupt is enabled
22 ICLPIE	ICLC frame for Loopback On received 0 Interrupt is disabled 1 Interrupt is enabled
23 ICCTIE	ICLC frame for Clk Test mode on received 0 Interrupt is disabled 1 Interrupt is enabled
24 ICTDIE	ICLC frame for LFAST Slaves Tx Interface Disable received

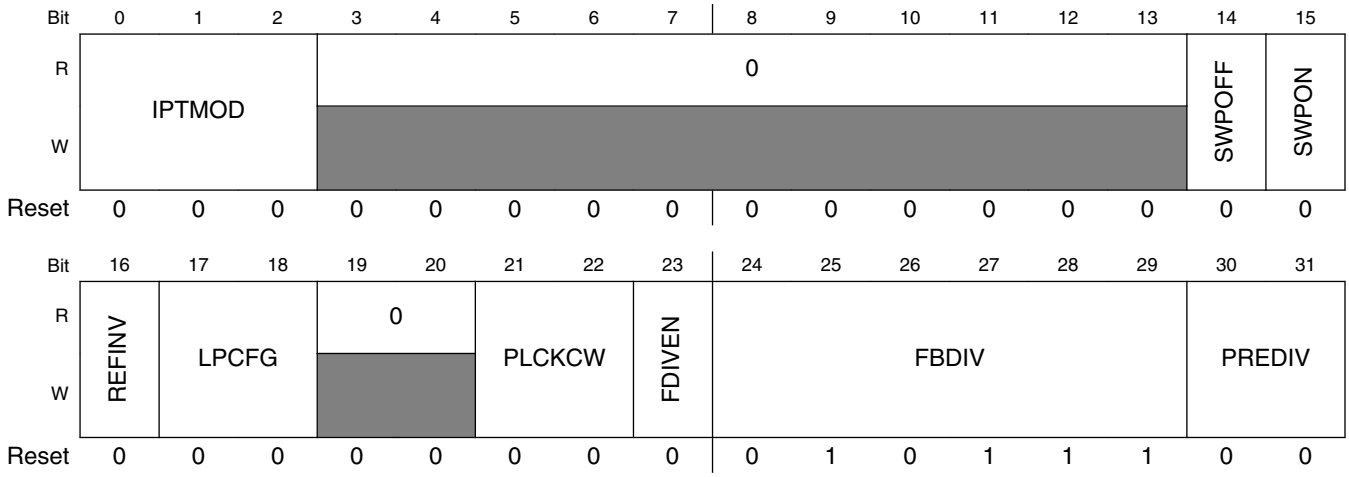

Table continues on the next page...

LFAST_RIIER field descriptions (continued)

Field	Description
	0 Interrupt is disabled 1 Interrupt is enabled
25 ICTEIE	ICLC frame for LFAST Slaves Tx Interface Enable received 0 Interrupt is disabled 1 Interrupt is enabled
26 ICRFIE	ICLC frame for LFAST Slaves Rx Interface fast mode switch received 0 Interrupt is disabled 1 Interrupt is enabled
27 ICRSIE	ICLC frame for LFAST Slaves Rx Interface slow mode switch received 0 Interrupt is disabled 1 Interrupt is enabled
28 ICTFIE	ICLC frame for LFAST Slaves Tx Interface fast mode switch received 0 Interrupt is disabled 1 Interrupt is enabled
29 ICTSIE	ICLC frame for LFAST Slaves Tx Interface slow mode switch received 0 Interrupt is disabled 1 Interrupt is enabled
30 ICPOFIE	ICLC frame for PLL OFF received 0 Interrupt is disabled 1 Interrupt is enabled
31 ICPONIE	ICLC frame for PLL ON received 0 Interrupt is disabled 1 Interrupt is enabled

51.6.14 LFAST PLL Control Register (LFAST_PLLCR)

Address: 0h base + 3Ch offset = 3Ch

LFAST_PLLCR field descriptions

Field	Description
0–2 IPTMOD	Test mode programmability 000 Functional mode 001 Closed Loop 1 010 Force Vctrl 011 Charge Pump Up 100 Charge Pump Up Internal Test 101 Charge Pump Idle 110 Charge Pump Down 111 Closed Loop 2
3–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14 SWPOFF	SW signal to turn OFF the PLL. Set by user software and cleared by system hardware. 0 No effect 1 PLL will be turned OFF.
15 SWPON	SW signal to turn ON the PLL. Set by user software and cleared by system hardware. 0 No effect 1 PLL will be turned ON
16 REFINV	Inverts reference clock edge to PFD. If System PLL PFD using same reference clock, enabling this feature will minimize noise injection crosstalk via the substrate. 0 Do not inverted 1 Invert

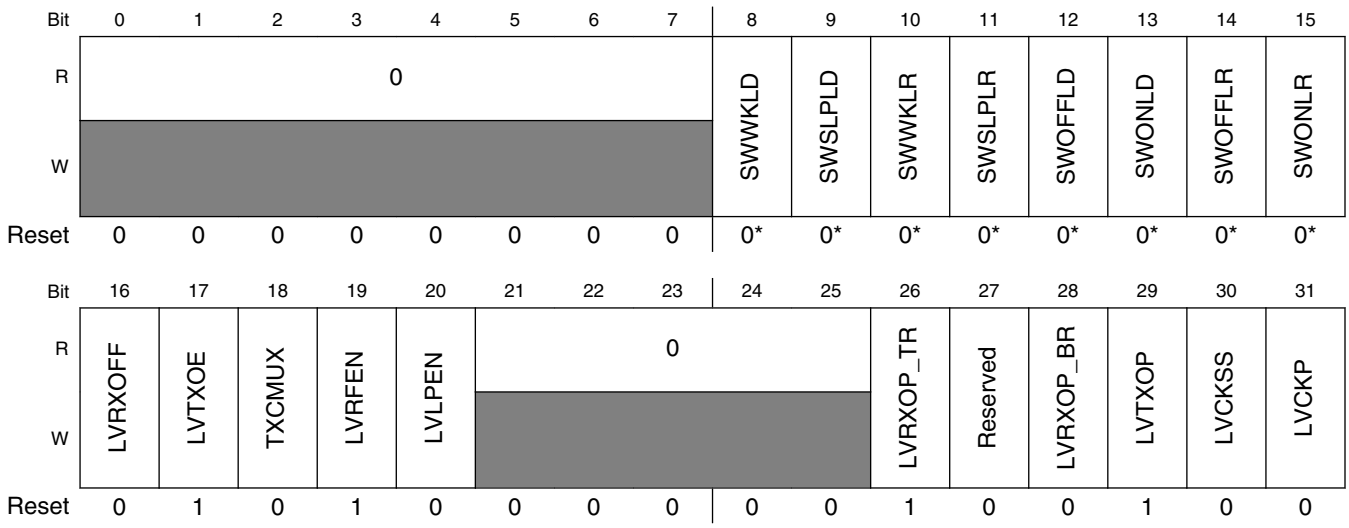

Table continues on the next page...

LFAST_PLLCR field descriptions (continued)

Field	Description
17–18 LPCFG	PLL Loop Optimization for sysclk frequency 00 1 × IBASE current 01 0.5 × IBASE current 10 1.5 × IBASE current 11 2 × IBASE current
19–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21–22 PLCKCW	PLL Lock Ready Count Width. Defines the number of cycles PLL waits for before asserting lock_ready flag High 00 1040 cycles 01 520 cycles 10 320 cycles 11 200 cycles
23 FDIVEN	Enable fraction division mode in feedback divider. Enables the division of vco clock output by a factor of (FBDIV + 0.5). 0 Fraction division mode not enabled 1 Fraction division mode enabled
24–29 FBDIV	Feedback Division factor for VCO output clock. This field can only be written when LFAST_MCR[DRFEN] = 0. 00h No clock output 01h – 0Ah Reserved 0Bh Divide by 12 (11.5, if FDIVEN = 1) ... ... 1Fh Divide by 32 (31.5, if FDIVEN = 1) 20h – 3Fh Reserved
30–31 PREDIV	Division factor for PLL Reference Clock input. This field can only be written when LFAST_MCR[DRFEN] = 0. 00 Direct clock passed 01 Divide by 2 10 Divide by 3 11 Divide by 4

51.6.15 LFAST LVDS Control Register (LFAST_LCR)

Address: 0h base + 40h offset = 40h

* Notes:
- SWONLR field: Set by user software and cleared by system hardware.
- SWOFFLR field: Set by user software and cleared by system hardware.
- SWONLD field: Set by user software and cleared by system hardware.
- SWOFFLD field: Set by user software and cleared by system hardware.
- SWSLPLR field: Set by user software and cleared by system hardware.
- SWWKLR field: Set by user software and cleared by system hardware.
- SWSLPLD field: Set by user software and cleared by system hardware.
- SWWKLD field: Set by user software and cleared by system hardware.

LFAST_LCR field descriptions

Field	Description
0–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8 SWWKLD	SW signal to take LVDS LD out of Sleep mode. This field can only be written when LFAST_MCR[DRFEN] = 1. **NOTE:** Writes are not reflected in the read of this field. 0 No effect 1 LVDS LD will be taken out of sleep (provided no other source is trying to put it in sleep)
9 SWSLPLD	SW signal to put LVDS LD into Sleep mode. This field can only be written when LFAST_MCR[DRFEN] = 1. **NOTE:** Writes are not reflected in the read of this field. 0 No effect 1 LVDS LD will be put in sleep

Table continues on the next page...

LFAST_LCR field descriptions (continued)

Field	Description
10 SWWKLR	SW signal to take LVDS LR out of Sleep mode. This field can only be written when LFAST_MCR[DRFEN] = 1. **NOTE:** Writes are not reflected in the read of this field. 0 No effect 1 LVDS LR will be taken out of sleep (provided no other source is trying to put it in sleep)
11 SWSLPLR	SW signal to put LVDS LR into Sleep mode. This field can only be written when LFAST_MCR[DRFEN] = 1. **NOTE:** Writes are not reflected in the read of this field. 0 No effect 1 LVDS LR will be put in sleep (provided no other source is trying to wake it up)
12 SWOFFLD	SW signal to turn OFF the LVDS LD. This field can only be written when LFAST_MCR[DRFEN] = 1. **NOTE:** Writes are not reflected in the read of this field. 0 No effect 1 LVDS LD will be turned OFF(provided no other source is trying to turn the LD ON)
13 SWONLD	SW signal to turn ON the LVDS LD. This field can only be written when LFAST_MCR[DRFEN] = 1. **NOTE:** Writes are not reflected in the read of this field. 0 No effect 1 LVDS LD will be turned ON
14 SWOFFLR	SW signal to turn OFF the LVDS LR. This field can only be written when LFAST_MCR[DRFEN] = 1. **NOTE:** Writes are not reflected in the read of this field. 0 No effect 1 LVDS LR will be turned OFF (provided no other source is trying to turn the LR ON)
15 SWONLR	SW signal to turn ON the LVDS LR. This field can only be written when LFAST_MCR[DRFEN] = 1. **NOTE:** Writes are not reflected in the read of this field. 0 No effect 1 LVDS LR will be turned ON
16 LVRXOFF	Indicates the value driven onto LVDS LR output when in shutdown mode
17 LVTXOE	LVDS LD output buffer enable. 0 LVDS LD output buffer enable is disabled. 1 LVDS LD output buffer enabled
18 TXCMUX	Tx and Clock Mux. The bit can be used to bring out PLL Phase 0 clock on Tx LVDS pad. 0 No effect 1 PLL Phase 0 clock will be brought out to Tx LVDS pad
19 LVRFEN	LVDS pad reference enable 0 LVDS reference pad disabled 1 LVDS reference pad enabled

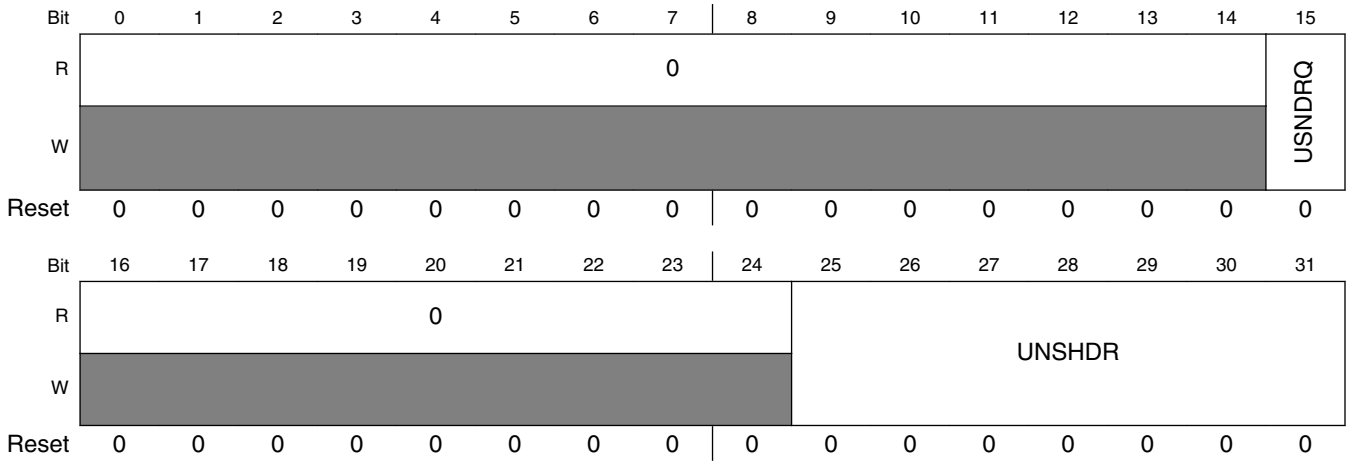

Table continues on the next page...

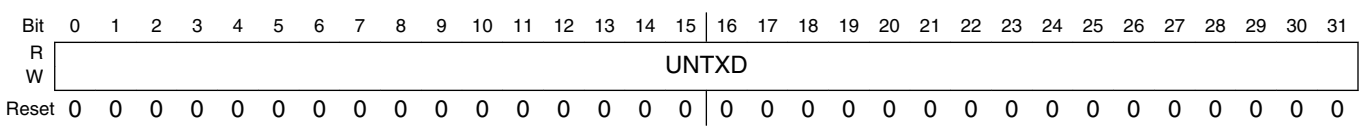
LFAST_LCR field descriptions (continued)

Field	Description
20 LVLPEN	Tx LVDS internal loopback enable The bit is reflected by output signal ipp_digrf_lvds_lpbk_en.The internal loopback is not intended for board level functionality, so this feature should not be implemented. 0 Tx LVDS normal mode enabled 1 Tx LVDS internal loopback mode enabled
21–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26 LVRXOP_TR	Used to enable or disable the on-chip receiver termination resistor in LFAST mode (applies to LVDS pad use for LFAST only): 0 Disable on-chip LFAST receiver termination 1 Enable on-chip LFAST receiver termination
27 Reserved	This field is reserved.
28 LVRXOP_BR	Used to set the bias current for the receiver in LFAST mode. It is recommended to always write 1 to this bit when using the LFAST interface. Writing 0 will allow for a small power savings during lower baud rates (applies to LVDS pad use for LFAST only): 0 Use for LFAST receiver baud rates less than the maximum baud rate. 1 Required for LFAST receiver maximum baud rate.
29 LVTXOP	Control signal for LFASTand Micro-Second Bus selection. 0 Micro-Second Bus selection 1 LFAST Bus selection
30 LVCKSS	LVDS Clock Sync Select This bit is used to adjust the LVDS data sampling to the duty cycle of the clock. It is recommended that a value of zero is used in all cases. A value of one is reserved for specific devices/revisions with different clock timing. 0 normal clock used to sample the LVDS data 1 adjusted clock used to sample the LVDS data
31 LVCKP	LVDS clock select. This bit is used for selecting use of direct pll clock or inverted pll clock in LVDS. 0 Direct pll clock to be used inside the LVDS 1 Inverted pll clock to be used inside the LVDS

51.6.16 LFAST Unsolicited Tx Control Register (LFAST_UNSTCR)

Address: 0h base + 44h offset = 44h

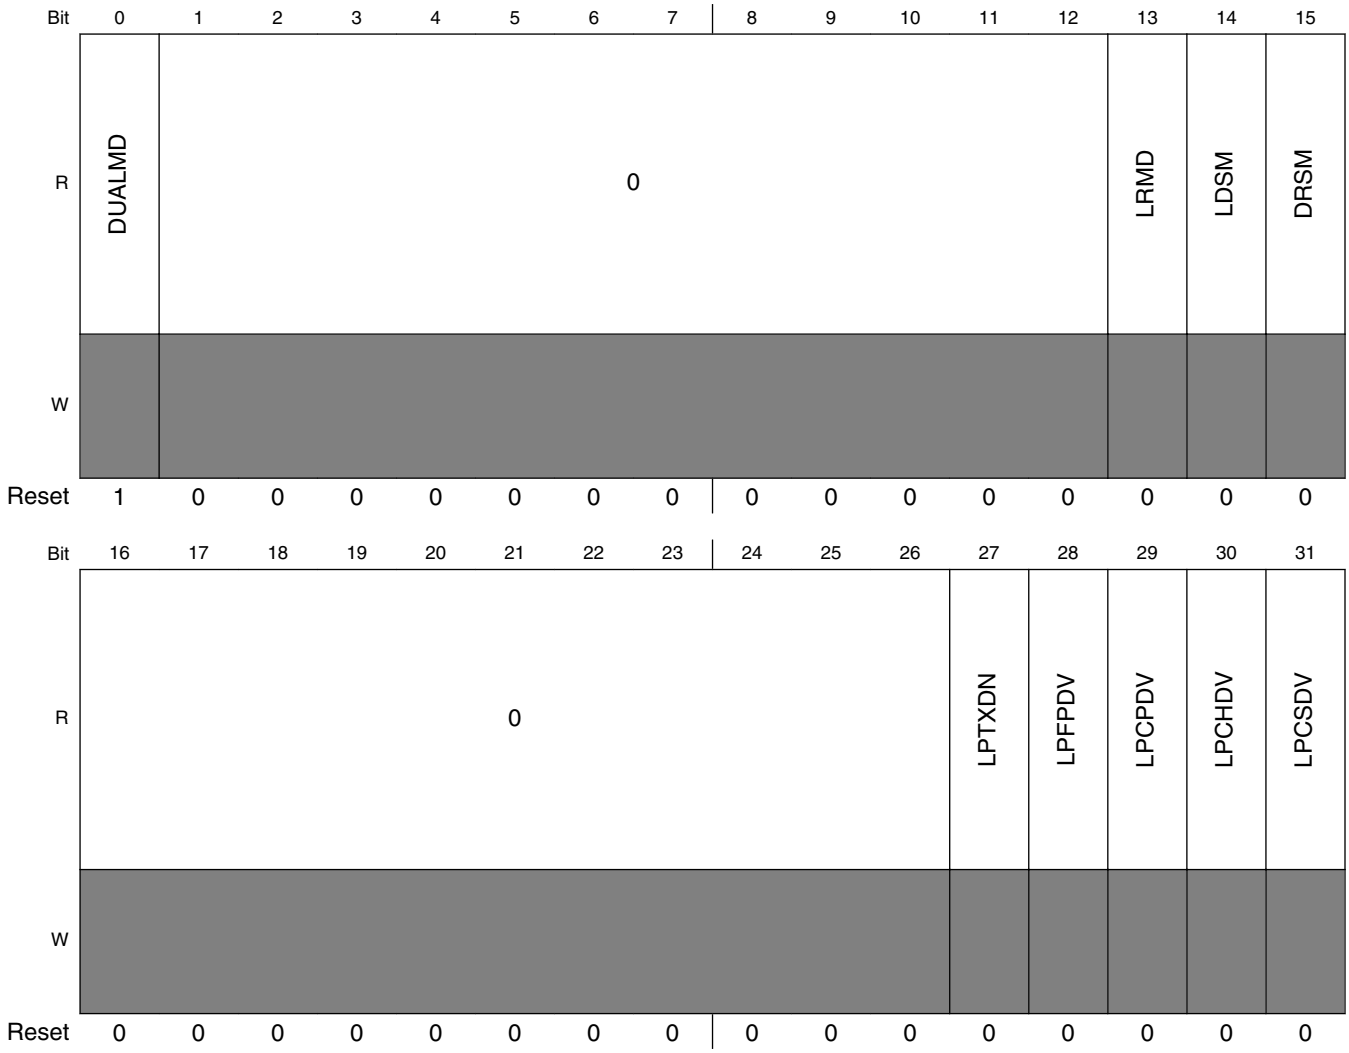


LFAST_UNSTCR field descriptions

Field	Description
0–14 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15 USNDRQ	Tx Unsolicited send request. Set by user software and cleared by system hardware. 0 No valid Unsolicited frame exists 1 Valid Unsolicited frame exists for transmission
16–24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25–31 UNSHDR	Tx Unsolicited message header. This field can only be written when LFAST_UNSTCR[USNDRQ] = 0

51.6.17 LFAST Unsolicited Tx Data Registers (LFAST_UNSTDR*n*)

Address: 0h base + 48h offset + (4d × i), where i=0d to 8d



LFAST_UNSTDR*n* field descriptions

Field	Description
0–31 UNTXD	Unsolicited Transmit Data 8-0. This represents 9 registers for Unsolicited transmit data. The first bit to transmitted as part of the payload will be from UNTXD8[31], second bit from UNTXD8[30], and so on. So the last bit transmitted will be from UNTXD0[0] in case of 288 bit payload.

51.6.18 LFAST Global Status Register (LFAST_GSR)

Address: 0h base + 80h offset = 80h

LFAST_GSR field descriptions

Field	Description
0 DUALMD	Indicates the LFAST module is in Dual mode 0 LFAST Module in Slave only mode 1 LFAST Module in Dual mode
1–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13 LRMD	Indicates if the Rx Controller is idle/active and that the Rx clocks are enabled. In functional mode this will always be active.

Table continues on the next page...

LFAST_GSR field descriptions (continued)

Field	Description
	0 Rx Controller is in Idle state 1 Rx Controller is active
14 LDSM	Transmit Interface Data Rate Status. Indicates the current speed rate of the Tx controller 0 Data rate of LOW speed mode 1 Data rate of HIGH speed mode
15 DRSM	Receive Interface Data Rate Status. Indicates the current speed rate of the Rx controller 0 Data rate of LOW speed mode 1 Data rate of HIGH speed mode
16–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 LPTXDN	Auto loopback frame transmission count reached. The Count of frame is defined by LFAST_ALCR[LPFMCNT]. 0 Auto loopback frame transmission count not reached. 1 Auto loopback frame transmission count reached.
28 LPFPDV	Loopback frame pass threshold reached. 0 Pass frame threshold not reached. 1 Pass frame threshold achieved
29 LPCPDV	Valid payload received during loopback check mode. Indicates whether the Loop back frame received payload is CBh. 0 Payload received is not CBh 1 Payload received is CBh
30 LPCHDV	Valid header received during loopback check mode. Indicates whether the Loop back frame received header is 13h. 0 Header received is not 13h 1 Header received is 13h
31 LPCSDV	Valid synchronization received. 0 Valid Synchronization pattern not detected 1 Valid Synchronization pattern detected

51.6.19 LFAST Ping Status Register (LFAST_PISR)

Address: 0h base + 84h offset = 84h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0																								RXPNGD							
W

LFAST_DFSR field descriptions

Field	Description
0–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2–7 RXDCNT	Unread Rx Frame Data Count. Indicates the number of unread data stored in the Rx Data FIFO.
8–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13–15 RXFCNT	Unread Rx Frame Count. Indicates the number of unread data frames stored in the Rx Data FIFO.
16–17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
18–23 TXDCNT	Unread Tx Frame Data Count. Indicates the number of unread data stored in the Tx Data FIFO.
24–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29–31 TXFCNT	Unread Tx Frame Count.Count of pending Data Frames programed by System Side Module.

51.6.21 LFAST Tx Interrupt Status Register (LFAST_TISR)

Address: 0h base + 98h offset = 98h

LFAST_TISR field descriptions

Field	Description
0–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14 TXIEF	TxData Interface not enabled. Tx Data Interface not enabled and a frame is ready to be transmitted 0 Interrupt event has not occurred 1 Interrupt event has occurred
15 TXOVF	Transmit Data FIFO Overflow Interrupt 0 Interrupt event has not occurred 1 Interrupt event has occurred
16–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 TXPNGF	Ping response frame transmitted interrupt 0 Interrupt event has not occurred 1 Interrupt event has occurred
28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

LFAST_TISR field descriptions (continued)

Field	Description
29 TXUNSF	Unsolicited Frame transmitted Interrupt 0 Interrupt event has not occurred 1 Interrupt event has occurred
30 TXICLCF	ICLC Frame transmitted Interrupt 0 Interrupt event has not occurred 1 Interrupt event has occurred
31 TXDTF	Data Frame transmitted Interrupt 0 Interrupt event has not occurred 1 Interrupt event has occurred

51.6.22 LFAST Rx Interrupt Status Register (LFAST_RISR)

Address: 0h base + 9Ch offset = 9Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0								RXUOF	RXMNF	RXMXF	RXUFF	RXOFF	RXSZF	RXICF	RXLCEF

LFAST_RISR field descriptions

Field	Description
0–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

LFAST_RISR field descriptions (continued)

Field	Description
8 RXUOF	Unsolicited frame register overflow. Indicates existing unsolicited frame hasn't been read and a new unsolicited frame has arrived. 0 Interrupt event has not occurred 1 Interrupt event has occurred
9 RXMNF	Rx Data FIFO Min Threshold reached. 0 Interrupt event has not occurred 1 Interrupt event has occurred
10 RXMXF	Rx Data FIFO Max Threshold reached. 0 Interrupt event has not occurred 1 Interrupt event has occurred
11 RXUFF	Rx Data FIFO Underflow. 0 Interrupt event has not occurred 1 Interrupt event has occurred
12 RXOFF	Rx Data FIFO Overflow. 0 Interrupt event has not occurred 1 Interrupt event has occurred
13 RXSZF	Frame with unsupported frame size received. See "Frames Supported by LFAST interfaces" table for details. 0 Interrupt event has not occurred 1 Interrupt event has occurred - On reception of frame with payload size for a frame other than mentioned in the "Frames Supported by LFAST interfaces" table.
14 RXICF	Invalid ICLC code Received. 0 Interrupt event has not occurred 1 Interrupt event has occurred
15 RXLCEF	Invalid Logical Channel Type. 0 Interrupt event has not occurred 1 Interrupt event has occurred - On reception of frame other than mentioned in the "Frames Supported by LFAST interfaces" table.
16–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28 RXCTSF	Frame with CTS bit Low Received. 0 Interrupt event has not occurred 1 Interrupt event has occurred
29 RXDF	Data frame received. 0 Interrupt event has not occurred 1 Interrupt event has occurred
30 RXUNSF	Unsolicited Frame received. 0 Interrupt event has not occurred 1 Interrupt event has occurred

Table continues on the next page...

LFAST_RISR field descriptions (continued)

Field	Description
31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

51.6.23 LFAST Rx ICLC Interrupt Status Register (LFAST_RIISR)

Address: 0h base + A0h offset = A0h

18 ICPFF	Ping Frame Response failed 0 Interrupt event has not occurred 1 Interrupt event has occurred
19 ICPSF	Ping Frame Response successful 0 Interrupt event has not occurred 1 Interrupt event has occurred
20 ICPRF	ICLC Ping Frame Request received

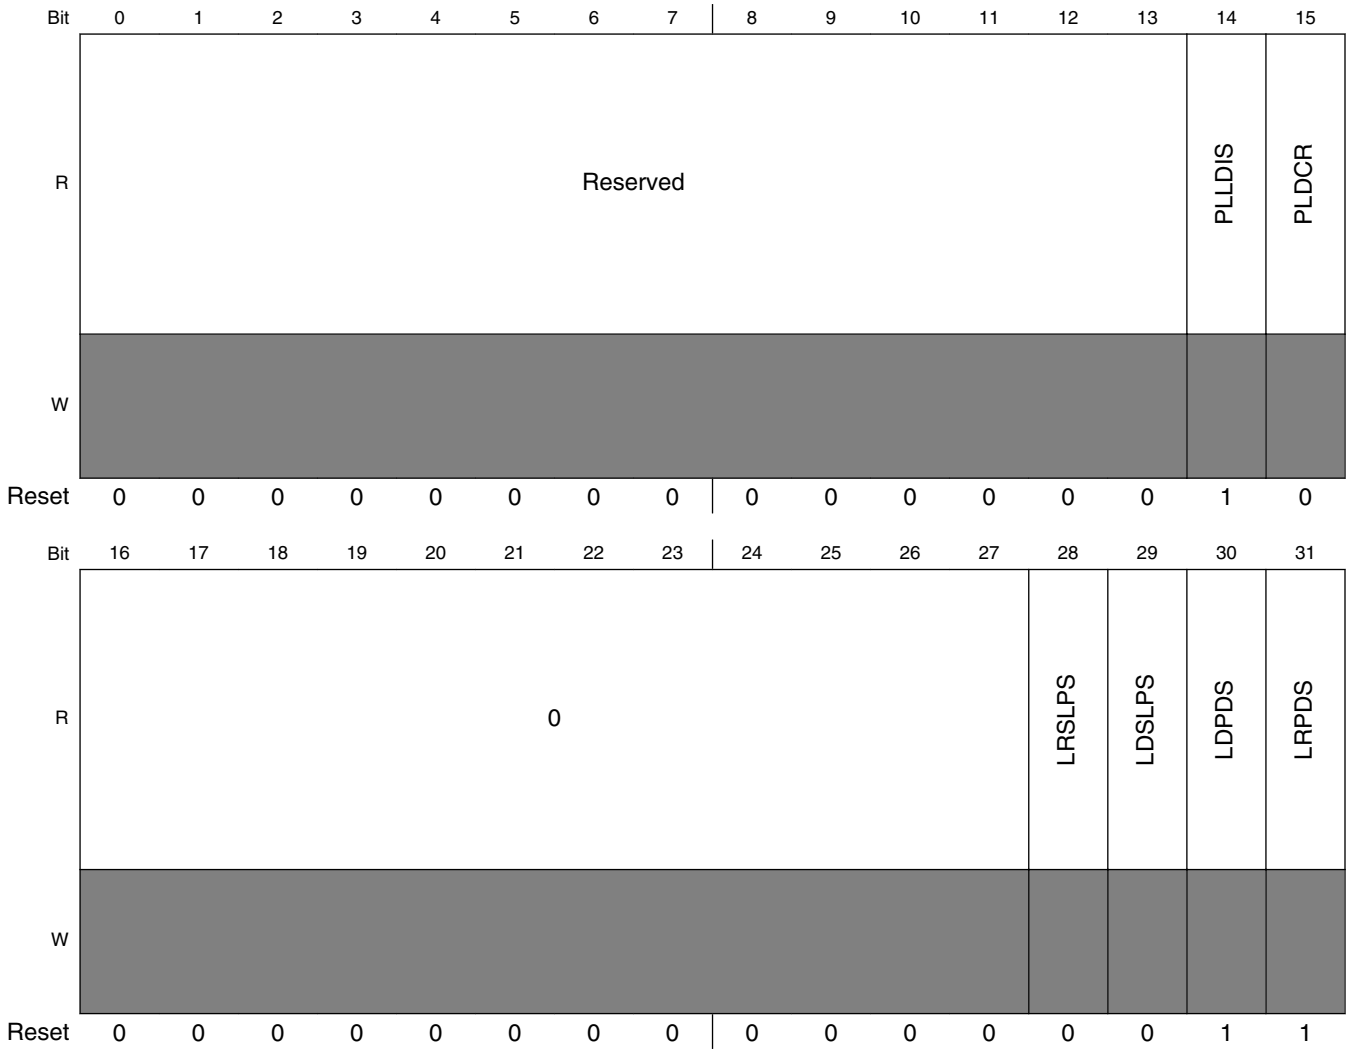

Table continues on the next page...

LFAST_RIISR field descriptions (continued)

Field	Description
	0 Interrupt event has not occurred 1 Interrupt event has occurred
21 ICTOF	ICLC frame for Test mode off received 0 Interrupt event has not occurred 1 Interrupt event has occurred
22 ICLPF	ICLC frame for Loopback On received 0 Interrupt event has not occurred 1 Interrupt event has occurred
23 ICCTF	ICLC frame for Clk Test mode received 0 Interrupt event has not occurred 1 Interrupt event has occurred
24 ICTDF	ICLC frame for LFAST Slaves Tx Interface Disable received 0 Interrupt event has not occurred 1 Interrupt event has occurred
25 ICTEF	ICLC frame for LFAST Slaves Tx Interface Enable received 0 Interrupt event has not occurred 1 Interrupt event has occurred
26 ICRFF	ICLC frame for LFAST Slaves Rx Interface fast mode switch received 0 Interrupt event has not occurred 1 Interrupt event has occurred
27 ICRSF	ICLC frame for LFAST Slaves Rx Interface slow mode switch received 0 Interrupt event has not occurred 1 Interrupt event has occurred
28 ICTFF	ICLC frame for LFAST Slaves Tx Interface fast mode switch received 0 Interrupt event has not occurred 1 Interrupt event has occurred
29 ICTSF	ICLC frame for LFAST Slaves Tx Interface slow mode switch received 0 Interrupt event has not occurred 1 Interrupt event has occurred
30 ICPOFF	ICLC frame for PLL OFF received 0 Interrupt event has not occurred 1 Interrupt event has occurred
31 ICPONF	ICLC frame for PLL ON received 0 Interrupt event has not occurred 1 Interrupt event has occurred

51.6.24 LFAST PLL and LVDS Status Register (LFAST_PLLLSR)

Address: 0h base + A4h offset = A4h

LFAST_PLLLSR field descriptions

Field	Description
0–13 Reserved	This field is reserved.
14 PLLDIS	PLL disable Status. When asserted, PLL is put in the power down state. 0 PLL disable signal is negated. 1 PLL disable signal is asserted.
15 PLDCR	PLL Lock Delay Counter Ready. When asserted this bit indicates that the PLL is locked after N number of reference/PLLCR[PREDIV] cycles 0 PLL Lock delay counter is not decremented to 0 1 PLL Lock delay counter is decremented to 0

Table continues on the next page...

LFAST_PLLLSR field descriptions (continued)

Field	Description
16–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28 LRSLPS	This bit indicates the real time status of LR sleep signal 0 LR power sleep signal is negated. 1 LR power sleep signal is asserted.
29 LDSLPS	This bit indicates the real time status of LD sleep signal 0 LD sleep signal is negated. 1 LD sleep signal is asserted.
30 LDPDS	This bit indicates the real time status of LD power down signal When asserted, LD is put in the power down state. 0 LD power down signal is negated. 1 LD power down signal is asserted.
31 LRPDS	This bit indicates the real time status of LR power down signal When asserted, LR is put in the power down state. 0 LR power down signal is negated. 1 LR power down signal is asserted.

51.6.25 LFAST Unsolicited Rx Status Register (LFAST_UNSRSR)

Address: 0h base + A8h offset = A8h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

LFAST_UNSRSR field descriptions

Field	Description
0–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23 URXDV	Unsolicited data valid. Indicates a valid frame exists in the Unsolicited Data registers.
24–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29–31 URPCNT	Rx Unsolicited payload. Indicates the number of bytes of valid Rx unsolicited Data payload present in the LFAST_UNSRDR[8:0].

51.6.26 LFAST Unsolicited Rx Data Register (LFAST_UNSRDR*n*)

Address: 0h base + ACh offset + (4d × i), where i=0d to 8d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

LFAST_UNSRDR*n* field descriptions

Field	Description
0–31 UNRXD	Unsolicited Receive Data. This represents 9 registers for Unsolicited received data.It is read only register. The first bit received as part of the payload will be stored at UNRXD8[31], second bit at UNRXD8[30], and so on. So the last bit will be stored at UNRXD0[0] in case of 288 bit payload.

51.7 Functional description

51.7.1 Startup procedure

The LFAST requires a sequence of operations before it can be used for communication. The procedure to enable LFAST for proper operation is listed below.

51.7.1.1 LFAST master interface startup procedure

1. After reset the SLCR and RCDCR are programed according to the LVDS parameters in the device data sheet.
2. The PLLCR is programmed with configuration parameters for the PLL.

3. The LCR is programed with configuration parameters of the LVDS.
4. Write MCR[MSEN] = 1. Then select LFAST modes by configuring MCR[CTSEN]and MCR[DATAEN].
5. Write MCR[DRFEN] = 1 to enable the LFAST.
6. Write MCR[RXEN] = 1 and MCR[TXEN] = 1 to negate the LD powerdown, LR disable and LR powerdown signals.
7. Write ICR[ICLCPLD] = 31h to enable the Slaves Tx Interface.
8. Write ICR[SNDICLC] = 1 and ICR[ICLCSEQ] = 1.
9. Write MCR[TXARBD] = 0.
10. The ICLC transmission is confirmed by verifying one of the following:
    - ICR[SNDICLC] = 0.
    - TISR[TXICLCF] = 1.
11. Write ICR[ICLCPLD] = 00h to check the LFAST slaves status.
12. Write ICR[SNDICLC] = 1.
13. The LFAST slave status is confirmed by occurrence of one of the following:
    - LFAST slave is enabled if RIISR[ICPSF] = 1. Proceed to step 14.
    - LFAST slave is disabled if RIISR[ICPFF] = 1. The LFAST master must wait and restart from Step 7.

Speed mode change:

14. Write PLLCR[SWPON] = 1 to enable the LFAST masters PLL.
15. Write ICLC start PLL frame, ICR[ICLCPLD] = 02h.
16. Write ICR[SNDICLC] = 1.
17. The ICLC transmission is confirmed by occurrence of one of the following:
    - ICR[SNDICLC] = 0.
    - TISR[TXICLCF] = 1.
18. To change LFAST masters Tx interface speed both of the following operations are performed:

Note

(The slaves Rx interface speed should be changed first.)

- Write ICR[ICLCPLD] = 10h for Tx data fast frame.
- Write ICR[SNDICLC] = 1.

19. Both of the following operations are performed to change the LFAST masters Rx interface speed:

Note

(The slaves Tx interface speed mode should be changed first)

- Write ICR[ICLCPLD] = 80h to select Rx data fast frame.
- Write ICR[SNDICLC] = 1.

20. The ICLC transmission is confirmed by the occurrence of one of the following:
    - ICR[SNDICLC] = 0
    - TISR[TXICLCF] = 1.
21. Write SCR[TDR] = 1 to change the LFAST masters Tx interface speed.
22. Write SCR[RDR] = 1 to change the LFAST masters Rx interface speed.
23. Write ICR[ICLCPLD] = 00h to confirm the change in speed of the LFAST slave. This frame should be written after waiting for the expected delay in the start of the PLL and speed mode change delay at the LFAST slave.
24. Write ICR[SNDICLC] = 1
25. Write MCR[TXARBD] = 1, after some delay to ensure the step 24 ICLC frame is send but no other frame is sent to arbitation.
26. The LFAST slaves speed mode is confirmed by the occurrence of the following:
    - If RIISR[ICPSF] = 1. The LFAST slave is in High Speed mode.
    - If RIISR[ICPFF] = 1. The LFAST slave is in Low Speed mode.
27. If RIISR[ICPSF] = 1, then all frame arbitration is enabled by both of the following operations:

- Write ICR[ICLCSEQ] = 0.
- Write MCR[TXARBD] = 0.

28. If RIISR[ICPFF] = 1 modifying the LFAST slaves speed needs to be repeated by:
    - Write SCR[TDR] = 0 to return the Tx interface to Low Speed mode.
    - Write MCR[TXARBD] = 0, to enable frame transmission.
    - The operations from step 14 need to be executed again.

51.7.1.2 LFAST slave interface startup procedure

1. After reset the SLCR and RCDCR are programed according to the LVDS datasheet.
2. The PLLCR is programed with the configuration parameters for the PLL.
3. The LCR is programed with the configuration parameters for the LVDS.
4. Write MCR[MSEN] = 0. Then select LFAST modes by configuring MCR[CTSEN] and MCR[DATAEN].
5. Write MCR[DRFEN] = 1 to enable the LFAST.
6. The LR is enabled by writing MCR[RXEN] = 1. This negates the LR disable signaland LR's power down signal.
7. The LD enable signal needs to be asserted. This is done when one of the following are true:
    - When an ICLC frame with payload 31h is received the H/W will write RIISR[ICTEF] = 1 and MCR[TXEN] = 1.
    - MCRMCR[TXEN] = 1.
8. After a write to MCR[TXARBD] = 0, a ping frame will be sent on one of the following conditions:
    - When PICR[PNGAUTO] = 1 and an ICLC frame with payload 00h frame is received. H/W writes [ICRPF] = 1.
    - PICR[PNGREQ] = 1.

Speed mode change:

9. The PLL will start when one of the following conditions is met:

- When an ICLC frame with payload 02h is received. H/W writes RIISR[IPONF] = 1.
- Write PLLCR[SWPON] = 1.

10. The speed of the Tx interface is changed on one of the following conditions:
    - When SCR[DRMD] = 1 and an ICLC frame with payload 80h is received. H/W writes RIISR[ICTFF] = 1 and SCR[TDR] = 1.
    - SCR[TDR] = 1, when SCR[DRMD] = 0.
11. The speed of the Rx interface is changed on one of the following conditions:
    - When SCR[DRMD] = 1 and an ICLC frame with payload 10h is received. H/W writes RIISR[ICRFF] = 1 and SCR[RDR] = 1.
    - SCR[RDR] = 1, when SCR[DRMD] = 0.
12. A Ping Frame is sent on one of the following conditions:
    - When PICR[PNGAUTO] = 1 and an ICLC frame with payload 00h is received. H/W writes RIISR[ICRPF] = 1.
    - Write PICR[PNGREQ] = 1.
    - Write PICR[PNGREQ] = .

51.7.2 Line Receiver

This section describes the Line Receiver.

51.7.2.1 Introduction

The LR detects the voltage swing on the differential pair and converts it to a CMOS logic level that feeds the adaptive auto correlation block. The received data is sampled using the best of the 8 (default) or 4 (alternative setting) possible sampling edges from the high speed clock or 4 phases using the low speed clock. The sampling edge is chosen by checking which of the 8/4 Correlators provide the maximum correlation. If more than one sampling edge provides the maximum then the state machine will choose the sampling edge based on a defined selection algorithm.

After the correct sampling edge is chosen, the remaining unused sampling edges are turned off. Once the header is received the length of the frame (payload size) and logical channel definition can be obtained. The logical channel definition will determine the data

type of the payload and therefore will determine the destination for the payload. Decoding of the ICLC commands from the payload is required in order to extract the interface control, rate mode and PLL commands.

Figure 51-48 shows the block diagram of Uplink Controller.

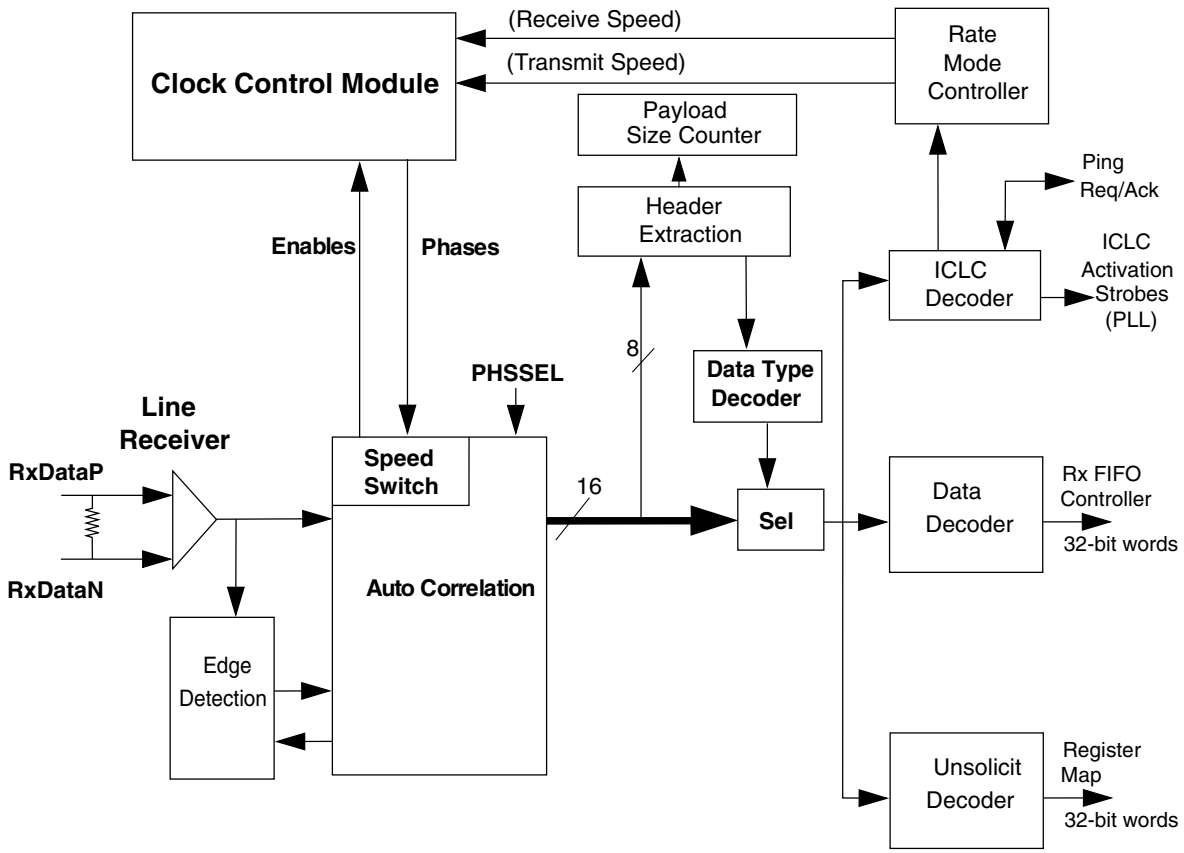

Figure 51-48. Top Level Receive Controller

51.7.2.2 Edge detection and auto-correlation

The edge detection and auto correlation are described together, as the mode setting of the auto-correlation block impacts largely on whether the edge detection circuitry is used or not. The edge detection will be performed first if required before auto-correlation.

51.7.2.2.1 Auto-Correlation modes

This section describes the Auto-Correlation modes.

51.7.2.2.1.1 Hunt Correlation mode

On reset the Receive Controller will always come up in Hunt Correlation mode. In this mode all the Correlators are enabled and the Receive Controller is always hunting for the synchronization pattern. The phase enables (either 8 or 4) to the external clock control module are always high. There is no edge detection for the first bit of the synchronization pattern. Hunt Correlation mode is considered the safest mode as the Receive Controller is always checking for the synchronization pattern, but it is the mode that consumes the most power. In Hunt Correlation mode the correlation is performed over all 16 bits of the synchronization pattern.

Figure 51-49 shows the block diagram of Hunt Correlation mode.

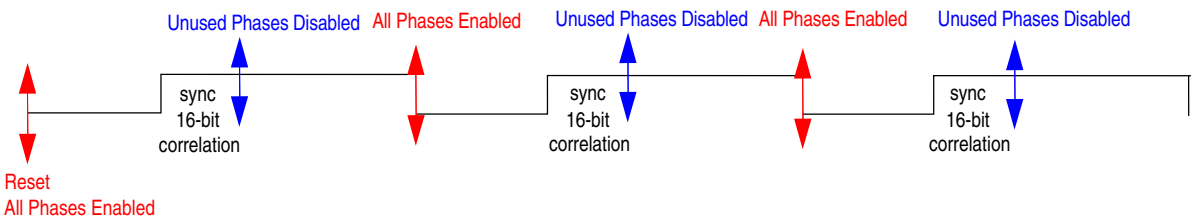

Figure 51-49. Hunt Correlation mode

51.7.2.2.2 Edge Detection

The edge detector is disabled in Hunt Correlation mode.

51.7.2.2.3 Auto correlation

The data transmission between the 2 devices LD and LR is asynchronous in nature. Hence the Receive Controller does not have the knowledge about the correct clock phase to be used for extracting the data. The task of the auto correlation (or synchronization) scheme is to estimate the best clock phase (8 or 4) for extraction of data as shown in the following figure.

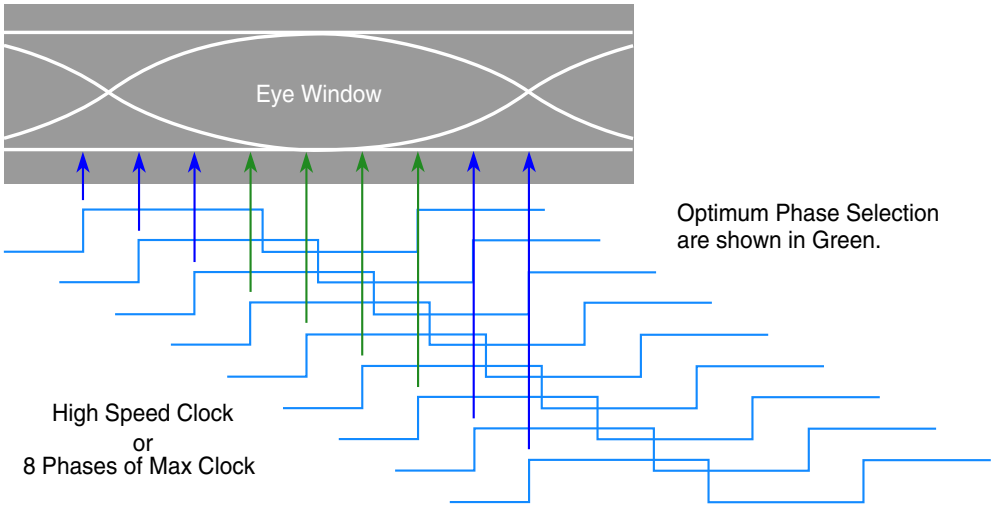

Figure 51-50. High Speed 8 Phase Selection

The objective of the auto correlation is to select the clock phase that occurs closest to the center of the eye diagram window. For 8 Phase clock alignment the worst case selection is when the clock edge is just after the LR output transition. The 8 clock phases will sample the correct value but the middle clock phases are the ideal selection. If one of the middle phases are selected then the minimum distance to the LR transition is 3 clock phases as shown in the following figure.

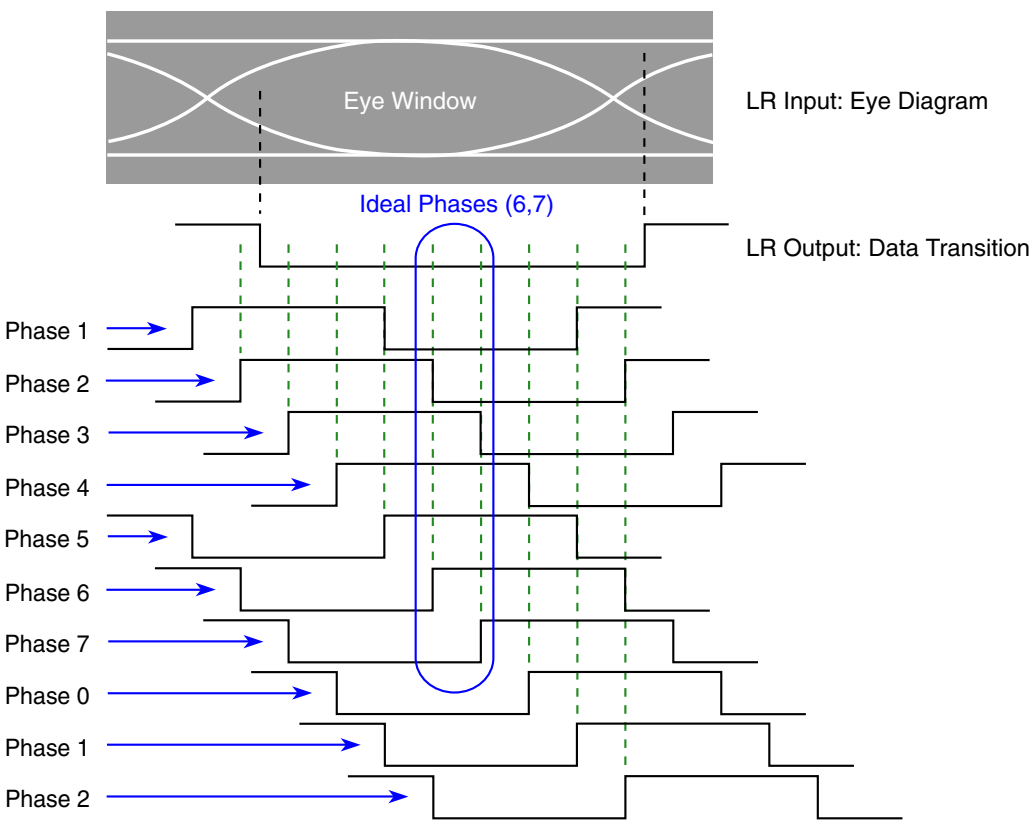

Figure 51-51. High Speed 8 Phase Clock Alignment Example

Each of the 8 high speed phases are 45 degrees separated. For 4 phases, whether high or low speed, the phases are 90 degrees separated but can have different phases enabled as shown in Figure 51-52 and Figure 51-53.

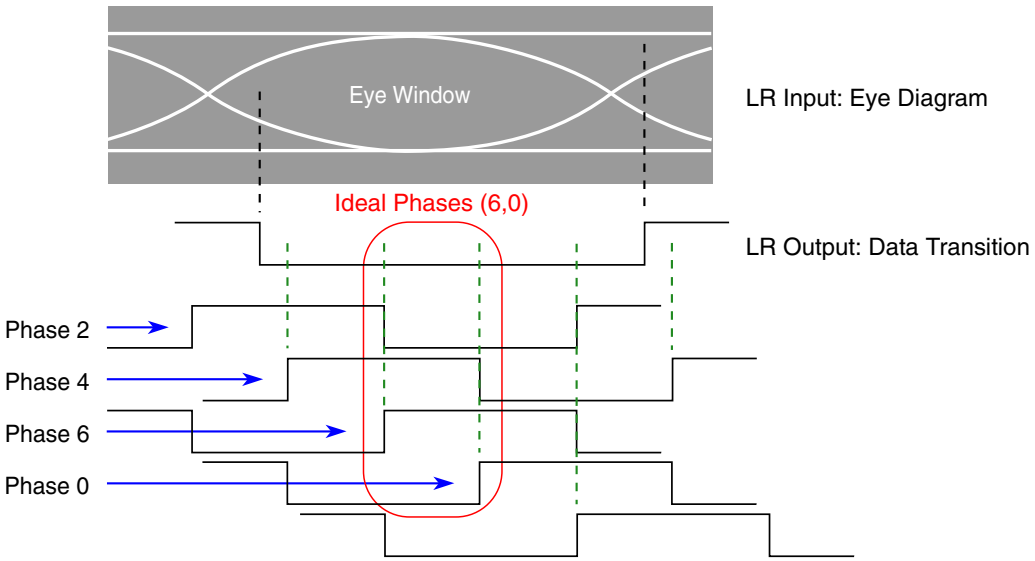

Figure 51-52. High Speed 4 Phase Clock Alignment Example

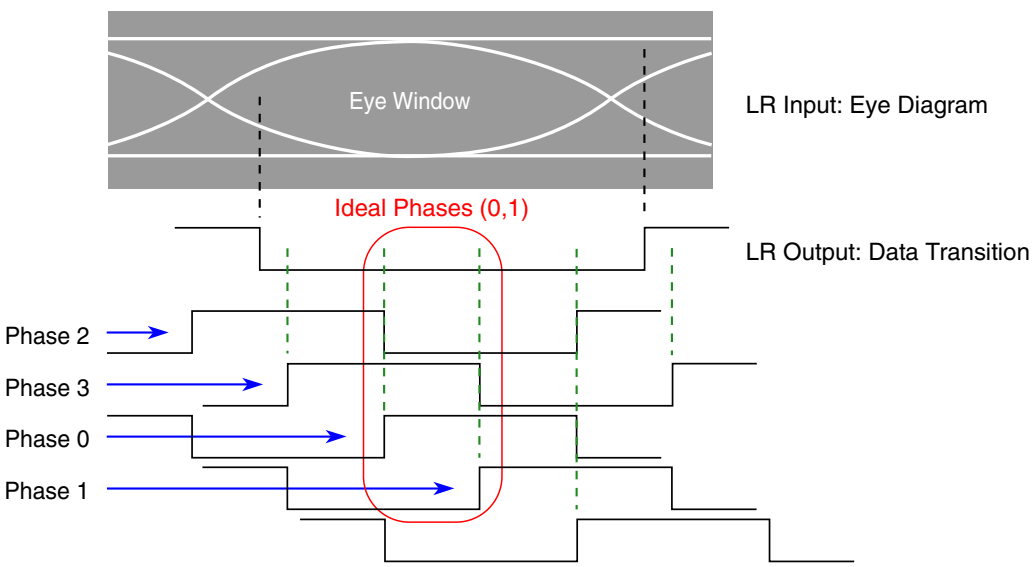

Figure 51-53. Low speed 4 phase clock alignment example

The auto correlation and selection of the correct clock phase starts after the edge detection finds a 0 to 1 transition. The high speed 8 or 4 phases from the PLL and the low speed 4 phases (generated inside the Clocking Module) are muxed inside the clocking module. The LFAST interface block will determine which phases are to be enabled and disabled. The only time the interface does not choose the phases is when the Clocking Module overrides the phase enables using COCR[SMPSEL].

The input data path can be sampled by different samplers depending on the configuration:

- High speed 8-phases: Samplers 0,1,2,3,4,5,6,7
- High speed 4-phases: Samplers 0,2,4,6
- Low Speed 4-phases: Samplers 0,1,2,3

Each sampler block samples the data path with a different clock phase from the Clocking Module, and resamples it to a intermediate phase as shown in Table 51-47, Table 51-48, and Table 51-49 before resampling it to Phase 0. The intermediate phase is used to make static timing between the initial phase and the final phase 0. The final phase, Phase 0 is chosen so all the clock trees after the sampler are clocked by the same clock.

Table 51-47. High speed 8 phase selection - sampling procedure

Samplers	InitialSample	Intermediate Sample	Final Sample
0	Phase 0	Phase 0	Phase 0
1	Phase 1	Phase 0	Phase 0
2	Phase 2	Phase 0	Phase 0
3	Phase 3	Phase 0	Phase 0
4	Phase 4	Phase 2	Phase 0
5	Phase 5	Phase 2	Phase 0
6	Phase 6	Phase 4	Phase 0
7	Phase 7	Phase 4	Phase 0

Table 51-48. High speed 4 phase selection - sampling procedure

Samplers	InitialSample Phase	Intermediate Sample Phase	Final Sample Phase
0	Phase 0	Phase 0	Phase 0
1	Disabled	Disabled	Disabled
2	Phase 2	Phase 0	Phase 0
3	Disabled	Disabled	Disabled
4	Phase 4	Phase 2	Phase 0
5	Disabled	Disabled	Disabled
6	Phase 6	Phase 4	Phase 0
7	Disabled	Disabled	Disabled

For High speed 4 Phase selection, See Table 51-48, Samplers 1, 3, 5, 7 are disabled. In the Phase Select algorithm Phase 1 is mapped to Phase0, Phase 3 is mapped to Phase 2, Phase 5 is mapped to Phase 4, Phase 7 is mapped to Phase 6 so it simplifies the algorithm and allows the algorithm to be the same independent of 4 or 8 Phases in high speed.

Table 51-49. Low speed 4 phase selection - sampling procedure

Samplers	InitialSample Phase	Intermediate Sample Phase	Final Sample Phase
0	Phase 0	Phase 0	Phase 0

Table continues on the next page...

Table 51-49. Low speed 4 phase selection - sampling procedure (continued)

Samplers	InitialSample Phase	Intermediate Sample Phase	Final Sample Phase
1	Phase 1	Phase 0	Phase 0
2	Phase 2	Phase 0	Phase 0
3	Phase 3	Phase 0	Phase 0
4	Disabled	Disabled	Disabled
5	Disabled	Disabled	Disabled
6	Disabled	Disabled	Disabled
7	Disabled	Disabled	Disabled

For low speed 4 Phase selection, See Table 51-49, Samplers 4, 5, 6, 7 are disabled.The first four Samplers (0,1,2,3) of the low 4 phase speed selection algorithm are the same as the four samplers required for the high 8 phase speed. Therefore the same architecture can be used for both high speed and low speed with the other four data paths disabled for low speed.

51.7.2.2.4 Sampler block and phase enable and disable

There are 8 data sampler paths in total inside the auto correlation block, each data sampler has 3 sampling registers with the possibility of each register being clocked by a different phase (in example, Sampler 5 for high speed can have Phases 5, 2 and 0). Therefore, after the correct data sampler has been selected for either high or low speed, the block can turn off all the sampler paths except for one, therefore 3 out of 24 registers will remain enabled while the others are disabled, as shown in the following figure.

After correlation and the correct data sampler has been selected all the other data samplers whose initial phase does not match the select phase are disabled. The selected sampler will then keep the required phases needed enabled, this can be max 3 phases (for example, Sampler 5 has Phases 5, 2, 0) or min 1 phase (in example below, Sampler 0 has all Phase 0 content).

The end result is that the Rx Controller can disable the required number of unused sampler registers and disable any unnecessary phases from the Clocking Module by deasserting the respective phase enables.

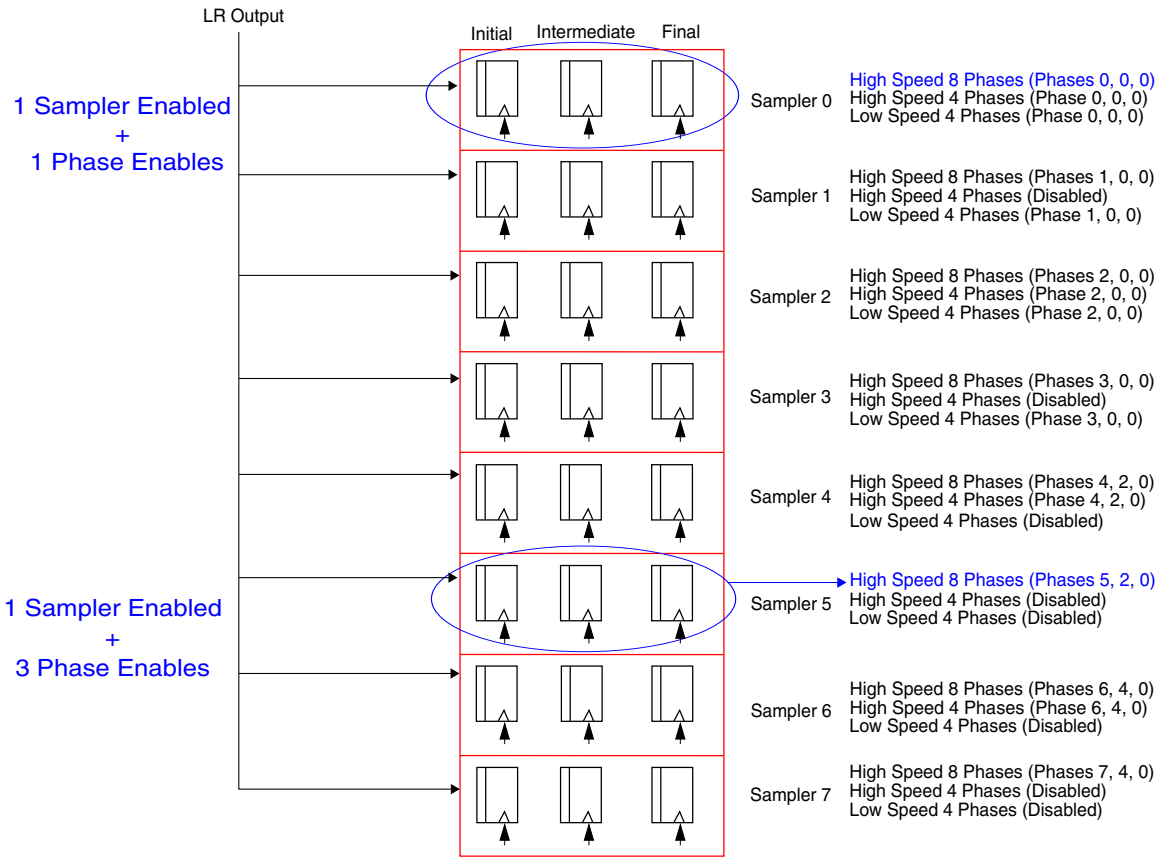

Figure 51-54. 8 Samplers, each Sampler has 3 Registers

In order to achieve the sampler and phase enable requirements each Sampler block will require the logic as shown in the following figure.

The Clock Gating Element resides inside the Clocking Module block. The interface will provide the enables to the Clocking Module and the Clocking Module will in return provide the individual clocks to the sampling registers.

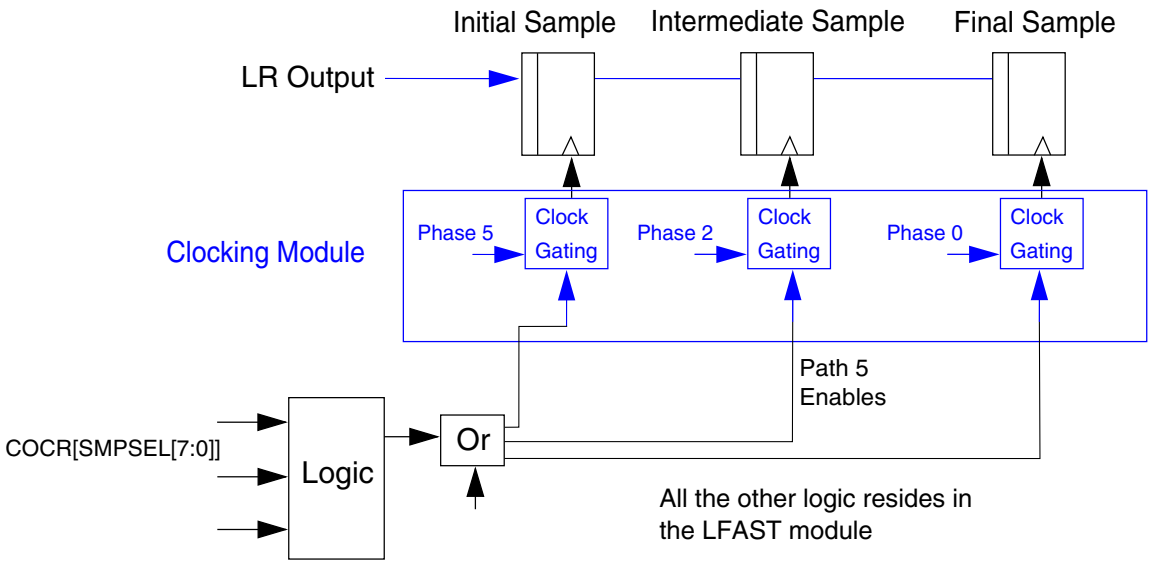

Figure 51-55. Sampler 5 Logic

51.7.2.3 Header and Payload Extraction

Once the Phases/Samplers are chosen after Synchronization and Correlation the next part of the flow is the header extraction. The Receive Controller will output a 16 bit word, bit shifted every Phase 0 clock as shown in the Figure 51-56.

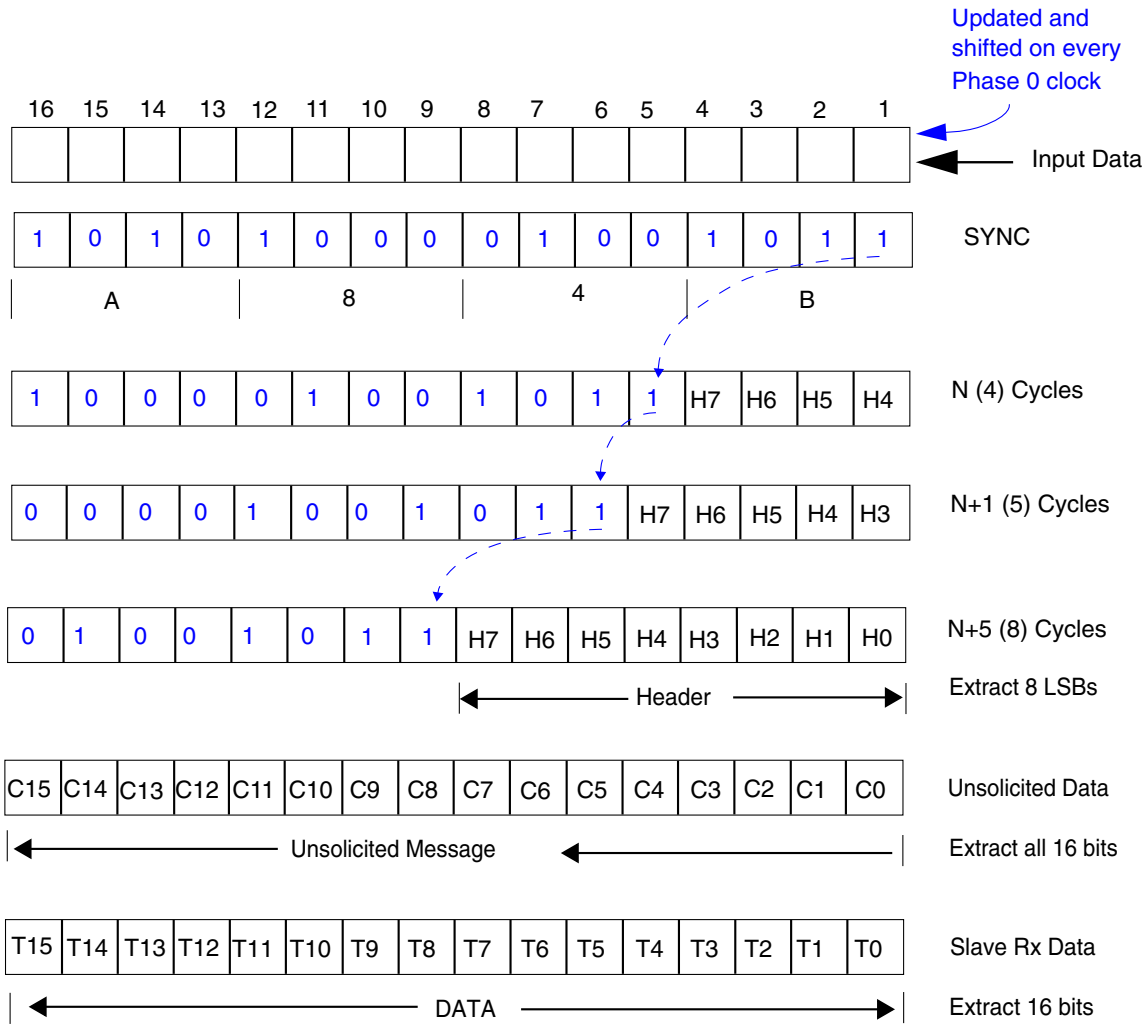

Figure 51-56. Extracting Header and Payload from the 16-bit output from Auto correlation.

51.7.3 Transmit Controller

This section describes the Transmit Controller.

51.7.3.1 Introduction

The Transmit Controller uses Rx information, status information and error control data and codes them into the appropriate frame structure for transmission to the LD. This includes the synchronization and header, in preparation for the LD, which transmits the frame to peer LFAST IC at either low or high speed. The Transmit Controller creates a frame structure that is converted to a serial format for the LD.

An arbitration block will determine which message has higher priority data, unsolicited, ICLC, CTS, ping, and so on. The data frames are extracted from the FIFO controller, the unsolicited message from the register block, the CTS messages from the Receive Controller and the ping response from the register block.

The Tx interface has two speed modes:

- Low Speed
- Fast Speed

The Transmit Controller consists of the following blocks as shown in the following figure.

- Arbitrator
- Framer
- Request Clock Control

The arbitrator will grant access to the framer from the request that has the highest priority. The framer block will extract the payload data from the granted request source and build the frame (adding synchronization or header if required). The frame is fed into a PISO (Parallel In Serial Out) and eventually sent to the LD.

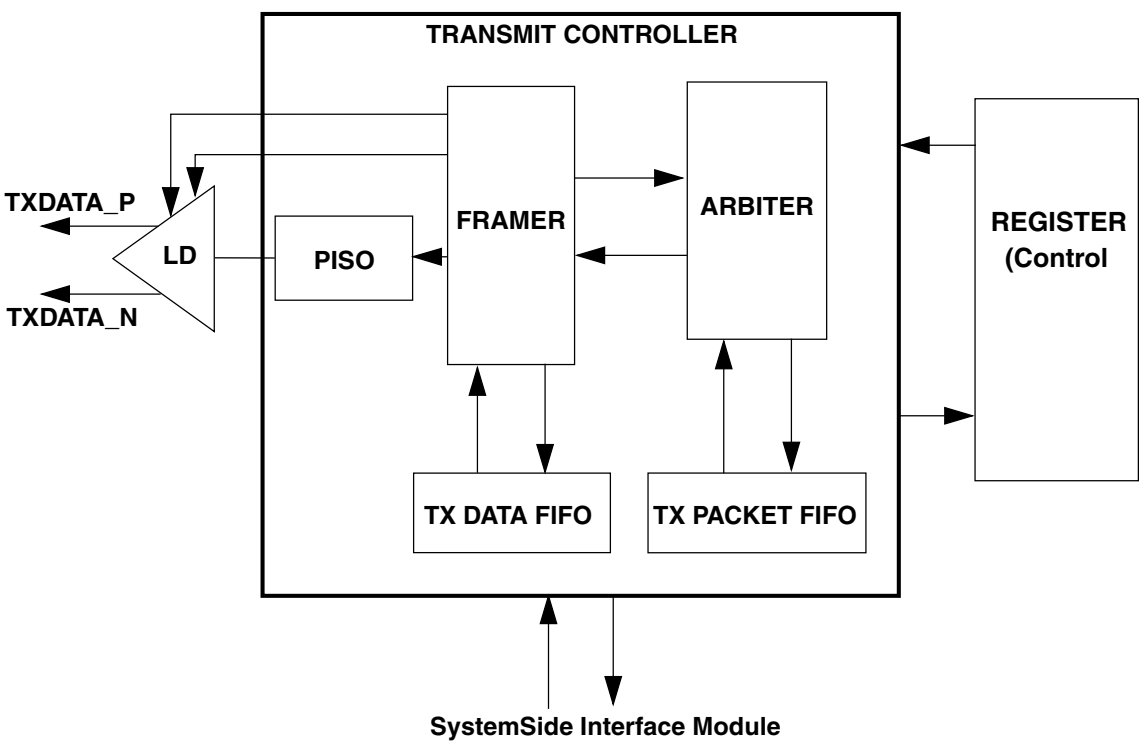

Figure 51-57. Transmit Controller Connections

51.7.3.2 Arbitration

The arbitration block prioritizes between requests from multiple sources like

- S/W programmable registers
- System side interface FIFO
- Rx interface controller

The level of priority for each request is shown in Table 51-50

Table 51-50. Priority Levels for the Transmit Controller

Request	LFAST MasterPriority	LFAST SlavePriority	Triggering Conditions *(at least one of the listed)*
LFAST interface enable	1	1	• LFAST interface enable is asserted • LFAST interface enable is negated
Tx Interface disabled	2	2	• MCR[DRFEN] = 0 • MCR[TXEN] = 0 • MCR[DRFRST] = 1 • MCR[TXARBD] = 1 • LFAST Slave: ICLC frame with payload for "Disable Rx interface" received
Tx Interface speedmode change	3	3	• SCR[TDR] is modified • LFAST Slave: ICLC frame with payload for changing Rx interface speed received
Loopback frame in Loopback mode	4	4	• TMCR[LPON] = 1Dig • RF Slave: ICLC frame with payload for loopback mode enable received **Note:** Valid only for following TMCR[LPMOD] settings: LPMOD[2:0] = 011b LPMOD[2:0] = 100b
ICLC frame request	5	-	• LFAST Master: ICR[SNDICLC] = 1 • LFAST Master: ICR[ICLCSEQ] = 1
Ping response request	-	5	• LFAST Slave: ICLC frame with payload for ping request received and PICR[PNGAUTO] = 1 • LFAST Slave: PICR[PNGREQ] = 1

Table continues on the next page...

Table 51-50. Priority Levels for the Transmit Controller (continued)

Request	LFAST MasterPriority	LFAST SlavePriority	Triggering Conditions *(at least one of the listed)*
Unsolicited frame request	6	6	• Last Frame with CTS = 1 received from the peer LFAST device • UNSTCR[USNDRQ] = 1
Data frame from Tx FIFO	7	7	• Tx FIFO contains one or more frames • Last Frame with CTS = 1 received from the peer LFAST device • MCR[DATAEN] = 1
CTSFrame	8	8	• MCR[CTSEN] = 1 • Rx FIFO reaches High/Low threshold, defined by TISR and no frame pending
Clock mode test	9	9	• TMCR[CLKTST] = 0 • LFAST Slave: ICLC frame with payload for clock test mode enable received

Once the arbitrator has granted access to a request, the Framer will commence building the frame. Any new requests for frame or data rate change will not be granted access until the framer has finished transmitting the current frame. If a data rate change request for the Tx interface is received while the Transmit controller is in the middle of sending a frame then the rate change request to the Clocking Module will be delayed. This allows for the frame to be completed before the change in speed mode. This prevents any speed mode change during the transmission of a frame. Once the speed mode request is sent to the Clocking Module by the Tx Interface Controller, it will then not allow any new requests to be processed for a specific time period defined by the bit field RCDCR[DRCNT].

51.7.3.3 Line Driver digital connections

51.7.3.3.1 Line Driver states

The LD has the following states:

- Shutdown

The LD enters the Shutdown state when the LD powerdown signal and the output buffer enable is high. In this state, the LD regulator is not supplying power and the LD outputs are connected to ground. Once LD powerdown signal is negated, a settling time is required before the LD may be used for communication.The settling time is defined by the SLCR[LWKCNT] and SLCR[HWKCNT] bitfields.

- Sleep

  The LD enters in sleep state when the signal is asserted. In this state, the LD is enabled, but held in a power-saving state. Sleep mode may be used during inter-frame gaps that are long compared to the frame durations but not long enough to allow the interface(s) or high-speed clock generators to be powered down completely. In the sleep state the LD outputs are connected to Vcm (common mode voltage). To exit from Sleep mode the LD sleep signal is negated. The LD is required to transmit a logic 0 level on the interface for a pre-defined minimum time. The minimum time is the summation of settling time of LD after negation of LD sleep signal and the wakeup time of the LR on the other side. This delay is programed in the SLCR[HSCNT] and SLCR[LSCNT] bitfields.

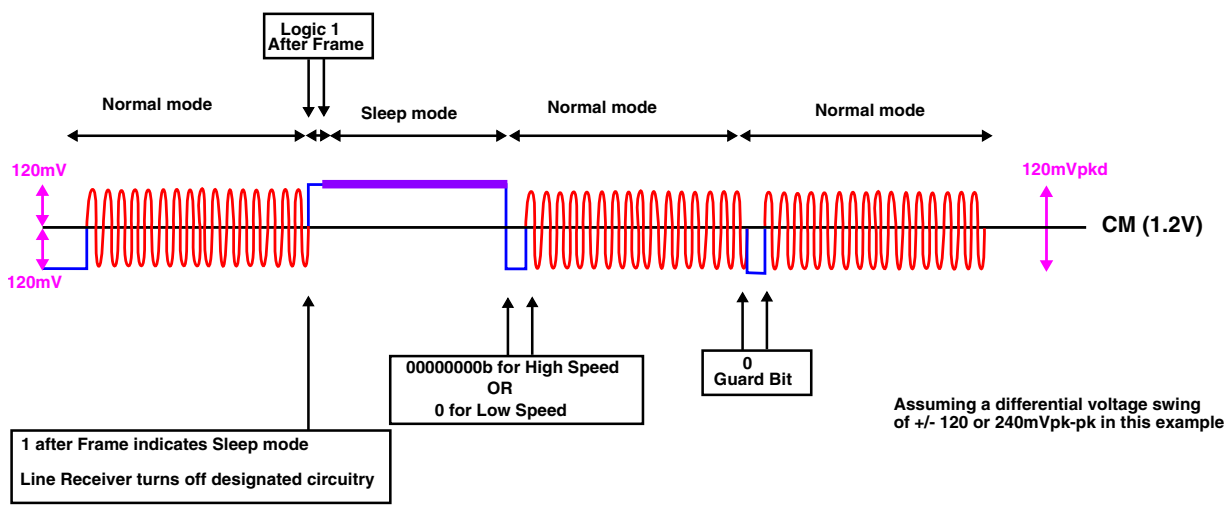

Figure 51-58. Example of Sleep mode

As shown in Figure 51-58 before every normal mode burst on the txdatap line there is one guard bit period (minimum inter-frame gap) where a logic 0 will be transmitted.

- Normal

  In the Normal state the LD is primed for transmission. The LD shall drive the interface as dictated by the input data bit that is supplied by a shift register under the control of a finite state machine. If the LD is not enabled, and the framer is activated,

and has a frame to transmit, an interrupt (TISR[TXIEF]) will be generated. The LD moves back to the shutdown state when the LFAST master sends an ICLC Rx data off command.

Table 51-51. Line Driver States

LD State	LFAST Master Triggers	LFAST Slave Triggers
Shutdown	• Programing LVDS[SWOFFLD] and LVDS[SWONLD] • Programing MCR[TXEN] and MCR[DRFEN]	• LFAST interface enable negation/assertion • Programing LVDS[SWOFFLD] and LVDS[SWONLD] • ICLC command from LFAST master • Programing MCR[TXEN] and MCR[DRFEN]
Sleep	• Programing LVDS[SWSLPLD] and LVDS[SWWKLD]	• No pending frame for transmission • Programing LVDS[SWSLPLD] and LVDS[SWWKLD]
Normal	Absence of above mentioned conditions	Absence of above mentioned conditions

51.7.4 CTS mode support

LFAST module supports flow control methods. The CTS (Clear to send) is a protocol defined method to ensure no loss of frame, due to Rx FIFO unavailability. The optimal use of bandwidth of LFAST, without losing frames, is ensured by proper programing of the Rx FIFO Lower threshold (RFCR[CTSMN]) and Higher threshold (RFCR[CTSMX]). The CTS is supported by both the LFAST Master and Slave.

CTS Transmission:

The LFAST device sends CTS information with each frame to the peer LFAST device.

If the CTS mode is enabled by write MCR[CTSEN] = 1 then:

- Sends CTS bit as 0 in LFAST frame (bit[0] of Header field) whenever the Rx FIFO reaches the higher threshold defined by the bitfield TISR[CTSMX]. This indicates that the LFAST device doesn't want the peer device to send data. The CTS bit of all frame are sent 0 untill the Rx FIFO pointer reaches the lower threshold, as described below.

- Sends CTS bit as 1 in LFAST frame (bit[0] of Header field) whenever the Rx FIFO reaches the Lower threshold defined by the bitfield TISR[CTSMN]. This indicates that the LFAST device is ready to receive data from the peer device. The CTS bit of all frame are sent 1 untill the Rx FIFO pointer reaches the Higher threshold, as described above.
- The CTS bit can be sent through any type of frame (data, unsolicited or ICLC). When there are no frames available in LFAST to send to the peer device, a CTS frame is sent. In this frame, bit[4-1] of Header field are sent as 0011b and 8-bit payload of 0.

If the CTS mode is not enabled (for example, bit MCR[CTSEN] = 0) then:

- All the frame sent will have CTS bit as 1 in LFAST frame (bit[0] of Header field).

CTS Reception:

The reception of a LFAST frame with CTS bit 0 indicates that the peer device is not ready to receive data frames. The transmission of all pending data and unsolicited frames are postponed untill a frame with CTS bit 1 is received.

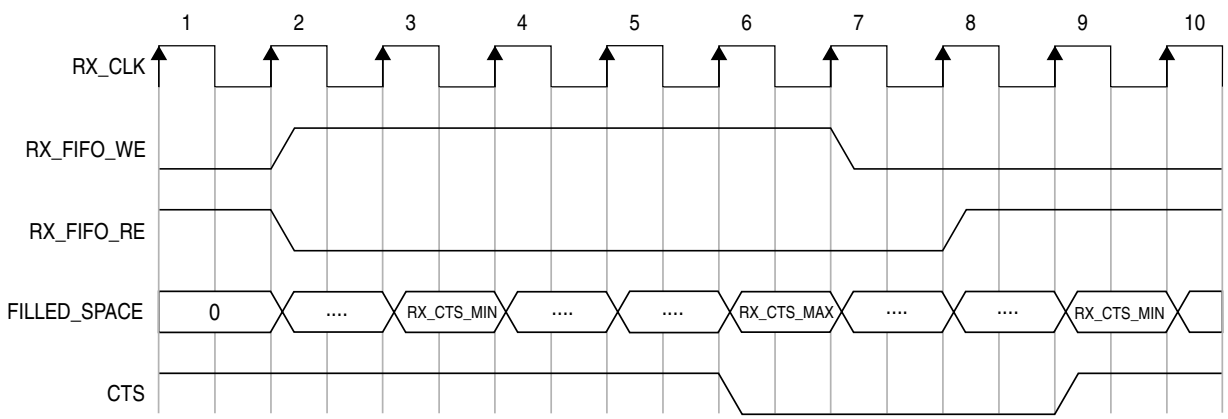

Figure 51-59. CTS generation

51.7.5 Frames supported

Table 51-52 provides the frames supported and their permissible payload sizes

Table 51-52. Frames supported by LFAST interfaces

Frame Type	LCT Code	Supported by 1. LFAST Master Tx2. LFAST Slave Rx	Supported by1. LFAST Slave Tx2. LFAST Master Rx	Payload Size (bits)
Data Frame	0100b – 1011b	YES	YES	32, 64, 96, 128, 256, 288
Unsolicited Frame	0001b	YES	YES	8, 32, 64, 96, 128, 256 and 288
ICLC Frame	0000b	YES	NO[1]	8
CTS Frame	0011b	YES	YES	8
Reserved	All others	—	—	—

1. Except the ICLC PING response frame.

If logical channel type (LCT) code other than the above mentioned are received then the interrupt flag RISR[RXLCEF] = 1. If the payload size received does not match any value in Table 51-52 then the flag RISR[RXSZF] = 1. In both these error conditions the received frame is ignored. The S/W may have to take the necessary steps to recover from such an error.

51.7.6 Frame flow

Following sections describe Data Frame Flow, ICLC Flow and Rx Unsolicited Data Flow.

51.7.6.1 Data flow

LFAST supports the transfer of data between master and slave LFAST devices.

51.7.6.1.1 Data transmit

System Side Module is the initiator of all the Tx data frame to LFAST peer device. Data frame transmit is triggered whenever the Tx Data FIFO has at least one valid frame. The MCR[DATAEN], MCR[DRFEN] and MCR[TXEN] bits, should be set to enable the transfer of Tx data.

If MCR[DATAEN] = 0, then the valid frames in the in Tx data FIFO will be ignored for transmission. The Payload Size and channel type of each frame is specified by the System Side Module interface during transfer of the frame to the LFAST interface. The frame header is stored in the Tx packet FIFO and the payload in the Tx data FIFO.Whenever the Tx FIFO has at least one frame then a data transmit request is made to the Tx arbiter of the LFAST. Tx block arbitrates the data transmit request and

schedules it depending on the priority of all the pending transmit requests. When data request is scheduled by Tx block, the required data is fetched from Tx data FIFO. The number of frames present in the Tx FIFO for transmission is indicated by the bitfield DFSR[TXFCNT].

51.7.6.1.1.1 Programing model for Tx data transmit

1. Program MCR[DATAEN] = 1, MCR[TXEN] = 1 and MCR[DRFEN] = 1 to enable the Tx path of LFAST device
2. Select the desired clock rate at which data should be transmitted, using ICLC transfers and appropriate programing of SCR[TDR] bits.
3. Frame present in TX FIFO (Data and Packet FIFO) are sent.
4. TISR[TXDTF] = 1 after each frame transfer
5. CTS is set depending on the push/pull mode setting defined by MCR[CTSEN].

51.7.6.1.2 Data receive

LFAST master and slave supports reception of data frame. The received frame is determined to be of data frame type by decoding channel type field of the header present in the received frame. The MCR[DATAEN], MCR[RXEN] and MCR[DRFEN] bits should be set to enable the data frame reception.When MCR[DATAEN] = 0 the received data frames will be ignored and will not be placed in the Rx data FIFO.

The Rx data frames received by Rx block are stored in the Rx FIFO. Whenever the frame is received in the Rx FIFO the System Side Module is indicated by assertion of LFAST Rx FIFO ready signal. The frame size and the Channel type is passed to the LFAST. The frame boundaries are indicated by start of frame and end of frame signals. The number of unread frames in the Rx Data FIFO are indicated by DFSR[RXFCNT]. When Rx DATA FIFO is full and cannot accommodate current frame completely, then the remaining data of the Rx frame is discarded. In this case, UNSRSR[RXOF] = 1 and an interrupt is generated if the RIER[RXOFIE] = 1.

51.7.6.2 Unsolicited flow

51.7.6.2.1 Unsolicited frame transmit flow

The S/W is the initiator for unsolicited frames to the LFAST peer device. The unsolicited frame header and payload is programed into the Unsolicited Data and Control registers. Once the Payload is programed UNSTCR[USNDRQ] is set, generating a request for unsolicited frame transfer to the Tx arbiter.

51.7.6.2.1.1 Programing model for unsolicited frame transmit

1. Program MCR[TXEN] = 1 and MCR[DRFEN] = 1 in the Mode Configuration Register (MCR) to enable the Tx path
2. Select the desired clock rate at which data should be transmitted, using ICLC transfers and appropriate programing of SCR[TDR].
3. Read the UNSTCR[USNDRQ].
   - If UNSTCR[USNDRQ] = 1 then wait for either of the following:
     - UNSTCR[USNDRQ] = 0
     - TISR[TXUNSF] = 1
   - If UNSTCR[USNDRQ] = 0 then:
     - Program the unsolicited payload in UNSTDR0–UNSTDR8, and can be written up to a payload of frame of a maximum of 288 bits.
     - Program the unsolicited frame header in UNSTCR[UNSHDR].
     - Program UNSTCR[USNDRQ] = 1.
4. UNSTCR[USNDRQ] is cleared by the Tx Block after the frame transfer.
5. TISR[TXUNSF] = 1 when the frame is transmitted.
6. CTS is set depending on the Push-Pull mode setting defined by MCR[CTSEN].

51.7.6.2.2 Unsolicited frame receive flow

Whenever an Unsolicited frame is received from the peer device, the following steps are performed:

If UNSRSR[URXDV] = 0 then:

1. The payload size field of the header is first saved into the UNSRSR[URPCNT].
2. The payload is stored in the UNSTDR0–UNSTDR8.

3. UNSRSR[URXDV] = 1 and the RISR[RXUNSF] = 1 indicating the successful reception of the frame.

If UNSRSR[URXDV] = 1 then:

1. The current unsolicited frame is ignored.
2. RISR[RXUOF] = 1.

Typical steps by the processor after RISR[RXUNSF] = 1 is as follows:

1. The processor reads UNSRSR to get the payload size of the frame.
2. It then reads the complete frame by reading UNSRDR8–UNSRDR0 for the payload size as received in the frame.
3. Then it clears the interrupt (write RISR[RXUNSF] = 1) and also the UNSRSR[URXDV] bit.

51.7.6.3 ICLC flow

The ICLC (Interface Control Logical Channel) is a separate logical channel type, which is mainly meant for implementing the data rate change in the LFAST interface and initiating the test modes.

51.7.6.3.1 ICLC data transmit flow

Whenever the processor intends to transfer an ICLC frame to the LFAST slave then the following steps are to be followed.

1. Write the ICLC frame payload in the ICR[ICLCPLD] (see Table 51-53 for payloads as defined by the standard).
2. Program ICR[SNDICLC] = 1 to initiate the ICLC frame transfer. This bit clears itself when the ICLC frame has been transmitted. The processor needs to poll this bit to make sure it is cleared before setting this bit again (even when ICR[ICLCSEQ] = 1).
3. TISR[TXICLCF] = 1 after the transfer of the ICLC frame.
4. CTS is set depending on the Push-Pull mode setting defined by MCR[CTSEN].

To determine whether the ICLC frame has been sent or not, either the ICR[SNDICLC] bit can be polled, or wait for TISR[TXICLCF] = 1.

Table 51-53. Supported ICLC Payloads

ICLC Code(hex)	ICLC Function
00	Ping Request from LFAST Master to LFAST Slave
01	Reserved
02	Start PLLIn preparation for High Speed mode
04	Stop PLL Fallback to low speed mode
08	Select TxData Slow (LFAST Slave Rx Interface)
10	Select TxData Fast (LFAST Slave Rx Interface)
20	Select RxData Slow (LFAST Slave Tx Interface)
40	Not Supported
80	Select RxData Fast (LFAST Slave Tx Interface)
31	Enable RxData Interface (LFAST Slave Tx Interface)
32	Disable RxData Interface (LFAST Slave Tx Interface)
34	Clock Test mode Send 101010… continuously using the currently configured clock rate (slow, fast);
FF	Turn payload loopback on
38	Turn Test mode (Loopback and Clock Test) off

Programing model for ICLC frame transmit:

1. Set the ICR[ICLCSEQ] bit (optional)
2. Write the ICLC frame payload in the ICR[ICLCPLD], corresponding to the desired Tx/Rx data rate change, as described in the Table 51-53.
3. Write ICR[SNDICLC] = 1 to initiate the ICLC frame transfer.
4. LFAST master will schedule the ICLC transfer. Data present in ICR[ICLCPLD] is transmitted to the LFAST slave at the old Tx data rate. LFAST slave will configure its Tx/Rx interface data rate accordingly.
5. Reset the ICR[ICLCSEQ] to allow the scheduling of other types of frames, which will be sent at the new data rate.

When ICR[ICLCSEQ] = 0, though the ICLC frame transfer still has highest arbitration priority, other frames may be scheduled if no valid ICLC frame request exist.

Note

ICLC frame transmit will not trigger the internal data rate change of LFAST Master Tx/Rx interface. LFAST master Tx/Rx interface data rate will only be changed, when corresponding SCR[TDR] and SCR[RDR] bits are appropriately configured.

Processor requires to take care that no data frames are to be transmitted while data rate change is happening or ICLC is transmitting frames by setting ICR[ICLCSEQ] bit in Table 51-53.

51.7.6.3.2 ICLC data receive flow

When the bits 4 to 1 of a receive frame are 0000b it indicates that the payload is an ICLC. ICLC payloads are always 8 bits.

The reception of an ICLC frame is indicated by an interrupt to the system. The ICLC status register RISR indicates the type of the ICLC frame received. The Rx block will decode and generate the appropriate signals. An invalid ICLC code besides the ones listed in Table 51-53 will cause RISR[RXICF] = 1.

51.7.6.3.2.1 Ping request ICLC

The LFAST slaves ICLC decoder will decode the ping request and set RIISR[ICPRF]. The S/W can also write to PICR[PNGREQ] to indicate to the Tx block that a ping response frame needs to be transmitted. The PICR[PNGAUTO] indicates whether Tx block can respond automatically to the request by the LFAST master ICLC Ping Request frame. The Tx block will arbitrate the ping response frame request and send a ping frame with ping data defined by bitfield PICR[PNGPLYD]. Once the ping response frame has been sent the Tx block will set TISR[TXPNGF] and clear PICR[PNGREQ], if set.

51.7.6.3.2.2 LFAST Slaves RxData Interface Slow/Fast ICLC

The LFAST Slaves Rx Interface has two speed modes supported: slow (Low speed) and fast (High speed). The ICLC command will write RIISR[ICRSF] = 1 (Low speed) or RIISR[ICRFF] = 1 (High speed).

51.7.6.3.2.3 LFAST Slaves TxData Interface Slow/Fast ICLC

The LFAST slaves Tx Interface Controller has two speed modes: slow (Low speed), and fast (High speed). The ICLC command will write RIISR[ICTSF] = 1 (Low speed) or RIISR[ICTFF] = 1 (High speed).

51.7.6.3.2.4 Enable/Disable LFAST Slaves TxData Interface ICLC

The ICLC commands, Enable RxData Interface and Disable RxData Interface are decoded and the appropriate enable/disable signal sent to the Tx block Controller. These ICLC command writes RIISR[ICTEF] = 1 and RIISR[ICTDF] = 1. The ICLC Tx enable command will write MCR[TXEN] = 1.

No frames can be sent on the LFAST Slave Tx interface until the either LFAST master has enabled it via an ICLC frame or S/W programs MCR[TXEN] = 1.

51.7.6.3.2.5 Clock Test mode ICLC

This ICLC command is decoded, and then is used to write TMCR[CLKTST] = 1. This indicates to the Tx interface to output an alternating pattern of 1 and 0 at the currently configured clock rate. The Rx interface generates RIISR[ICCTF] = 1 on reception of this ICLC command.

The exit from this mode happens on reception of Test mode off ICLC command.

51.7.6.3.2.6 Loopback payload on ICLC

This ICLC command is decoded and TMCR[LPON] = 1 to indicate to the Tx Block that the received payload is to be sent back. The exit from this mode happens on reception of Test mode off ICLC command. The Rx interface causes RIISR[ICLPF] = 1 on reception of this ICLC command.

51.7.6.3.2.7 Test mode off ICLC

This ICLC command is decoded and TMCR[LPON] and TMCR[CLKTST] are cleared to indicate to the Tx block to exit from loopback mode or clock test mode.

Another option is for the payload loopback option to remain enabled until negated on the toggling of LFAST interface enable.

51.7.6.3.2.8 Ping response ICLC

The LFAST master considers any ICLC frame payload as ping response data. The LFAST masters Rx block will store the received ping data in PISR[RXPNGD] and match it with PICR[PNGPYLD]. RIISR[ICPSF] = 1 if the Ping received matches with the one stored in PICR[PNGPYLD], or RIISR[ICPFF] = 1.

51.7.6.4 CTS flow

51.7.6.4.1 CTS Tx flow

The CTS frame, if enabled by the S/W, indicates the status of the Receive Data FIFO. CTS frame is triggered whenever Rx Data FIFO reaches either the High/Low threshold and no data, ICLC or unsolicited frame is ready for transmission.

Programing model for CTS frame transmit:

- Program RFCR[CTSMX] and RFCR[CTSMN].
- Enable the CTS frame Transmission by programming MCR[CTSEN] = 1.
- Program MCR[TXEN] = 1 and MCR[DRFEN] = 1 to enable the Tx path.
- The CTS bit sent with a valid frame (for example, data, ICLC and unsolicited) is 1 until the Rx Data FIFO reaches High Threshold.
- When the Rx Data FIFO reaches higher threshold and no valid frame (data, ICLC and unsolicited) is pending for transmission, then the CTS frame is triggered, with CTS bit of header = 0 and the status bit RISR[RXMXF] = 1.
- When the Rx Data FIFO reaches Low Threshold, due to system side reads and no valid frame (data, ICLC and unsolicited) is pending for transmission, then the CTS frame is triggered, with CTS bit of header = 1, and status bit RISR[RXMNF] = 1.

51.7.6.4.2 CTS Rx flow

Whenever a CTS frame header or any other frame with valid header is received with CTS bit = 0, then RISR[RXCTSF] = 1. The Tx Interface arbitration for unsolicited frame and data frame transmit request is turned off on reception of frame with CTS bit 0. The arbitration for unsolicited frame and data frame is enabled on reception of frame with CTS bit 1. Frame with LCT type CTS are not stored in the LFAST.

51.7.7 Test and Debug Support

The test and debug interface helps to debug the LFAST module. These signals can be brought out for ease of validation.

51.7.7.1 Loopback Test mode

The loopback function allows to verify the correct operation of the physical interface and the basic checks for the LFAST module without a peer device.

There are certain prerequisites before entering the Loopback mode:

- LD and LR should be turned on.
- Tx and Rx mode should be enabled.
- Interrupts needed for S/W should be enabled.
- Both Tx and Rx interface should be in same speed mode.
- For Automatic Test mode TMCR[LPFRMTH] should be programed.

The LFAST module supports four loopback modes, defined by TMCR[LPMOD].

Table 51-54. Loopback modes

LPMOD[2:0]	Mode Selected
000	Rx Loopback (default)
001	Rx LVDS Loopback
010	Tx Loopback without Automatic frame generation
011	Tx Loopback with Automatic frame generation
100	Tx LVDS Loopback (external) with Automatic frame generation

The TMCR[LPON] bit controls the state of the loopback function, and the default setting is 0 (off). This can be written by S/W, or in the case of the LFAST slave, the TMCR[LPON] bit can be modified by the Rx interface controller on decoding of a valid ICLC loopback on or Test mode off commands. The LPMOD should not be changed when the LPON bit is set.

In all loopback modes, except Tx loopback without automatic frame generation, the decoding of frame and error flags is stopped. Only decoding of following is done:

- ICLC Turn Test mode Off frame.

- CTS bit of all frames.
- Automatic Loopback frame decoding (only in Automatic frame generation mode).

51.7.7.1.1 Rx Loopback mode

For Rx loopback mode the output of the LR is passed to the LD with manipulation via the Rx and Tx Interface controllers. CTS bit (Bit 0) of the header is guaranteed to be asserted when the incoming data from the other device is looped back. In Rx Loopback mode the Rx Interface controller operates in normal mode, decoding the frames (header, payloads). This allows the LFAST Master to control the Loopback mode on and off by sending ICLC commands.

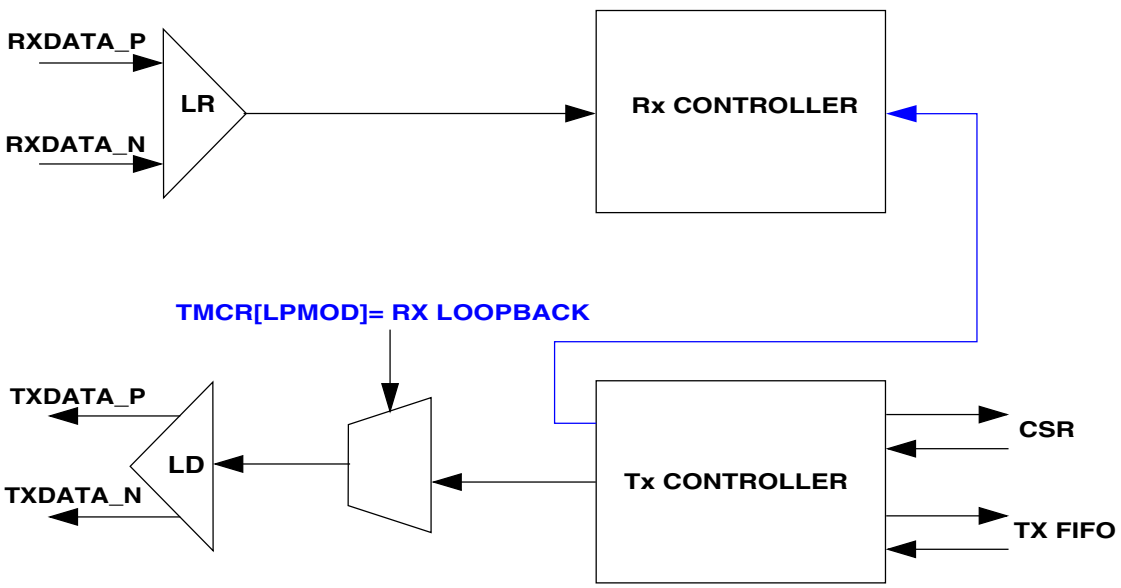

Figure 51-60. Rx LoopBack mode

Entry to Rx Loopback mode:

1. S/W programs TMCR[LPMOD] = 000b.
2. Loopback can be turned on by either of the following methods:
   - S/W programs TMCR[LPON] = 1.
   - For Slave Only: - Reception of ICLC Frame with Payload FFh (Loopback mode on), from LFAST Master

Exit from Rx Loopback mode can be done by any of the following methods:

- S/W programs TMCR[LPON] = 0
- For LFAST Slave: - Transmission of ICLC Frame with payload 38h (Test mode off), from LFAST Master

The peer LFAST device is required to maintain at least 2-bit IFG between two Loopback frames in this mode.

51.7.7.1.2 Rx LVDS LoopBack mode

This loopback mode is provided to verify and characterize the LVDS pads. In this loopback mode the data received by LFAST on Rx LVDS input is loopback to Tx LVDS output, bypassing LFAST. For LVDS loopback the output of the LR is passed to the LD via "Rx LVDS LoopBack Mux". Bit 0 of the header cannot be guaranteed to be asserted when the incoming data from the other device is looped back. In this loopback, the Rx Interface Controller operates in normal mode, decoding the frames (header, payloads) but the Tx Interface Controller is ignored.

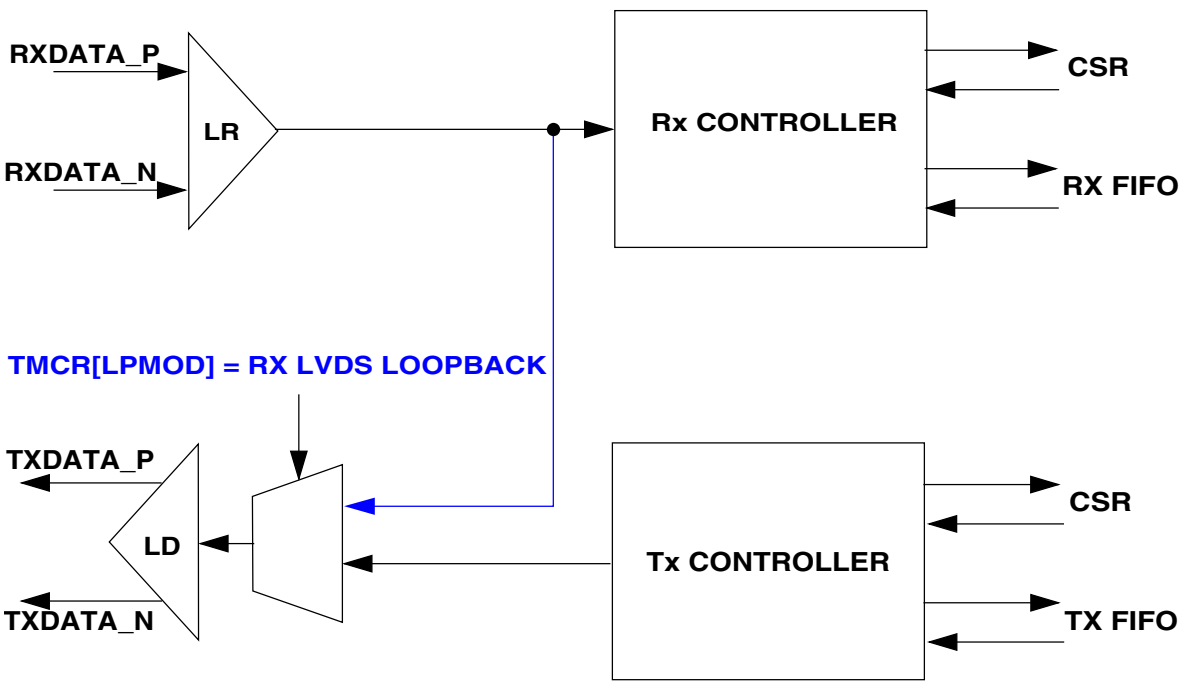

Figure 51-61. Rx LVDS LoopBack mode

Entry to Rx LVDS Loopback mode:

1. S/W programs TMCR[LPMOD] = 001b.
2. Loopback can be turned ON by either of the following methods:

- S/W writes TMCR[LPON] = 1.
- For Slave Only: - Reception of ICLC Frame with Payload = FFh (Loopback mode ON), from LFAST Master.

Exit from Rx LVDS Loopback mode can be done by any of the following methods:

- S/W programs TMCR[LPON] = 0.
- For LFAST Slave:
  - Transmission of ICLC frame with payload 38h (Test mode off), from LFAST Master.

51.7.7.1.3 Tx loopback mode without automatic frame generation

This loopback mode is provided to verify the LFAST functionality, if LVDS pads are not functional. In this loopback mode the data transmitted by LFAST on Tx LVDS output is loopbacked internally on Rx LVDS input, bypassing LVDS pads.

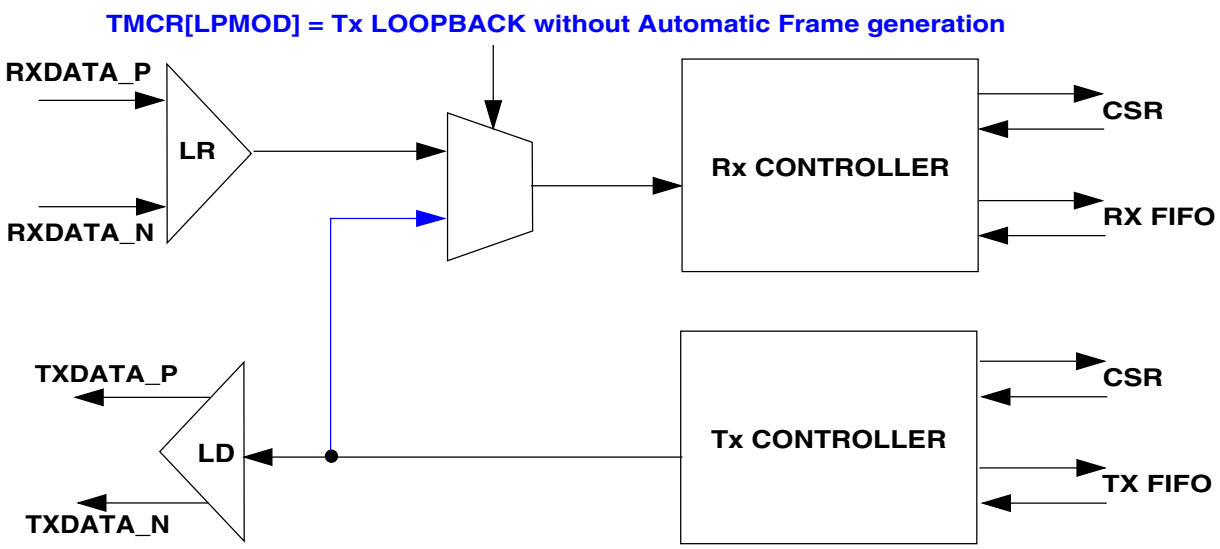

Figure 51-62. Tx LoopBack mode without automatic frame generation

Entry to Tx Loopback without Automatic frame generation mode:

1. S/W programs TMCR[LPMOD] = 010b.
2. Loopback can be turned on by either of the following methods:
   - S/W programs TMCR[LPON] = 1.
   - For Slave Only: Reception of ICLC frame with payload FFh (Loopback mode on), from LFAST Master

Exit from Tx Loopback without Automatic frame generation mode can be done by any of the following methods:

- S/W programs TMCR[LPON] = 0.
- For LFAST Slave: Reception of ICLC frame with payload 38h (Test mode off), from Tx interface (using unsolicited frame).

All frames and error flags are decoded in this mode.

51.7.7.1.4 Automatic frame generation

The LFAST module supports two Loopback modes where pre-defined frames are generated automatically by the Tx Interface and Rx Interface indicates its successful reception by dedicated signals and status registers. These modes are defined for BIST like check for the LFAST, with minimal S/W intervention.

The Control register used for these modes are:

- ALCR[LPCNTEN] defines whether fixed number of auto loopback frames to be transmitted
- ALCR[LPFMCNT] defines the number of loopback frames to be transmitted if ALCR[LPCNTEN] = 1.

The Status signals and register used for these modes are:

- GSR[LPCSDV]: Valid Synchronization received.
- GSR[LPCHDV]: Frame with Header of 13h received.
- GSR[LPCPDV]: Frame with Payload of CBh received.
- GSR[LPTXDN]: Number of Auto Loopback frame transmitted with valid Synchronization, Header (13h) and Payload (CBh) is equal to ALCR[LPFMCNT].

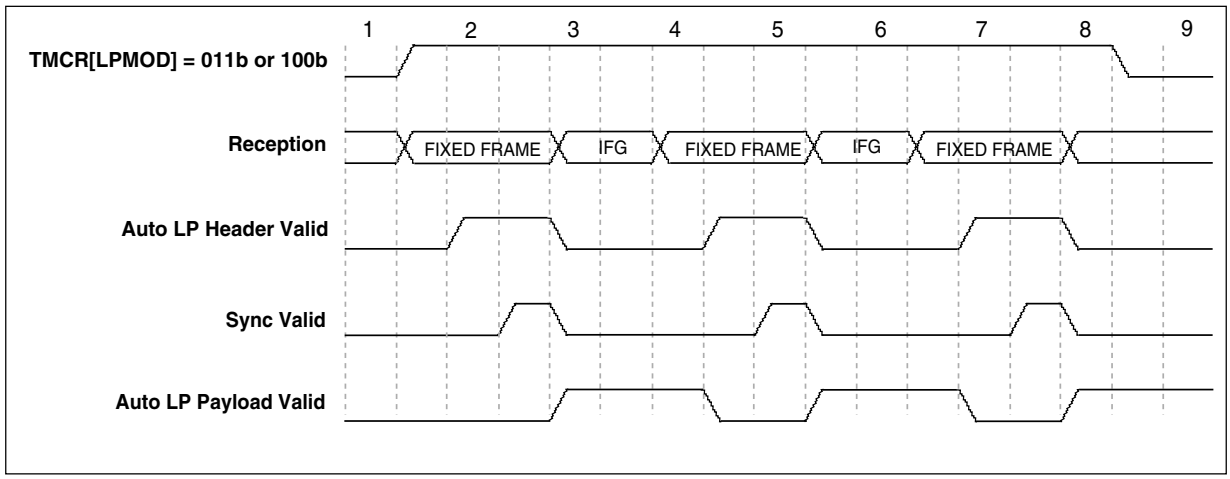

Figure 51-63. Automatic Loopback Test status signal timings

The two Loopback with automatic frame generation modes are:

1. Tx Loopback with Automatic frame generation
2. Tx LVDS (external) with Automatic frame generation

51.7.7.1.4.1 Tx loopback mode with automatic frame generation

When TMCR[LPMOD] = 011b (Tx Loopback mode with Automatic frame generation) the frames are generated by the Tx Interface. This mode helps to validate the Tx and Rx Path with minimal intervention from the S/W. The frames generated have fixed header of 13h and payload of CBh. The successful reception of this frame is indicated by the status signals and registers.

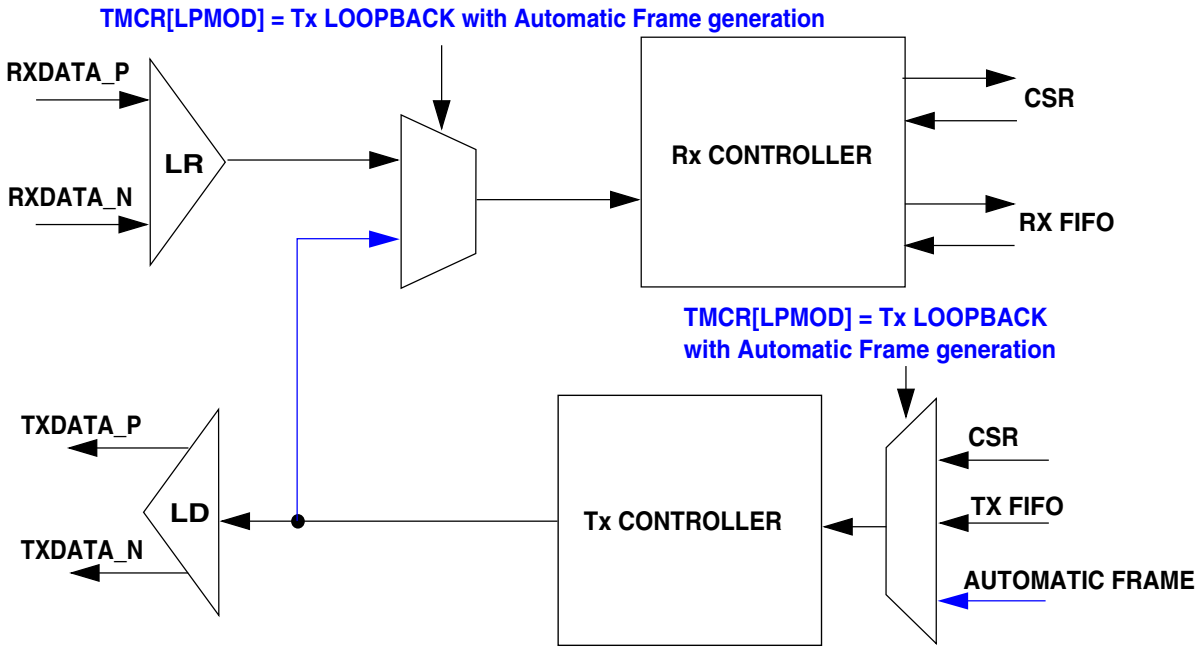

Figure 51-64. Tx LoopBack mode with automatic frame generation

Entry to Tx Loopback with automatic frame generation mode:

1. S/W programs TMCR[LPMOD] = 011b.
2. Loopback can be turned on by either of the following methods:
   - S/W programs TMCR[LPON] = 1.
   - For Slave Only: Reception of ICLC frame with payload FFh (Loopback mode on), from LFAST Master

Exit from Tx Loopback with Automatic frame generation mode can be done by any of the following methods:

- S/W programs TMCR[LPON] = 0.

51.7.7.1.4.2 Tx LVDS loopback (external) mode with automatic frame generation

In this mode the LD/Tx Controller is used to test the LR/Rx Controller. The idea is to use a test frame (predefined) from the Tx Controller out through the LD, loopback completed on the DUT-board (LD connected to LR via a transmission line), back into the LR, synchronized and correlated in the Rx Controller and compared to what was sent in the Downlink controller.

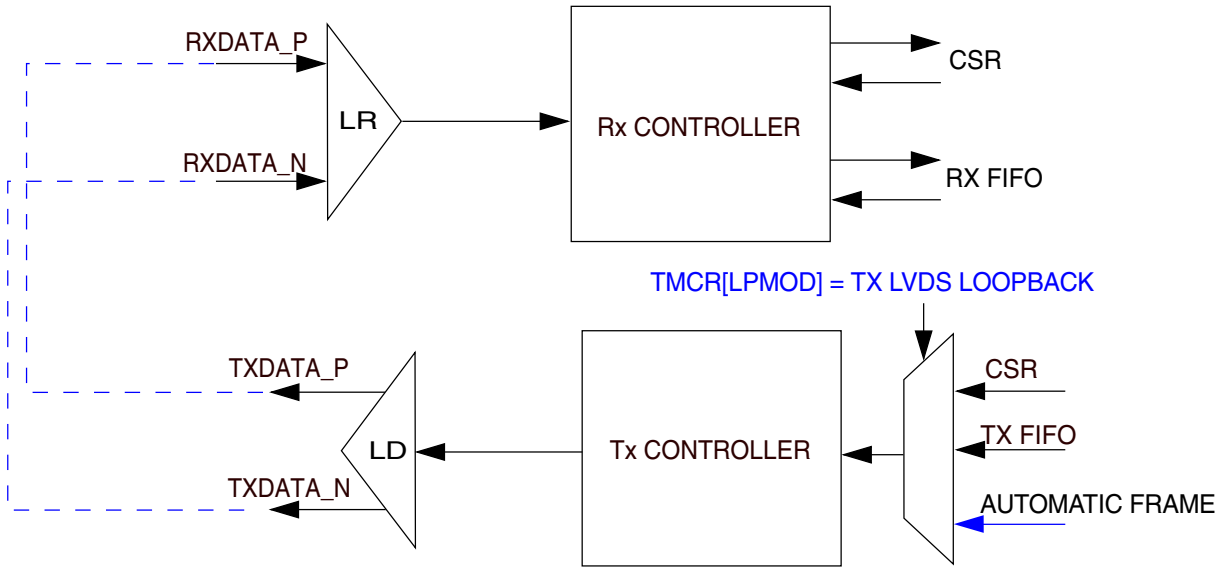

Figure 51-65. Tx LVDS loopback (external) mode with automatic frame generation

Entry to Tx LVDS loopback with automatic frame generation mode:

1. S/W programs TMCR[LPMOD] = 100b.
2. Loopback can be turned on by either of the following methods:
   - S/W programs TMCR[LPON] = 1.
   - For Slave Only: Reception of ICLC frame with payload FFh (Loopback mode on), from LFAST Master

Exit from Tx LVDS loopback with automatic frame generation mode can be done by the following method:

- S/W programs TMCR[LPON] = 0.

51.7.7.2 Clock test mode

The bit TMCR[CLKTST] enables or disables the Clock Test mode of the LFAST module. In this mode the LFAST sends fixed pattern out on the LD at the current configured RxData clock rate. It is a RWM bitfield and the default setting is 0 (off). This bit can be set under one of the following conditions:

- S/W programs TMCR[CLKTST].

The Tx Controller will send out a pattern of alternating 1 and 0 (pattern 101010...). This provides a divide by 2 test clock of the current Tx clock.

The Clock Test mode can be cancelled by either of the following methods:

- S/W programs TMCR[CLKTST] = 0.
- For LFAST Slave: Reception of ICLC frame with payload 38h (Test mode off) from LFAST Master

In clock test mode the Tx Controller does not output any synchronization pattern or header, just a pattern of alternating 1's and 0's.

This mode doesn't affect the functionality of the Rx Interface.

51.7.8 Interrupts

The LFAST module generates five interrupts to the processor:

- Transmit complete interrupt
- Transmit exception interrupt
- Receive complete interrupt
- Receive exception interrupt
- ICLC recieve interrupt

Each interrupt is asserted when any one of their status conditions is met.

51.7.8.1 Transmit complete interrupt

This interrupt indicates a transfer compeletion of a frame. This interrupt is asserted whenever any of the following bits are set in the TISR and also the corresponding mask bits are set in the TIER.

- TXDTF
- TXICLCF
- TXUNSF
- TXPNGF

Each of these bits can be individually maskable. So, those bits that are not required to generate an interrupt to the processor can be masked. Once the interrupt is asserted, it can be negated by clearing the corresponding flag bit in the TISR.

51.7.8.2 Transmit exception interrupt

This interrupt indicates occurrence of an exception condition in the Tx block. This interrupt is asserted whenever any of the following bits are set in the TISR along with the corresponding mask bits in the TIER.

- TXOVF
- TXIEF

Each of these bits can be individually masked. So, those bits that are not required to generate an interrupt to the processor can be masked. Once the interrupt is asserted, it can be negated by clearing the corresponding flag bit in the TISR.

Table 51-55. Recommended transmit exception handling

Exception	Recommendation
TXOVF	• MCR[TXEN] = 0 • The system level interfaces transmit is reseted and enabled again • For Slave: After reception of ICLC Ping Response Request the MCR[TXEN] may be set • For Master: The MCR[TXEN] should be set and an ICLC frame Ping Response Request should be sent
TXIEF	• The MCR[TXEN] should be set

51.7.8.3 Receive complete interrupt

This interrupt indicates a reception of a frame. This interrupt is asserted whenever any of the following bits is set in the RISR along with the corresponding interrupt enable bit is also set in the RIER.

- RXCTSF
- RXDF
- RXUNSF

Each of these bits are individually maskable. So, the bits that are not required to generate an interrupt to the processor can be masked by clearing its bit in the RIER. Once the interrupt is asserted, it can be negated by clearing the corresponding flag bit in the RISR.

51.7.8.4 Receive exception interrupt

This interrupt indicates occurrence of an exception condition in Rx block. This interrupt is asserted whenever any of the following bits is set in the RISR and corresponding enable mask bit is also set in the RIER.

- RXLCEF
- RXICF
- RXSZF
- RXUOF
- RXUFF
- RXMXF
- RXMNF
- RXOFF

Each of these bits are individually maskable. So, those bits that are not required to generate an interrupt to the processor can be masked by clearing the appropriate bit in the RIER. For details on the cause of assertion of each bit refer to the RISR description. Once the interrupt is asserted, it can be negated by clearing the corresponding flag bit in the RISR.

Table 51-56. Recommended receive exception handling mechanism

Exception	Recommendation
RXLCEF	The MCR[RXEN] may be set and cleared, as this exception can result in loss of subsequent packet
RXICF	No action required
RXSZF	The MCR[RXEN] may be set and cleared, as this exception can result in loss of subsequent packet
RXOFF	• The MCR[RXEN] may be cleared • The system level interfaces receive may be reset and enabled, as current transfer may be corrupted
RXUFF	No action required
RXMXF	The system level interfaces receive should be enabled, if not enabled
RXMNF	No action required
RXUNSF	No action required

51.7.8.5 ICLC receive interrupt

This interrupt indicates reception of a valid ICLC frame. This interrupt is asserted whenever any of the following bits is set in the RIISR along with the corresponding enable bit mask bit is set in the RIIER.

- ICPONF
- ICPOFF
- ICTSF
- ICTFF
- ICRSF
- ICRFF
- ICTEF
- ICTDF
- ICCTF
- ICLPF
- ICTOF
- ICPRF
- ICPSF
- ICPFF

Each of these bits are individually maskable. So those bits that are not required to generate an interrupt to the processor can be masked. For details on the cause of assertion of each bit, refer RIISR. Once the interrupt is asserted, it can be negated by clearing the corresponding flag bit in RIISR.

51.8 Packet memory

The LFAST stores packet frames for transmission, and reads packet frames after reception. The transmitter has its own dedicated buffer and the receiver has it own dedicated buffer, and they are not shared between each other.

Table 51-57. Frames Supported by LFAST interfaces

Frame Type	Tx Buffer(in bits)	Rx Buffer(in bits)	Memory Type
Data Frame	38 × 32 max 6 packets	38 × 32 max 6 packets	FIFO
Unsolicited Frame	9 × 32 max 1 packet	9 × 32 max 1 packet	Registers UNSTD[8-0], UNSRDR[8-0]
ICLC Frame	1 × 7 max 1 packet[1]	1 × 8 max 1 packet[2]	Registers ICR, PISR
CTS Frame	N/A	N/A	N/A

1. Only for MCR[MSEN] = 1
2. Only for ping response data when MCR[MSEN] = 1

51.9 Resets

The various blocks in LFAST are reset as described in the table below.

Table 51-58. Recommended receive exception handling mechanism

Reset	Blocks Reset
Asynchronous Hardware reset	Polarity: Active Low • Clock control module (CCM) • LFAST Domain Logic (Rx and Tx block) • System Side Module Interface FIFOs • LFAST Register Space
DRFRST bit of Mode Configuration Register (MCR)	Polarity: Active High • Clock control module (CCM) • LFAST Domain Logic (Rx and Tx block) • System Side Module Interface FIFOs • LFAST Register Space
DRFEN bit of Mode Configuration Register (MCR)	Polarity: Active Low • Clock control module (CCM) • LFAST Domain Logic (Rx and Tx block) • System Side Module Interface FIFOs • LFAST Status Registers • SCR[RDR] and SCR[TDR] • TMCR[CLKTST] and TMCR[LPON] • ICR[ICLCSEQ] and ICR[SNDICLC] • PICR[PNGREQ] • UNSTCR[USNDRQ]

51.10 Clocks

The LFAST mainly works on three clocks:

- System Bus Clock used to program the registers.
- Protocol clock, which is either High Speed PLL clock or Low Speed clock depending on the speed mode, used for LFAST protocol operation.
- System Side Module clock, which is synchronous to the System Bus clock.

51.10.1 Clocking strategy

The following figure shows the clock domain in which each module functions. The PLL provides eight phases of the high speed clock to the Clock Muxing portion of the Clock Control Module. The Clock Module will then generate four phases of slow speed clock using both the edges of lfast_sysclk, muxes high speed and low speed clocks and provides a muxed clock to the Sampler Module.

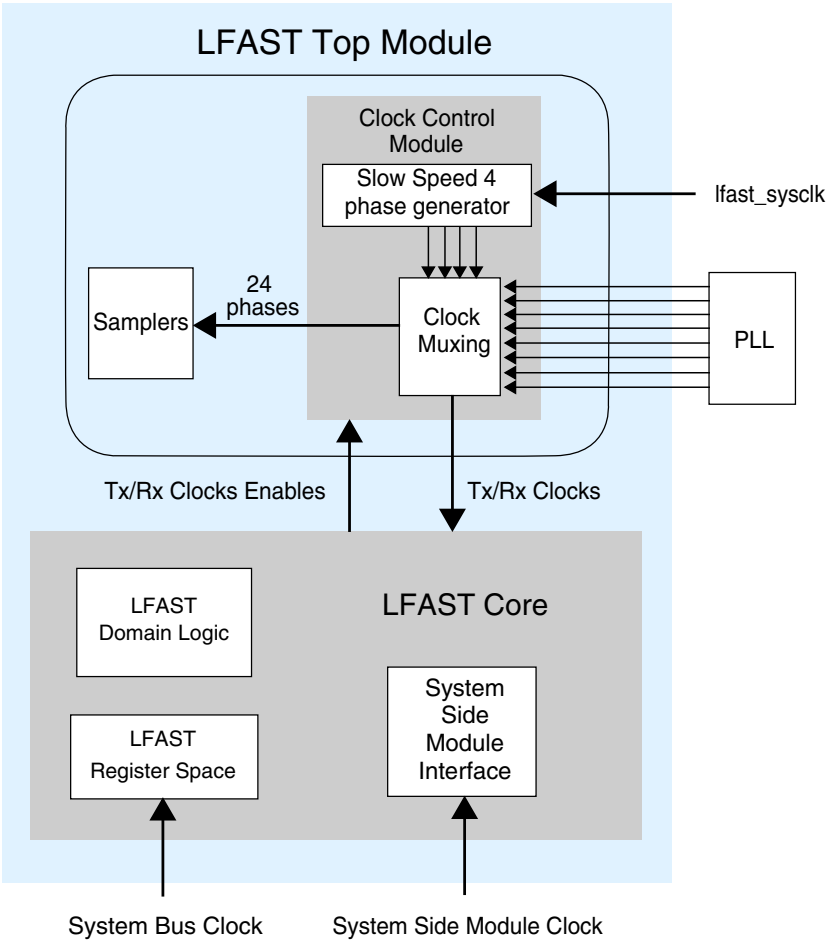

Figure 51-66. LFAST module clock domains

51.10.2 Slow speed clock

51.10.2.1 External muxing

The Clock Control Module will receive lfast_sysclk from the clocking subsystem as shown in Figure 51-67, Figure 51-68 and Figure 51-69.

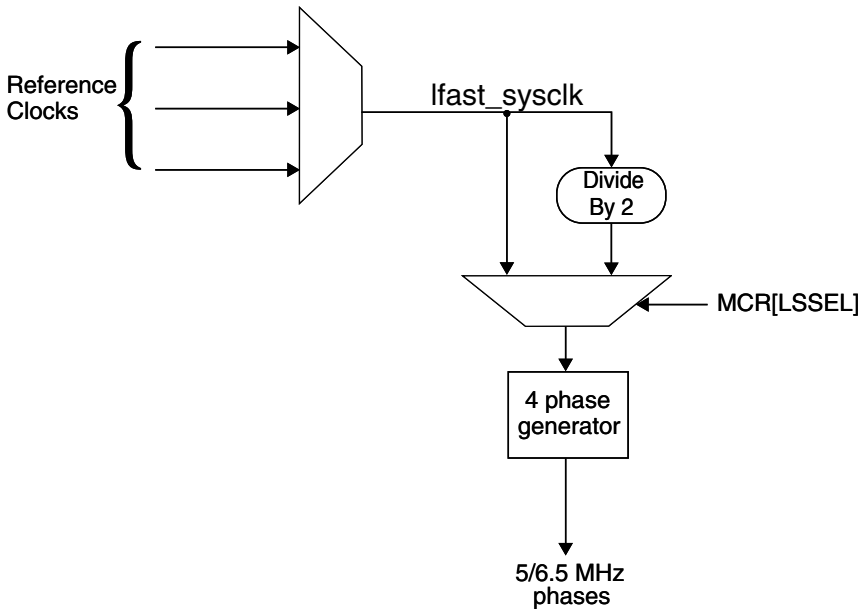

Figure 51-67. External clock muxing of lfast_sysclk

All the reference clocks will be muxed first to provide lfast_sysclk to the module and then either div/2 or direct muxed clock will be used to generate 4 slow speed phases in the Clock Control Module of LFAST as shown in Figure 51-67.

The lfast_sysclk could be either 20/26 MHz or 10/13 MHz. When lfast_sysclk is 20/26 MHz frequency, the clock control module will generate 4 phases of slow speed clock of frequency lfast_sysclk/4 when MCR[LSSEL] = 1. If lfast_sysclk is 20/26 MHz it needs to be first divided by 2 before using it for 4 phase generation in LFAST Clock Module, which generates 4 phases of half of the input frequency as shown in Figure 51-68 (selected clock path shown in green).

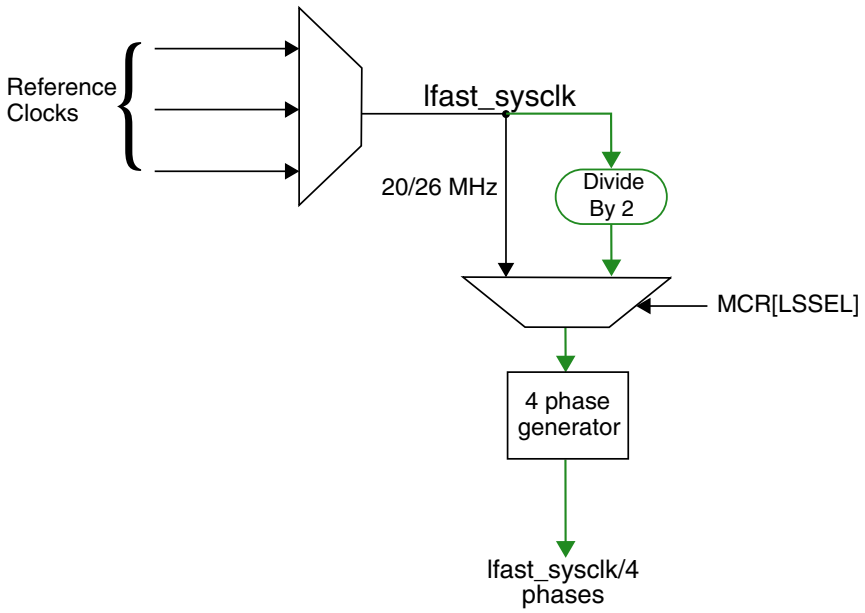

Figure 51-68. External clock muxing of lfast_sysclk of 20/26 MHz

In this case, lfast_sysclk is 10/13 MHz frequency, the clock control module will generate 4 phases of slow speed clock of frequency lfast_sysclk/2 when MCR[LSSEL] = 0. If lfast_sysclk is 10/13 MHz then it does not need to be first divided by 2 before using it for 4 phase generation in LFAST Clock Module, which generates 4 phases of half of the input frequency as shown in Figure 51-69 (selected clock path selected shown in magenta).

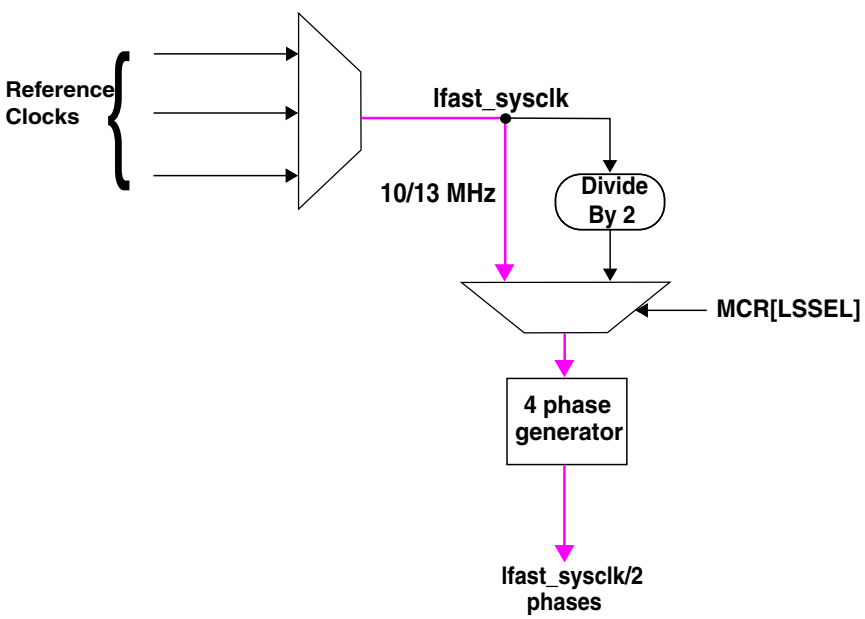

Figure 51-69. External clock muxing of lfast_sysclk of 10 MHz

51.10.2.2 Slow Speed 4 phase generator

Clock control module will generate 4 phases of slow speed clock of frequency of 10/13 MHz. For instance, if lfast_sysclk is 10 MHz then 4 phases of 5 MHz will be generated. The following figure shows 4 phases getting generated using lfast_sysclk.

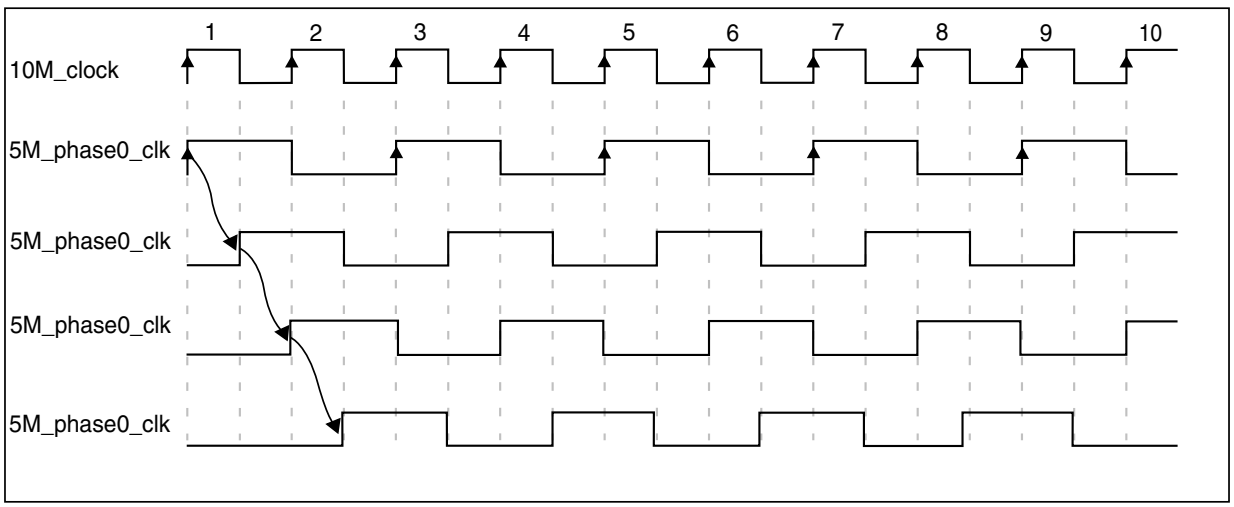

Figure 51-70. Slow speed 4 phases generation

51.10.3 Rx Controller Clocks

51.10.4 Clocking Module Requirements for High Speed Phases

The high speed phases are obtained from the PLL via the Clocking Module as shown in the following figure.

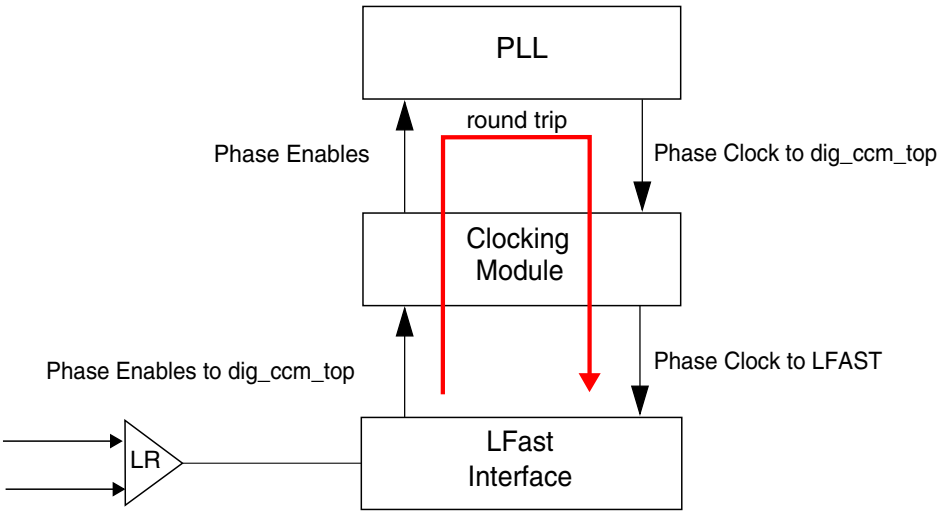

Figure 51-71. Clock enables and clock paths

The LFAST block will know which of the phases will be required for the different modes of operations. Therefore the LFAST block will provide enables and speed mode switches to the Clocking Module. The Clocking Module will use these signals to control the enables to the clock phases to reduce the power consumption.

The 8 phases of clocks signal are fed to the Clocking Module and muxed with the low speed phases. Depending on enables and data rate speed modes, the selected clocks are passed to the Sampler block and interface block.

COCR[PHSSEL] is connected to the Clocking Module, which selects whether 8 or 4 phases are selected for High Speed mode. It is only valid for high speed.

The routing of the 8 high speed phases to the interface is critical. Each clock phase will need to have the same routing track length from the PLL to the interface of Clocking Module. Each of the 8 high speed phases are separated by 45 degrees. This separation needs to be maintained from the phase generator to the interface.

51.10.5 Clock module requirements for low speed phases

51.10.5.1 Low speed

The low speed clock phases are generated in Clocking Module. These four phases are required to sample the data correctly at Low Speed mode. The LFAST block will provide the enable for the phases. The clock source for the low speed phases is SYSCLK. The Clocking Module block will need to generate the 4 phases of low speed clock 90 degrees apart.

Using the Low Speed mode on the interface allows the polyphase generation logic to be turned off and the requirement of high-speed-freq × 8 MHz clock from the PLL is not needed.

Table 51-59. Rx clocks summary

Rx Speed mode	Source
Low Speed	lfast_sysclk
High Speed	PLL

51.10.6 Tx Controller Clocks

51.10.6.1 Clocking Module Requirements for Speed Phases

The low speed phase 0 clock is sourced from the lfast_sysclk and the high speed phase 0 clock is sourced from the PLL. See the following table.

Table 51-60. Tx clocks summary

Tx Speed mode	Source
Low Speed	lfast_sysclk
High Speed	PLL

51.10.6.2 Transmit Clock Muxing

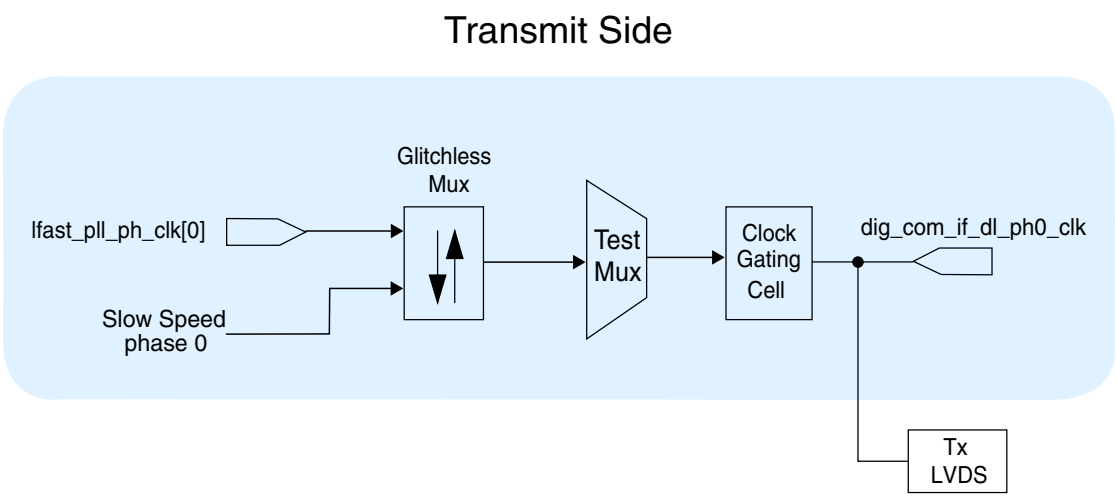

Figure 51-72. Transmit Clocks Muxing

51.10.6.3 Tx Request Clock Control

The Tx phase 0 clock is enabled when all the resets are negated.

Chapter 52
Fast Ethernet Controller (FEC)

52.1 Fast Ethernet Controller (FEC) chip-specific module information

52.1.1 FEC interface selection

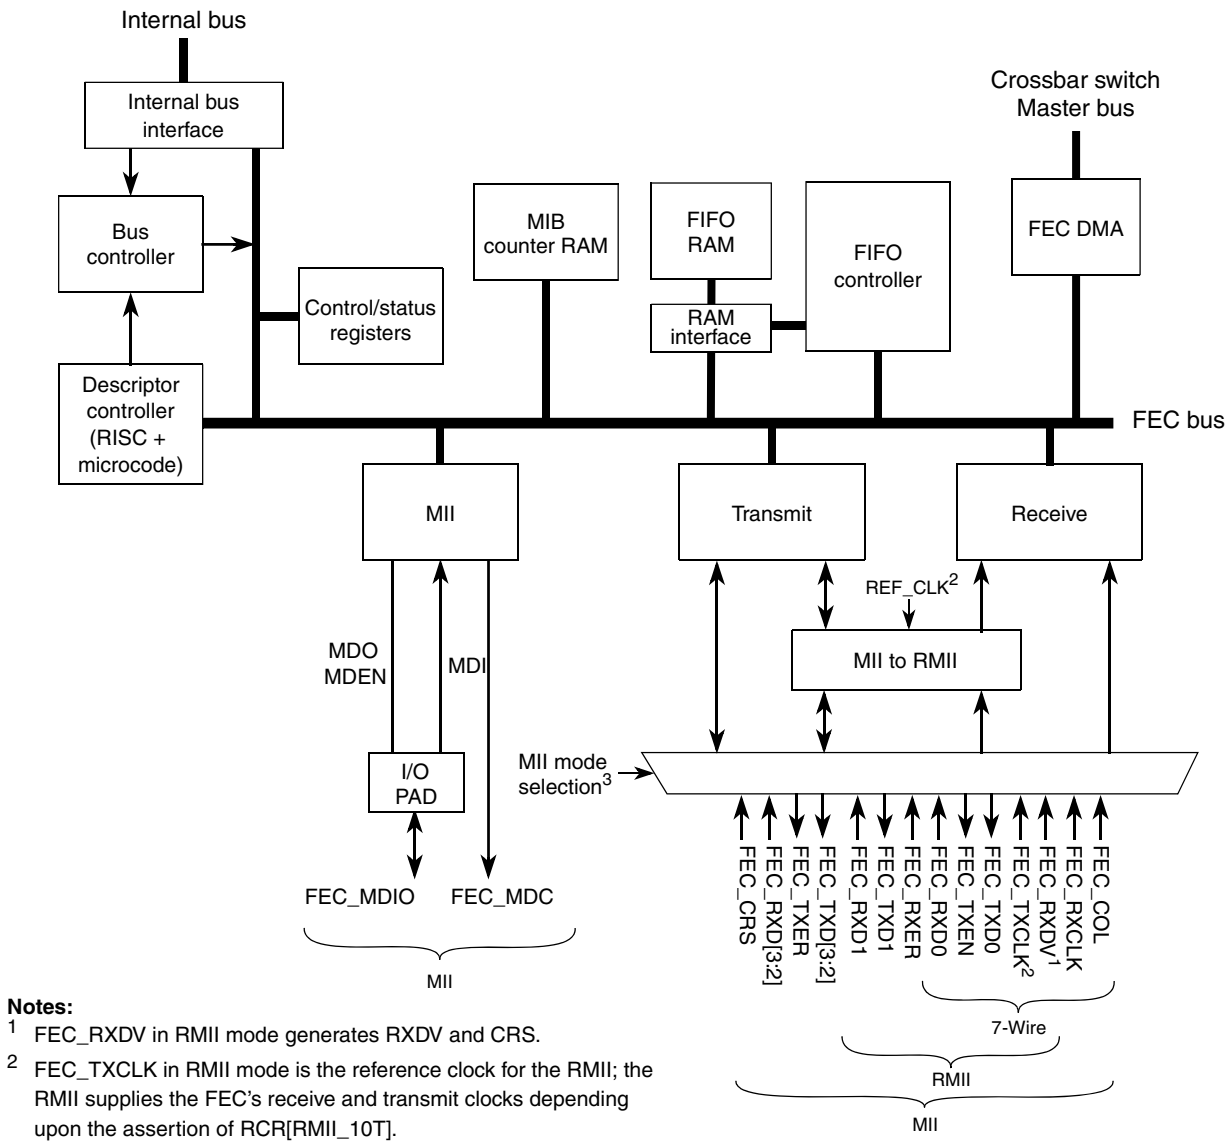
On this chip, the FEC interface depends on the settings of the RCR (in the FEC) and SIUL2_SCR0 (in the SIUL2), as shown in the following table.

Table 52-1. FEC interface selection

RCR[MII_MODE]	SIUL2_SCR0[FEC_MODE]	Interface used by the FEC
0	0 or 1	7-wire
1	0	RMII
	1	MII-Lite[1]

1. MII-Lite supported only on BGA packages. Full MII is not supported on this chip.

52.2 Introduction



The Fast Ethernet Controller (FEC) is a communication controller that supports 10 and 100 Mbps Ethernet/IEEE 802.3 networks. An external transceiver interface and transceiver function are required to complete the interface to the media. The FEC supports five different standard MAC-PHY (physical) interfaces for connection to an external Ethernet transceiver. The FEC supports the 10/100 Mbps MII, 10/100 Mbps MII-Lite, 10/100 Mbps reduced MII, and the 10 Mbps-only 7-wire interface.

52.2.1 Block diagram

Figure 52-1 shows the block diagram of the FEC. The FEC is implemented with a combination of hardware and microcode. The off-chip (Ethernet) interfaces are compliant with industry and IEEE 802.3 standards.

NOTE

When MII-Lite is used on this chip, the FEC_TXER, FEC_RXER, FEC_COL, and FEC_CRS signals shown in Figure 52-1 are not used.

Notes:

1. FEC_RXDV in RMII mode generates RXDV and CRS.
2. FEC_TXCLK in RMII mode is the reference clock for the RMII; the RMII supplies the FEC's receive and transmit clocks depending upon the assertion of RCR[RMII_10T].
3. Interface selection is chip-specific; see the chapter that describes how modules are configured and connected.

Figure 52-1. FEC block diagram

The following table provides a brief description of the blocks in the previous figure.

Table 52-2. FEC sub-block descriptions

Block	Description
Control and status registers (CSR)	Provides global control (Ethernet reset and enable) and interrupt managing registers
Descriptor controller	A RISC-based controller providing these functions in the FEC: • Initialization (those internal registers not initialized by you or hardware) • High-level control of the DMA channels (initiating DMA transfers) • Interpreting buffer descriptors • Address recognition for receive frames • Random number generation for transmit collision backoff timer
DMA block	Provides multiple channels allowing transmit data, transmit descriptor, receive data and receive descriptor accesses to all run independently **Note:** In this document, "DMA" refers to the DMA block within the FEC, and is not related to any other DMA controllers that may be present on the chip.
Media independent interface (MII)	Provides a serial channel for control/status communication with the external physical layer device (transceiver). This serial channel consists of: • The management data clock (FEC_MDC) • The management data input/output lines (FEC_MDIO) of the MII interface
Message information block (MIB)	Maintains counters for a variety of network events and statistics. It is not necessary for operation of the FEC, but provides valuable counters for network management. The counters supported are: • The RMON (RFC 1757) Ethernet Statistics group • Some of the IEEE 802.3 counters
RAM	Serves as the focal point of all data flow in the Fast Ethernet controller and divides into transmit and receive FIFOs. The FIFO boundaries are programmable using the FRSR register. User data flows to/from the DMA block from/to the receive/transmit FIFOs. Transmit data flows from the transmit FIFO into the transmit block. Receive data flows from the receive block into the receive FIFO.
Transmit and receive blocks	Provide the Ethernet MAC functionality (with some assist from microcode)

52.2.2 Features

The FEC incorporates the following features:

- Support for the following Ethernet physical interfaces:[1]
  - 100-Mbps IEEE 802.3 MII
  - 10-Mbps IEEE 802.3 MII

1. For interface selection options, see the chip-specific FEC information.

    - 100-Mbps IEEE 802.3 MII-Lite
    - 10-Mbps IEEE 802.3 MII-Lite
    - 100-Mbps reduced media independent interface (RMII)
    - 10-Mbps reduced media independent interface (RMII)
    - 10-Mbps 7-wire interface (industry standard)
- IEEE 802.3 full duplex flow control
- Programmable max frame length supports IEEE 802.1 VLAN tags and priority
- Support for full-duplex operation (200 Mbps throughput) with a minimum internal bus clock rate of 50 MHz
- Support for half-duplex operation (100 Mbps throughput) with a minimum internal bus clock rate of 25 MHz
- Retransmission from transmit FIFO following a collision (no processor bus utilization)
- Automatic internal flushing of the receive FIFO for runts (collision fragments) and address recognition rejects (no processor bus utilization)
- Address recognition
    - Frames with broadcast address may be always accepted or always rejected
    - Exact match for single 48-bit individual (unicast) address
    - Hash (64-bit hash) check of individual (unicast) addresses
    - Hash (64-bit hash) check of group (multicast) addresses
    - Promiscuous mode

52.2.3 Clocking requirements

The FEC system clock frequency must be equal to or greater than the FEC protocol reference clock frequency (for example, 25 MHz system frequency for 100 Mbps protocol frequency). This requirement is true regardless of the reference selected by the application.

52.3 Modes of operation

This section describes the FEC operating modes.

52.3.1 Full and half duplex operation

Full duplex mode is for use on point-to-point links between switches or end node to switch. Half duplex mode works in connections between an end node and a repeater or between repeaters. TCR[FDEN] controls duplex mode selection.

When configured for full duplex mode, flow control may be enabled. For more details, see:

- The RFC_PAUSE and TFC_PAUSE fields in the TCR
- The RCR[FCE] field
- Full duplex flow control

52.3.2 Interface options

The following interface options are supported[2]. A detailed discussion of the interface configurations is provided in Network interface options.

52.3.2.1 10 Mbps and 100 Mbps MII interface

The IEEE 802.3 standard defines the media independent interface (MII) for 10/100 Mbps operation. The MAC-PHY interface may be configured to operate in MII mode by programming RCR[MII_MODE]=1.

The operation speed is determined by the FEC_TXCLK and FEC_RXCLK pins driven by the external transceiver. The transceiver auto-negotiates the speed or software controls it via the serial management interface (FEC_MDC/FEC_MDIO pins) to the transceiver. Refer to the MMFR and MSCR register descriptions, as well as the section on the MII, for a description of how to read and write registers in the transceiver via this interface.

2. For interface selection options, see the chip-specific FEC information.

52.3.2.2 10 Mbps and 100 Mbps MII-Lite interface

MII-Lite refers to MII without the following signals:

- FEC_COL
- FEC_CRS
- FEC_RXER
- FEC_TXER

The MII-Lite connection is for PHYs that do not have all the MII pins and signals that are available for MII.

The following table provides additional information on the behavior of these signals when MII-Lite is used.

Table 52-3. MII signals not used in MII-Lite

Signal	Information
FEC_COL	This signal is asserted by the PHY when there has been a collision. With full-duplex links, this would always be low, so this signal's absence implies either that the link in full-duplex or that collisions are handled internally within the PHY. The signal is only asserted high on simultaneous Rx and Tx on half-duplex links. As this must be handled by the PHY if the signal is not available, it can be safely pulled low.
FEC_CRS	Carrier sense is asserted high by the PHY to indicate that receive medium is non-idle. As in the case with the COL signal, this never occurs with full-duplex links. Again, it is recommended that this signal be pulled low using an external pulldown.
FEC_RXER	This signal is asserted high by the PHY to signal an error to the MAC. However, in these circumstances the PHY will deliberately corrupt the CRC of the incoming frame before passing to the MAC. This input to the FEC can therefore be pulled low and any RXER can be detected by a CRC error in the received frame where the CR bit is set in the receive buffer descriptor (RxBD).
FEC_TXER	This FEC output can be left unconfigured and unused. The signal was originally included for the test case in some PHY designs where the MAC layer in the FEC can demand that the PHY corrupt data during transmission. However, it is readily possible to do this within the MAC by setting the ABC (Append Bad CRC) bit in the transmit buffer descriptor (TxBD) for the frame being sent.

52.3.2.3 10 Mbps and 100 Mbps RMII interface

The reduced media independent interface (RMII) is a low-cost alternative to the IEEE802.3 MII standard. This interface provides the functionality of the MII interface on a total of 8 pins instead of 18. The RMII interface for 10/100 Ethernet MAC-PHY interface was defined by an industry consortium and is not currently included in the IEEE 802.3 standard. This functionality is selected as described in the chip configuration chapter, and is reflected in the read-only RCR[RMII_MODE] bit. The RCR[RMII_10T] bit determines the speed of operation. The reference clock for RMII is always 50 MHz, but this clock can be divided by 10 within the RCR register to support 10 Mbps operation. The PHY must be configured accordingly.

52.3.2.4 10 Mbps 7-wire interface operation

The FEC supports 7-wire interface used by many 10 Mbps Ethernet transceivers. The RCR[MII_MODE] bit controls this functionality. If this bit is cleared, MII mode is disabled and the 10 Mbps 7-wire mode is enabled.

52.3.3 Address recognition options

The address options supported are:

- Promiscuous
- Broadcast reject
- Individual address (hash or exact match)
- Multicast hash match

Address recognition options are discussed in detail in Ethernet address recognition.

52.3.4 Internal loopback

Internal loopback mode is selected via RCR[LOOP]. Loopback mode is discussed in detail in MII internal and external loopback.

52.4 External signal description

The following table describes the various FEC signals, as well as indicating which signals work in available modes.

Table 52-4. FEC signal descriptions

Signal name	MII	7-wire	RMII	Description
FEC_COL	X[1, 1]	X	—	Asserted upon detection of a collision and remains asserted while the collision persists. This signal is not defined for full-duplex mode.
FEC_CRS	X[1]	—	—	Carrier sense. When asserted, indicates transmit or receive medium is not idle. In RMII mode, this signal is present on the FEC_RXDV pin.
FEC_MDC	X	—	X	Output clock provides a timing reference to the PHY for data transfers on the FEC_MDIO signal.

Table continues on the next page...

Table 52-4. FEC signal descriptions (continued)

Signal name	MII	7-wire	RMII	Description
FEC_MDIO	X	—	X	Transfers control information between the external PHY and the media-access controller. Data is synchronous to FEC_MDC. This signal is an input after reset. When the FEC operates in 10Mbps 7-wire interface mode, this signal should be connected to VSS.
FEC_RXCLK	X	X	—	Provides a timing reference for FEC_RXDV, FEC_RXD[3:0], and FEC_RXER.
FEC_RXDV	X	X	X	Asserting the FEC_RXDV input indicates PHY has valid nibbles present on the MII. FEC_RXDV must remain asserted from the first recovered nibble of the frame through to the last nibble. Assertion of FEC_RXDV must start no later than the SFD and exclude any EOF. In RMII mode, this pin also generates the CRS signal.
FEC_RXD0	X	X	X	This pin contains the Ethernet input data transferred from PHY to the media-access controller when FEC_RXDV is asserted.
FEC_RXD1	X	—	X	This pin contains the Ethernet input data transferred from PHY to the media access controller when FEC_RXDV is asserted.
FEC_RXD[3:2]	X	—	—	These pins contain the Ethernet input data transferred from PHY to the media access controller when FEC_RXDV is asserted.
FEC_RXER	X[1]	—	X	When asserted with FEC_RXDV, indicates PHY detects an error in the current frame. When FEC_RXDV is not asserted, FEC_RXER has no effect.
FEC_TXCLK	X	X	X	Input clock which provides a timing reference for FEC_TXEN, FEC_TXD[3:0] and FEC_TXER. In RMII mode, this signal is the reference clock for receive, transmit, and the control interface.
FEC_TXD0	X	X	X	The serial output Ethernet data and only valid during the assertion of FEC_TXEN.
FEC_TXD1	X	—	X	This pin contains the serial output Ethernet data and valid only during assertion of FEC_TXEN.
FEC_TXD[3:2]	X	—	—	These pins contain the serial output Ethernet data and valid only during assertion of FEC_TXEN.
FEC_TXEN	X	X	X	Indicates when valid nibbles are present on the MII. This signal is asserted with the first nibble of a preamble and is negated before the first FEC_TXCLK following the final nibble of the frame.
FEC_TXER	X[1]	—	—	When asserted for one or more clock cycles while FEC_TXEN is also asserted, PHY sends one or more illegal symbols. FEC_TXER has no effect at 10 Mbps or when FEC_TXEN is negated.
Note: Interface selection is chip-specific; see the chapter that describes how modules are configured and connected.				

1. This signal is not available in the MII-Lite interface.

52.5 Memory map and register definition

The FEC is programmed by a combination of control/status registers (CSRs) and buffer descriptors. The CSRs control operation modes and extract global status information. The descriptors pass data buffers and related buffer information between the hardware and software.

Each FEC implementation requires a 1 KB memory map space, which is divided into two sections of 512 bytes each for:

- Control/status registers
- Event/statistic counters held in the MIB block

The following table defines the top-level memory map.

Table 52-5. FEC memory map

Address offset	Function
000h–1FFh	Control/status registers
200h–3FFh	MIB block counters

The following table shows the FEC register map. Any address offset not explicitly mentioned in this table is reserved. Do not modify the content of reserved fields. All accesses to and from the registers must be via 32-bit accesses. There is no support for accesses other than 32-bit. Accessing reserved or unimplemented register spaces in the FEC will not return transfer errors.

The MIB counters (shown in the following table) define the locations in the MIB RAM space where hardware-maintained counters reside. The counters are divided into two groups:

- RMON counters include the Ethernet statistics counters defined in RFC 1757
- Truncated frames counter (only frames with lengths up to 2047 bytes are supported)

The transmit and receive RMON counters are independent, which ensures accurate network statistics when operating in full duplex mode.

The included IEEE counters support the mandatory and recommended counter packages defined in Section 5 of ANSI/IEEE Std. 802.3 (1998 edition). The FEC supports IEEE Basic Package objects, but these do not require counters in the MIB block. In addition, some of the recommended package objects supported do not require MIB counters. Counters for transmit and receive full duplex flow control frames are also included.

FEC memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page

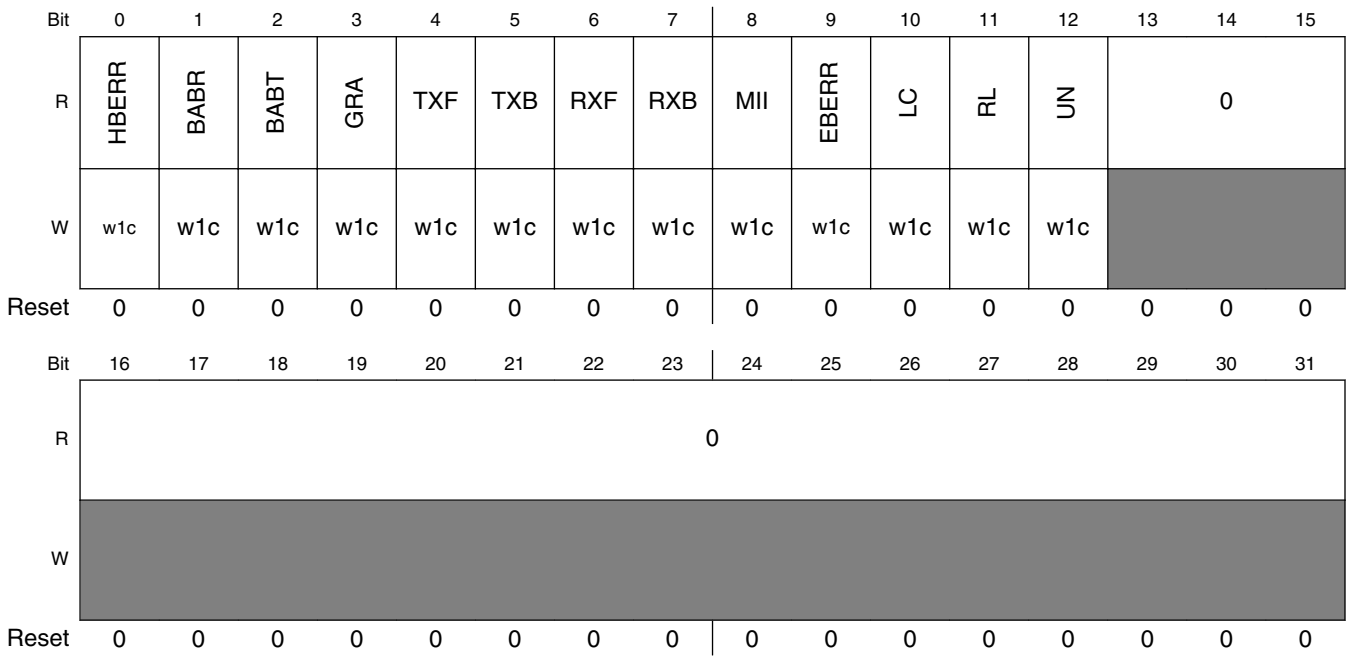
52.5.1 Interrupt Event Register (FEC_EIR)

When an event occurs that sets a bit in EIR, an interrupt occurs if the corresponding bit in the interrupt mask register (EIMR) is also set. Writing a 1 to an EIR bit clears it; writing 0 has no effect. This register is cleared upon hardware reset.



These interrupts can be divided into operational interrupts, transceiver/network error interrupts, and internal error interrupts. Interrupts which may occur in normal operation are GRA, TXF, TXB, RXF, RXB, and MII. Interrupts resulting from errors/problems detected in the network or transceiver are HBERR, BABR, BABT, LC, and RL. Interrupts resulting from internal errors are HBERR and UN.

Some of the error interrupts are independently counted in the MIB block counters:

- HBERR - IEEE_T_SQE
- BABR - RMON_R_OVERSIZE (good CRC), RMON_R_JAB (bad CRC)
- BABT - RMON_T_OVERSIZE (good CRC), RMON_T_JAB (bad CRC)
- LATE_COL - IEEE_T_LCOL
- COL_RETRY_LIM - IEEE_T_EXCOL
- XFIFO_UN - IEEE_T_MACERR

Software may choose to mask off these interrupts because these errors are visible to network management via the MIB counters.

Address: 0h base + 4h offset = 4h

FEC_EIR field descriptions

Field	Description
0 HBERR	Heartbeat error. Indicates TCR[HBC] is set and that the COL input was not asserted within the heartbeat window following a transmission.
1 BABR	Babbling receive error. Indicates a frame was received with length in excess of RCR[MAX_FL] bytes.
2 BABT	Babbling transmit error. Indicates the transmitted frame length exceeds RCR[MAX_FL] bytes. Usually this condition is caused by a frame that is too long is placed into the transmit data buffer(s). Truncation does not occur.
3 GRA	Graceful stop complete. Indicates the graceful stop is complete. During graceful stop the transmitter is placed into a pause state after completion of the frame currently being transmitted. This bit is set by one of these conditions: • A graceful stop initiated by the setting of the TCR[GTS] bit is now complete. • A graceful stop initiated by the setting of the TCR[TFC_PAUSE] bit is now complete. • A graceful stop initiated by the reception of a valid full duplex flow control pause frame is now complete. See Full duplex flow control.
4 TXF	Transmit frame interrupt. Indicates a frame has been transmitted and the last corresponding buffer descriptor has been updated.
5 TXB	Transmit buffer interrupt. Indicates a transmit buffer descriptor has been updated.
6 RXF	Receive frame interrupt. Indicates a frame has been received and the last corresponding buffer descriptor has been updated.
7 RXB	Receive buffer interrupt. Indicates a receive buffer descriptor not the last in the frame has been updated.
8 MII	MII interrupt. Indicates the MII has completed the data transfer requested.
9 EBERR	Ethernet bus error. Indicates a system bus error occurred when a DMA transaction is underway. When the EBERR bit is set, ECR[ETHER_EN] is cleared, halting frame processing by the FEC. When this occurs, software needs to ensure that the FIFO controller and DMA also soft reset.

Table continues on the next page...

FEC_EIR field descriptions (continued)

Field	Description
10 LC	Late collision. Indicates a collision occurred beyond the collision window (slot time) in half duplex mode. The frame truncates with a bad CRC and the remainder of the frame is discarded.
11 RL	Collision retry limit. Indicates a collision occurred on each of 16 successive attempts to transmit the frame. The frame is discarded without being transmitted and transmission of the next frame commences. This error can only occur in half duplex mode.
12 UN	Transmit FIFO underrun. Indicates the transmit FIFO became empty before the complete frame was transmitted. A bad CRC is appended to the frame fragment and the remainder of the frame is discarded.
13–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

52.5.2 Interrupt Mask Register (FEC_EIMR)

The EIMR controls which interrupt events are allowed to generate actual interrupts. A hardware reset clears this register. If the corresponding bits in the EIR and EIMR registers are set, an interrupt is generated. The interrupt signal remains asserted until a 1 is written to the EIR bit (write 1 to clear) or a 0 is written to the EIMR bit.

Each bit in this register corresponds to an interrupt source defined by the EIR. The corresponding EIMR bit determines whether an interrupt condition can generate an interrupt. At every processor clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR bit reflects the state of the interrupt signal even if the corresponding EIMR bit is set.

Address: 0h base + 8h offset = 8h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Field	Description
	0 The interrupt source is masked. 1 The interrupt source is not masked.
13–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

52.5.3 Receive Descriptor Active Register (FEC_RDAR)

RDAR is a command register, written by the user, indicating the receive descriptor ring is updated (the driver produced empty receive buffers with the empty bit set).

When the register is written, the RDAR bit is set. This is independent of the data actually written by the user. When set, the FEC polls the receive descriptor ring and processes receive frames (if ECR[ETHER_EN] is also set). After the FEC polls a receive descriptor whose empty bit is not set, FEC clears the RDAR bit and ceases receive descriptor ring polling until the user sets the bit again, signifying that additional descriptors are placed into the receive descriptor ring.

The RDAR is cleared at reset and when ECR[ETHER_EN] is cleared.

Address: 0h base + 10h offset = 10h

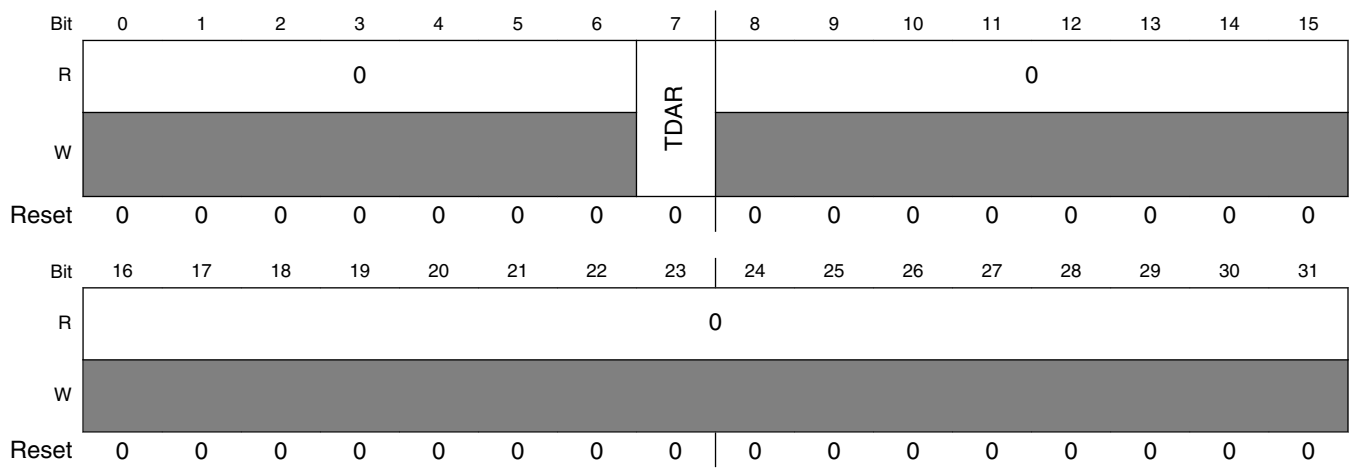
Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0							RDAR	0							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FEC_RDAR field descriptions

Field	Description
0–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 RDAR	Set to 1 when this register is written, regardless of the value written. Cleared by the FEC when no additional empty descriptors remain in the receive ring. Also cleared when ECR[ETHER_EN] is cleared.
8–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

52.5.4 Transmit Descriptor Active Register (FEC_TDAR)



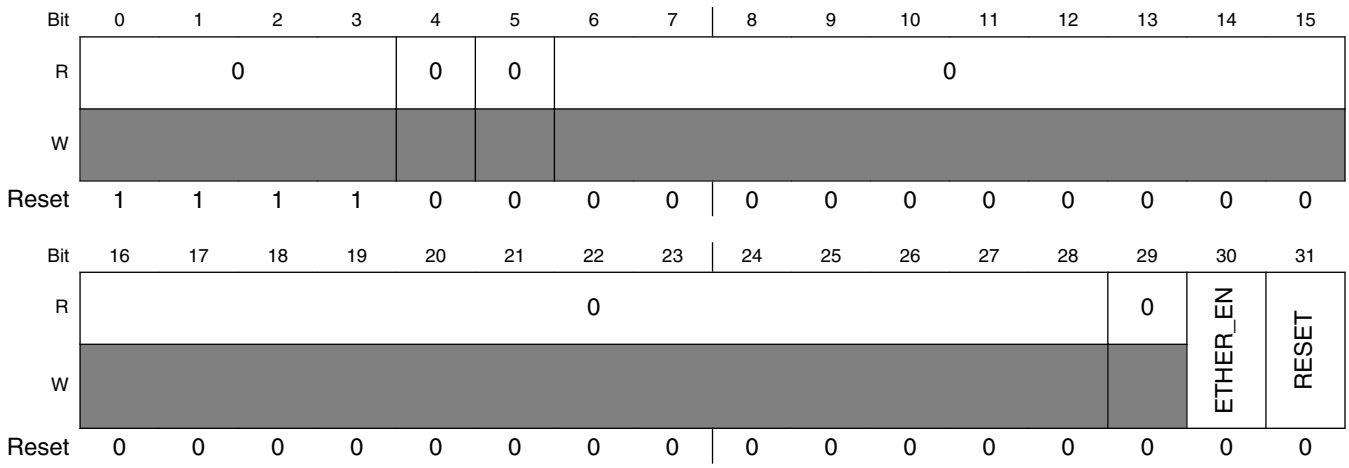
The TDAR is a command register which the user writes to indicate the transmit descriptor ring is updated (transmit buffers have been produced by the driver with the ready bit set in the buffer descriptor).

When the register is written, the TDAR field is set. This value is independent of the data actually written by the user. When set, the FEC polls the transmit descriptor ring and processes transmit frames (provided ECR[ETHER_EN] is also set). After the FEC polls a transmit descriptor that is a ready bit not set, FEC clears the TDAR field and ceases transmit descriptor ring polling until the user sets the bit again, signifying additional descriptors are placed into the transmit descriptor ring.

The TDAR field is cleared when any of the following events occur:

- Chip reset
- When ECR[ETHER_EN] is cleared
- When ECR[RESET] is set

Address: 0h base + 14h offset = 14h



FEC_TDAR field descriptions

Field	Description
0–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 TDAR	Set to 1 when this register is written, regardless of the value written. Cleared by the FEC device when no additional ready descriptors remain in the transmit ring. Also cleared when ECR[ETHER_EN] is cleared.
8–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

52.5.5 Ethernet Control Register (FEC_ECR)

ECR is a read/write user register, though hardware may alter fields in this register as well. The ECR enables/disables the FEC.

Address: 0h base + 24h offset = 24h

FEC_ECR field descriptions

Field	Description
0–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30 ETHER_EN	When this bit is set, FEC is enabled, and reception and transmission are possible. When this bit is cleared, reception immediately stops and transmission stops after a bad CRC is appended to any currently transmitted frame. The buffer descriptor(s) for an aborted transmit frame are not updated after clearing this bit. When ETHER_EN is cleared, the DMA, buffer descriptor, and FIFO control logic are reset, including the buffer descriptor and FIFO pointers. Hardware alters the ETHER_EN bit under the following conditions: • ECR[RESET] is set by software, in which case ETHER_EN is cleared. • An error condition causes the EIR[EBERR] bit to set, in which case ETHER_EN is cleared.
31 RESET	When this bit is set, the equivalent of a hardware reset is performed but it is local to the FEC. ECR[ETHER_EN] is cleared and all other FEC registers take their reset values. Also, any transmission/reception currently in progress is abruptly aborted. This bit is automatically cleared by hardware during the reset sequence. The reset sequence takes approximately eight internal bus clock cycles after this bit is set.

52.5.6 MII Management Frame Register (FEC_MMFR)

The MMFR is used to communicate with the attached MII compatible PHY device(s), providing read/write access to their MII registers. Performing a write to the MMFR causes a management frame to be sourced unless the MSCR is programmed to 0. If MSCR is cleared while MMFR is written and then MSCR is written with a non-zero value, an MII frame is generated with the data previously written to the MMFR. This allows MMFR and MSCR to be programmed in either order if MSCR is currently zero.

The MMFR does not reset to any predefined value.

To perform a read or write operation on the MII Management Interface, write the MMFR. To generate a valid read or write management frame, ST field must be written with a 01 pattern, and the TA field must be written with a 10. If other patterns are written to these fields, a frame is generated, but does not comply with the IEEE 802.3 MII definition.

To generate an IEEE 802.3-compliant MII Management Interface write frame (write to a PHY register), write {01 01 PHYAD REGAD 10 DATA} to the MMFR. Writing this pattern causes the control logic to shift out the data in the MMFR following a preamble generated by the control state machine. During this time, contents of the MMFR register are altered as the contents are serially shifted and are unpredictable if read by the user. After the write management frame operation completes, the MII interrupt is generated. At this time, contents of the MMFR match the original value written.

To generate an MII management interface read frame (read a PHY register), write {01 10 PHYAD REGAD 10 XXXX} to the MMFR (the content of the DATA field is unimportant). Writing this pattern causes the control logic to shift out the data in the MMFR following a preamble generated by the control state machine. During this time, contents of the MMFR register are altered as the contents are serially shifted and are unpredictable if read by the user. After the read management frame operation completes, the MII interrupt is generated. At this time, the contents of the MMFR register match the original value written except for the DATA field whose contents are replaced by the value read from the PHY register.

If the MMFR register is written while frame generation is in progress, the frame contents are altered. Software must use the MII interrupt to avoid writing to the MMFR while frame generation is in progress.

Address: 0h base + 40h offset = 40h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

* Notes:

- x = Undefined at reset.

FEC_MMFR field descriptions

Field	Description
0–1 ST	Start of frame delimiter. These bits must be programmed to 0b01 for a valid MII management frame.
2–3 OP	Operation code. 00 Write frame operation, but not MII compliant. 01 Write frame operation for a valid MII management frame. 10 Read frame operation for a valid MII management frame. 11 Read frame operation, but not MII compliant.
4–8 PA	PHY address. This field specifies one of up to 32 attached PHY devices.
9–13 RA	Register address. This field specifies one of up to 32 registers within the specified PHY device.
14–15 TA	Turn around. This field must be programmed to 10 to generate a valid MII management frame.
16–31 DATA	Management frame data. This is the field for data to be written to or read from the PHY register.

52.5.7 MII Speed Control Register (FEC_MSCR)

The MSCR:

- Provides control of the MII clock (FEC_MDC pin) frequency
- Allows a preamble drop on the MII management frame

The MII_SPEED field must be programmed with a value to provide an FEC_MDC frequency of less than or equal to 2.5 MHz to be compliant with the IEEE 802.3 MII specification. The MII_SPEED must be set to a non-zero value to source a read or write management frame. After the management frame is complete, the MSCR register may optionally be set to 0 to turn off the FEC_MDC. The FEC_MDC generated has a 50% duty cycle except when MII_SPEED changes during operation (change takes effect following a rising or falling edge of FEC_MDC).

If the internal bus clock is 25 MHz, programming this register to 0000_0005h results in an FEC_MDC as stated the equation below.

$$25\,\mathrm{MHz} \times \frac{1}{5 \times 2} = 2.5\,\mathrm{MHz}$$

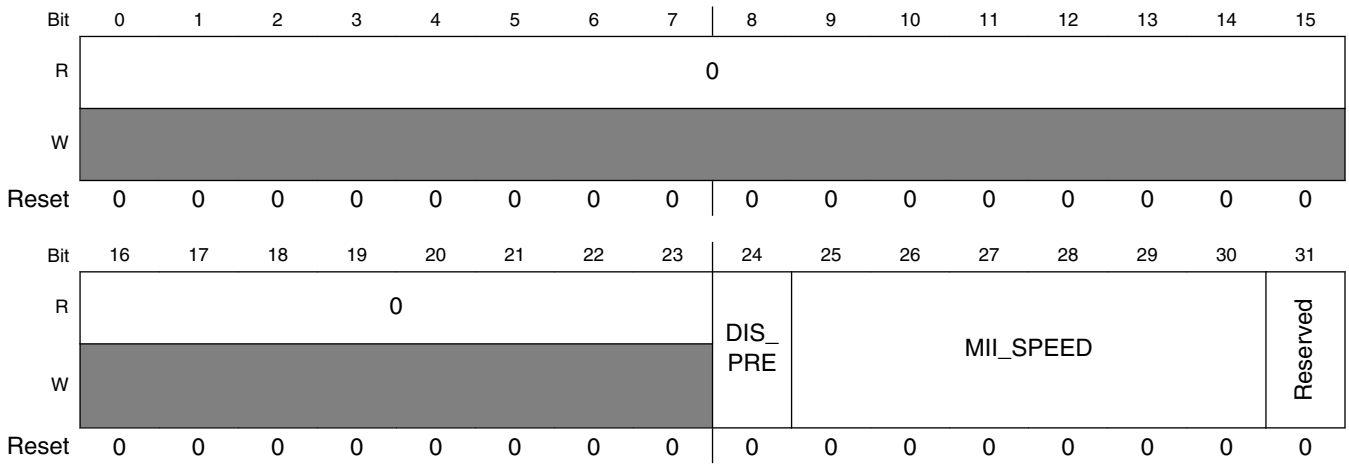

Figure 52-9. FEC_MDC example

Table 52-14 shows optimum values for MII_SPEED as a function of internal bus clock frequency.

Table 52-14. Programming examples for MSCR

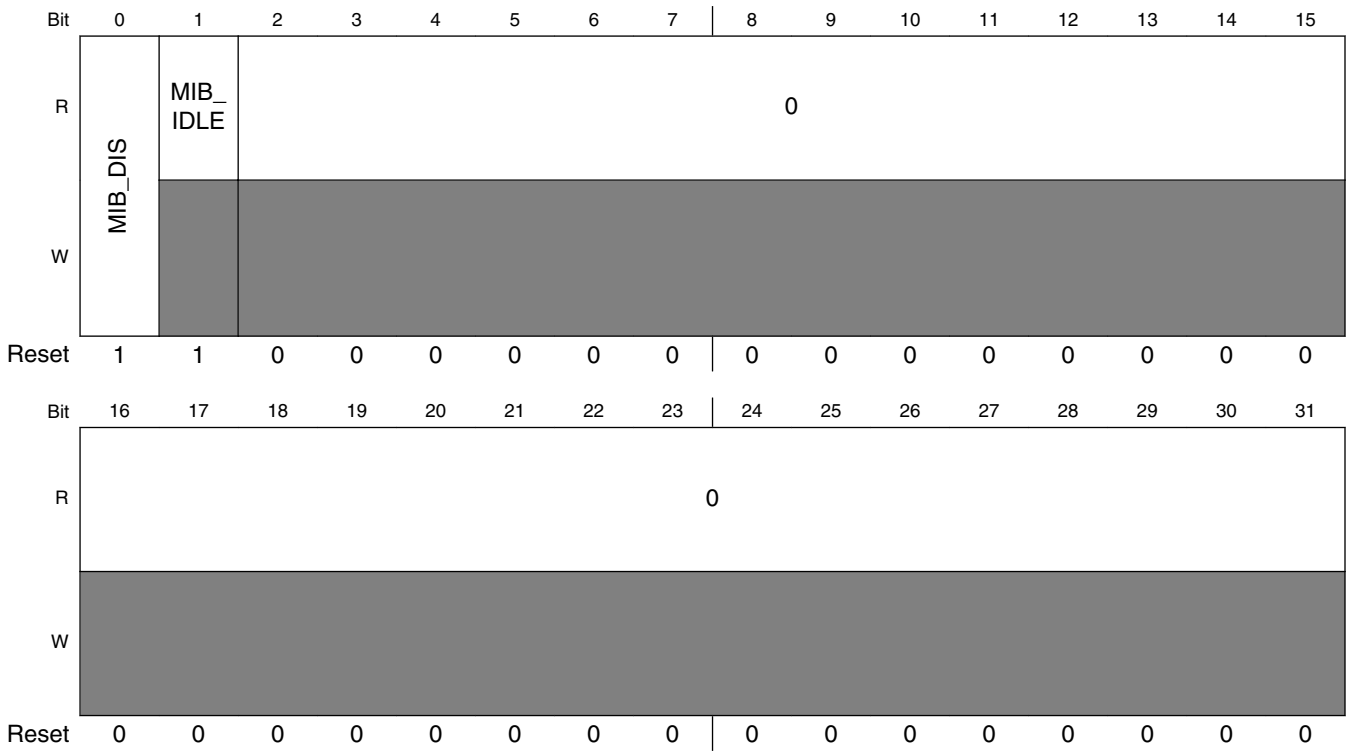
Internal FEC clock frequency	MSCR[MII_SPEED]	FEC_MDC frequency
25 MHz	5h	2.50 MHz
33 MHz	7h	2.36 MHz
40 MHz	8h	2.50 MHz
50 MHz	Ah	2.50 MHz
66 MHz	Eh	2.36 MHz
80 MHz	10h	2.50 MHz
83 MHz	10h	2.59 MHz

Address: 0h base + 44h offset = 44h

FEC_MSCR field descriptions

Field	Description
0–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24 DIS_PRE	Setting this bit causes the preamble (32 ones) not to be prepended to the MII management frame. The MII standard allows the preamble to be dropped if the attached PHY device(s) does not require it.
25–30 MII_SPEED	Controls the frequency of the MII management interface clock (FEC_MDC) relative to the internal bus clock. A value of 0 in this field turns off the FEC_MDC and leaves it in low voltage state. Any non-zero value results in the FEC_MDC frequency of 1/(MII_SPEED x 2) of the internal bus frequency.
31 Reserved	This field is reserved. Reserved

52.5.8 MIB Control Register (FEC_MIBC)



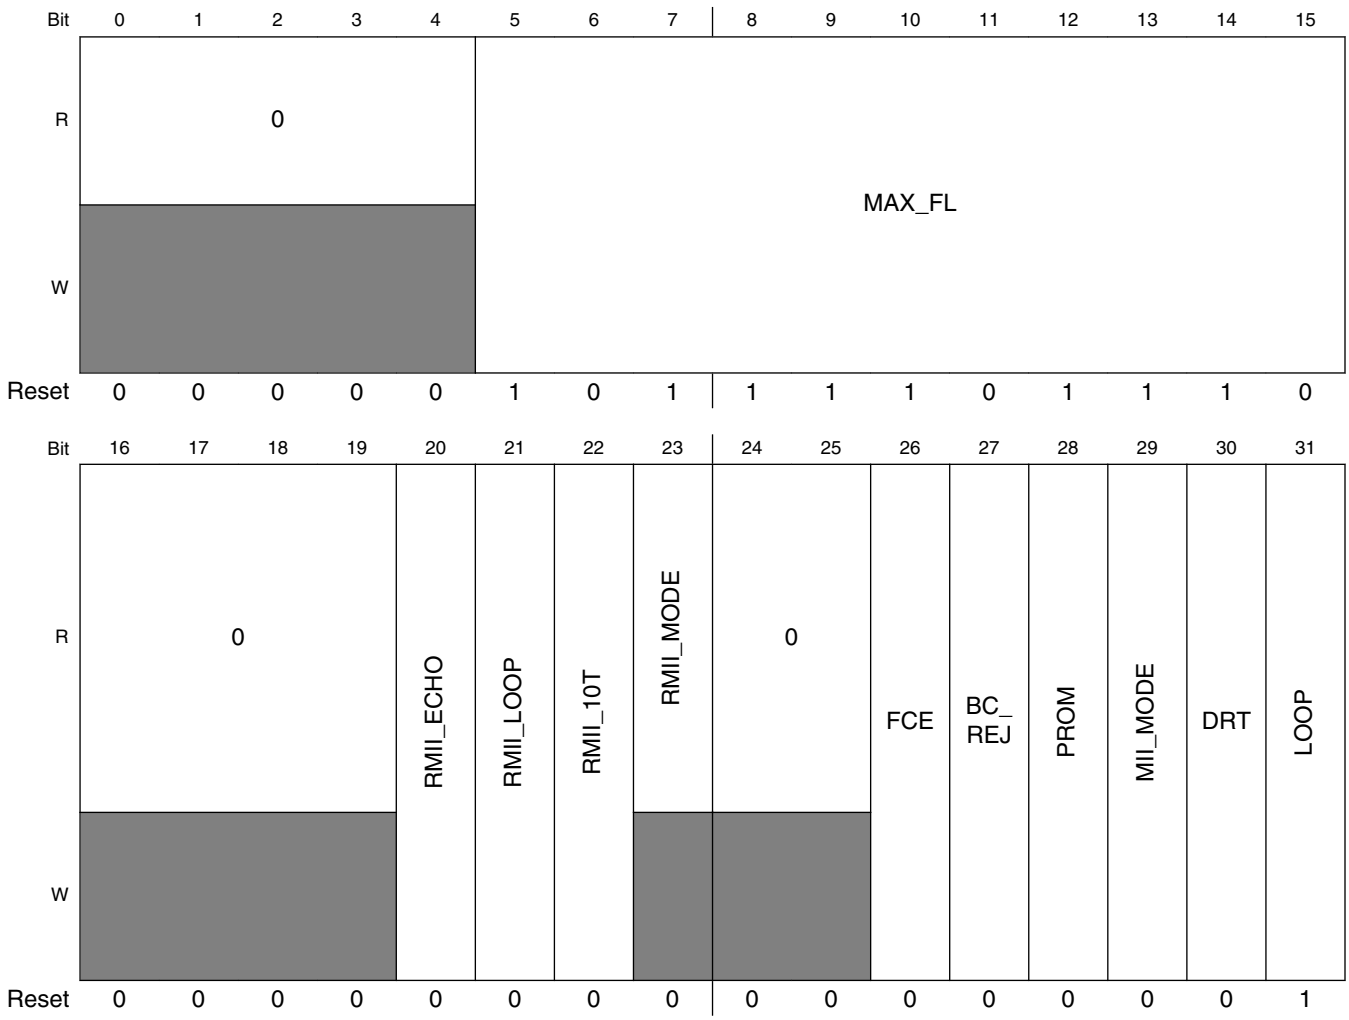
The MIBC is a read/write register controlling and observing the state of the MIB block. User software accesses this register if there is a need to disable the MIB block operation. For example, to clear all MIB counters in RAM:

1. Disable the MIB block

2. Clear all the MIB RAM locations
3. Enable the MIB block

The MIB_DIS bit is reset to 1. See the memory map for the locations of the MIB counters.

Address: 0h base + 64h offset = 64h



FEC_MIBC field descriptions

Field	Description
0 MIB_DIS	If MIB_DIS = 1, the MIB logic halts and not update any MIB counters.
1 MIB_IDLE	If MIB_IDLE = 1, the MIB block is not currently updating any MIB counters.
2–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

52.5.9 Receive Control Register (FEC_RCR)

RCR controls the operational mode of the receive block and must be written only when ECR[ETHER_EN] is cleared (initialization time).

Address: 0h base + 84h offset = 84h

FEC_RCR field descriptions

Field	Description
0–4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5–15 MAX_FL	Maximum frame length. Length is measured starting at DA and includes the CRC at the end of the frame. Transmit frames longer than MAX_FL causes the BABT interrupt to occur. Receive frames longer than MAX_FL causes the BABR interrupt to occur and sets the LG bit in the end of frame receive buffer descriptor.

Table continues on the next page...

FEC_RCR field descriptions (continued)

Field	Description
	The recommended default value to be programmed is 1518 or 1522 if VLAN tags are supported.
16–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20 RMII_ECHO	RMII Echo. Enables RMII echo mode. RMII 2-bit receive data is processed through the RMII receive logic to the FEC and also routes through the RMII's transmit logic to become RMII 2-bit transmit data out. 0 Normal operation. 1 RMII echo mode enabled. **NOTE:** When RMII_ECHO is set, proper operation is guaranteed only when RMII_MODE = 1, RMII_LOOP = 0 and LOOP = 0.
21 RMII_LOOP	RMII loopback. Enables RMII loopback mode. Causes the MII transmit outputs from the Ethernet controller to loop back to the Ethernet controllers's MII receive inputs through the RMII transmit/receive logic. 0 Normal operation. 1 RMII loopback mode enabled. **NOTE:** When RMII_LOOP is set, proper operation is guaranteed only when RMII_MODE = 1, RMII_ECHO = 0, LOOP = 0, and TCR *n* [FDEN] = 1.
22 RMII_10T	RMII 10-Base T. Enables 10Mbps mode of the RMII. Determines the clock frequency of the clock source to the FEC logic to support 10/100Mbps operations. 0 100 Mbps operation. The 50 MHz RMII reference clock on FEC_TXCLK is sent to the RMII, while a divided-by-2 version (25 MHz) is sent to the FEC. 1 10 Mbps operation. The 50 MHz RMII reference clock on FEC_TXCLK is divided by 10 (5 MHz) and sent to the RMII, while a divided-by-20 version (2.5 MHz) is sent to the FEC.
23 RMII_MODE	RMII Mode. Indicates if the FEC is in RMII or MII/7-wire mode. See the chip configuration chapter for more details. **NOTE:** Interface selection is chip-specific; see the chapter that describes how modules are configured and connected. 0 FEC is in true MII mode. 1 FEC is in RMII mode.
24–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26 FCE	Flow control enable. If asserted, the receiver detects PAUSE frames. Upon PAUSE frame detection, the transmitter stops transmitting data frames for a given duration.
27 BC_REJ	Broadcast frame reject. If asserted, frames with DA (destination address) equal to FFFF_FFFF_FFFF are rejected unless the PROM bit is set. If BC_REJ and PROM are set, frames with broadcast DA are accepted and the M (MISS) is set in the receive buffer descriptor.
28 PROM	Promiscuous mode. All frames are accepted regardless of address matching.
29 MII_MODE	Media independent interface mode. Selects the external interface mode for transmit and receive blocks. **NOTE:** Interface selection is chip-specific; see the chapter that describes how modules are configured and connected. 0 7-wire mode (used only for serial 10 Mbps) 1 MII or RMII mode as indicated by the RMII_MODE bit

Table continues on the next page...

FEC_RCR field descriptions (continued)

Field	Description
30 DRT	Disable receive on transmit. 0 Receive path operates independently of transmit (use for full duplex or to monitor transmit activity in half duplex mode). 1 Disable reception of frames while transmitting (normally used for half duplex mode).
31 LOOP	Internal loopback. If set, transmitted frames are looped back internal to the device and transmit output signals are not asserted. The internal bus clock substitutes for the FEC_TXCLK when LOOP is asserted. DRT must be set to 0 when setting LOOP.

52.5.10 Transmit Control Register (FEC_TCR)

The TCR configures the transmit block.

Address: 0h base + C4h offset = C4h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0											RFC_PAUSE	TFC_PAUSE	FDEN	HBC	GTS
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FEC_TCR field descriptions

Field	Description
0–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 RFC_PAUSE	Receive frame control pause. This read-only status bit is asserted when a full duplex flow control pause frame is received and the transmitter pauses for the duration defined in this pause frame. This bit automatically clears when the pause duration is complete.
28 TFC_PAUSE	Transmit frame control pause. Transmits a PAUSE frame when asserted. When this bit is set, the MAC stops transmission of data frames after the current transmission is complete. At this time, GRA interrupt in the EIR is asserted. With transmission of data frames stopped, MAC transmits a MAC Control PAUSE frame. Next, the MAC clears the TFC_PAUSE bit and resumes transmitting data frames. If the transmitter pauses due to user assertion of GTS or reception of a PAUSE frame, the MAC may continue transmitting a MAC Control PAUSE frame.
29 FDEN	Full duplex enable. If set, frames transmit independent of carrier sense and collision inputs. This field must be modified only when ECR[ETHER_EN] = 0.
30 HBC	Heartbeat control. If set, the heartbeat check performs following end of transmission and the HB bit in the status register is set if the collision input does not assert within the heartbeat window. This field must be modified only when ECR[ETHER_EN] = 0.
31 GTS	Graceful transmit stop. When this bit is set, MAC stops transmission after any frame currently transmitted is complete and GRA interrupt in the EIR is asserted. If frame transmission is not currently underway, the GRA interrupt is asserted immediately. After transmission finishes, clear GTS to restart. The next frame in the transmit FIFO is then transmitted. If an early collision occurs during transmission when GTS is set, transmission stops after the collision. The frame is transmitted again after GTS is cleared. There may be old frames in the transmit FIFO that transmit when GTS is reasserted. To avoid this situation, program ECR[ETHER_EN] = 0 following the GRA interrupt.

52.5.11 Physical Address Low Register (FEC_PALR)

PALR contains the lower 32 bits (bytes 0, 1, 2, 3) of the 48-bit address used in the address recognition process to compare with the DA (destination address) field of receive frames with an individual DA. In addition, this register is used in bytes 0 through 3 of the 6-byte source address field when transmitting PAUSE frames.

This register is not reset and you must initialize it.

Address: 0h base + E4h offset = E4h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

FEC_PALR field descriptions

Field	Description
0–31 PADDR1	Bytes 0 (bits 31:24), 1 (bits 23:16), 2 (bits 15:8), and 3 (bits 7:0) of the 6-byte individual address are used for exact match and the source address field in PAUSE frames.

52.5.12 Physical Address High Register and Type Field (FEC_PAUR)

PAUR contains the upper 16 bits (bytes 4 and 5) of the 48-bit address used in the address recognition process to compare with the DA (destination address) field of receive frames with an individual DA. In addition, this register is used in bytes 4 and 5 of the 6-byte Source Address field when transmitting PAUSE frames. Bits 15:0 of PAUR contain a constant type field (8808h) for transmission of PAUSE frames. The upper 16 bits of this register are not reset and you must initialize them.

Address: 0h base + E8h offset = E8h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

* Notes:
- u = Unaffected by reset.

FEC_PAUR field descriptions

Field	Description
0–15 PADDR2	Bytes 4 (bits 31:24) and 5 (bits 23:16) of the 6-byte individual address used for exact match, and the source address field in PAUSE frames.
16–31 TYPE	Type field in PAUSE frames. These 16 read-only bits are a constant value of 8808h.

52.5.13 Opcode/Pause Duration (FEC_OPD)

The OPD contains the 16-bit opcode and 16-bit pause duration fields used in transmission of a PAUSE frame. The opcode field is a constant value, 0001h. When another node detects a PAUSE frame, that node pauses transmission for the duration specified in the pause duration field.

The lower 16 bits of this register are not reset and you must initialize them.

Address: 0h base + ECh offset = ECh

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

* Notes:
- x = Undefined at reset.

FEC_OPD field descriptions

Field	Description
0–15 OPCODE	Opcode field used in PAUSE frames. These read-only bits are a constant, 0001h.
16–31 PAUSE_DUR	Pause Duration field used in PAUSE frames.

52.5.14 Descriptor Individual Upper Address Register (FEC_IAUR)

IAUR contains the upper 32 bits of the 64-bit individual address hash table. The address recognition process uses this table to check for a possible match with the destination address (DA) field of receive frames with an individual DA.

This register is not reset and you must initialize it.

Address: 0h base + 118h offset = 118h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

* Notes:
- u = Unaffected by reset.

FEC_IAUR field descriptions

Field	Description
0–31 IADDR1	The upper 32 bits of the 64-bit hash table used in the address recognition process for receive frames with a unicast address. Bit 31 of IADDR1 contains hash index bit 63. Bit 0 of IADDR1 contains hash index bit 32.

52.5.15 Descriptor Individual Lower Address Register (FEC_IALR)

IALR contains the lower 32 bits of the 64-bit individual address hash table. The address recognition process uses this table to check for a possible match with the DA field of receive frames with an individual DA.

This register is not reset and you must initialize it.

Address: 0h base + 11Ch offset = 11Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

FEC_IALR field descriptions

Field	Description
0–31 IADDR2	The lower 32 bits of the 64-bit hash table used in the address recognition process for receive frames with a unicast address. Bit 31 of IADDR2 contains hash index bit 31. Bit 0 of IADDR2 contains hash index bit 0.

52.5.16 Descriptor Group Upper Address Register (FEC_GAUR)

GAUR contains the upper 32 bits of the 64-bit hash table used in the address recognition process for receive frames with a multicast address.

This register is not reset and you must initialize it.

Address: 0h base + 120h offset = 120h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

FEC_GAUR field descriptions

Field	Description
0–31 GADDR1	The GADDR1 register contains the upper 32 bits of the 64-bit hash table used in the address recognition process for receive frames with a multicast address. Bit 31 of GADDR1 contains hash index bit 63. Bit 0 of GADDR1 contains hash index bit 32.

52.5.17 Descriptor Group Lower Address Register (FEC_GALR)

GALR contains the lower 32 bits of the 64-bit hash table used in the address recognition process for receive frames with a multicast address.

This register is not reset and you must initialize it.

Address: 0h base + 124h offset = 124h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

FEC_GALR field descriptions

Field	Description
0–31 GADDR2	The GADDR2 register contains the lower 32 bits of the 64-bit hash table used in the address recognition process for receive frames with a multicast address. Bit 31 of GADDR2 contains hash index bit 31. Bit 0 of GADDR2 contains hash index bit 0.

52.5.18 Transmit FIFO Watermark (FEC_TFWR)

The TFWR controls the amount of data required in the transmit FIFO before transmission of a frame can begin. This allows you to minimize transmit latency (TFWR = 00 or 01) or allow for larger bus access latency (TFWR = 11) due to contention for the system bus. Setting the watermark to a high value minimizes the risk of transmit FIFO underrun due to contention for the system bus. The byte counts associated with the TFWR field may need to be modified to match a given system requirement (worst case bus access latency by the transmit data DMA channel).

Address: 0h base + 144h offset = 144h

0–29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30–31 TFWR	Number of bytes written to transmit FIFO before transmission of a frame begins 00 64 bytes written

Table continues on the next page...

FEC_TFWR field descriptions (continued)

Field	Description
	01 64 bytes written 10 128 bytes written 11 192 bytes written

52.5.19 FIFO Receive Bound Register (FEC_FRBR)

FRBR indicates the upper address bound of the FIFO RAM. Drivers can use this value, along with the FRSR, to appropriately divide the available FIFO RAM between the transmit and receive data paths.

Address: 0h base + 14Ch offset = 14Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

FEC_FRBR field descriptions

Field	Description
0–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21 Reserved	This field is reserved. This read-only field is reserved and always has the value 1.
22–29 R_BOUND	Highest valid FIFO RAM address.
30–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

52.5.20 FIFO Receive Start Register (FEC_FRSR)

FRSR indicates the starting address of the receive FIFO. FRSR marks the boundary between the transmit and receive FIFOs. The transmit FIFO uses addresses from the start of the FIFO to the location four bytes before the address programmed into the FRSR. The receive FIFO uses addresses from FRSR to FRBR inclusive.

Hardware initializes the FRSR at reset. FRSR only needs to be written to change the default value.

Address: 0h base + 150h offset = 150h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

FEC_FRSR field descriptions

Field	Description
0–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21 Reserved	This field is reserved. This read-only field is reserved and always has the value 1.
22–29 R_FSTART	Address of first receive FIFO location. Acts as delimiter between receive and transmit FIFOs. For proper operation, ensure that R_FSTART is set to 48h or greater.
30–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

52.5.21 Receive Descriptor Ring Start Register (FEC_ERDSR)

ERDSR points to the start of the circular receive buffer descriptor queue in external memory. This pointer must be 32-bit aligned; however, it is recommended it be made 128-bit aligned (evenly divisible by 16). You should write zeros to bits 1 and 0. Hardware ignores non-zero values in these two bit positions.

This register is undefined at reset and must be initialized prior to operation.

Address: 0h base + 180h offset = 180h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

FEC_ERDSR field descriptions

Field	Description
0–29 R_DES_START	Pointer to start of receive buffer descriptor queue.
30–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

52.5.22 Transmit Buffer Descriptor Ring Start Register (FEC_ETDSR)

ETSDR provides a pointer to the start of the circular transmit buffer descriptor queue in external memory. This pointer must be 32-bit aligned; however, it is recommended it be made 128-bit aligned (evenly divisible by 16). You should write zeros to bits 1 and 0. Hardware ignores non-zero values in these two bit positions.

This register is undefined at reset and must be initialized prior to operation.

Address: 0h base + 184h offset = 184h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

FEC_ETDSR field descriptions

Field	Description
0–29 X_DES_START	Pointer to start of transmit buffer descriptor queue.
30–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

52.5.23 Receive Buffer Size Register (FEC_EMRBR)

The EMRBR dictates the maximum size of all receive buffers. This value should take into consideration that the receive CRC is always written into the last receive buffer. To allow one maximum size frame per buffer, EMRBR must be set to RCR[MAX_FL] or larger. To properly align the buffer, EMRBR must be evenly divisible by 16. To ensure this, bits 3-0 are forced low.

To minimize bus utilization (descriptor fetches), it is recommended that EMRBR be greater than or equal to 256 bytes.

The EMRBR is undefined at reset and must be initialized by the user.

Address: 0h base + 188h offset = 188h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

FEC_EMRBR field descriptions

Field	Description
0–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21–27 R_BUF_SIZE	Maximum size of receive buffer size in bytes. To minimize bus utilization (descriptor fetches), set this field to 256 bytes (10h) or larger. 10h: 256 + 15 bytes (minimum size recommended) 11h: 272 + 15 bytes ... 7Fh: 2032 + 15 bytes. The FEC writes up to 2047 bytes in the receive buffer. If data larger than 2047 is received, the FEC truncates it and shows 7FFh in the receive descriptor
28–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

52.5.24 Count of frames not counted correctly (FEC_RMON_T_DROP)

See Using the RMON and IEEE registers.

Address: 0h base + 200h offset = 200h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

Field	Description
0–31 IEEE_R_ OCTETS_OK	Octet count for frames received without error

52.5.79 Using the RMON and IEEE registers

In order to use the RMON and IEEE registers to monitor FEC performance, you must prepare them using the sequence below:

1. Write zeros to the registers.
2. Enable the FEC.

Until you complete this sequence, the registers are read/write, and their reset value is undefined. After you complete this sequence, the registers become read-only, and you may read them as necessary.

52.6 Functional description

This section describes the operation of the FEC, beginning with the description of two different types of MII frames, the buffer descriptors, the hardware and software initialization sequence, then the software (Ethernet driver) interface for transmitting and receiving frames.

Following the software initialization and operation sections are sections providing a detailed description of the functions of the FEC.

52.6.1 MII data frame

Ethernet/802.3 data frames transmitted across the MII have the format specified in Figure 52-81 and Table 52-86.

<inter-frame> <preamble> <sfd> <data> <efd>

Figure 52-81. MII data frame format

Table 52-86. MII data frame components

Component	Description
<inter-frame>	Inter-frame period. This is an unspecified amount of time during which no data activity occurs on the MII. The de-assertion of RX_DV and TX_EN indicate the absence of data activity.
<preamble>	Preamble that begins a frame. It has the following value: 10101010 10101010 10101010 10101010 10101010 10101010 10101010 The leftmost 1 represents the LSB of the byte.
<sfd>	Start of a frame. It has the value 10101011.
<data>	Data portion of the frame. It consists of N octets which corresponds to 2N nibbles being transmitted. The order of each nibble is defined in Figure 52-82.

Table continues on the next page...

Table 52-86. MII data frame components (continued)

Component	Description
<efd>	End-of-frame delimiter. For TXD data, it is indicated by the de-assertion of the TX_EN signal. For RXD data, it is indicated by the de-assertion of the RX_DV signal.

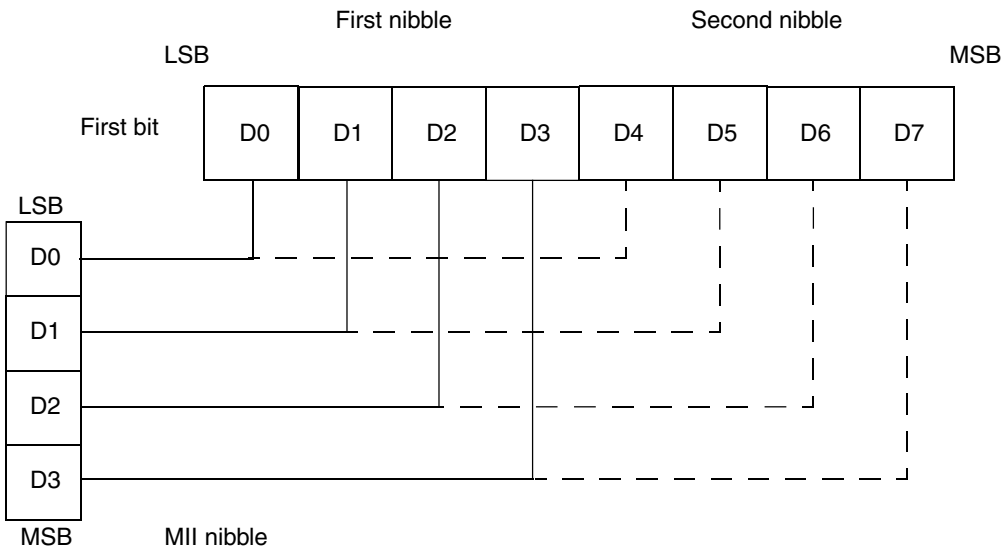

Figure 52-82. MII nibble/octet to octet/nibble mapping

52.6.2 MII management frame structure

A transceiver management frame being transmitted on the MII management interface uses the MDIO and MDC pins. A transaction or frame on this serial interface has the format specified in Figure 52-83 and Table 52-87.

<preamble> <st> <op> <phyad> <regad> <ta> <data> <idle>

Figure 52-83. MII management frame format

Table 52-87. MII management frame components

Component	Description
<preamble>	Optional preamble, consisting of a sequence of 32 continuous logic 1's.
<st>	Start of frame, consisting of a 01 pattern.
<op>	Operation code. 01 Write operation 10 Read instruction

Table continues on the next page...

Table 52-87. MII management frame components (continued)

Component	Description
<phyad>	Five-bit field that allows up to 32 PHYs to be addressed. The first address bit transmitted is the MSB of the address.
<regad>	Five-bit field that allows for 32 registers to be addressed within each PHY. The first register bit transmitted is the MSB of the address.
<ta>	Two-bit field that provides spacing between the register address field and the data field to avoid contention on the MDIO signal during a read operation.
<data>	16-bit data field. Bit 15 is the first data bit transmitted and received.
<idle>	Idle condition (MDIO is in the high-impedance state).

The MII management register set located in the PHY may consist of a basic register set and an extended register set as defined in Table 52-88.

Table 52-88. MII management register set

Register address	Register name	Register set
0	Control	Basic
1	Status	
2-3	PHY identifier	Extended
4	Auto-negotiation advertisement

52.6.3 Buffer descriptors

This section provides a description of the operation of the driver/DMA via the buffer descriptors. It is followed by a detailed description of the receive and transmit descriptor fields.

52.6.3.1 Driver/DMA operation with buffer descriptors

The data for the FEC frames resides in one or more memory buffers external to the FEC. Associated with each buffer is a buffer descriptor (BD), which contains a starting address (32-bit aligned pointer), data length, and status/control information (which contains the current state for the buffer). To permit maximum user flexibility, the BDs are also located in external memory and are read by the FEC DMA engine.

Software produces buffers by allocating/initializing memory and initializing buffer descriptors. Setting the RxBD[E] or TxBD[R] bit produces the buffer. Software writing to TDAR or RDAR tells the FEC that a buffer is placed in external memory for the transmit or receive data traffic, respectively. The hardware reads the BDs and consumes the buffers after they have been produced. After the data DMA is complete and the DMA engine writes the buffer descriptor status bits, hardware clears RxBD[E] or TxBD[R] to signal the buffer has been consumed. Software may poll the BDs to detect when the buffers are consumed or may rely on the buffer/frame interrupts. The driver may process these buffers, and they can return to the free list.

The ECR[ETHER_EN] bit operates as a reset to the BD/DMA logic. When ECR[ETHER_EN] is cleared, the DMA engine BD pointers are reset to point to the starting transmit and receive BDs. The buffer descriptors are not initialized by hardware during reset. At least one transmit and receive buffer descriptor must be initialized by software before ECR[ETHER_EN] is set.

The buffer descriptors operate as two separate rings. ERDSR defines the starting address for receive BDs and ETDSR defines the starting address for transmit BDs. The wrap (W) bit defines the last buffer descriptor in each ring. When W is set, the next descriptor in the ring is at the location pointed to by ERDSR and ETDSR for the receive and transmit rings, respectively. Buffer descriptor rings must start on a 32-bit boundary; however, it is recommended they be 128-bit aligned.

52.6.3.1.1 Driver/DMA operation with transmit BDs

Typically, a transmit frame is divided between multiple buffers. An example is to have an application payload in one buffer, TCP header in a second buffer, IP header in a third buffer, and Ethernet/IEEE 802.3 header in a fourth buffer. The Ethernet MAC does not prepend the Ethernet header (destination address, source address, length/type field(s)), so the driver must provide this in one of the transmit buffers. The Ethernet MAC can append the Ethernet CRC to the frame. TxBD[TC], which must be set by the driver, determines whether the MAC or driver appends the CRC.

The driver (TxBD software producer) should set up Tx BDs so a complete transmit frame is given to the hardware at once. If a transmit frame consists of three buffers, the BDs should be initialized with pointer, length, and control (W, L, TC, ABC) and then the TxBD[R] bit should be set in reverse order (third, second, then first BD) to ensure that the complete frame is ready in memory before the DMA begins. If the TxBDs are set up in order, the DMA controller could DMA the first BD before the second was made available, potentially causing a transmit FIFO underrun.

In the FEC, the driver notifies the DMA that new transmit frame(s) are available by writing to TDAR. When this register is written to (data value is not significant), the FEC RISC tells the DMA to read the next transmit BD in the ring. After started, the RISC + DMA continues to read and interpret transmit BDs in order and DMA the associated buffers until a transmit BD is encountered with the R bit cleared. At this point, the FEC polls this BD one more time. If the R bit is cleared the second time, RISC stops the transmit descriptor read process until software sets up another transmit frame and writes to TDAR.

When the DMA of each transmit buffer is complete, the DMA writes back to the BD to clear the R bit, indicating that the hardware consumer is finished with the buffer.

52.6.3.1.2 Driver/DMA operation with receive BDs

Unlike transmit, the length of the receive frame is unknown by the driver ahead of time. Therefore, the driver must set a variable to define the length of all receive buffers. In the FEC, this variable is written to the EMRBR register.

The driver (RxBD software producer) should set up some number of empty buffers for the Ethernet by initializing the address field and the E and W bits of the associated receive BDs. The hardware (receive DMA) consumes these buffers by filling them with data as frames are received and clearing the E bit and writing to the L bit (1 indicates last buffer in frame), the frame status bits (if L is set), and the length field.

If a receive frame spans multiple receive buffers, the L bit is only set for the last buffer in the frame. For non-last buffers, the length field in the receive BD is written by the DMA (at the same time the E bit is cleared) with the default receive buffer length value. For end-of-frame buffers, the receive BD is written with L set and information written to the status bits (M, BC, MC, LG, NO, CR, OV, TR). Some of the status bits are error indicators which, if set, indicate the receive frame should be discarded and not given to higher layers. The frame status/length information is written into the receive FIFO following the end of the frame (as a single 32-bit word) by the receive logic. The length field for the end of frame buffer is written with the length of the entire frame, not only the length of the last buffer.

For simplicity, the driver may assign a large enough default receive buffer length to contain an entire frame, keeping in mind that a malfunction on the network or out-of-spec implementation could result in giant frames. Frames of 2K (2048) bytes or larger are truncated by the FEC at 2047 bytes so software never sees a receive frame larger than 2047 bytes.

Similar to transmit, the FEC polls the receive descriptor ring after the driver sets up receive BDs and writes to the RDAR register. As frames are received, the FEC fills receive buffers and updates the associated BDs, then reads the next BD in the receive

descriptor ring. If the FEC reads a receive BD and finds the E bit cleared, it polls this BD once more. If RxBD[E] is clear a second time, FEC stops reading receive BDs until the driver writes to RDAR.

52.6.3.2 Ethernet Receive Buffer Descriptor (RxBD)

In the RxBD, the user initializes the E and W bits in the first longword and the pointer in the second longword. When the buffer has been DMA'd, the Ethernet controller modifies the E, L, M, BC, MC, LG, NO, CR, OV, and TR bits and writes the length of the used portion of the buffer in the first longword. The M, BC, MC, LG, NO, CR, OV, and TR bits in the first longword of the buffer descriptor are only modified by the Ethernet controller when the L bit is set.

Table 52-89. Receive Buffer Descriptor (RxBD)

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Offset+0	E	RO1	W	RO2	L	—	—	M	BC	MC	LG	NO	—	CR	OV	TR
Offset+2	Data Length															
Offset+4	Rx Data Buffer Pointer - A[31:16]															
Offset+6	Rx Data Buffer Pointer - A[15:0]															

Table 52-90. Receive Buffer Descriptor field descriptions

Word	Field	Description
Offset + 0	E	Empty. Written by the FEC (=0) and user (=1). 0: The data buffer associated with this BD is filled with received data, or data reception has aborted due to an error condition. The status and length fields have been updated as required. 1: The data buffer associated with this BD is empty, or reception is currently in progress.
Offset + 0	RO1	Receive software ownership. This field is reserved for use by software. This read/write bit is not modified by hardware, nor does its value affect hardware.
Offset + 0	W	Wrap. Written by user. 0: The next buffer descriptor is found in the consecutive location 1: The next buffer descriptor is found at the location defined in ERDSR.
Offset + 0	RO2	Receive software ownership. This field is reserved for use by software. This read/write bit is not modified by hardware, nor does its value affect hardware.
Offset + 0	L	Last in frame. Written by the FEC. 0: The buffer is not the last in a frame. 1: The buffer is the last in a frame.

Table continues on the next page...

Table 52-90. Receive Buffer Descriptor field descriptions (continued)

Word	Field	Description
Offset + 0	M	Miss. Written by the FEC. This bit is set by the FEC for frames accepted in promiscuous mode, but flagged as a miss by the internal address recognition. Therefore, while in promiscuous mode, you can use the M-bit to quickly determine whether the frame was destined to this station. This bit is valid only if the L-bit is set and the PROM bit is set. 0: The frame was received because of an address recognition hit. 1: The frame was received because of promiscuous mode.
Offset + 0	BC	Set if the DA is broadcast (FFFF_FFFF_FFFF).
Offset + 0	MC	Set if the DA is multicast and not BC.
Offset + 0	LG	Rx frame length violation. Written by the FEC. A frame length greater than RCR[MAX_FL] was recognized. This bit is valid only if the L-bit is set. The receive data is not altered in any way unless the length exceeds 2047 bytes.
Offset + 0	NO	Receive non-octet aligned frame. Written by the FEC. A frame that contained a number of bits not divisible by 8 was received, and the CRC check that occurred at the preceding byte boundary generated an error. This bit is valid only if the L-bit is set. If this bit is set, the CR bit is not set.
Offset + 0	CR	Receive CRC error. Written by the FEC. This frame contains a CRC error and is an integral number of octets in length. This bit is valid only if the L-bit is set.
Offset + 0	OV	Overrun. Written by the FEC. A receive FIFO overrun occurred during frame reception. If this bit is set, the other status bits, M, LG, NO, CR, and CL lose their normal meaning and are zero. This bit is valid only if the L-bit is set.
Offset + 0	TR	Set if the receive frame is truncated (frame length > 2047 bytes). If the TR bit is set, the frame must be discarded and the other error bits must be ignored as they may be incorrect.
Offset + 2	Data Length	Data length. Written by the FEC. Data length is the number of octets written by the FEC into this BD's data buffer if L equals 0 (the value is equal to EMRBR), or the length of the frame including CRC if L is set. It is written by the FEC once as the BD is closed.
0ffset + 4	A[31:16]	RX data buffer pointer, bits [31:16][1]
Offset + 6	A[15:0]	RX data buffer pointer, bits [15:0]

1. The receive buffer pointer, containing the address of the associated data buffer, must always be evenly divisible by 16. The buffer must reside in memory external to the FEC. The Ethernet controller never modifies this value.

Note

When the software driver sets an E bit in one or more receive descriptors, the driver should follow with a write to RDAR.

52.6.3.3 Ethernet Transmit Buffer Descriptor (TxBD)

Data is presented to the FEC for transmission by arranging it in buffers referenced by the channel's TxBDs. The Ethernet controller confirms transmission by clearing the ready bit (TxBD[R]) when DMA of the buffer is complete. In the TxBD, the user initializes the R, W, L, and TC bits and the length (in bytes) in the first longword and the buffer pointer in the second longword.

The FEC clears the R bit when the buffer is transferred. Status bits for the buffer/frame are not included in the transmit buffer descriptors. Transmit frame status is indicated via individual interrupt bits (error conditions) and in statistic counters in the MIB block.

Table 52-91. Transmit Buffer Descriptor (TxBD)

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Offset+0	R	TO1	W	TO2	L	TC	ABC	—	—	—	—	—	—	—	—	—
Offset+2	Data Length															
Offset+4	Tx Data Buffer Pointer - A[31:16]															
Offset+6	Tx Data Buffer Pointer - A[15:0]															

Table 52-92. Transmit Buffer Descriptor field descriptions

Word	Field	Description
Offset + 0	R	Ready. Written by the FEC and you. 0: The data buffer associated with this BD is not ready for transmission. You are free to manipulate this BD or its associated data buffer. The FEC clears this bit after the buffer has been transmitted or after an error condition is encountered. 1: The data buffer, prepared for transmission by you, has not been transmitted or currently transmits. You may write no fields of this BD after this bit is set.
Offset + 0	TO1	Transmit software ownership. This field is reserved for software use. This read/write bit is not modified by hardware nor does its value affect hardware.
Offset + 0	W	Wrap. Written by user. 0: The next buffer descriptor is found in the consecutive location 1: The next buffer descriptor is found at the location defined in ETDSR.
Offset + 0	TO2	Transmit software ownership. This field is reserved for use by software. This read/write bit is not modified by hardware nor does its value affect hardware.
Offset + 0	L	Last in frame. Written by user. 0: The buffer is not the last in the transmit frame 1: The buffer is the last in the transmit frame
Offset + 0	TC	Transmit CRC. Written by user (only valid if L is set). 0: End transmission immediately after the last data byte 1: Transmit the CRC sequence after the last data byte
Offset + 0	ABC	Append bad CRC. Written by user (only valid if L is set). 0: No effect 1: Transmit the CRC sequence inverted after the last data byte (regardless of TC value)
Offset + 2	Data Length	Data length, written by user. Data length is the number of octets the FEC should transmit from this BD's data buffer. It is never modified by the FEC.
Offset + 4	A[31:16]	Tx data buffer pointer, bits [31:16] [1]
Offset + 6	A[15:0]	Tx data buffer pointer, bits [15:0]

1. The transmit buffer pointer, containing the address of the associated data buffer, must always be evenly divisible by 4. The buffer must reside in memory external to the FEC. This value is never modified by the Ethernet controller.

Note

After the software driver has set up the buffers for a frame, it should set up the corresponding BDs. The last step in setting up the BDs for a transmit frame is setting the R bit in the first BD for the frame. The driver must follow that with a write to TDAR that triggers the FEC to poll the next BD in the ring.

52.6.4 Initialization sequence

This section describes which registers are reset due to hardware reset, which registers are reset by the FEC RISC, and what locations you must initialize prior to enabling the FEC.

52.6.4.1 Hardware Controlled Initialization

In the FEC, hardware resets registers and control logic that generate interrupts. A hardware reset negates output signals and resets general configuration bits.

Other registers reset when the ECR[ETHER_EN] bit is cleared (which is accomplished by a hard reset or software to halt operation). By clearing ECR[ETHER_EN], configuration control registers such as the TCR and RCR are not reset, but the entire data path is reset.

Table 52-93. ECR[ETHER_EN] De-Assertion Effect on FEC

Register/Machine	Reset Value
XMIT block	Transmission is aborted (bad CRC appended)
RECV block	Receive activity is aborted
DMA block	All DMA activity is terminated
RDAR	Cleared
TDAR	Cleared
Descriptor Controller block	Halt operation

52.6.5 User initialization (Prior to Setting ECR[ETHER_EN])

You need to initialize portions the FEC prior to setting the ECR[ETHER_EN] bit. The exact values depend on the particular application. The sequence is not important.

The following registers require initialization:

- EIMR
- EIR (clear by writing FFFF_FFFFh)
- TFWR (optional)
- IALR / IAUR
- GAUR / GALR
- PALR / PAUR (only needed for full duplex flow control)
- OPD (only needed for full duplex flow control)
- RCR
- TCR
- MSCR (optional)
- MIB_RAM (clear)
- FRSR (optional)
- EMRBR
- ERDSR
- ETDSR
- Transmit Descriptor ring (empty)
- Receive Descriptor ring (empty)

52.6.6 Microcontroller initialization

In the FEC, the descriptor control RISC initializes some registers after ECR[ETHER_EN] is asserted. After the microcontroller initialization sequence is complete, hardware is ready for operation.

The sequence is as follows:

1. Initialize the backoff random number seed.
2. Activate receiver.
3. Activate transmitter.

4. Clear transmit FIFO.
5. Clear receive FIFO.
6. Initialize the transmit ring pointer.
7. Initialize the receive ring pointer.
8. Initialize FIFO count registers.

52.6.7 User initialization (after setting ECR[ETHER_EN])

After setting ECR[ETHER_EN], you can set up the buffer/frame descriptors and write to TDAR and RDAR. See Buffer descriptors, for more details.

52.6.8 Network interface options

The FEC supports an MII and reduced MII interface for 10/100 Mbps Ethernet, as well as a 7-wire serial interface for 10 Mbps Ethernet. The RCR[MII_MODE] and RCR [RMII_MODE] bits select the interface mode. In MII mode (RCR[MII_MODE]=1 and RCR [RMII_MODE]=0), there are 18 signals defined by the IEEE 802.3 standard and supported by the EMAC. The following table shows these signals.

Table 52-94. MII mode

Signal description	EMAC pin
Transmit Clock	FEC_TXCLK
Transmit Enable	FEC_TXEN
Transmit Data	FEC_TXD[3:0]
Transmit Error	FEC_TXER
Collision	FEC_COL
Carrier Sense	FEC_CRS
Receive Clock	FEC_RXCLK
Receive Data Valid	FEC_RXDV
Receive Data	FEC_RXD[3:0]
Receive Error	FEC_RXER
Management Data Clock	FEC_MDC
Management Data Input/Output	FEC_MDIO

In RMII mode (RCR[MII_MODE]=1 and RCR[RMII_MODE]=1), the EMAC supports 8 external signals. These signals are shown in the table below.

Table 52-95. RMII mode configuration

Signal description	EMAC pin
Reference Clock	FEC_TXCLK
Transmit Enable	FEC_TXEN
Transmit Data	FEC_TXD[1:0]
Receive Data Valid	FEC_RXDV
Receive Data	FEC_RXD[1:0]
Receive Error	FEC_RXER

The 7-wire serial mode interface (RCR[MII_MODE]=1 and RCR[RMII_MODE]=0 or 1) is generally referred to as AMD mode. The following table shows the 7-wire mode connections to the external transceiver.

Table 52-96. 7-Wire mode configuration

Signal description	EMAC pin
Transmit Clock	FEC_TXCLK
Transmit Enable	FEC_TXEN
Transmit Data	FEC_TXD[0]
Collision	FEC_COL
Receive Clock	FEC_RXCLK
Receive Data Valid	FEC_RXDV
Receive Data	FEC_RXD[0]

52.6.9 FEC frame transmission

The Ethernet transmitter is designed to work with almost no intervention from software. After ECR[ETHER_EN] is set and data appears in the transmit FIFO, the Ethernet MAC can transmit onto the network. The Ethernet controller transmits bytes least significant bit (lsb) first.

When the transmit FIFO fills to the watermark (defined by TFWR), MAC transmit logic asserts FEC_TXEN and starts transmitting the (PA) sequence, the start frame delimiter (SFD), and then the frame information from the FIFO. However, the controller defers the transmission if the network is busy (FEC_CRS is asserted). Before transmitting, the controller waits for carrier sense to become inactive, then determines if carrier sense stays inactive for 60 bit times. If so, transmission begins after waiting an additional 36 bit times (96 bit times after carrier sense originally became inactive). See "Transmission errors" for more details.

If a collision occurs during transmission of the frame (half duplex mode), the Ethernet controller follows the specified backoff procedures and attempts to retransmit the frame until the retry limit is reached. The transmit FIFO stores at least the first 64 bytes of the transmit frame, so they do not have to be retrieved from system memory in case of a collision. This improves bus utilization and latency in case immediate retransmission is necessary.

When all the frame data is transmitted, FCS (frame check sequence) or 32-bit cyclic redundancy check (CRC) bytes are appended if the TC bit is set in the transmit frame control word. If the ABC bit is set in the transmit frame control word, a bad CRC is appended to the frame data regardless of the TC bit value. Following the transmission of the CRC, the Ethernet controller writes the frame status information to the MIB block. Transmit logic automatically pads short frames (if the TC bit in the transmit buffer descriptor for the end of frame buffer is set).

Settings in the EIMR determine interrupts generated to the buffer (TXB) and frame (TXF).

The transmit error interrupts are HBERR, BABT, LC, RL, and UN. If the transmit frame length exceeds MAX_FL bytes, BABT interrupt is asserted. However, the entire frame is transmitted (no truncation).

To pause transmission, set TCR[GTS] (graceful transmit stop). The FEC transmitter stops immediately if transmission is not in progress; otherwise, it continues transmission until the current frame finishes or terminates with a collision. After the transmitter has stopped, the GRA (graceful stop complete) interrupt is asserted. If TCR[GTS] is cleared, the FEC resumes transmission with the next frame.

52.6.9.1 Duplicate frame transmission

The FEC fetches transmit buffer descriptors (TxBDs) and the corresponding transmit data continuously until the transmit FIFO is full. It does not determine whether the TxBD to be fetched is already being processed internally (as a result of a wrap). As the FEC nears the end of the transmission of one frame, it begins to DMA the data for the next frame. To remain one BD ahead of the DMA, it also fetches the TxBD for the next frame. It is possible that the FEC fetches from memory a BD that has already been processed but not yet written back (it is read a second time with the R bit remains set). In this case, the data is fetched and transmitted again.

Using at least three TxBDs fixes this problem for large frames, but not for small frames. To ensure correct operation for large or small frames, one of the following must be true:

- The FEC software driver ensures that there is always at least one TxBD with the ready bit cleared.
- Every frame uses more than one TxBD and every TxBD but the last is written back immediately after the data is fetched.
- The FEC software driver ensures a minimum frame size, *n.* The minimum number of TxBDs is then (Tx FIFO Size ÷ (*n*+4)) rounded up to the nearest integer (though the result cannot be less than three). The default Tx FIFO size is 192 bytes; this size is programmable.

52.6.10 FEC frame reception

The FEC receiver works with almost no intervention from the host and can perform address recognition, CRC checking, short frame checking, and maximum frame length checking. The Ethernet controller receives serial data lsb first.

When the driver enables the FEC receiver by setting ECR[ETHER_EN], it immediately starts processing receive frames. When FEC_RXDV is asserted, the receiver first checks for a valid PA/SFD header. If the PA/SFD is valid, it is stripped and the receiver processes the frame. If a valid PA/SFD is not found, the frame is ignored.

In serial mode, the first 16 bit times of RX_D0 following assertion of FEC_RXDV are ignored. Following the first 16 bit times, the data sequence is checked for alternating 1/0s. If a 11 or 00 data sequence is detected during bit times 17 to 21, the remainder of the frame is ignored. After bit time 21, the data sequence is monitored for a valid SFD (11). If a 00 is detected, the frame is rejected. When a 11 is detected, the PA/SFD sequence is complete.

In MII mode, the receiver checks for at least one byte matching the SFD. Zero or more PA bytes may occur, but if a 00 bit sequence is detected prior to the SFD byte, the frame is ignored.

After the first 6 bytes of the frame are received, the FEC performs address recognition on the frame.

After a collision window (64 bytes) of data is received and if address recognition has not rejected the frame, the receive FIFO signals the frame is accepted and may be passed on to the DMA. If the frame is a runt (due to collision) or is rejected by address recognition, the receive FIFO is notified to reject the frame. Therefore, no collision fragments are presented to you except late collisions, which indicate serious LAN problems.

During reception, the Ethernet controller checks for various error conditions and after the entire frame is written into the FIFO, a 32-bit frame status word is written into the FIFO. This status word contains the M, BC, MC, LG, NO, CR, OV, and TR status bits, and the frame length. See "Reception errors" for more details.

Receive buffer (RXB) and frame interrupts (RFINT) may be generated if enabled by the EIMR register. A receive error interrupt is a babbling receiver error (BABR). Receive frames are not truncated if they exceed the max frame length (MAX_FL); however, the BABR interrupt occurs and the LG bit in the receive buffer descriptor (RxBD) is set. See Ethernet Receive Buffer Descriptor (RxBD), for more details.

When the receive frame is complete, the FEC sets the L-bit in the RxBD, writes the other frame status bits into the RxBD, and clears the E-bit. The Ethernet controller next generates a maskable interrupt (RFINT bit in EIR, maskable by RFIEN bit in EIMR), indicating that a frame is received and is in memory. The Ethernet controller then waits for a new frame.

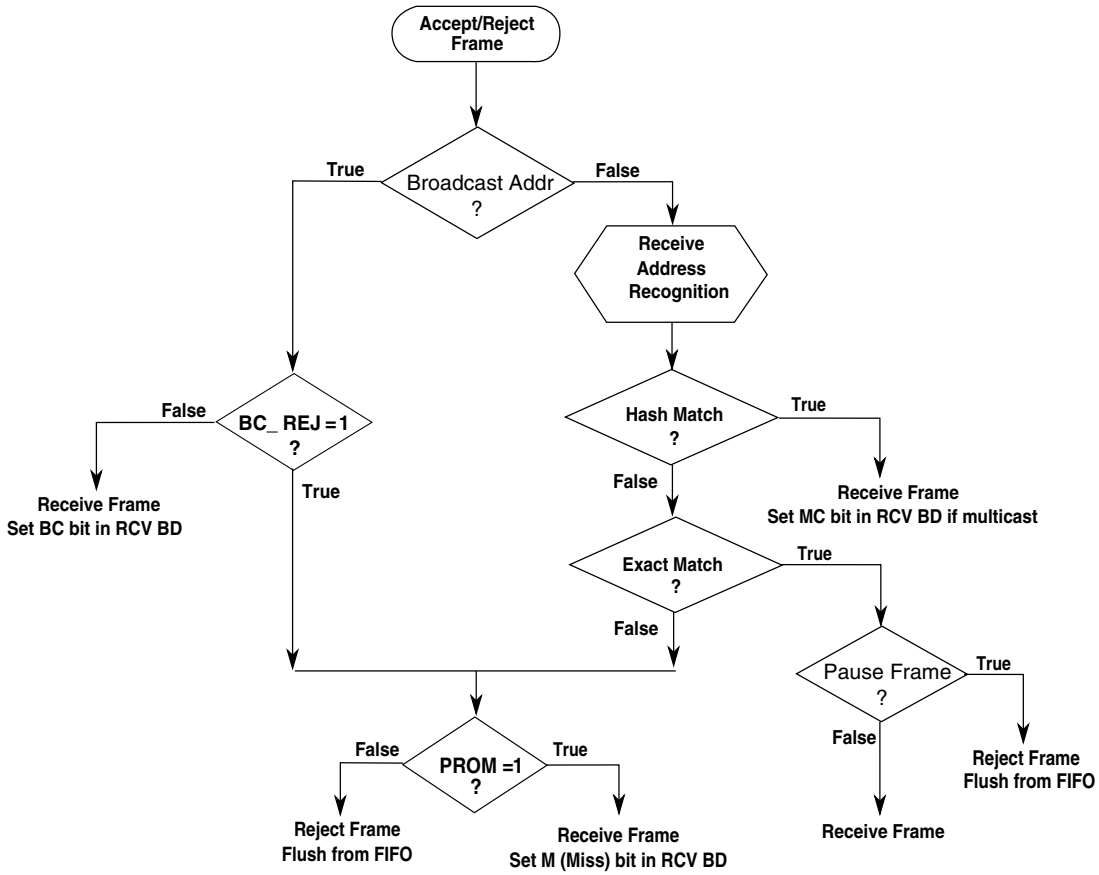
52.6.11 Ethernet address recognition

The FEC filters the received frames based on destination address (DA) type — individual (unicast), group (multicast), or broadcast (all-ones group address). The difference between an individual address and a group address is determined by the I/G bit in the destination address field. A flowchart for address recognition on received frames appears in the figures below.

Address recognition is accomplished through the use of the receive block and microcode running on the microcontroller. The flowchart shown in Figure 52-84 illustrates the address recognition decisions made by the receive block, while Figure 52-85 illustrates the decisions made by the microcontroller.

If the DA is a broadcast address and broadcast reject (RCR[BC_REJ]) is cleared, then the frame is accepted unconditionally, as shown in Figure 52-84. Otherwise, if the DA is not a broadcast address, then the microcontroller runs the address recognition subroutine, as shown in Figure 52-85.

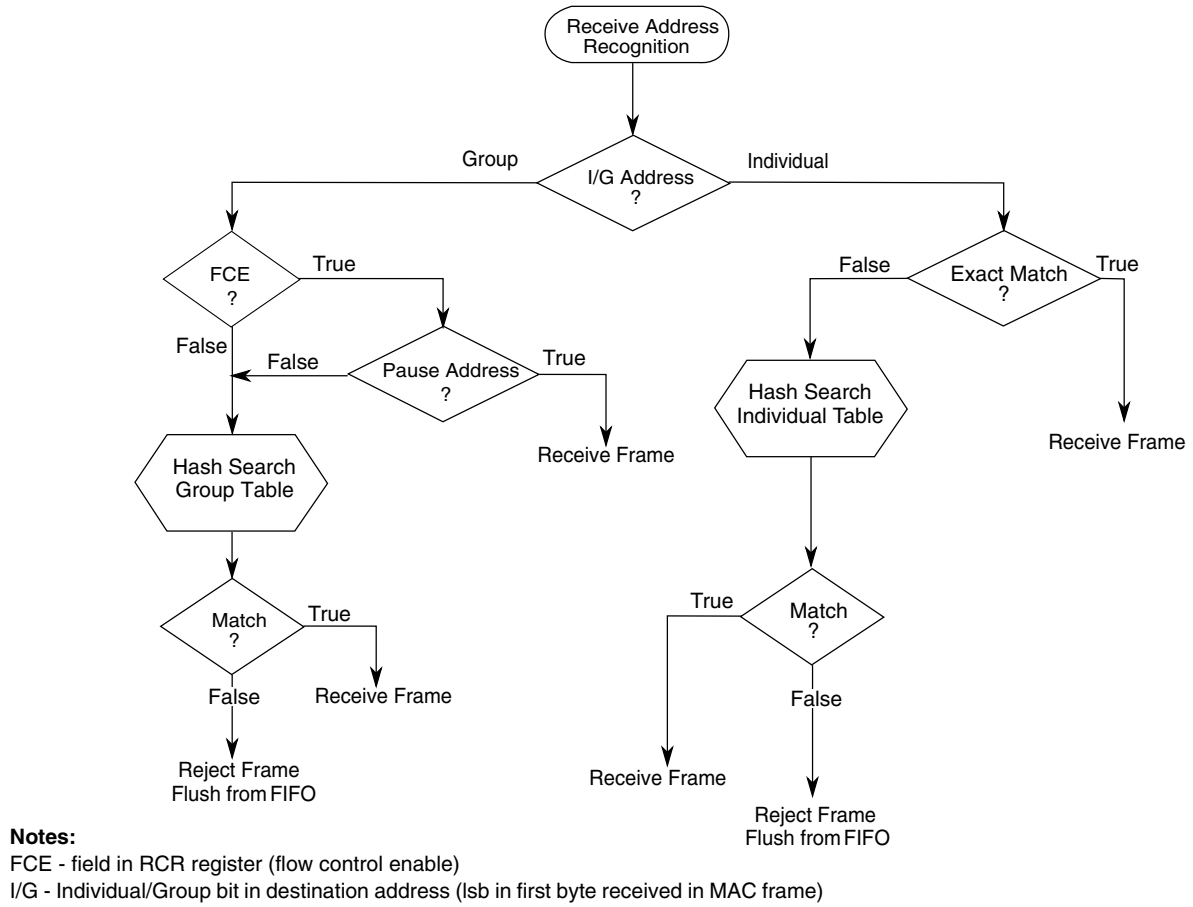
If the DA is a group (multicast) address and flow control is disabled, then the microcontroller performs a group hash table lookup using the 64-entry hash table programmed in GAUR and GALR. If a hash match occurs, the receiver accepts the frame.



If flow control is enabled, the microcontroller does an exact address match check between the DA and the designated PAUSE DA (01:80:C2:00:00:01). If the receive block determines the received frame is a valid PAUSE frame, the frame is rejected. The receiver detects a PAUSE frame with the DA field set to the designated PAUSE DA or the unicast physical address.

If the DA is the individual (unicast) address, the microcontroller performs an individual exact match comparison between the DA and 48-bit physical address that you program in the PALR and PAUR registers. If an exact match occurs, the frame is accepted; otherwise, the microcontroller does an individual hash table lookup using the 64-entry hash table programmed in registers, IAUR and IALR. In the case of an individual hash match, the frame is accepted. Again, the receiver accepts or rejects the frame based on PAUSE frame detection, shown in Figure 52-84.

If neither a hash match (group or individual) nor an exact match (group or individual) occur, and if promiscuous mode is enabled (RCR[PROM] set), the frame is accepted and the MISS bit in the receive buffer descriptor is set; otherwise, the frame is rejected.



Similarly, if the DA is a broadcast address, broadcast reject (RCR[BC_REJ]) is asserted, and promiscuous mode is enabled, the frame is accepted and the MISS bit in the receive buffer descriptor is set; otherwise, the frame is rejected.

In general, when a frame is rejected, it is flushed from the FIFO.

Notes:
BC_REJ - field in RCR register (BroadCast REJect)
PROM - field in RCR register (PROMiscous mode)
Pause Frame - valid PAUSE frame received

Figure 52-84. Ethernet address recognition—receive block decisions

Notes:
FCE - field in RCR register (flow control enable)
I/G - Individual/Group bit in destination address (lsb in first byte received in MAC frame)

Figure 52-85. Ethernet address recognition—microcode decisions

52.6.12 Hash algorithm

The hash table algorithm used in the group and individual hash filtering operates as follows. The 48-bit destination address is mapped into one of 64 bits, represented by 64 bits stored in GAUR, GALR (group address hash match), or IAUR, IALR (individual address hash match). This mapping is performed by passing the 48-bit address through the on-chip 32-bit CRC generator and selecting the six most significant bits of the CRC-encoded result to generate a number between 0 and 63. The msb of the CRC result selects GAUR (msb = 1) or GALR (msb = 0). The five least significant bits of the hash result select the bit within the selected register. If the CRC generator selects a bit set in the hash table, the frame is accepted; otherwise, it is rejected.

For example, if eight group addresses are stored in the hash table and random group addresses are received, the hash table prevents roughly 56/64 (87.5%) of the group address frames from reaching memory. Those that do reach memory must be further filtered by the processor to determine if they truly contain one of the eight desired addresses.

The effectiveness of the hash table declines as the number of addresses increases.

The user must initialize the hash table registers. Use this CRC32 polynomial to compute the hash:

$$X^{32}+X^{26}+X^{23}+X^{22}+X^{16}+X^{12}+X^{11}+X^{10}+X^{8}+X^{7}+X^{5}+X^{4}+X^{2}+X+1$$

Figure 52-86. CRC32 polynomial for hash computation

The following table contains example destination addresses and corresponding hash values.

Table 52-97. Destination address to 6-bit hash

48-BIT DA	6-bit hash (in hex)	Hash decimal value
65FF_FFFF_FFFF	0h	0
55FF_FFFF_FFFF	1h	1
15FF_FFFF_FFFF	2h	2
35FF_FFFF_FFFF	3h	3
B5FF_FFFF_FFFF	4h	4
95FF_FFFF_FFFF	5h	5
D5FF_FFFF_FFFF	6h	6
F5FF_FFFF_FFFF	7h	7
DBFF_FFFF_FFFF	8h	8
FBFF_FFFF_FFFF	9h	9
BBFF_FFFF_FFFF	Ah	10
8BFF_FFFF_FFFF	Bh	11
0BFF_FFFF_FFFF	Ch	12
3BFF_FFFF_FFFF	Dh	13
7BFF_FFFF_FFFF	Eh	14
5BFF_FFFF_FFFF	Fh	15
27FF_FFFF_FFFF	10h	16
07FF_FFFF_FFFF	11h	17
57FF_FFFF_FFFF	12h	18

52.6.13 Full duplex flow control

Full-duplex flow control allows you to transmit pause frames and to detect received pause frames. Upon detection of a pause frame, MAC data frame transmission stops for a given pause duration.

To enable PAUSE frame detection, the FEC must operate in full-duplex mode (TCR[FDEN] set) with flow control (RCR[FCE] set). The FEC detects a pause frame when the fields of the incoming frame match the pause frame specifications, as shown in the following table. In addition, the receive status associated with the frame should indicate that the frame is valid.

Table 52-98. PAUSE frame field specification

48-bit destination address	0180_C200_0001h or Physical Address
48-bit source address	Any
16-bit type	8808h
16-bit opcode	0001h
16-bit PAUSE duration	0000h — FFFFh

The receiver and microcontroller modules perform PAUSE frame detection. The microcontroller runs an address recognition subroutine to detect the specified pause frame destination address, while the receiver detects the type and opcode pause frame fields. On detection of a pause frame, TCR[GTS] is set by the FEC internally. When transmission has paused, the EIR[GRA] interrupt is asserted and the pause timer begins to increment. The pause timer uses the transmit backoff timer hardware for tracking the appropriate collision backoff time in half-duplex mode. The pause timer increments once every slot time, until OPD[PAUSE_DUR] slot times have expired. On OPD[PAUSE_DUR] expiration, TCR[GTS] is cleared allowing MAC data frame transmission to resume. The receive flow control pause status bit (TCR[RFC_PAUSE]) is set while the transmitter pauses due to reception of a pause frame.

To transmit a pause frame, the FEC must operate in full-duplex mode and you must set flow control pause (TCR[TFC_PAUSE]). After TCR[TFC_PAUSE] is set, the transmitter sets TCR[GTS] internally. When the transmission of data frames stops, the EIR[GRA] (graceful stop complete) interrupt asserts and the pause frame is transmitted. TCR[TFC_PAUSE,GTS] are then cleared internally.

You must specify the desired pause duration in the OPD register.

When the transmitter pauses due to receiver/microcontroller pause frame detection, TCR[TFC_PAUSE] may remain set and cause the transmission of a single pause frame. In this case, the EIR[GRA] interrupt is not asserted.

52.6.14 Inter-Packet Gap (IPG) time

The minimum inter-packet gap time for back-to-back transmission is 96 bit times. After completing a transmission or after the backoff algorithm completes, the transmitter waits for carrier sense to be negated before starting its 96 bit time IPG counter. Frame transmission may begin 96 bit times after carrier sense is negated if it stays negated for at least 60 bit times. If carrier sense asserts during the last 36 bit times, it is ignored and a collision occurs.

The receiver accepts back-to-back frames with a minimum spacing of at least 28 bit times. If an inter-packet gap between receive frames is less than 28 bit times, the receiver may discard the following frame.

52.6.15 Collision managing

If a collision occurs during frame transmission, the Ethernet controller continues the transmission for at least 32 bit times, transmitting a JAM pattern consisting of 32 ones. If the collision occurs during the sequence, a JAM pattern is sent after the end of the preamble sequence.

If a collision occurs within 512 bit times (one slot time), the retry process is initiated. The transmitter waits a random number of slot times. If a collision occurs after 512 bit times, then no retransmission is performed and the end of frame buffer is closed with a Late Collision (LC) error indication.

52.6.16 MII internal and external loopback

Internal and external loopback are supported by the Ethernet controller. In loopback mode, both of the FIFOs are used and the FEC actually operates in a full-duplex fashion. Internal and external loopback are configured using combinations of the RCR[LOOP, DRT] and TCR[FDEN] bits.

Set FDEN for internal and external loopback.

For internal loopback, set RCR[LOOP] and clear RCR[DRT]. FEC_TXEN and FEC_TXER do not assert during internal loopback. During internal loopback, the transmit/receive data rate is higher than in normal operation because the transmit and receive blocks use the internal bus clock instead of the clocks from the external transceiver. This causes an increase in the required system bus bandwidth for transmit

and receive data being DMA'd to/from external memory. It may be necessary to pace the frames on the transmit side and/or limit the size of the frames to prevent transmit FIFO underruns and receive FIFO overflows.

For external loopback, clear RCR[LOOP] and RCR[DRT], and configure the external transceiver for loopback.

52.6.17 RMII loopback

The FEC also supports RMII loopback. In this mode, transmit data is sent to the RMII receive logic and out the FEC_TXD[1:0] pins. To enable RMII loopback mode, set RCR[RMII_MODE, RMII_LOOP] and TCR[FDEN] and clear RCR[RMII_ECHO, LOOP].

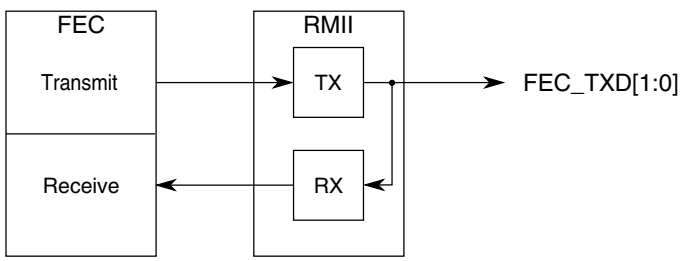

Figure 52-87. RMII loopback mode

52.6.18 RMII echo

The Ethernet controller also supports RMII echo mode, which transmits data on FEC_TXD[1:0] as it is received on FEC_RXD[1:0]. To enable RMII echo mode, set RCR[RMII_MODE, RMII_ECHO] bits and clear RCR[RMII_LOOP, LOOP].

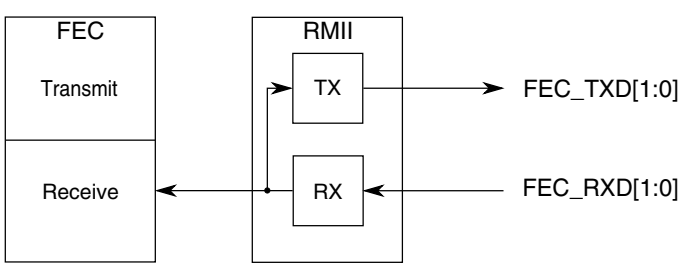

Figure 52-88. RMII echo mode

52.6.19 Ethernet error-managing procedure

The Ethernet controller reports frame reception and transmission error conditions using the MIB block counters, the FEC RxBDs, and the EIR register.

52.6.19.1 Transmission errors

52.6.19.1.1 Transmitter underrun

If this error occurs, the FEC sends 32 bits that ensure a CRC error and stops transmitting. All remaining buffers for that frame are then flushed and closed, and EIR[UN] is set. The FEC then continues to the next transmit buffer descriptor and begin transmitting the next frame. The UN interrupt is asserted if enabled in the EIMR register.

52.6.19.1.2 Retransmission attempts limit expired

When this error occurs, the FEC terminates transmission. All remaining buffers for that frame are flushed and closed, and EIR[RL] is set. The FEC then continues to the next transmit buffer descriptor and begins transmitting the next frame. The RL interrupt is asserted if enabled in the EIMR register.

52.6.19.1.3 Late collision

When a collision occurs after the slot time (512 bits starting at the Preamble), the FEC terminates transmission. All remaining buffers for that frame are flushed and closed, and EIR[LC] is set. The FEC then continues to the next transmit buffer descriptor and begins transmitting the next frame. The LC interrupt is asserted if enabled in the EIMR register.

52.6.19.1.4 Heartbeat

Some transceivers have a self-test feature called heartbeat or signal quality error. To signify a good self-test, the transceiver indicates a collision to the FEC within four microseconds after completion of a frame transmitted by the Ethernet controller. This indication of a collision does not imply a real collision error on the network, but is rather an indication that the transceiver continues to function properly. This is the heartbeat condition.

If TCR[HBC] is set and the heartbeat condition is not detected by the FEC after a frame transmission, a heartbeat error occurs. When this error occurs, the FEC closes the buffer, sets EIR[HB], and generates the HBERR interrupt if it is enabled.

52.6.19.2 Reception errors

52.6.19.2.1 Overrun error

If the receive block has data to put into the receive FIFO and the receive FIFO is full, FEC sets RxBD[OV]. All subsequent data in the frame is discarded and subsequent frames may also be discarded until the receive FIFO is serviced by the DMA and space is made available. At this point the receive frame/status word is written into the FIFO with the OV bit set. The driver must discard this frame.

52.6.19.2.2 Non-octet error (dribbling bits)

The Ethernet controller manages up to seven dribbling bits when the receive frame terminates past an non-octet aligned boundary. Dribbling bits are not used in the CRC calculation. If there is a CRC error, the frame non-octet aligned (NO) error is reported in the RxBD. If there is no CRC error, no error is reported.

52.6.19.2.3 CRC error

When a CRC error occurs with no dribble bits, FEC closes the buffer and sets RxBD[CR]. CRC checking cannot be disabled, but the CRC error can be ignored if checking is not required.

52.6.19.2.4 Frame length violation

When the receive frame length exceeds MAX_FL bytes the BABR interrupt is generated, and RxBD[LG] is set. The frame is not truncated unless the frame length exceeds 2047 bytes.

52.6.19.2.5 Truncation

When the receive frame length exceeds 2047 bytes, frame is truncated and RxBD[TR] is set.

Chapter 53
SENT Receiver (SRX)

53.1 SENT chip-specific modules information

The Single Edge Nibble Transmission (SENT) module is designed as a receiver for transmitting sensor nodes using the SENT protocol (as documented by the SAE J2716 information report). SENT is a unidirectional communications scheme from a sensor (transmitting) device to a controller (receiving) device which does not include a coordination signal from the controller/receiving device.

Table 53-1. SENT modules/channels implemented on this device

Instantiated module	Base address
SENT_0	FFE5C000
SENT_1	FBE5C000

53.1.1 SRX_GBL_CTRL[NIB_LEN_VAR_LIMIT] setting

Software must set SRX_GBL_CTRL[NIB_LEN_VAR_LIMIT] to 1 to guarantee the performance of this module on this chip.

53.2 Introduction

The Single Edge Nibble Transmission (SENT) Receiver (SRX) module is a multi-channel receiver for receiving serial data frames which are being transmitted by a sensor implementing the SENT encoding scheme and present them to the CPU for further processing.

This module is based on the SAE J2716 information report titled "SENT - Single Edge Nibble Transmission for Automotive Applications" and released on January 27, 2010 (http://www.sae.org), Apr2007 and Feb2008. As per this standard, the SENT protocol is intended for use in applications where high resolution sensor data needs to be communicated from a sensor to an Engine Control Unit (ECU). It is intended as a replacement for the lower resolution methods of 10 bit A/Ds and PWM and as a simpler low-cost alternative to CAN or LIN. The implementation assumes that the sensor is a smart sensor containing a microprocessor or dedicated logic device (ASIC) to create the signal.

The SENT encoding scheme is a unidirectional communications scheme from the sensor / transmitting device to the controller /receiving device which does not include a coordination signal from the controller/receiving device. The sensor signal is transmitted as a series of pulses with data encoded as falling to falling edge periods.

53.2.1 Features

The SENT receiver module has the following features:

- The number of SENT channels supported are device-specific. See the device configuration details.
- Unified message read logic to transfer all messages received to system memory via interrupts or DMA
  - Programmable option per channel to support reading of messages via DMA or Interrupt
  - Internal round robin arbitration sequencer to loop across channels to read messages from each channel leaving CPU/DMA transparent to this process
  - All received messages are stored excluding the synchronization pulse (for Fast messages) and identifiers (for Slow Serial Messages)

    - Separate buffers for storing Fast and Slow Serial Messages
    - Separate DMA and Interrupts generated for Fast and Slow Serial Messages
- Supports compensation for variation in SENT Tx Clock up to ±25% and adjusts its measurement for drift in the Transmitter and Receiver clocks per channel
    - Calibration pulse correction factor per channel is available for use by software
- Implements for each channel all receiver diagnostics as specified by the SAE Specifications
- Internal 4-bit CRC calculator that can be configured to compute CRC in both Legacy and Recommended method (as given in SAE SENT Specification) for both Fast and Short Serial Message per channel
- Internal 6-bit CRC calculator for Enhanced Serial Messages per channel
- Supports all bit rates by having per channel configurable Rx clock periods from 3 µs to 90 µs
- Support for configurable number of data nibbles per channel
- Option to disable individual channel via programmable control bit
- Time stamping on start of each valid message (i.e. without errors) across all channels. This time stamp is appended to each message for synchronization of messages and for application to understand how much time has elapsed between successive sensor readings
- Support for pause pulse per channel. This can be enabled by programming a bit in the control register for that channel
- Input Programmable Filter on each channel to filter any glitches on input. This filter duration is programmable by the user software.
- 32-bit register interface for programming the module's registers and reading the received messages
- Works on two clocks, one for accurate receive operations (high frequency receiver clock or protocol clock) and other for message read logic (system bus clock) and the module can work irrespective of the frequency relationship between the two clocks. See Clocks and resets for more details on the clocks.

53.2.2 Modes of operation

Modes of operation.

53.2.2.1 Debug mode

In debug mode, message reception will be halted (without waiting for the current message being received to be completed) and all existing status and messages will be retained. DBG_FRZ bit is required to be set for this mode. On debug exit, a calibration length error (CAL_LEN_ERR) can be reported and the channels will start receiving messages from a valid calibration pulse.

53.2.2.2 Low power modes

SENT Receiver behavior is affected by chip-specific low power modes (for example, STOP or WAIT modes). These low power modes should either gate-off both the system bus clock and the protocol clocks or reduce their frequencies, depending on the application.

On exiting from these low power modes, calibration length error (CAL_LEN_ERR) can get set in channel status registers as the SENT sensor (transmitter) could be in the middle of a message transmission at that point. Thus, software should clear all error status bits after exiting the low power modes.

Modes where both system bus clock and protocol clock are gated: In this case, both message reception and interrupt / DMA request generation will halt. The internal receiver channels will freeze (since clock is not there) and will not receive any messages. Messages which are completely received before entering the low power mode can be read after the low power mode exit.

Modes where frequency of system bus clock is changed: For reduced power consumption the system bus clock can be reduced but not below a minimum value (See System bus clock requirements) to avoid overflow of received messages. Protocol clock should not go below the minimum value (See High frequency receiver clock (protocol clock) requirements) for accurate receive operations.

Note

Gating of clocks in the low power mode is chip-specific, see the chapter that refers how the modules behave in low power modes.

NOTE

If the SOC requests entry to debug or stop mode, the message being received currently is discarded and the SOC enters debug/ stop mode immediately. This does not affect the messages received completely prior to entering debug mode and will still be present on the message buffer and registers until they are read out.

NOTE

The message read registers [Channel ‘n' Fast Message Data Read Register (n = 0 to (CH-1)) (CHn_FMSG_DATA), Channel ‘n' Fast Message CRC Read Register (n = 0 to (CH-1)) (CHn_FMSG_CRC), Channel ‘n’ Fast Message Time Stamp Read Register (n = 0 to (CH-1)) (CHn_FMSG_TS), Channel ‘n’ Serial Message Read Register (Bit 3) (n = 0 to (CH-1)) (CHn_SMSG_BIT3), Channel ‘n’ Serial Message Read Register (Bit 2) (n = 0 to (CH-1)) (CHn_SMSG_BIT2), Channel ‘n’ Serial Message Time Stamp Read Register (n = 0 to (CH-1)) (CHn_SMSG_TS), DMA Fast Message Data Read Register (DMA_FMSG_DATA), DMA Fast Message CRC Read Register (DMA_FMSG_CRC), DMA Fast Message Time Stamp Read Register (DMA_FMSG_TS), DMA Slow Serial Message Bit3 Read Register (DMA_SMSG_BIT3), DMA Slow Serial Message Bit2 Read Register (DMA_SMSG_BIT2) and DMA Slow Serial Message Time Stamp Read Register (DMA_SMSG_TS)] will appear to lose their contents in the following conditions:

- The very first message is being received but not yet completely received and the MCU enters debug or freeze mode, the current message reception will get discarded and message read registers (as mentioned above) will read zeros
- Auto clear functionality is enabled (GBL_CTRL[FAST_CLR] = 1). In this case, when first message is read, it will get clear the message read registers (due to auto clear functionality being enabled). On reading again, the message read registers (as mentioned above) might read zeros.

If the MCU requests entry to debug or stop mode, the message being received currently by SENT Receiver is discarded and the MCU enters debug/stop mode immediately. This does not affect the messages received completely, prior to entering debug

mode and these messages will still be present on the message buffer and registers until they are read out. Thus allow one message to be received completely and do not enable "Auto Clear" (GBL_CTRL[FAST_CLR] = 0), to allow messages to be read in debug or stop mode.

53.2.3 Block diagram

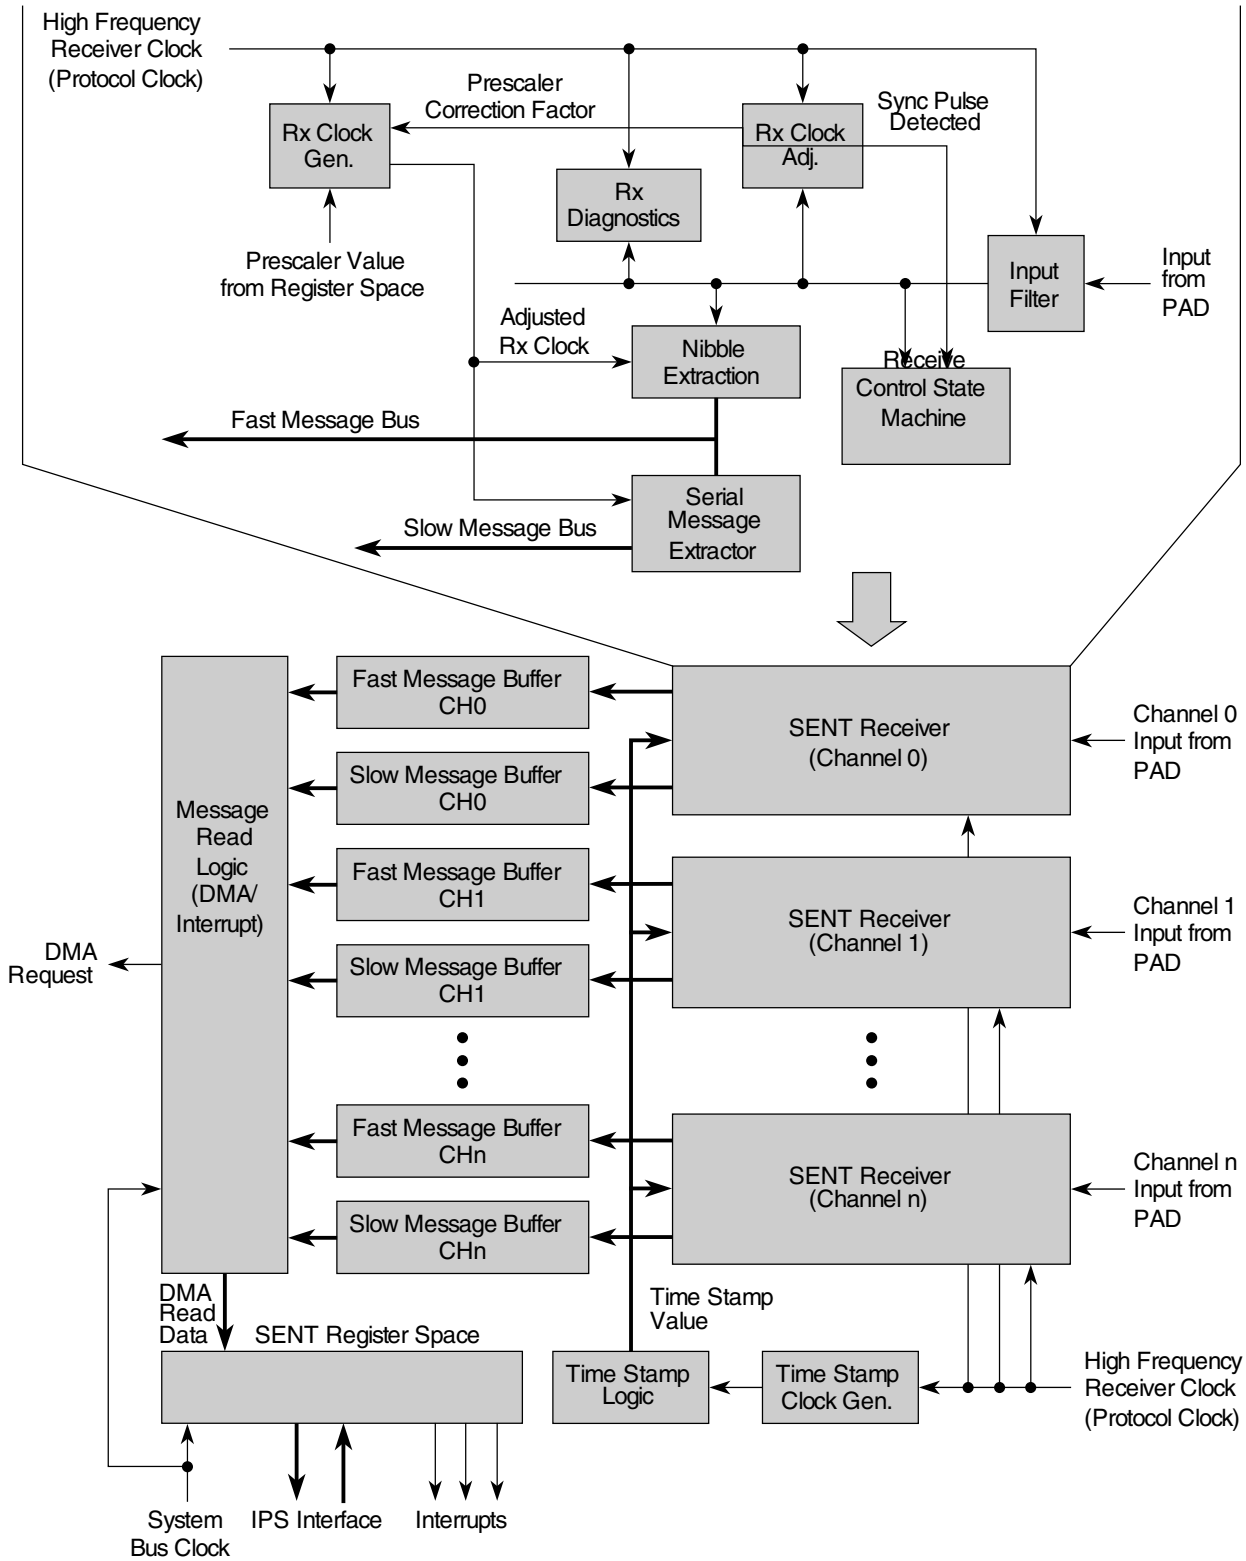

Figure 53-1. SENT Receiver block diagram

53.2.4 Design overview

The SENT Receiver Module is a unified receiver module comprising of a number of receiver channels and a unified DMA and Register Space for accessing the messages from each channel. Figure 53-1 shows the top level block diagram for the SENT Receiver module.

Each channel of the SENT Receiver is composed of a Clock Generation and Adjustment block to generate the receiver clock and adjust it for frequency variation in the transmitter clock. This block also detects the synchronization/calibration pulse which is present in every SENT message.

The SENT Receiver State Machine controls the sequencing of decoding the messages and combining the information as nibbles. In parallel a diagnostic block is running that monitors the incoming messages for any errors and also verifies the CRC of the received messages. The fast and serial message extractors collate the message nibbles and add the channel number and time stamp information to the messages.A free running time stamp counter is used to add the time stamp value to each message received. The value of this counter is input to each channel and the channel logic appends the time stamp to each message. These messages are then formatted to be stored in the corresponding message read buffer. Only the messages that pass the diagnostics checks are forwarded to be stored in the buffers.

The SENT Receiver provides two mechanisms for reading the received messages, which are via DMA transfers and via Interrupts. Based on the control bit settings in the control registers, a DMA request or Interrupt is asserted to signal the DMA controller or CPU that messages are available to be read.

The free running time stamp counter, register block and DMA interface are common for all channels configured. The register space contains all the necessary registers for all channels. The register space is 32-bit aligned and accessible via 8-/16-/32-bit accesses. The registers for all un-configured channels are marked as reserved.

53.2.4.1 Functional overview

After reset, the SENT module comes up in the disabled state. All channel enable bits and the global enable bit are set to 0 and the user software must program the SENT module parameters correctly before enabling it. The user software must correctly configure all parameters to avoid any underflow or overflow in the message buffers.

Once enabled, the Receiver Clock Generation and Adjustment block detects the synchronization pulse. Until then, the state machine blocks all subsequent operations of the receiver. Once the synchronization pulse is detected, the receiver clock tick period is compensated for variation in transmitter clock tick period and the state machine then waits for the reception of data nibbles. The adjusted receiver clock is used to sample the data nibbles from the incoming serial message. The state machine waits until the status and communication nibble and configured number of data nibbles are received. The state machine then waits for the pause pulse (if configured to receive a pause pulse). The fast and serial message extractor block provides the state machine with the information on how many nibbles have been received. All diagnostics checks are computed in parallel. Once all required data nibbles are received, the CRC is checked, time stamp and channel number is added to the message. The time stamp for a Fast Message is sampled at the falling edge that comes at the end of the calibration pulse (which is also the start of the status and communication nibble pulse) and is stored in the message read buffer along with the message. This final message is stored in the message buffer as described in the subsequent sections. Any error detected during the receive process causes the status bits in the corresponding channel's status register to be set.

The above process repeats across each enabled channel in parallel and keeps pushing error free messages into the buffers on high frequency receiver clock. The module's message read logic synchronizes all these messages on the bus clock and pops out these messages on any DMA or CPU read access. Any DMA underflow errors are stored in the global status register while the overflow errors are stored in the corresponding channel's status register. In case of an overflow in Fast Messages, the newer messages received will overwrite the previous message.

For detailed description on the complete functionality of each block, see Functional description.

53.3 External signal description

This section lists all inputs to the SENT Receiver block.

53.3.1 SENT_RX [(CH-1):0]

These pins serve as the serial data input for each of the SENT Receiver channel. There is one bit per channel supported by the device. The SENT sensor input pads on the device using this module should have pull-up enabled to ensure a 1'b1 is seen at the module input when SENT sensor is not driving any data.

Note

The value of CH is device-specific. See the device configuration details.

53.4 Memory map and register definition

This section provides a detailed description of all registers accessible in the SENT Receiver block.

The following table gives an overview on all SENT Receiver registers. The memory map comprises of 32-bit aligned registers which can be accessed via 8-bit, 16-bit, or 32-bit accesses. Write access to reserved locations will generate transfer error. Read access to reserved locations will also generate transfer error and the read data bus will show all 0s. The Memory Map and complete module is in Big Endian Format.

The module will not check for correctness of programmed values in Register Space and software must ensure that correct values are being written.

NOTE

Register Address = Base Address + Address Offset, where the Base Address is defined at the MCU level and the Address Offset is defined at the module level. The number of registers are device specific. See the device configuration section for details.

NOTE

The value of the CH is device-specific. See the device configuration section for details.

53.4.1 Global Control Register (SRX_GBL_CTRL)

This register provides the global control and setting for the SENT Receiver Module. The SENT_EN bit must be programmed after all other modules settings and control bits have been written to.

Address: 0h base + 0h offset = 0h

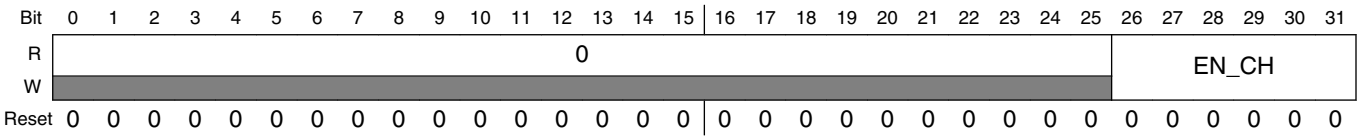
SRX_GBL_CTRL field descriptions

Field	Description
0–7 TSPRSC	Time Stamp Prescaler Value. Value in number of clock cycles of high frequency receiver clock set in order to obtain a clock frequency for the time stamp counter block. 0 to 255 - Time Stamp Clock = (High Frequency Clock)/(Value + 1). Value set by user software should be such that the clock period is at least 1 µs. If the high frequency clock input is 75 MHz, then the value set in this field would be 0x4A (or 74) to obtain a 1 µs clock. Note: Since the time stamp clock is common for all channels, the timestamp clock frequency must be at least twice the fastest receiver channel in the application. This is to ensure that the time stamp clock is fast enough to show change in timestamp from message to message.
8–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 NIB_LEN_VAR_LIMIT	Decides the allowable jitter/clock drift limit for nibble length measurement. **NOTE:** This bit should be set to 1 for proper functioning of Sent Rx. 0 Allows a jitter/clock drift of approx upto 12.5% of transmitter clock tick period. This actual allowed jitter/drift value is dependent on the transmitter clock tick period and HF receiver clock period. 1 Allows a jitter/clock drift as per SAE spec (50%).

Table continues on the next page...

SRX_GBL_CTRL field descriptions (continued)

Field	Description
17–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22 FMDUIE	Fast Message DMA Underflow Interrupt Enable: Enables interrupt assertion when there is an underflow condition on Fast Message DMA registers. Default value is 0. 0 Interrupt is disabled 1 Interrupt is enabled
23 SMDUIE	Slow Serial Message DMA Underflow Interrupt Enable: Enables interrupt assertion when there is an underflow condition on Slow Message DMA registers. Default value is 0. 0 Interrupt is disabled 1 Interrupt is enabled
24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 FAST_CLR	Fast Clearing Enable bit. Enables clearing of ready status (for both fast and slow) bit automatically when corresponding message is read. Default value is 1. See Fast Message Ready Status Register (SRX_FMSG_RDY) and Slow Serial Message Ready Status Register (SRX_SMSG_RDY) for details on the ready status bits. 0 Fast Clearing is disabled. Bits will be cleared by writing 1 1 Fast Clearing is enabled
28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29 DBG_FRZ	Debug Freeze. This bit will enable the debug mode support. SENT Module will freeze in debug mode if this bit is set. Default is 0. 0 No effect in debug mode 1 Freeze in debug mode
30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 SENT_EN	SENT Receiver Global Enable. This bit enables or disables the complete receiver module irrespective of the setting of individual channel enable bits. User software must program all channel parameters before setting this bit. Default is 0. 0 Entire module is disabled 1 Module is enabled



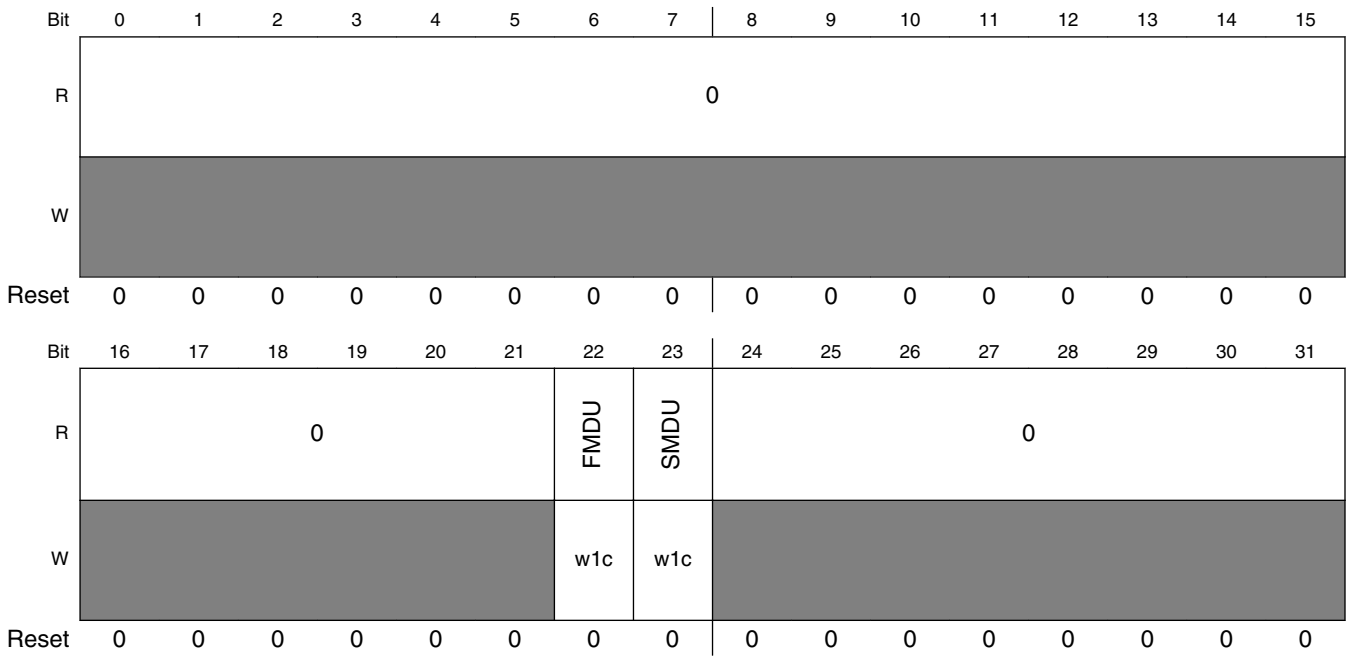
53.4.2 Channel Enable Register (SRX_CHNL_EN)

This register is used to enable individual SENT Receiver channels in the module. The user software must ensure all channel parameters and control settings have been programmed before writing to this bit. In case these parameters are changed while the channel is enabled, normal operation is not guaranteed.

NOTE

Reads of bits beyond those for the supported number of channels should be ignored, and these bits must be written to 0.

Address: 0h base + 4h offset = 4h



SRX_CHNL_EN field descriptions

Field	Description
0–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26–31 EN_CH	Enable bits for channels 5 to 0 . All channels are disabled after reset. User software must program all channel parameters before setting this bit. Once set, other channel parameters in registers should not be changed until this bit is cleared. Only Interrupt Enable and Status bits can be written to. 0 Channel is disabled 1 Channel is enabled. Channel parameter registers are locked for writing

53.4.3 Global Status Register (SRX_GBL_STATUS)

This register provides the status of various conditions in the module that are common across all channels.

Address: 0h base + 8h offset = 8h

SRX_GBL_STATUS field descriptions

Field	Description
0–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22 FMDU	Fast Message DMA Underflow: Interrupt Status bit that indicates when there is an underflow in Fast Message buffers in any channel which has DMA enabled. This bit is set when there is no message in the DMA buffers for read and the software still reads the Fast Message DMA register. Default value is 0. 0 No underflow 1 Underflow occurred
23 SMDU	Slow Serial Message DMA Underflow: Interrupt Status bit that indicates when there is an Underflow in Slow Serial Message DMA buffers on channel which has DMA enabled. The bit is set when there is no message in the DMA buffers for read and the software still reads the Slow Serial Message registers. Default value is 0. 0 No underflow 1 Underflow occurred
24–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

53.4.4 Fast Message Ready Status Register (SRX_FMSG_RDY)

The bits of this register are asserted when a Fast Message arrives on a corresponding channel that is not configured to be read via DMA. If a channel is not configured for DMA (viaFast Message DMA Control Register (SRX_FDMA_CTRL)), it is assumed to be read via Interrupt or Polling this status bit. Even if the Interrupt Enable bit for that channel is not set (viaFast Message Ready Interrupt Control Register (SRX_FRDY_IE)) and the channel is enabled, the message ready status bit in this register will be asserted on Fast Message reception. Software must ensure that if a channel is enabled; either DMA or Interrupt must be enabled for that channel. Proper flow cannot be guaranteed if neither is selected.

These bits can be configured to be cleared via "Write 1 to Clear" or "Fast Clearing Mechanism". The configuration is done by writing to the FAST_CLR bit in theGlobal Control Register (SRX_GBL_CTRL) .

NOTE

Reads of bits beyond those for the supported number of channels should be ignored. Writes to these bits is ignored by the Receiver.

Address: 0h base + Ch offset = Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

SRX_FMSG_RDY field descriptions

Field	Description
0–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26–31 F_RDY	Fast Message Data Ready Status bits for channels 5 to 0 . Each bit indicates that a Fast Message is ready to be read by CPU from that specific channel. This bit is asserted only when DMA is NOT enabled for that channel (from the DMA Control Register) and an error free message is received, irrespective of the value of corresponding enable bit in Message Ready Interrupt Control Register. Reading the message from the corresponding memory-mapped Fast Message Read Registers would automatically clear this bit (Fast Clearing Mechanism). **NOTE:** These bits are either "write 1 to clear" (w1c) or self-clearing depending on the value of the FAST_CLR BIT in the Global Control Register (GBL_CTRL). The clearing mechanism is selected by user by programming the FAST_CLR bit in the Global Control register. See Section Global Control Register (SRX_GBL_CTRL) for details on FAST_CLR bit. **NOTE:** When using the fast clearing option, these bits will not clear till the complete message is read out which requires the CPU to read all 3 fast message registers via 32-bit read accesses. For 8/16-bit accesses fast clearing mechanism should not be used as it is not supported.

Table continues on the next page...

SRX_FMSG_RDY field descriptions (continued)

Field	Description
	NOTE: When the fast clearing option is not configured, the bits will be cleared only if 1 is written to those bits. 0 No Fast Message is available to be read out via Interrupt 1 Fast Message is available to be read out via Interrupt

53.4.5 Slow Serial Message Ready Status Register (SRX_SMSG_RDY)

The bits of this register are asserted when a Slow Serial Message arrives on a corresponding channel that is not configured to be read via DMA. If a channel is not configured for DMA (viaFast Message DMA Control Register (SRX_FDMA_CTRL) andSlow Serial Message DMA Control Register (SRX_SDMA_CTRL)), it is assumed to be read via Interrupt or Polling this status bit. Even if the Interrupt Enable bit for that channel is not set (viaFast Message Ready Interrupt Control Register (SRX_FRDY_IE) andSlow Serial Message Ready Interrupt Enable Register (SRX_SRDY_IE)) and the channel is enabled, the message ready status bit in this register will be asserted on Slow Message reception. Software must ensure that if a channel is enabled; either DMA or Interrupt must be enabled for that channel. Erroneous flow can happen if neither is selected.

These bits can be configured to be cleared via "Write 1 to Clear" or "Fast Clearing Mechanism". The configuration is done by writing to the FAST_CLR bit in theGlobal Control Register (SRX_GBL_CTRL).

NOTE

Reads of bits beyond those for the supported number of channels should be ignored. Writes to these bits is ignored by the Receiver.

SRX_SRDY_IE field descriptions

Field	Description
0–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26–31 SRDY_IE	Enable for Slow Serial Message Ready Interrupt on channels 5 to 0 . These bits are writable when corresponding DMA enable bits are set to 0 in the Slow Serial DMA Control Register. The availability of message is indicated via assertion of corresponding bit in Slow Serial Message Ready Status Register irrespective of the value set in corresponding interrupt enable bit and DMA is not enabled. When a bit in this register is asserted, an interrupt for corresponding channel is generated. 0 Interrupt on reception of Slow Serial Messages is disabled 1 Interrupt on reception of Slow Serial Messages is enabled

53.4.11 DMA Fast Message Data Read Register (SRX_DMA_FMSG_DATA)

DMA Source Size must be set to 32 bits when reading this register (DMA_FMSG_DATA) via DMA.

Address: 0h base + 40h offset = 40h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

SRX_DMA_FMSG_DATA field descriptions

Field	Description
0–3 CHNUM	Channel Number. Indicates the channel number of the received message being read by DMA. Valid values are 0 to 5 .
4–7 SCNIB	Status and Communication Nibble of message
8–11 DNIB1	Data Nibble 1. Always supported
12–15 DNIB2	Data Nibble 2. Should be ignored if number of data nibbles supported by channel is 1
16–19 DNIB3	Data Nibble 3. Should be ignored if number of data nibbles supported by channel is 2 or less
20–23 DNIB4	Data Nibble 4. Should be ignored if number of data nibbles supported by channel is 3 or less
24–27 DNIB5	Data Nibble 5. Should be ignored if number of data nibbles supported by channel is 4 or less
28–31 DNIB6	Data Nibble 6. Should be ignored if number of data nibbles supported by channel is 5 or less

53.4.12 DMA Fast Message CRC Read Register (SRX_DMA_FMSG_CRC)

DMA Source Size must be set to 32 bits when reading this register (DMA_FMSG_CRC) via DMA.

Address: 0h base + 44h offset = 44h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

SRX_DMA_FMSG_TS field descriptions

Field	Description
0–31 TS	Time Stamp for received message. Indicates the relative time when the falling edge that comes at the end of the calibration pulse (which is also the start of the status and communication nibble pulse) was detected

53.4.14 DMA Slow Serial Message Bit3 Read Register (SRX_DMA_SMSG_BIT3)

The above register (DMA_SMSG_BIT3) is common for all types of slow serial messages. Bit C defines the type of enhanced packet and bit TYPE defines whether it is short serial or enhanced serial message. Since this register is used to read both Short and Enhanced Serial Messages, the register fields have been placed in such a way to match the bit positions in actual message defined by SAE Specification as shown inTable 53-83,Table 53-84 andTable 53-85.Table 53-83 andTable 53-84 shows the enhanced serial messages format to be used when reading this register for these two types of messages.Table 53-85 shows the short serial message.

DMA Source Size must be set to 32 bits when reading this register via DMA.

NOTE

If the TYPE bit in the register reads '0', then remainder bits (for CFG, ID and DATA) will be redundant and read zeros. The short serial message will be located in DMA_SMSG_BIT2 register fields. If TYPE bit is '1', then the message in register is Enhanced Serial Message and using CFG bit, software can decode the ID and DATA fields.

Address: 0h base + 50h offset = 50h

SRX_DMA_SMSG_BIT3 field descriptions

Field	Description
0–3 CHNUM	Channel Number. Indicates the channel number of the received message being read by DMA. Valid values are 0 to 5 .
4 TYPE	Serial Message Type. Indicates the type of Serial Message received 0 Short Serial Message 1 Enhanced Serial Message
5–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21 CFG	Configuration bit 'C'. Indicates the type of Enhanced Serial message 0 Enhanced Serial Message with 8-bit ID field 1 Enhanced Serial Message with 4-bit ID field
22–25 ID7_4_ID3_0	ID Field. Value depends on setting of 'C' bit. If 'C' bit is 0, this field is ID[7:4] and if the 'C' bit is 1, this field is ID[3:0]
26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27–30 ID3_0_DATA15_12	ID or Data Field. Value depends on setting of 'C' bit. If 'C' bit is 0, this field is ID[3:0] and if the 'C' bit is 1, this field is Data[15:12]
31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

53.4.15 DMA Slow Serial Message Bit2 Read Register (SRX_DMA_SMSG_BIT2)

This register (DMA_SMSG_BIT2) is common for all types of slow serial messages. Hence, the register fields have been placed in such a way to match the bit positions in actual message defined by SAE Specification as shown inTable 53-83,Table 53-84 andTable 53-85.Table 53-83, andTable 53-84 shows the enhanced serial messages format to be used when reading this register for these two types of messages.Table 53-85 shows the short serial message.

DMA Source Size must be set to 32 bits when reading this register via DMA.

Address: 0h base + 54h offset = 54h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

SRX_DMA_SMSG_BIT2 field descriptions

Field	Description
0–9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
10–15 SMCRC	6-bit CRC value of the message. When TYPE bit in DMA Slow Serial Message Bit3 Read Register (SRX_DMA_SMSG_BIT3) is set to 0, this CRC is of 4-bits for Short Serial Messages and when TYPE bit is set to 1, this CRC is of 6-bits for Enhanced Serial Messages.
16–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20–31 DATA[11:0]	12-bit Data Value

53.4.16 DMA Slow Serial Message Time Stamp Read Register (SRX_DMA_SMSG_TS)

The resolution of the time stamp is set by programming the Time Stamp Prescaler Value in the Global Control Register (SRX_GBL_CTRL) register.

DMA Source Size must be set to 32 bits when reading this register (DMA_SMSG_TS) via DMA.

Address: 0h base + 58h offset = 58h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

SRX_DMA_SMSG_TS field descriptions

Field	Description
0–31 TS	Time Stamp for the received message. Indicates the relative time of detection of the falling edge that comes at the end of the calibration pulse (which is also the start of the status and communication nibble pulse) of the last Fast Message that completed the Serial Message. Time Stamp for Slow Serial Messages is not latched when the Slow Serial Message starts but when the Slow Serial Message is completely received.

53.4.17 Channel 'n' Clock Control Register (n = 0 to (CH-1)) (SRX_CH*n*_CLK_CTRL)

NOTE

The value of the CH is device-specific. See the device configuration section for details.

The SENT Receiver module generates the Receiver Sensor Clock (or simply Receiver Clock) internally to sample the incoming filtered sensor data. The user software must program the prescaler value (for Receiver Clock) to match the ideal Sensor Tx Clock period. The generated Receiver Clock is compensated for variations and clock drift that might occur in the Sensor Tx Clock. SeeAdjustment for variation in sensor (Tx) clock for more details.

This register configures the generation and subsequent compensation logic of the Receiver Clock. User must program the contents of this register before enabling the channel by writing to the corresponding channel enable bit in theChannel Enable Register (SRX_CHNL_EN) .

Address: 0h base + 60h offset + (16d × i), where i=0d to 5d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

W																
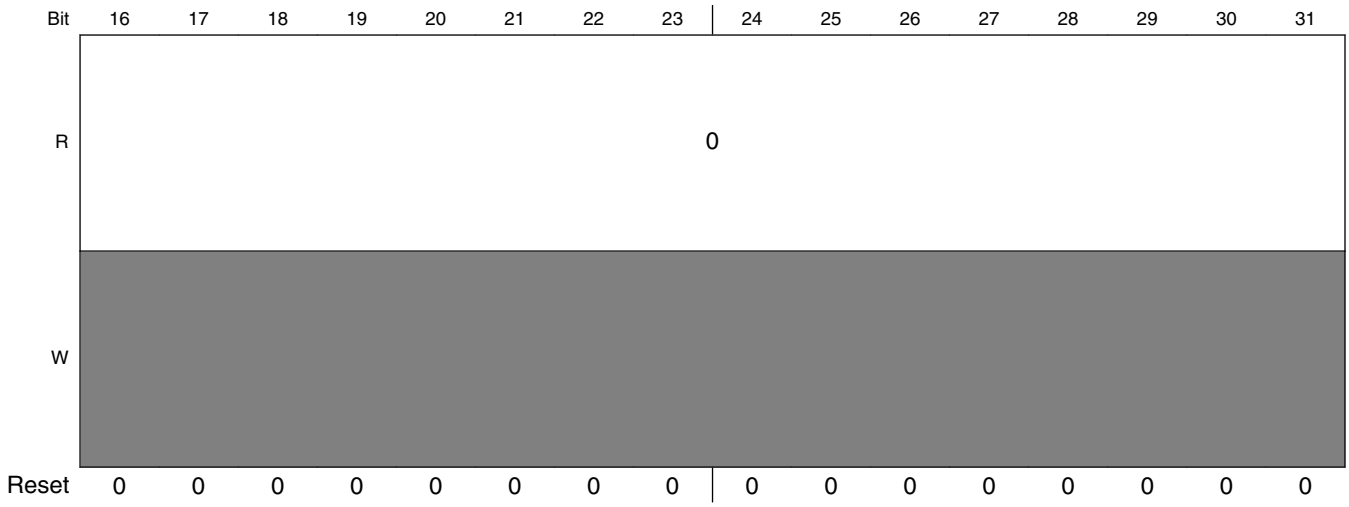
Reset	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SRX_CH*n*_CLK_CTRL field descriptions

Field	Description
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1–15 CM_PRSC	Compensated Prescaler Value. This is the compensated prescaler value calculated by Clock Compensation logic and this value is used to compensate for sensor Tx clock variation. This value is indicated as a read only field for use by user software, if needed. This is a 15-bit value. '= Rx Prescaler Value' No variation, hence no compensation or Compensation is disabled '< Rx Prescaler Value' Tx Clock is SLOWER than the programmed receive clock '> Rx Prescaler Value' Tx Clock is FASTER than the programmed receive clock Thus, the new Receiver Clock Tick Period can be computed by software as Compensated Prescaler Value x High Frequency Receiver Clock Period Note: The value provided in this field is ceil value of actual tick period as measured by the Receiver.
16 COMP_EN	Compensation Enable. To enable compensation logic to adjust the receiver clock against variation in Tx clock on this channel. User must set the Prescaler Value before enabling this bit. 0 Compensation is disabled 1 Compensation is enabled
17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
18–31 PRSC	Rx Prescaler Value. This factor is required to generate required Receiver Clock tick from the High Frequency Receiver Clock. This value can only be written when Channel Enable bit is Zero. Hence this value must be programmed before enabling the channel. If required receiver clock tick period (Trx_clk) is not divisible by the high frequency receiver clock (protocol clock) period (Thf_clk), the required prescaler value will have a fractional part which cannot be programmed. In this case then user is advised to program the prescaler value to the lower integer value. 0 Prescaler is bypassed. Should not be used. Non-Zero Value Enables Prescaler The required value is computed by software as follows: $\text{Prescaler_value} = \text{floor}\left(\frac{T_{\text{rx_clk}}}{T_{\text{hf_clk}}}\right)$ (both clock periods taken in µs). Please seeHigh frequency receiver clock (protocol clock) requirements before setting this value. e.g. if the required receiver clock tick period is 43 µs and the High Frequency Receiver clock is selected to be 62.5 MHz (or 0.016 µs) then, Prescaler Value = 43/0.016 = 2687.5. Hence user must program 2687 in this register.

53.4.18 Channel 'n' Status Register (n=0 to (CH-1)) (SRX_CH*n*_STATUS)

This registers stores information about certain events and error conditions that occur in the channel during the message reception process. The assertion of these bit is not linked to any message but it is a general alert to the CPU that a particular condition (error or normal event) happened in the recent past. Messages are automatically discarded when an error is detected.



User software can clear these bit at any time by writing 1 to them. This register can be updated at any time irrespective of the setting in the Channel Enable Register (SRX_CHNL_EN) bit for the corresponding channel.

NOTE

The value of the CH is device-specific. See the device configuration section for details.

Address: 0h base + 64h offset + (16d × i), where i=0d to 5d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

SRX_CH*n*_STATUS field descriptions

Field	Description
0 BUS_IDLE	Bus Idle Status. This bit indicates that the sensor interface has been idle for more than the period defined by the programmed Bus Idle Count value(in Channel 'n' Configuration Register (n=0 to (CH-1)) (SRX_CH*n*_CONFIG)). CPU should write 1 to this clear this bit once it is read. 0 Bus is not idle 1 Channel has been idle for more than the allowed value
1–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4 CAL_RESYNC	Successive Calibration Check (Option 2 of SAE SENT Spec) Resynchronized. This bit indicates that Successive Calibration Check (Option 2 of SAE Spec) has failed three times and has resynchronized to assume 3rd message to be correct and will be received. The successive calibration check error will also be asserted during re-synchronization (to indicate the 3rd error being detected). 0 No interrupt 1 Interrupt Status condition has occurred
5 CAL_20_25	Calibration Variation 20 - 25% Interrupt Status. This bit indicates that the calibration pulse received on this channel has variation in between ±20% to ±25% from 56 ticks. 0 No Interrupt 1 Interrupt Status condition has occurred
6 SMSG_OFLW	Slow Serial Message Overflow Status. This bit indicates overflow occurred on this channel. Overflow will cause state machine to halt stopping reception of new messages. 0 No Interrupt 1 Interrupt Status condition has occurred
7 FMSG_OFLW	Fast Message Overflow Status. This bit indicates overflow occurred on this channel. Overflow happens when effective data read rate by CPU is slower than data receive rate on channel. On overflow, new incoming messages will overwrite the previous messages (that are not read out) stored in the receiver buffers. However, any message that is currently being read out by DMA or CPU will not get over-written. 0 No Interrupt 1 Interrupt Status condition has occurred

Table continues on the next page...

SRX_CH*n*_STATUS field descriptions (continued)

Field	Description
8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
9 PP_DIAG_ERR	This diagnostic checks status bit indicates that the ratio of calibration pulse length to overall message length (with pause pulse) is more than ±1.5625% between two messages. This check is valid only for messages with pause pulse. This bit indicates whether this diagnostic has failed or passed on this channel, and is cleared by writing a 1 to it. 0 Error Check has passed 1 Error Check has failed
10 CAL_LEN_ERR	This diagnostic checks status bit indicates that Calibration pulse is more than 56 ticks ±25%. This bit indicates whether this diagnostic has failed or passed on this channel, and is cleared by writing a 1 to it. 0 Error Check has passed 1 Error Check has failed
11 CAL_DIAG_ERR	Successive Calibration pulses differ by ±1.56%. SAE spec defines it be 1.5625% but the accuracy of this check depends on the frequency of protocol clock (SeeHigh frequency receiver clock (protocol clock) requirements). This diagnostic checks status bit indicates whether this diagnostic has failed or passed on this channel, and is cleared by writing a 1 to it. 0 Error Check has passed 1 Error Check has failed
12 NIB_VAL_ERR	Any nibble data value <0 or >15. This diagnostic checks status bit indicates whether this diagnostic has failed or passed on this channel, and is cleared by writing a 1 to it. 0 Error Check has passed 1 Error Check has failed
13 SMSG_CRC_ERR	Checksum error in Slow Serial Message. This diagnostic checks status bit indicates whether this diagnostic has failed or passed on this channel, and is cleared by writing a 1 to it. 0 Error Check has passed 1 Error Check has failed
14 FMSG_CRC_ERR	Checksum error in Fast Message. This diagnostic checks status bit indicates whether this diagnostic has failed or passed on this channel, and is cleared by writing a 1 to it. 0 Error Check has passed 1 Error Check has failed
15 NUM_EDGES_ERR	Not the expected number of negative edges between calibration pulse. This diagnostic checks status bit indicates whether this diagnostic has failed or passed on this channel. This bit will not set in case of "Option 2" for successive calibration pulse check is selected. This error will only set when "Option 1" for successive calibration check is selected (SUCC_CAL_CHK). This bit is cleared by writing a 1 to it. 0 Error Check has passed 1 Error Check has failed
16–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

53.4.19 Channel 'n' Configuration Register (n=0 to (CH-1)) (SRX_CH*n*_CONFIG)

This register (CHn_CONFIG) provides the configurability for interrupt assertion for various events and error as explained in Channel 'n' Status Register (n=0 to (CH-1)) (SRX_CH*n*_STATUS) and control bits for selection of various receive options that might be required by the user software. This register also configures the width of noise glitches (on the sensor input) to be filtered out by the input programmable filter.

User must program the contents of this register before enabling the channel by writing to the corresponding channel enable bit in the Channel Enable Register (SRX_CHNL_EN) .

NOTE

The value of the CH is device-specific. See the device configuration section for details.

Address: 0h base + 68h offset + (16d × i), where i=0d to 5d

SRX_CH*n*_CONFIG field descriptions

Field	Description
0–3 BUS_IDLE_CNT	Bus Idle Count. This register value defines the maximum allowable idle period on the sensor interface of this channel. The value is defined as follows: 0000 Disabled. 0001 127*2 Receiver Clock Tick Counts 0010 127*4 Receiver Clock Tick Counts 0100 127*8 Receiver Clock Tick Counts 1000 127*16 Receiver Clock Tick Counts

Table continues on the next page...

SRX_CH*n*_CONFIG field descriptions (continued)

Field	Description
4 IE_CAL_ RESYNC	Successive Calibration Check Resynchronized Interrupt Enable: This bit enables interrupt assertion when Successive Calibration diagnosis has failed three times in case of "Option 2" being selected for Successive Calibration Check Method and the check resynchronizes the take the third message to be correct. 0 Interrupt is disabled 1 Interrupt is enabled
5 IE_CAL_20_25	Calibration Variation 20 - 25% Interrupt Enable. This bit enables interrupt assertion when corresponding status bit is set. 0 Interrupt is disabled 1 Interrupt is enabled
6 IE_SMSG_OFLW	Slow Serial Message Overflow Interrupt Enable. This bit enables interrupt assertion when overflow occurs on reception of Slow Serial Messages in corresponding channel 0 Interrupt is disabled 1 Interrupt is enabled
7 IE_FMSG_OFLW	Fast Message Overflow Interrupt Enable. This bit enables interrupt assertion when overflow occurs on reception of Fast Messages in corresponding channel. 0 Interrupt is disabled 1 Interrupt is enabled
8 FCRC_CHK_ OFF	Fast Message CRC Check Off: This bit can be used to switch off CRC check in Fast Message 0 Check is enabled 1 Check is disabled/off
9 IE_PP_DIAG_ ERR	Ratio of calibration pulse length to message length varies by more than ±1.5625% between two frames. Valid for messages with pause pulse. This bit enables interrupt assertion when its respective diagnostic check fails on the corresponding channel. 0 Interrupt is disabled 1 Interrupt is enabled
10 IE_CAL_LEN_ ERR	Calibration pulse is wider than 56 ticks ±25%. This bit enables interrupt assertion when its respective diagnostic check fails on the corresponding channel. 0 Interrupt is disabled 1 Interrupt is enabled
11 IE_CAL_DIAG_ ERR	Successive Calibration pulses differ by more than ±1.56%. SAE spec defines it be 1.5625% but the accuracy of this check depends on the protocol clock. For instance for 62.5 MHz, this check will fail for 1.56% and passes for 1.55%. This bit enables interrupt assertion when its respective diagnostic check fails on the corresponding channel. 0 Interrupt is disabled 1 Interrupt is enabled
12 IE_NIB_VAL_ ERR	Any nibble data value <0 or >15. This bit enables interrupt assertion when its respective diagnostic check fails on the corresponding channel. 0 Interrupt is disabled 1 Interrupt is enabled

Table continues on the next page...

SRX_CH*n*_CONFIG field descriptions (continued)

Field	Description
13 IE_SMSG_CRC_ERR	Checksum error in Slow Serial Message. This bit enables interrupt assertion when its respective diagnostic check fails on the corresponding channel. 0 Interrupt is disabled 1 Interrupt is enabled
14 IE_FMSG_CRC_ERR	Checksum error in Fast Message. This bit enables interrupt assertion when its respective diagnostic check fails on the corresponding channel. 0 Interrupt is disabled 1 Interrupt is enabled
15 IE_NUM_EDGES_ERR	Not the expected number of negative edges between calibration pulse. This bit enables interrupt assertion when its respective diagnostic check fails on the corresponding channel. 0 Interrupt is disabled 1 Interrupt is enabled
16 DCHNG_INT	Enable for Interrupt on Reception of Fast Message with Changed Data: This bit is used to enable storing and generating corresponding DMA or Message Ready Interrupt Request for Fast Message only when any of the data nibbles after different from previously received Fast Message on that channel. If a new Fast Message is received that has same values for all data nibbles as that of previous message then the current message will be discarded and will not be stored in the buffer, and neither Fast Message Ready Interrupt nor DMA request will be generated. 0 All Fast Messages will be received even if data nibbles are same 1 Only Fast Messages with differing values of data nibbles will be received
17 CAL_RNG	Valid Calibration Pulse Range Selection: This bit is used to control whether 20% variation or 25% variation in Calibration Pulse will be tolerated when detecting a Calibration Pulse 0 20% variation is acceptable 1 25% variation is acceptable
18 PP_CHKSEL	Pause Pulse Diagnostic Check Selection: This bit controls which diagnostic checks to run when messages are enabled to be received with pause pulses. 0 Both Successive Calibration Pulse Check and Pause Pulse Diagnostic are run 1 Only Pause Pulse Diagnostic is run. Successive Calibration Pulse Check is disabled.
19 FCRC_TYPE	Fast Message CRC Type. This indicates the type of CRC method to be used for CRC Diagnostic Check on the received fast messages 0 Recommended implementation (additional 0 data nibble XORed with the rest of the nibbles) 1 Legacy implementation (no additional 0 data nibble is XORed)
20 FCRC_SC_EN	Fast Message CRC Status and Communication Nibble Enable. This bit enables the inclusion of Status and Communication Nibble when CRC is calculated for Fast Messages. 0 Status and Communication Nibble not included in CRC calculation 1 Status and Communication Nibble is included in CRC calculation
21 SCRC_TYPE	Slow Serial Message CRC Type. This indicates the type of CRC method to be used for CRC Diagnostic Check on the received slow serial messages. 0 Recommended implementation (additional 0 data nibble XORed with the rest of the nibbles) 1 Legacy implementation (no additional 0 data nibble XORed)
22 PAUSE_EN	Pause Pulse Enable. Enables the channel receiver to detect a pause pulse.

Table continues on the next page...

SRX_CH*n*_CONFIG field descriptions (continued)

Field	Description
	0 Detection of Pause Pulse is disabled 1 Detection of Pause Pulse enabled
23 SUCC_CAL_CHK	Successive Calibration Pulse Check Method. This bit indicates the method to be used for performing the successive calibration pulse check. Default value is 1. 0 Option 2 i.e. Low Latency Option as per SAE Specification 1 Option 1 i.e. Preferred but High Latency Option as per SAE Specification
24–31 FIL_CNT	Input Filter Sample Count. This indicates twice the number of Protocol Clock (of High Frequency Receiver Clock) cycles required for channel input from device's pad to remain stable before it is sampled as 0 or 1. This field defines the width of glitches to be filtered out by the input programmable filter on that channel. Only one bit should be set in this field and the output of filter will be offset by twice the same number of clocks plus additional 3 clocks due to synchronization. Default value is '4'. 0 No filtering. Input from device's pad is only synchronized 1 Non-Zero Filtering is enabled

53.4.20 Channel 'n' Fast Message Data Read Register (n=0 to (CH-1)) (SRX_CH*n*_FMSG_DATA)

Address offset: 0x0160 + 0x18 x n

This is register CHn_FMSG_DATA. The contents of this register are same as DMA Fast Message Data Read Register (SRX_DMA_FMSG_DATA) .

NOTE

The value of the CH is device-specific. See the device configuration section for details.

Address: 0h base + 160h offset + (24d × i), where i=0d to 5d

SRX_CH*n*_SMSG_TS field descriptions

Field	Description
0–31 TS	Time Stamp for the received message. Indicates the relative time of detection of the falling edge that comes at the end of the calibration pulse (which is also the start of the status and communication nibble pulse) of the last Fast Message that completed the Serial Message. Time Stamp for Slow Serial Messages is not latched when the Slow Serial Message starts but when the Slow Serial Message is completely received.

53.5 Functional description

This section describes the function of the SRX.

53.5.1 Initialization sequence

All the channels are required to be configured before enabling them by writing into corresponding channel enable bit in the Channel Enable Register (SRX_CHNL_EN). There are some registers which must be configured and some which are to be changed if reset value is not as required for that channel. After enabling the channel, no configuration should be changed and if required to be changed, the user needs to first disable the channel and then reconfigure the channel parameters. The following must to be configured before enabling the corresponding channel:

- Time Stamp Prescaler Value in Global Control Register (SRX_GBL_CTRL) to generate the time stamping clock

- Rx Prescaler Value in Channel 'n' Clock Control Register (n = 0 to (CH-1)) (SRX_CH*n*_CLK_CTRL) togenerate the channel's receiver clock
- Compensation enable in Channel 'n' Clock Control Register (n = 0 to (CH-1)) (SRX_CH*n*_CLK_CTRL)
- Channel Configuration settings in the Channel 'n' Configuration Register (n=0 to (CH-1)) (SRX_CH*n*_CONFIG)
- Number of Data Nibbles in Channel in the Data Control Register 1 (SRX_DATA_CTRL1)
- Control bits that control whether messages received in channel are to read by interrupt or DMA in Fast Message DMA Control Register (SRX_FDMA_CTRL), Slow Serial Message DMA Control Register (SRX_SDMA_CTRL), Fast Message Ready Interrupt Control Register (SRX_FRDY_IE) and Slow Serial Message DMA Control Register (SRX_SDMA_CTRL)

53.5.2 DMA read logic

The SENT Receiver module generates separate DMA requests for all Fast Messages and Slow Serial Messages received. The DMA requests are common for all channels. Each packet stored in the channels' buffers are appended with a time stamp taken from a free running time keeping counter and the channel number on which it was received. Details on this time stamp counter can be found in Time stamp logic.

53.5.2.1 DMA request for Fast Message reading

Fast Messages received are stored in a single system bus clock domain buffer to be read out by the DMA Controller via the DMA Fast Message Read register set. Note the DMA Controller must read all 3 DMA Read Registers to obtain the complete message. The data flow will happen as follows:

- A DMA request will be asserted when any of the DMA enabled channels has successfully received one complete Fast Message. The request is kept asserted till all messages (across DMA enabled channels) have been read out.
- DMA Controller should read the complete message by accessing each register of the DMA Fast Message Read register set, the registers being:
  - DMA Fast Message Data Read Register (SRX_DMA_FMSG_DATA)

  - DMA Fast Message CRC Read Register (SRX_DMA_FMSG_CRC)
  - DMA Fast Message Time Stamp Read Register (SRX_DMA_FMSG_TS)

- A fixed round robin sequencing runs, as shown in Figure 53-81, and this logic checks for messages in sequence 0→1→3 →5→7 and back to channel 0 and so on. Channel 2 is skipped as it is not DMA enabled) and channel 4 and 6 are skipped as message is not received completely. This sequence continues like this.
- The sequence in which messages are read through DMA interface is not deterministic and depends on the sequence in which they are completely received.
- When the sequencing logic detects a message ready to be read, it will update the DMA Fast Message Read register set for DMA read and move to the next channel when this message is read out completely (i.e., 3 read accesses to the above mentioned registers)
- The DMA controller should be programmed to read only one message in one DMA transfer (i.e. 12 bytes). If it is programmed to read more than one message in one DMA transfer, underflow in buffers might occur
- User software should ensure there is no overflow in channels. In case overflow occurs, the message in the channel buffer will get overwritten by the newly received message. However, when a DMA read is in progress, the buffers will not be overwritten if overflow occurs to maintain data integrity.
- The Round Robin sequencing logic loops through each DMA enabled channel and halts at any channel having data till it is read out by the DMA Controller.

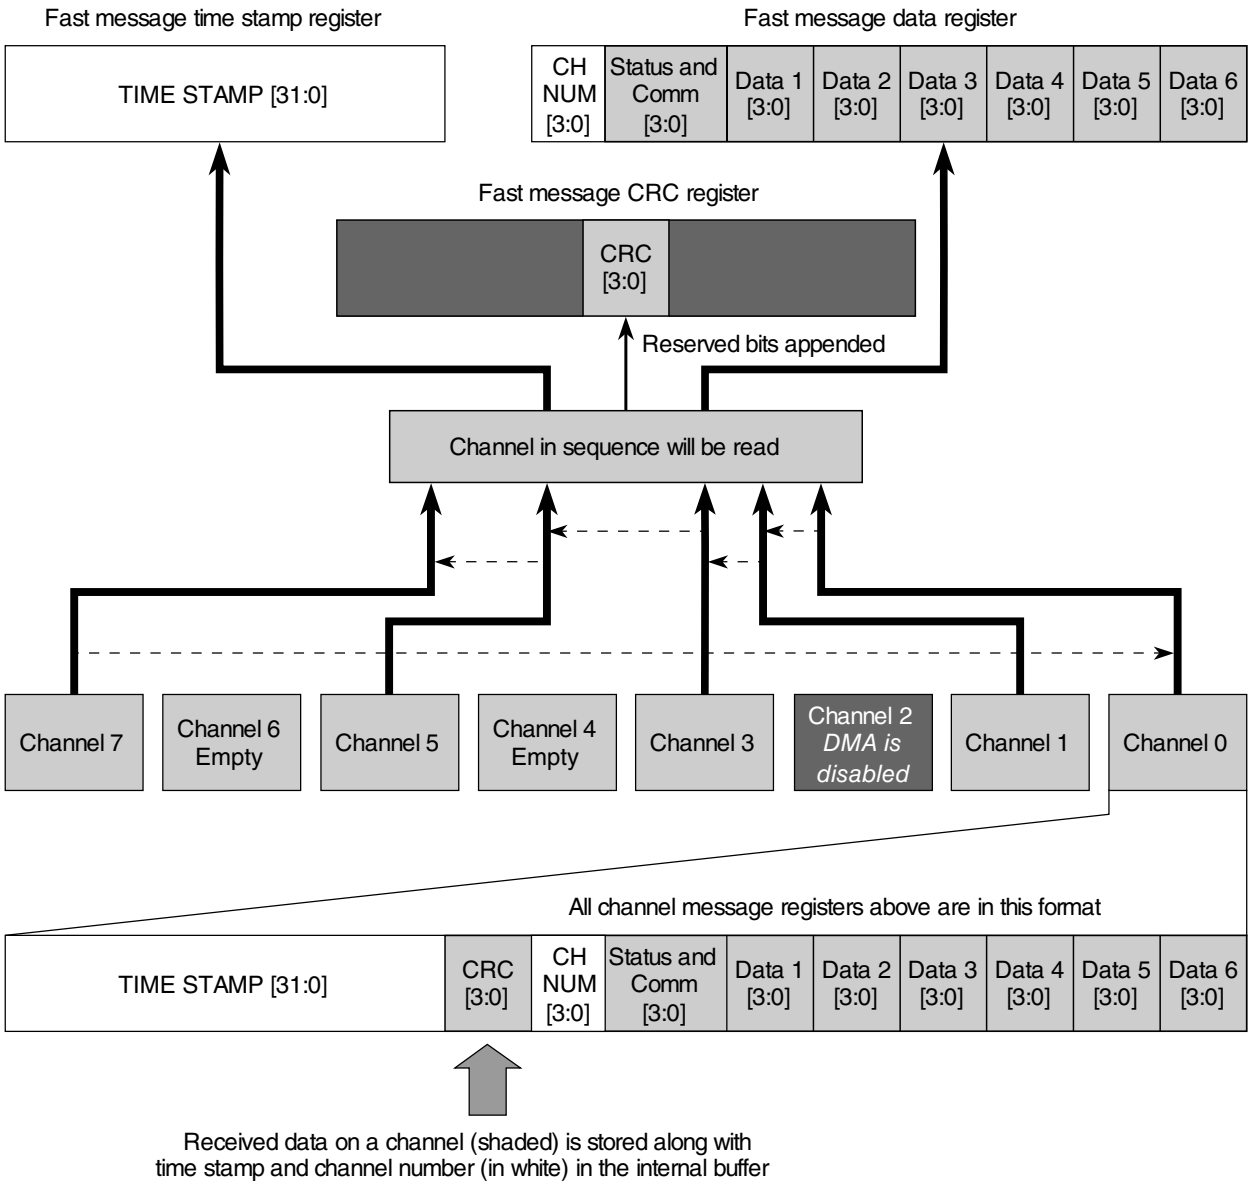

Figure 53-81. Fast Message DMA read logic

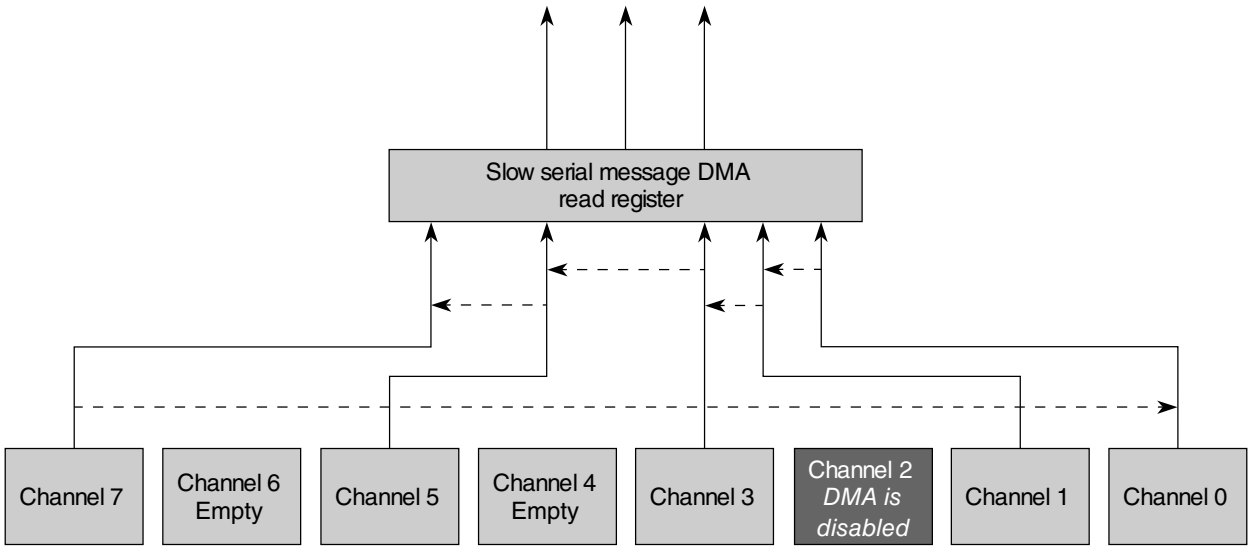

53.5.2.2 DMA request for Slow Serial Message reading

A separate DMA request (different from DMA request for Fast Message) is generated for all slow serial messages received on all channels. The data flow will happen as follows:

- Request will be asserted when any of the DMA enabled channels has successfully received one complete serial message (short or enhanced) and kept asserted till all messages have been read from their respective memory-mapped registers

- Similar to DMA read for Fast Messages, data for slow serial messages will be read from DMA Slow Serial Message Read register set in memory map, the register set comprising of:
  - DMA Slow Serial Message Bit3 Read Register (SRX_DMA_SMSG_BIT3)
  - DMA Slow Serial Message Bit2 Read Register (SRX_DMA_SMSG_BIT2)
  - DMA Slow Serial Message Time Stamp Read Register (SRX_DMA_SMSG_TS)
- A fixed round robin sequencing logic will be running and it will update the DMA Slow Serial Message Read register set for DMA read and move to the next channel when this message is read out completely (i.e., 3 DMA read accesses to the above mentioned registers)
- The channel number and time stamp will also be appended for every message
- A message type bit (TYPE) will also be appended to distinguish between short and enhanced serial messages
- The DMA controller should be programmed to read only one message in one DMA transfer (i.e. 12 bytes). If it is programmed to read more than one message in one DMA transfer, underflow in buffers might occur
- Since serial messages receive rate is very slow, user software should ensure there is no overflow
- The fixed round robin sequence logic for DMA read is the same as that used for Fast Messages (see DMA request for Fast Message reading)

Figure 53-82 shows the sequencing of channels for serial messages to be read when DMA read is done on DMA Slow Serial Message Read register set.

Note: The arrows in the figure indicate next DMA transfer. One DMA Read Register set (3 registers) will be read in

Figure 53-82. Slow Serial Message DMA read logic

The formats in which the 3 types of Serial Messages will be stored in the buffers are shown in figures below.

Table 53-83. Enhanced Serial Message with 8-bit ID field

31	1		16	15	0						0
CH NUM [3:0]	P				0	C	ID [7:4]	0	ID [3:0]		0
		CRC [5:0]			Data Field [11:0]						
TIME STAMP [31:0]											

Table 53-84. Enhanced Serial Message with 4-bit ID field

31	1		16	15	1						0
CH NUM [3:0]	P				0	C	ID [3:0]	0	Data Field [15:12]		0
		CRC [5:0]			Data Field [11:0]						
TIME STAMP [31:0]											

Table 53-83 and Table 53-84 shows the enhanced serial messages. Bit C (shown in figure) or CFG (as shown in DMA Slow Serial Message Bit3 Read Register (DMA_SMSG_BIT3) description) defines the type of enhanced packet and bit P (shown in figure) or bit TYPE (shown in DMA Slow Serial Message Bit3 Read Register (DMA_SMSG_BIT3) description) defines whether it is short serial or enhanced serial message. CRC, ID and Data fields are stored in format as received and shown in SAE specification with just one exception that CRC is shifted to align with 16-bit boundary.

Table 53-85 shows the short serial message. Field locations have been placed in such a way to allow a common register to read all the slow serial messages and also match the bit positions in actual message defined by SAE Specification.

Table 53-85. Short serial message

31	0	16	15	0
CH NUM [3:0]	P			
		CRC [3:0]	ID [3:0]	Data Field [7:0]
TIME STAMP [31:0]				

Again, three 32-bit accesses to be made by DMA to get one complete message with time stamp.

53.5.3 Message reading via interrupts

There is one interrupt request per channel for a Fast message received and one for a serial message received. Each channel is individually configurable to enable or disable interrupt on reception of Fast or Slow Serial messages separately. In case of interrupt request of Fast Message, an interrupt will be asserted when any of the channels has received a complete Fast Message without errors and that channel is not configured for DMA Reads. The interrupt routine should be coded in such a way to take the least amount of overhead (in CPU cycles) while entering the routine and start reading the available messages. The routine should be capable of accessing all channels that are enabled to give out messages via interrupts through the Register Interface.

In response to these interrupts, the CPU is expected to read interrupt status register for fast or Slow Messages (depending on which interrupt was asserted) and store it in system memory. Using this status register value, the interrupt routine can decide from which channels the message is to be read. For instance if bit corresponding to channel 0 is set then routine should read from the address location corresponding to Channel 0 Fast Message Read registers and move onto the next asserted bit. The interrupt routine should scan through all the bits of this stored interrupt status register value and read corresponding channel's fast or Slow Message registers. In this manner all available messages can be read. After scanning through all the bits of status register stored in system memory, routine can read again the message ready interrupt status register to find out if any other channel has received in the mean time. This will save another interrupt routine time mainly from stacking/unstacking delay.

It is assumed that the interrupt controller will be able to respond fast enough to avoid any overflow as only one message per channel will be stored and the system bus clock frequency is sufficient to avoid this.

53.5.3.1 Suggested software interrupt service routine steps

These are suggested step to have an interrupt routine that can read all messages quickly and avoid any underflow/overflow. Actual implementations can vary.

When separate Fast Message and Slow Serial Message Interrupts are used:

The Fast Message Interrupt should have higher priority than Slow Serial Message Interrupt. The suggested ISR steps for a Fast Message Interrupts can be

- Read the Fast Message Ready Register and store it in a variable
- Shift out bits starting from MSB from this variable
- If bit is 1, perform read operation on corresponding channel's memory-mapped Fast Message Read Register set (3 registers). Three read accesses will fetch complete message. Shift out new bit. Repeat Step.
- Else if bit is 0, shift out new bit
- When all bits are shifted out, read the Fast Message Status Registers again to ensure no new message has arrived during the ISR.
- If there are no bits set, exit the ISR, else repeat this process.

The ISR steps for Slow Serial Message Interrupt can be same as for Fast Message ISR.

When common Fast Message and Slow Serial Message Interrupts are used:

The suggested ISR steps can be

- Read the Fast Message Status Register and store it in a variable
- Shift out bits starting from MSB from this variable
- If bit is 1, perform read operation on corresponding channel's memory-mapped Fast Message Read Register. Three read accesses will fetch complete message. Shift out new bit. Repeat Step.
- Else if bit is 0, shift out new bit
- When all bits are shifted out, read the Slow Serial Message Status Register into a new variable

- Shift out bits starting from MSB from this new variable
- If bit is 1, perform read operation on corresponding channel's memory-mapped Slow Serial Message Read Register. Three read accesses will fetch complete message. Shift out new bit. Repeat Step.
- Else if bit is 0, shift out new bit
- When all bits are shifted out, software can again check both Fast and Slow Serial Message Ready register to ready any message that might have been received while the routine was being serviced, or can choose to exit the routine.

53.5.4 Overflow behavior

This section describes the overflow behavior.

53.5.4.1 Fast messages buffers

Overflow in Fast Message buffers can occur when the CPU or DMA does not read messages from that channel for a long period of time. The receiver channel stores two messages in its buffers and indicates an overflow when these buffers are full.

When an overflow event occurs, the newly received message overwrite the previously stored message and the overflow status bit is set. However, if overflow asserts while CPU/DMA is reading that channel (i.e. all 3 read registers have not yet been read), then that message is not overwritten. While messages are being overwritten, the slow message reception is not hampered.

NOTE

In the case of a fast message overflow and continuous reading of register SRX_CHn_FMSG_DATA, SRX_CHn_FMSG_CRC, and SRX_CHn_FMSG_TS without clearing the SRX_FMSG_RDY[F_RDYn] bit there is a possibility that one message will be lost. Additionally, if the pause pulse feature is enabled the module asserts up to two NUM_EDGES_ERR in the status register (SRX_CHn_STATUS). In this case up to two frames can be lost. Note that some debuggers perform a continuous read of memory which can cause this issue to occur.

In order to avoid this software should ensure that fast message overflow does not occur. If interrupts are used to read the SENT messages the interrupt for data reception should be enabled for every channel n (SRX_FRDY_IE[FRDY_IEn]=1) and the interrupt priority should be such that the software is able to read the message before the next message arrives. When using Direct Memory Accesses (eDMA) to access the messages the DMA request from the SENT module should be serviced before the next message arrives. The minimum duration between the reception of two consecutive messages in one channel is 92 times the utick length (time).

Else ensure that the SRX_CHn_FMSG_DATA, SRX_CHn_FMSG_CRC, and SRX_CHn_FMSG_TS registers are not read continuously either in the software code or as a result of a debugger being connected. They should be read once per message and the FMSG_RDY[F_RDYn] bit should be cleared after the reads.

53.5.4.2 Slow message buffers

Overflow in Slow Message buffers can occur when the CPU or DMA does not read messages from that channel for a long period of time. The receiver channel stores two messages in its buffers and indicates an overflow when these buffers are full.

When an overflow event occurs, further reception of slow messages is halted until the buffers are read out by CPU or DMA. Since it is less likely that CPU or DMA do not read the read registers for 32 or 36 fast message length duration, an overflow in slow messages would not be as frequent as in fast messages.

53.5.5 Adjustment for variation in sensor (Tx) clock

The clock used by the Channel Receiver (referred to as Receiver Clock, or Rx_CLK) to sample the message nibbles is generated from a High Frequency Receiver Clock or Protocol Clock. This high frequency receiver clock is divided using a prescaler counter which generates a tick when it rollovers on reaching a count equal to the Prescaler Value programmed in the channel's clock control register. The receive clock is generated separately for each channel. By varying this Prescaler Factor, we can control the period of the receive clock and make it close to the Transmitter clock used by the sensor for the particular channel.

After reset and once channel is enabled, the compensated prescaler value is set to Zero and the user software programs the Prescaler Value to obtain the desired receiver clock frequency for the particular channel. Thus, the receiver starts working by assuming that the transmitter is sending messages on the frequency that is programmed in its channel clock control register. The channel's input after filtering is continuously measured by the Prescaler Counter. The compensation logic checks each pulse length and determines the calibration pulse from them. When a calibration pulse is detected, the compensated prescaler value is computed and stored in the Channel's Clock Control Register (Channel 'n' Clock Control Register (n = 0 to (CH-1)) (SRX_CH*n*_CLK_CTRL)). Software can use this value to determine the variation in Tx Clock.

Note

A pause pulse may incidentally be detected as a synchronization/calibration pulse during start up after reset. The correction value would be computed on the pause pulse too but since the next synchronization pulse would follow, the logic would again detect the falling edge on the synchronization pulse and the correction value would now be correctly computed on the correct synchronization pulse.

The Clock Compensation or Correction happens for every messages that is received and the compensated prescaler value remains constant for that message.

53.5.5.1 Adjustment for nibble length variation

Section 6.2 of SAE Specifications specifies the maximum allowable limits for clock drift and jitter for the transmitter and receiver separately. This can cause the length of nibbles to vary and can cause incorrect sampling of data nibbles. This variation is adjusted by the SENT Receiver when nibbles are being sampled.

53.5.6 Input programmable filter

The Input Programmable Filter ensures that only valid input pin transitions are received by the SENT Receiver module. The input programmable filter is an 8-bit programmable up counter that increments on the high frequency receiver clock. The sensor input signal from device's pad is synchronized by high frequency receiver clock. When a state change occurs in the sensor input signal, the 8-bit counter resets and starts counting up on the high frequency receiver clock. As long as the new state is stable on the pin, the counter remains incrementing. If a counter overflows occurs, the new pin value (i.e. sensor input) is validated and latched in the filtered output flop (also running on high frequency

receiver clock). If the opposite edge appears on the sensor input before validation (i.e. overflow), the counter is reset and the input is not passed onto the filtered output. At the next pin transition, the counter starts counting again. Any pulse that is shorter than a full range of the masked counter is regarded as a glitch and it is not passed on to the filter output. The number of samples (or the match value of the up counter) is programmable by the user in the channel's configuration register Channel 'n' Configuration Register (n=0 to (CH-1)) (SRX_CH*n*_CONFIG). When zero is programmed into the registers, it bypasses the filter and the synchronized input is output as the filtered output. A non-zero value delays the filtered output by the number of clocks proportional to the programmed value in the Channel Configuration Register (Channel 'n' Configuration Register (n=0 to (CH-1)) (SRX_CH*n*_CONFIG)). A timing diagram of the input filter when FIL_CNT is 4, is shown in the following figure.

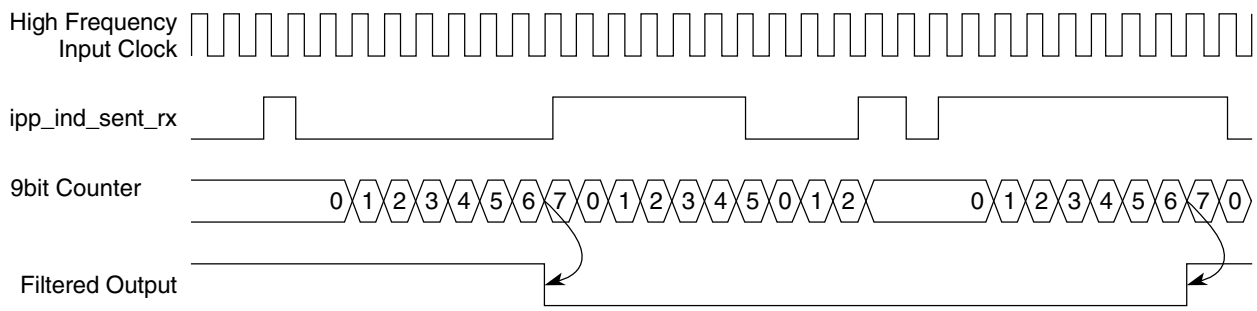

Figure 53-83. Input programmable filter timing diagram

53.5.7 Receiver diagnostics

Most of the receiver diagnostics are controlled by the Fast Message State Machine. The following checks are conducted by the receiver in each channel

- Calibration pulse length < 56 clock ticks – 25% or > 56 clock ticks + 25%
- Not the expected number of falling edges between calibration pulses. (Message length is pre-defined by each sensor device and programmed by user for each channel)
- Checksum error. Two 4-bit CRC checks and one 6-bit CRC check according to the message type. User has a programmable option to select the method of CRC to use i.e. Legacy or Recommended.
- Any nibble data values measured as < 0 or > 15

- Successive calibration pulses differ by > +1.5625% (1/64) or < -1.5625%. The accuracy of this check will depend on the frequency of the protocol clock used.
- For messages with pause pulse, an additional diagnostic is done; however, this diagnostic will not fail any message (to reduce latency in message reception) but the failure of this diagnostic will be indicated in the channel's status register.

On detection of any of the above errors, the receiver rejects the current packet until a new calibration pulse is detected. Occurrence of an error is flagged in the respective channel's status register (Channel 'n' Status Register (n=0 to (CH-1)) (SRX_CH*n*_STATUS)). If error interrupt is enabled, an error interrupt will be generated. There is a single error interrupt generated for all errors, so the CPU must read the status register to find out which error occurred. Once error condition is flagged, subsequent errors (except NUM_EDGES_ERR) are automatically masked out until a valid calibration pulse is detected, after which all checks are automatically enabled. This is done to avoid multiple assertions of the interrupt to CPU in case the channel become unstable and send wrong data continuously.

53.5.7.1 Calibration pulse length check

The calibration pulse length check happens in conjunction with Clock Compensation Logic since current calibration pulse is detected in this block. The Clock Compensation Logic detects a calibration pulse of length between 42 and 70 tick counts. This check will assert the CAL_LEN_ERR status bit on failure.

53.5.7.2 Successive calibration pulse check

The successive calibration pulse check checks if successive calibration pulses differ by > +1.5625% (1/64) or < -1.5625%. The accuracy of this check will depend on the frequency of the protocol clock used. Specifically, the higher the frequency, the closer the check will be to 1.5625%. So if protocol clock is T_{HF_CLK} and channel tick period is T_{TX_CLK} then the check will be of 1.5625% ± {100 × (4 × T_{HF_CLK}) / (42 × T_{TX_CLK})}. So it won't allow variance in clock of a channel by 1.5625% - {100 × (4 × T_{HF_CLK}) / (42 × T_{TX_CLK})}. This check will assert the CAL_DIAG_ERR status bit on failure.

When Option 2 of successive calibration pulse check is enabled, the CAL_RESYNC bit will be asserted on every third successive error detected by this check.

53.5.7.3 Not the expected number of edges check

The number of negative edges between two successive calibration pulses is counted and compared with expected number of edges in case of preferred option of successive calibration pulse check. The expected number of nibbles is the sum of following:

- Status and Communication nibble (1 No.)
- Data nibbles (Programmable as per user software)
- CRC nibble (1 No.)
- Pause Pulse, if configured (1 No.)

This check ("Not the expected number of edges check") will assert the NUM_EDGES_ERR status bit on failure. The check does not run when Option 2 (low latency) of successive calibration pulse check is enabled. This check is not masked after any other error is detected so it could be redundant if it is flagged along with CAL_DIAG_ERR and CAL_LEN_ERR. However, this is true only when CPU is clearing error status bits as and when they are asserted. If errors are accumulated, the above cannot be deduced.

53.5.7.4 Nibble value check

As part of this check, the lengths of the following nibbles are checked to remain in between 0 and 15 nibble values(11.5 ticks to 27.5 ticks):

- Status and Communication nibble
- all Data nibbles
- CRC nibble

The nibble value check will assert the NIB_VAL_ERR status bit on failure. This error can be flagged along with NUM_EDGES_ERR in which case the former can be ignored as the number of pulses in the message is incorrect. However, this is true only when CPU is clearing error status bits as and when they are asserted. In case, errors are accumulated, the above cannot be deduced.

53.5.7.5 CRC check

The CRC check will compute both 4-bit and 6-bit CRC as requested by State Machine control logic. Two 4-bit CRCs and one 6-bit CRC are supported to compute the CRC on Fast/Slow Serial Message (4-bit CRC) and Enhanced Serial Message (6-bit CRC) respectively. The SENT Receiver Module allows the user to calculate the 4-bit CRC using either the legacy CRC implementation method or the new recommended CRC implementation via a control bit in the channel's corresponding control register. Please refer to SAE SENT Specification for details on CRC algorithm.

Asserting the CHn_CONFIG_REG[11] bit, causes the Status and Communication nibble to be included in the 4-bit CRC calculation for Fast Serial Messages. De-asserting this bit enables normal operation as described above.

This check will assert the FMSG_CRC_ERR or SMSG_CRC_ERR status bit on failure, depending on whether the check is run for Fast Message or Slow Message.

The FMSG_CRC_ERR can be flagged along with the NUM_EDGES_ERR, in which case the CRC error can be ignored as the number of pulses in the message was incorrect. However, this is true only when CPU is clearing error status bits as and when they are asserted. If errors are accumulated, the above cannot be deduced.

53.5.7.6 Pause pulse diagnostic

The pause pulse diagnostic checks whether the ratio of calibration pulse length to full message length (including pause pulse) varies from one message to another by less than 1.5625% (as per spec). In order to have reduced latency of operation, message reception is not gated due to this check and no messages are discarded. However, when this check fails, a status bit is asserted to let the software know of this condition. The successive calibration pulse check can be configured to operate along with this check. This configurability is added to avoid conflicting results from the two checks.

There can be some inaccuracy in measuring pause pulse length as SAE specification specifies maximum clock drift/jitter up to maximum nibble length only and the frequency of high frequency receiver clock (protocol clock) used, allows clock compensation logic to ensure accuracy up to maximum nibble length. Hence there could be some inaccuracy in this check when sampling pause pulses that are larger than the maximum nibble pulse length.

This check will assert the PP_DIAG_ERR status bit on failure. This check does not run when reception of pause pulse is disabled.

When the Single Edge Nibble Transmission (SENT) Receiver (SRX) is configured to receive a pause pulse (Channel ‘n' Configuration Register - CHn_CONFIG[PAUSE_EN] = 1) and the length of the pause pulse from the sensor is in range of the valid calibration pulse length, the NUM_EDGES error can get asserted spuriously (Channel ‘n' Status Register - CHn_STATUS(NUM_EDGES_ERR] = 1) when there is any diagnostic error (other than number of expected edges error) or overflow in the incoming messages from the sensor.

Software can distinguish a spurious NUM_EDGES_ERR error from a real one by monitoring other error bits. The following tables will help distinguish between a false and real assertion of NUM_EDGES_ERR error and other errors. Software should handle the first error detected as per application needs and other bits can be evaluated based on these tables. Table 1 contains information due to erratum behavior and Table 2 below contains clarification of normal NUM_EDGES_ERR behavior.

Table 53-86. Behavior of NUM_EDGES_ERR

First Error Detected	Other error bits asserted	Cause for extra error bits getting asserted	Action
NIB_VAL_ERR	NUM_EDGES_ERR asserted twice	Upon detection of the first error, the state machine goes into a state where it waits for a calibration pulse, the first NUM_EDGES_ERR error is for the current message as the state machine does not detect an end of message. The second error comes when both the Pause pulse and the Calibration pulse are seen as back to back calibration pulses and no edges in between.	Ignore both NUM_EDGES_ERR error
FMSG_CRC_ERR	NUM_EDGES_ERR asserted twice	Upon detection of the first error, the state machine goes into a state where it waits for a calibration pulse, the first NUM_EDGES_ERR error is for the current message as the state machine does not detect an end of message. The second error comes when both the Pause pulse and the Calibration pulse are seen as back to back calibration pulses and no edges in between.	Ignore both NUM_EDGES_ERR errors

Table continues on the next page...

Table 53-86. Behavior of NUM_EDGES_ERR (continued)

CAL_LEN_ERR	NUM_EDGES_ERR asserted once	Since the calibration pulse is not detected as a valid calibration pulse, the internal edges counter does not detect the end of one message and start of bad message (which has CAL_LEN_ERR); hence the NUM_EDGES_ERR gets asserted.	Ignore NUM_EDGES_ERR error

Table 53-87. Expected behavior, clarification of NUM_EDGES_ERR cases

First Error Detected	Other error bits asserted	Cause for extra error bits getting asserted	Action
NUM_EDGES_ERR (when edges are less than expected)	NIB_VAL_ERR is asserted	When the actual number of edges in the message are less than expected, then a pause pulse gets detected as a nibble since the state machine expects nibbles when actually there is a pause pulse present. This generates NIB_VAL_ERR.	Ignore the NIB_VAL_ERR
NUM_EDGES_ERR (when edges are more than expected)	NIB_VAL_ERR and PP_DIAG_ERR are asserted	When the actual number of edges in a message are more than expected, then after receiving the programmed number of data nibbles, the state machine expects a pause pulse. However, the pause pulse comes later and gets detected as a nibble and hence NIB_VAL_ERR is asserted. Since the message length is not correct, PP_DIAG_ERR is also asserted.	Ignore NIB_VAL_ERR and PP_DIAG_ERR

53.5.8 Time stamp logic

A single counter maintains the time stamp for all channels which can be used by the software to determine the relative time of arrival of the messages for each channel. The time stamp counter is a 32-bit counter.

The clock for this counter is derived from the high frequency receiver clock using a Time Stamp Prescaler Counter that divides the high frequency receiver clock to generate the clock of required resolution. The user must program the time stamp prescaler value (in

Global Control Register (SRX_GBL_CTRL)) in order to generate the time stamp clock. The period of the time stamp clock must be less than that of the fastest receiver channel being used, or it can be set at some fixed value determined by application, such as 1 µs. For example, if the high frequency receiver clock is 60 MHz, the required prescaler value is 59 to generate a time stamp clock of 1 µs resolution.

Note

The rollover of time stamp values should be determined in user software, by comparing the time stamp values in previous and current messages that are read out. User software should adjust the time stamp values in these messages accordingly, after reading them.

The time stamp for a Fast Message is sampled at the falling edge that comes at the end of the calibration pulse (which is also the start of the status and communication nibble pulse) and is stored in the message read buffer. However, if the current message is found to be in error, the message buffer is discarded. Thus, the time stamp will be available to user software for only those messages which do not have any error.

The time stamp for a serial message is sampled at the end of the message i.e. when the serial message is completely received and when the message is found to have no errors. the time stamp is stored in the message read buffer to be read by the user software. Again, for messages with error the message and time stamp are discarded.

53.5.8.1 Limitation

Since the same counter is used for all channels, it may happen that more than 1 message is received within the same time stamp across different channels. Hence the software would not be able to determine the sequence of arrival of messages which have the same time stamp value.

53.5.9 Bus Idle Diagnostic

This diagnostic checks the connected sensors for inactivity. SENT module can indicate if the idle period on a particular channel has crossed the period defined by the programmed value in Bus Idle Count (in Channel 'n' Configuration Register (n=0 to (CH-1)) (SRX_CH*n*_CONFIG)). Status bit (bus_idle in Channel 'n' Status Register (n=0 to (CH-1)) (SRX_CH*n*_STATUS)) will be set when idle period crosses the allowed value. CPU should write 1 to this clear this bit once it is read.

53.6 Clocks and resets

The SENT Receiver works on two clocks. First is the System Bus Clock that is used to program the registers and read messages via DMA or Interrupt from the module's Register Interface. Second is the High Frequency Receiver Clock or Protocol Clock that is used for accurate message receiving operations. There is a single asynchronous reset which is the system asynchronous reset and one internal reset for each of the channel logic.

53.6.1 Clocking strategy

The following figure shows the clock domain in which each module is functioning.

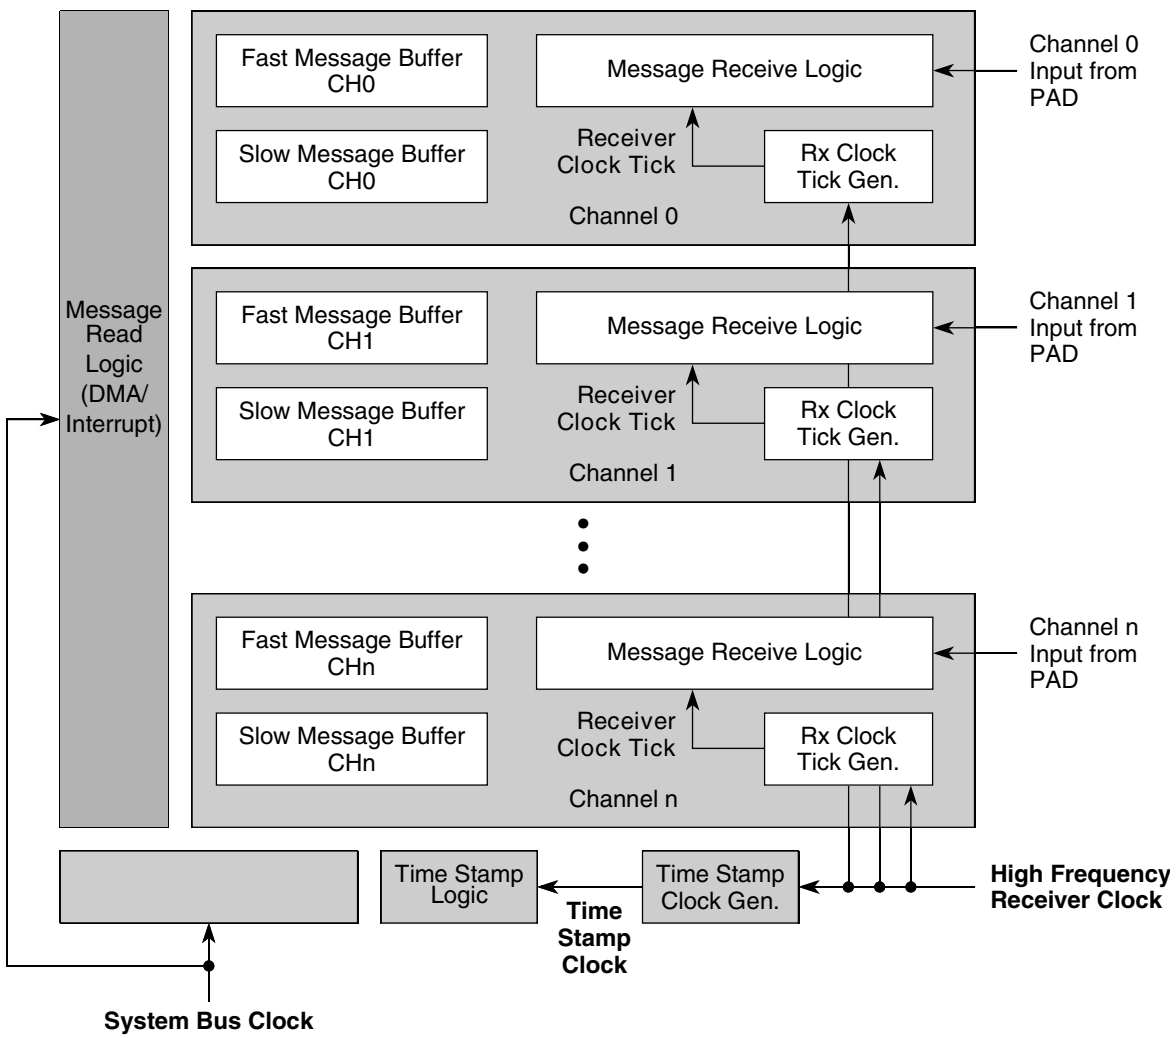

Figure 53-84. SENT Receiver module clock domains

53.6.2 System bus clock requirements

Since all the received messages are read on the System Bus Clock it is necessary that both the interrupt service routine and the DMA controller must be able to access all channels with messages ready to be read within a time to prevent overflow in any channel. The minimum time available to the CPU or DMA is the case when the smallest Fast Message is received back to back on all channels while working on the smallest receive clock tick period.

Now, the smallest Fast Message size with valid checksum as per SAE Specifications is 154 ticks. At 3 µs receive clock tick with a -20% variation in the transmitter clock tick, the effective receiver clock tick is 2.4 µs (after compensation). This gives us the time in which the minimum size Fast Message is received in any channel as 154 × 2.4 = 369.6 µs. Now since messages are arriving in parallel, 369.6 µs is the time available for CPU or DMA to access all channels to prevent an overflow in the channel that received the very first message.

Thus, if assume that 'N_{CHNL}' channels are being used and all channels have messages ready to be read together from either DMA or CPU then the time available to read a message in one channel will be 369.6/N_{CHNL} µs or ~370/N_{CHNL} µs. Since the CPU or the DMA needs to make three 32-bit accesses in order to read a complete message and taking the time required for one 32-bit read access as 'T_{RD}' (assuming it to be same for DMA and CPU); we can determine the minimum frequency for the System Bus Clock as:

For CPU,

$$3 \times T_{RD} + T_{ISR} + T_{WAKUP} < 370 / N_{CHNL}$$

where T_{ISR} is the overhead in initiating an ISR and T_{WAKUP} is the time to wakeup from low power mode

For DMA,

$$3 \times T_{RD} + T_{WAKUP} < 370 / N_{CHNL}$$

Replacing $T_{RD} = N_{RD} \times T_{SYS_CLK}$ and $T_{ISR} = N_{ISR} \times T_{SYS_CLK}$, where N_{RD} is the number of System Bus Clock cycles in one 32-bit read access, N_{ISR} is the number of System Bus Clock Cycles in initiating an interrupt service routine and T_{SYS_CLK} is the period of the same clock, we get

For CPU,

$$(3 \times N_{RD} + N_{ISR}) \times T_{SYS_CLK} + T_{WAKUP} < 370 / N_{CHNL}$$

(all units is µs)

For DMA,

$3 \times N_{RD} \times T_{SYS_CLK} + T_{WAKUP} < 370 / N_{CHNL}$

(all units is μs)

53.6.3 High frequency receiver clock (protocol clock) requirements

For accurate receive operations, the protocol is required to satisfy a minimum frequency defined as per formula: Guard Band > 2.5 * T_{HF_CLK}

where T_{HF_CLK} is the High Frequency Receiver Clock or Protocol Clock in ns and Guard Band is guard band in ns as specified in SAE specification, at particular transmitter uTick.

Note

T_{HF_CLK} in the above equation should be chosen based on the fastest sensor clock (with minimum guard band as specified in SAE spec) among all channels in the device.

Chapter 54
LINFlexD

54.1 LinFlexD chip-specific module information

The device contains 6 LinFlexD instances. The following table provides an overview of the modes supported by the instances.

Table 54-1. LINFlexD instances

LINFlexD instance	Master mode	Slave mode	LIN	Note
LINFLEX_0	Yes	Yes	Yes	LINFlex/UART interface compliant with LIN 1.3, LIN 2.0 and LIN 2.1 standards.
LINFLEX_1 , LINFLEX_2, LINFLEX_3	Yes	No	Yes	
LINFLEX_M0, LINFLEX_M1	No	Yes	No	For MSC operation the interface will support MSC upstream frames reception only.

NOTE

Only linflex_0 implements the IFCR register. All other LINFlexD instances do not implement the IFCR register.

NOTE

The LINFlex modules inplemented on MPC5746R do not support communication with Special Word Length in UART mode set (UARTCR[WLS]=1) in buffer mode or in FIFO mode with UARTCR[WL1, WL0]=0,1.

54.2 Introduction

The LINFlexD controller is designed to manage a high number of LIN messages efficiently with a minimum of CPU load. To reduce the CPU loading in Master mode, LINFlexD autonomously handles the LIN messages once software has triggered the header transmission, until the next header transmission request in transmitter mode or until checksum reception in the receiver mode.

The LINFlexD supports LIN protocol version 1.3, 2.0, and 2.1. It also consists of an 8-byte buffer for transmission/reception data.

The LINFlexD also provides support for some of the basic UART transfers of 8-bit, 9-bit, 16-bit, and 17-bit frames and also 12-bit data frame + parity reception in UART mode for MSC support.

The LINFlexD supports multi-channels and parametric DMA Tx/Rx interface in LIN/UART operating mode.

54.2.1 Glossary and acronyms

Table 54-2. Glossary and acronyms

Term	Description
LIN	Local interconnect network
UART	Universal asynchronous transmitter receiver
ID	LIN identifier field
DMA	Direct memory access
TCD	Transfer control descriptor
IPS	Peripheral Bus Interface
IRQ	Interrupt request
FSM	Finite state machine
WS	Wait state
SW	Software
CPU	Central processing unit
SoC	System on a chip

54.2.2 References

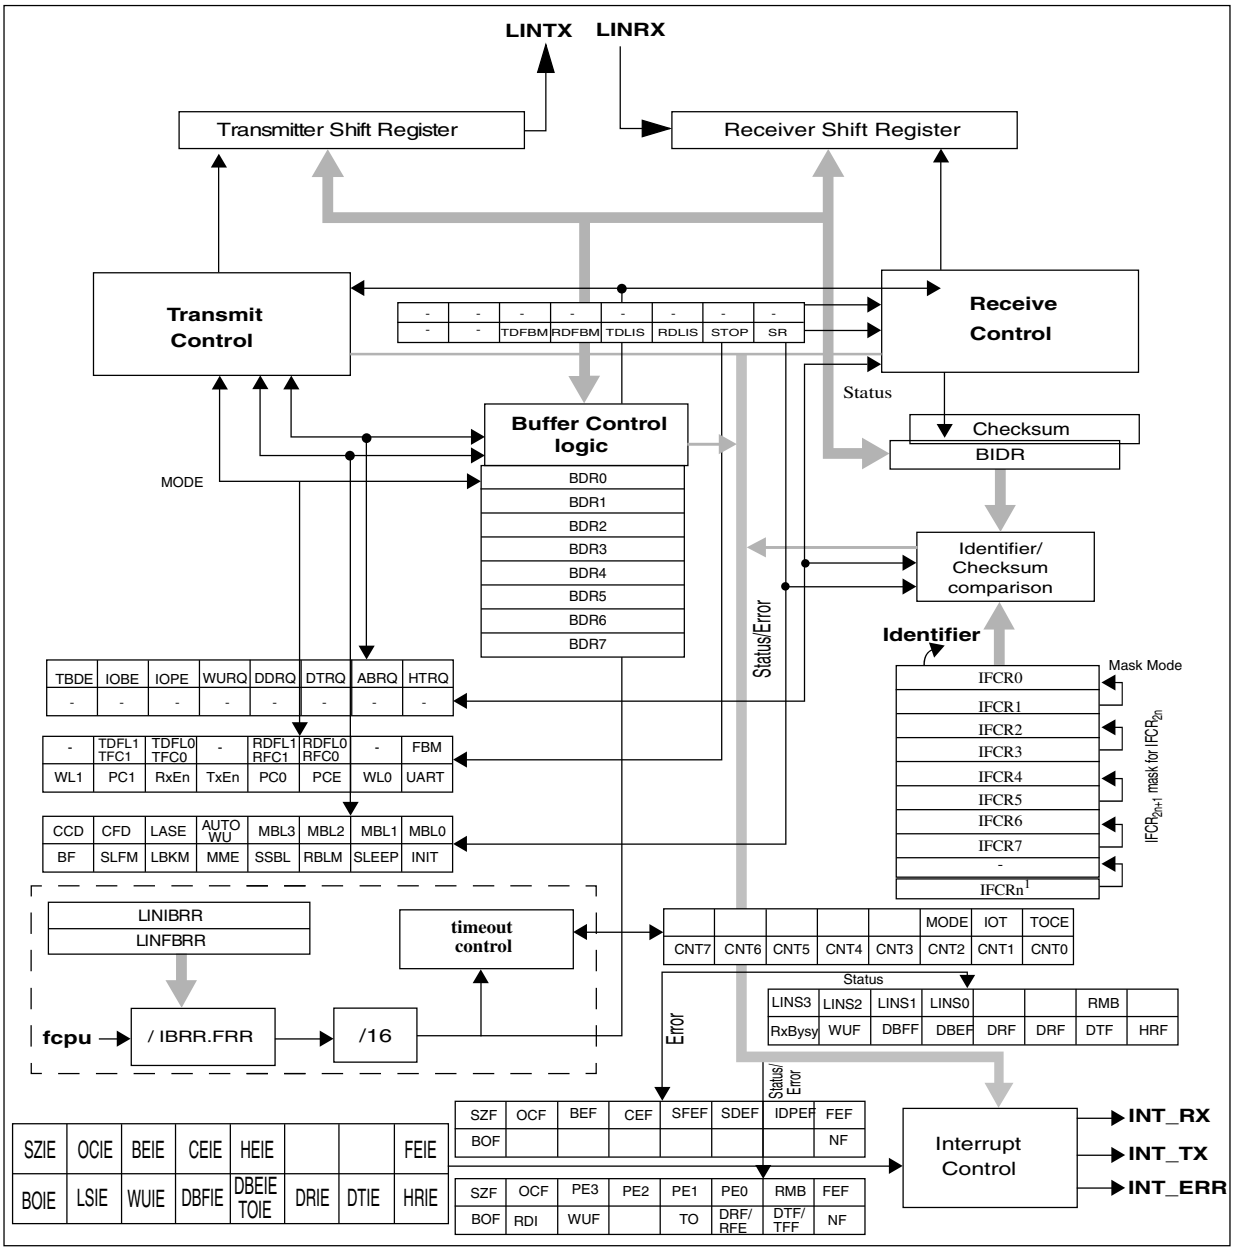

Figure 54-1. Block diagram

Notes:

1: The value of n depends on the no_of_filters. Refer to the chip configuration details to see the number of filters used in this device.

2: For LIN mode N = 16 and N is programmable by user in UART mode.

54.3 Main features

The LINFlexD controller can operate in several modes, each of which has a distinct set of features that are described in the following sections. In addition, the LINFlexD controller has several features common to all modes:

- Fractional baud rate generator
- 3 operating modes for power saving and configuration registers lock
  - Initialization
  - Normal
  - Sleep
- Test Mode:Loop Back
- Maskable interrupts
- A maximum of 16 possible identifiers can be programmed into the identifier list

54.3.1 LIN mode features

- Supports LIN protocol version 1.3, 2.0, and 2.1
- Bit rates up to 20 Kbit/s (LIN protocol)
- Master/Slave mode
- Classic and Enhanced Checksum calculation and check
- Single 8-byte buffer or FIFO for Transmission/Reception
- Timeout management
- Identifier filters
- DMA interface
- Supports a maximum of 16 possible identifiers
- Master mode with autonomous message handling
- Extended frame mode for in-application programming purposes
- Wakeup event on dominant bit detection

- True LIN field state machine
- Advanced LIN error detection
- Header, response, and frame timeout
- Slave mode
  - Autonomous header handling
  - Autonomous transmit/receive data handling
- Identifier filters for autonomous message handling in Slave mode
- Separate clock for baud rate calculation
  - The relationship “(2/3)* LIN_CLK > PBRIDGEx_CLK > 1/3*LIN_CLK” should be maintained.

54.3.2 UART mode features

- Full-duplex communication
- Baud rate is a function of baud clock, LINIBRR and LINFBRR registers - see Baud rate generation
- Separate clock for baud rate calculation
  - The relationship “(2/3)* LIN_CLK > PBRIDGEx_CLK > 1/3*LIN_CLK” should be maintained.
- 15/16/7/8 bits data, parity
- 1/2/3 stop bits
- 12-bit + parity reception
- 4-byte buffer for reception, 4-byte buffer for transmission
- 12-bit counter for timeout management
- The maximum baud rate achievable is 25 Mbit/s.
- For bit rate ≤ 6.25 Mbit/s
  - Sixteen times oversampling
  - 3:1 majority voting
- For 6.25 Mbit/s < bit rate ≤ 12.5 Mbit/s

- Reduced over sampling programmable by the user
- 3:1 majority voting for reduced over sampling of 8

- For 12.5 Mbit/s < bit rate ≤ 25 Mbit/s
  - Reduced over sampling programmable by the user
  - 1:1 voting for all reduced over sampling of 4, 5 and 6

54.4 Functional description

54.4.1 LIN protocol

The LIN (Local Interconnect Network) is a serial communication protocol. A LIN cluster consists of one master task and several slave tasks. A master node contains the master task as well as a slave task. All other nodes contain a slave task only. The master node decides when and which frame is transferred on the bus. The slave task provides the data to be transported by the frame.

54.4.1.1 Frames

A frame consists of a header provided by the master task and a response provided by the slave task. The header consists of a break, a sync pattern, and an identifier. The break is followed by the sync pattern and the sync pattern is followed by the identifier. The slave task associated with the identifier provides the response. The response consists of a data field and checksum. The slave task designated to receive the data associated with the identifier receives the response and verifies the checksum.

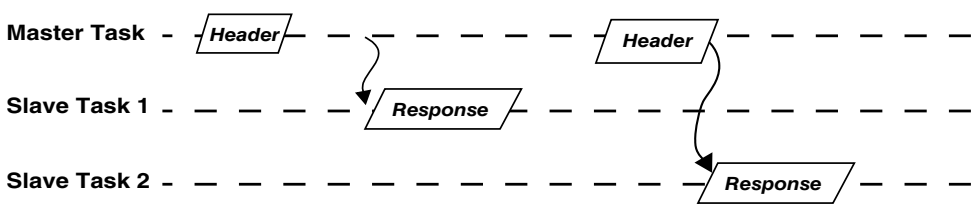

Figure 54-2. Frames

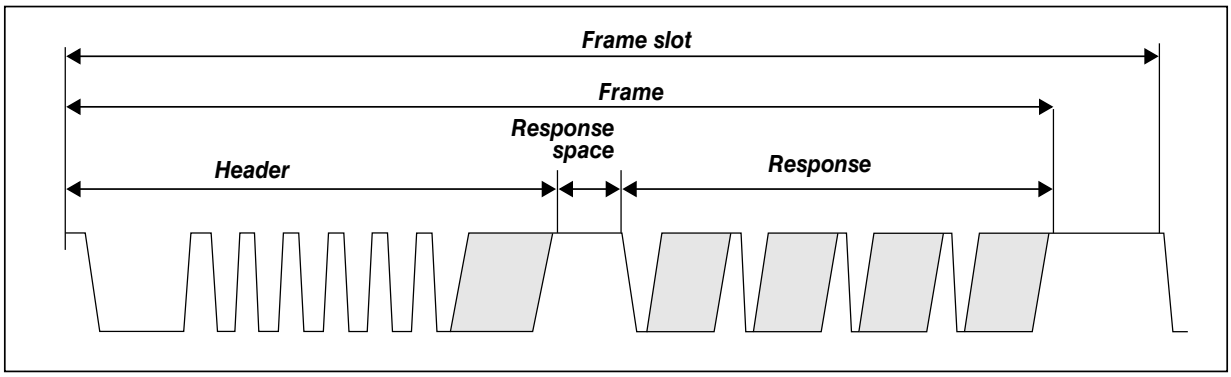

Figure 54-3. Structure of LIN frame

54.4.1.2 Data field

Each byte is transmitted as shown in Figure 54-4. The LSB of the data is sent first and the MSB is sent last. The start bit is encoded as a bit with value zero (dominant) and stop bit is encoded as bit value one (recessive).

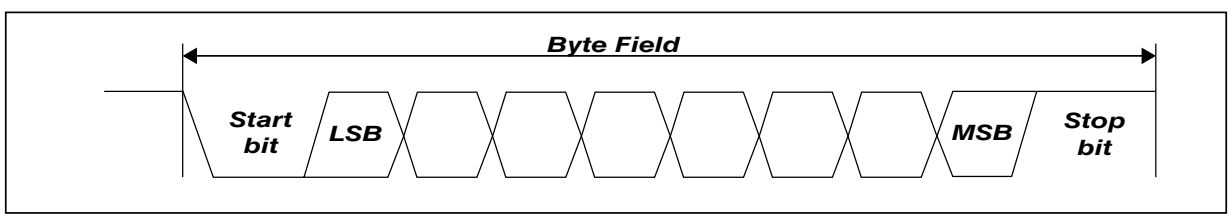

Figure 54-4. Structure of byte field

54.4.1.3 Break

The break symbol is used to signal the beginning of a new frame. It is the only field that does not comply with the above figure. The break is always generated by the master and shall be at least 13 bits of dominant value including the start bit, followed by a break delimiter as shown in Figure 54-5. The break delimiter must be of two-bit duration (to be compliant with LIN protocol 2.1).

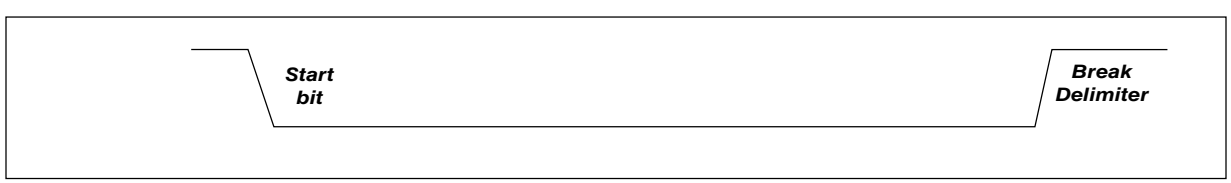

Figure 54-5. Break field

54.4.1.4 Sync byte

Sync is a byte field with the data value of 0x55.

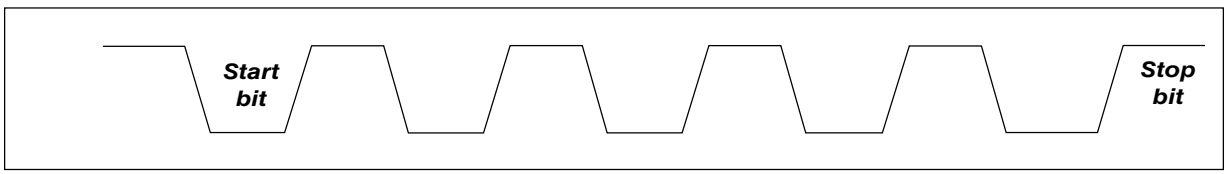

Figure 54-6. Sync byte field

54.4.1.5 Identifer

The Identifier field consists of two sub-fields, the identifier and the identifier parity. Bits 0 to 5 are the identifier and bits 6 and 7 indicate the parity.

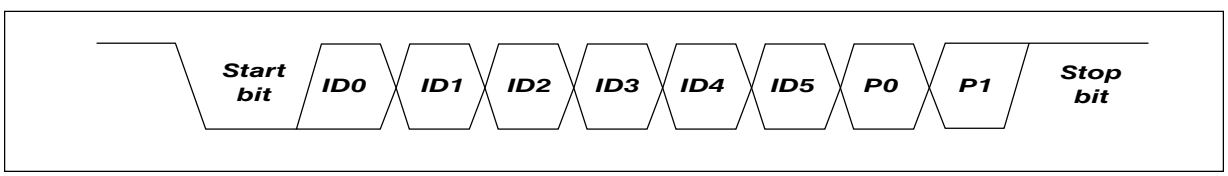

Figure 54-7. Identifier field

P0 = ID0 XOR ID1 XOR ID2 XOR ID4

P1 = NOT (ID1 XOR ID3 XOR ID4 XOR ID5)

54.4.1.6 Checksum

The last field of a frame is the checksum. The checksum contains the inverted 8-bit sum with carryover of all data bytes or all data bytes and the identifier. Checksum calculation over the data bytes only is called classic checksum and is used for communication with LIN 1.3 slaves. Checksum calculation over the data bytes and the protected identifier byte is called enhanced checksum and is used for communication with LIN 2.0 slaves.

54.4.2 LINFlexD features

54.4.2.1 Operating modes

The LINFlexD has three operating modes: **Initialization, Normal** and **Sleep** modes. After hardware reset, the LINFlexD enters sleep mode to reduce power consumption.

Initialization mode (INIT)

To enter this mode, software sets the INIT bit in the LINCR1. To exit the initialization mode, software should reset the INIT bit.

When in initialization mode, all message transfers to and from the LIN bus are stopped and the status of LIN bus output LINTX is recessive (high). If software invokes the initialization mode when a bus transfer is in progress, the transfer is aborted. The software should therefore check the LIN state before setting this bit.

To initialize the LINFlexD controller software must:

1. Set up the baud rate registers
2. Reset UART bit
3. Select the mode (master or slave)
4. Configure checksum control bits
5. Initialize the identifier list (Slave mode)

Normal mode (NM)

Once software has completed initialization of the LINFlexD controller, it can enter the Normal mode by clearing the INIT bit.

Sleep mode (SM)

Sleep mode in LINFlexD reduces power consumption. This mode is entered by setting the SLEEP bit in LINCR1. In this mode the LINFlexD clock is stopped. LINFlexD can be awakened from Sleep mode by clearing the SLEEP bit.

If software detects a wakeup pulse of 150 µs on the LIN Bus, it can request LINFlexD to wake up from Sleep mode. Refer to Wakeup management.

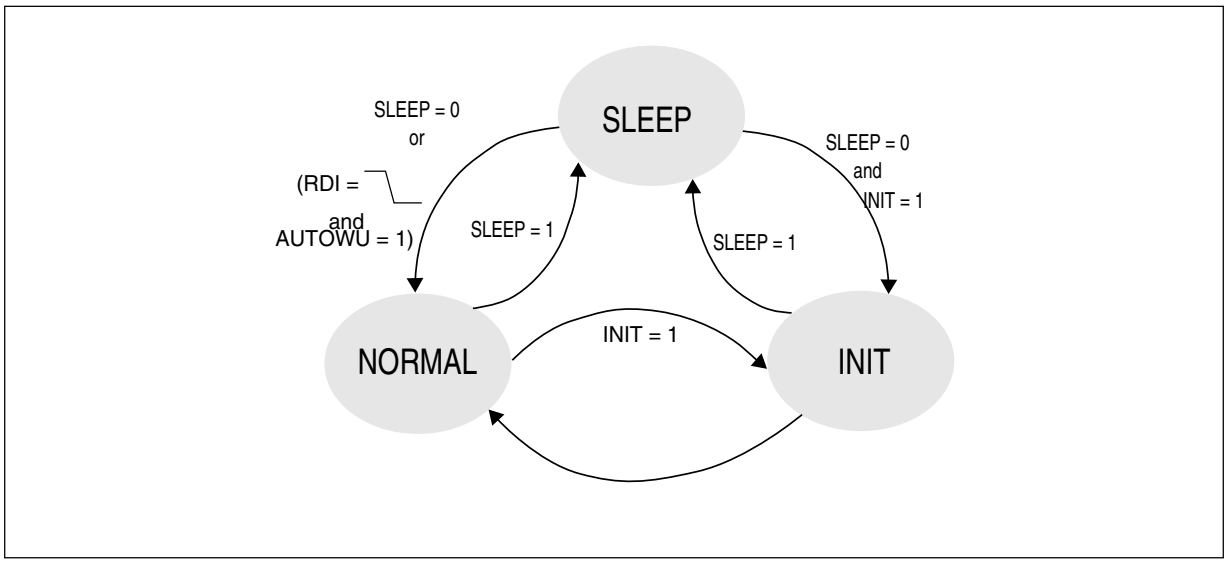

Figure 54-8. Operating modes

54.4.2.2 Test mode

Loop Back mode

This mode is entered by setting the LBKM bit in LINCR1. In this mode, the LINFlexD receives the Identifier and Data transmitted by itself and writes the same in the BIDR and Data buffers respectively. This mode is provided for selftest functions. Bit error is checked in this mode.

The LINFlexD ignores the LINRX signal. There is an internal feedback from its TX output to its RX input. The TX pin can be disconnected from LINTX pin by SIUL2 setting.

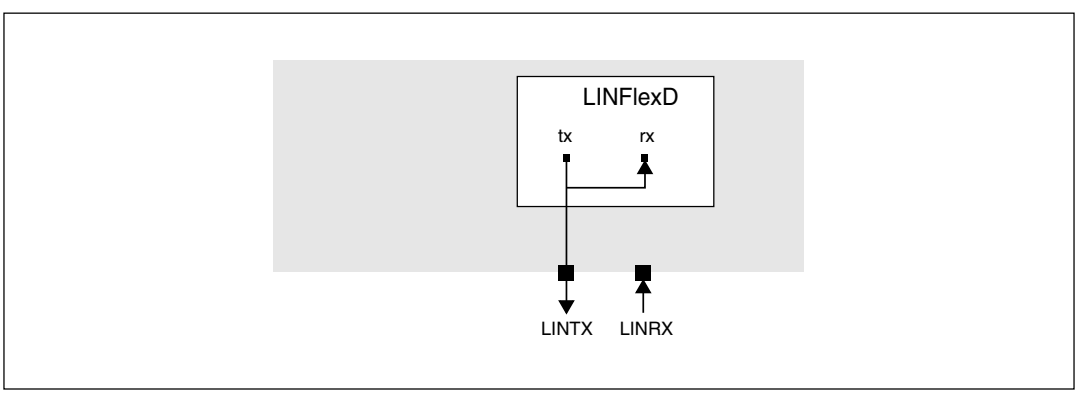

Figure 54-9. LINFlexD in Loop Back Mode

54.4.2.3 Master mode

Master mode is selected by means of the MME bit in LINCR1 register.

Header transmission

According to the LIN protocol any communication on the LIN bus is triggered by the master sending a header. The header is transmitted by the master task of a node while the response is transmitted by the slave task of a node.

To transmit the header, first program the Identifier, data field length, message direction and checksum enable in the BIDR register; then set the HTRQ bit in LINCR2. Once header transmission starts, the user should not modify BIDR register bits untill the current frame is complete. The transmitted ID is also received by the master node and copied to BIDR.

Data transmission

When the master node is the publisher of the data corresponding to the Identifier sent by the master, then the slave task of the node should send the data in the response part of the frame. Hence software must provide the data to the LINFlexD before the header transmission is requested. The data to be transmitted is stored in the message buffer BDRL and BDRM. The number of bytes to be transmitted depends on the Data Field length in BIDR. The software uses the BIDR[CCS] bit to configure the checksum type (classic or enhanced) for each message.

If the response has been sent successfully, LINSR[DTF] is set. In case of error, the DTF flag is not set and the corresponding error flag is set in the LINESR (refer to error handling).

It is possible to handle frames with a response size larger than eight bytes of data (extended frames). If the data field length in the BIDR is configured with a value higher than eight data bytes, LINSR[DBEF] is set once the first eight bytes have been transmitted. The application has to update the buffer BDR before resetting the DBEF bit. The transmission of the next bytes starts when the DBEF bit is reset. Once the last data byte (or the checksum byte) has been sent, the DTF flag is set.

The direction of the message buffer is decided by the DIR bit in the BIDR. The transmitted data is also received by the same node and copied to the buffer.

Data reception

To receive data from a slave node, the master sends a header with the corresponding Identifier. The data received from the slave is stored in the message buffer and the status of the message is stored in the LINSR.

If the response has been received successfully, the LINSR (DRF) bit is set. In case of error, the DRF flag is not set and the corresponding error flag is set in the LINESR (refer to Error handling).

It is possible to handle frames with a Response size larger than eight bytes of data (extended frames). If the data field length in the BIDR is configured with a value higher than eight data bytes, the LINSR (DBFF) bit is set once the first eight bytes have been received. The application has to read the buffer BDR before resetting the DBFF bit. Once the last data byte (or the checksum byte) has been received, the DRF flag is set.

Data Discard

If the user wants to discard the data after header transmission, then the DDRQ bit in LINCR2 should be set.

54.4.2.4 Slave mode

This mode is selected when the MME bit of the LINCR1 register is cleared.

Data transmission

On header reception, the HRF bit is set and an RX interrupt is generated. The software must then:

1. Read the received ID in the BIDR register
2. Fill the BDR[0:x] register
3. Program the CCS and DIR bits in the BIDR register
4. Specify the data field length DFL[5:0] bits in the BIDR register
5. Trigger the data transmission by setting the DTRQ bit

Note that the HRF bit should be reset only after the DTRQ bit is set. For the DTRQ to be effective, the HRF bit must be set. This is to ensure that DTRQ is not set randomly, but only after a header reception. It must be noted that you cannot set the DIR and DTRQ bits once RXbusy is asserted in LINSR.

Alternately, one or more Identifier filters are configured for transmission by setting the DIR bit, and activated by setting the enable bits in IFER. When at least one Identifier filter is active and configured for transmission and the received ID matches the filter, a TX interrupt is generated. The software can use the index in the IFMI register to point directly to the corresponding data array in the RAM and copy this data to the BDR[0:7].

The use of a filter saves software the processing time required to read the ID value in the BIDR, match it, and configure the data field length and checksum type.

If the number of filters provided by LINFlexD are not sufficient for the application, mask mode can be used for the filters.

The transmitted data is also received by the same node and copied to the buffer.

Data reception

When LINFlexD is the subscriber of the data of the received identifier, then on header reception the HRF flag is set and an RX interrupt is generated. The software must read the received ID from the BIDR register and specify the data field length before the reception of the stop bit of the first data byte. When the checksum is received, an RX interrupt is generated for software to read the received data from BDR[0:7] and the RMB bit is set. Software must then release the data buffer by resetting the RMB bit in the LINSR.

When at least one identifier filter is active and configured for reception, an RX interrupt is generated only after the checksum reception. No interrupt request is generated on reception of the ID.

If the Identifier is filtered by software then you can discard the data by setting the DDRQ bit in the LINCR2, while HRF is set.

Note that for software filtering, software must decide the type of checksum (configure the CCS bit of the BIDR register) before reception of data. Otherwise the previous value of the CCS bit is considered while calculating checksum.

54.4.2.5 Errors

54.4.2.5.1 Header error

A header error is an error during the header reception. The error types are:

1. Sync Del error (SDEF)
2. Sync field error (SFEF)
3. Identifier Parity error (IDPEF)

Sync Del error (SDEF)

The delimiter should be 1 for at least one bit time; otherwise it is considered short and consequently the receiver discards synchronization on the current header. Hence the frame is discarded. An interrupt is generated if *HEIE* bit of LINEIER is set.

Sync field error (SFEF)

The SFEF error condition is monitored differently depending on whether autosynchronization (LASE) is ON or OFF.

Case 1: Autosynchronization ON (LASE bit of LINCR1 = 1):

When Autosynchronization is enabled, the SFEF flag indicates:

- The deviation error on the Sync Field is outside the LIN specification, which allows up to 14% of period deviation between the slave and master oscillators or
- An overflow has occurred during the Sync Field Measurement, which leads to an overflow of the divider registers.

Deviation error on the Sync Field

The deviation error is checked by comparing the current baud rate (relative to the slave oscillator) with the received LIN Sync Field (relative to the master oscillator).

This check is based on a measurement between the first falling edge and the last falling edge of the Sync Field. Let's refer to this period deviation as D.

If SFEF field is asserted it means that:

D > 14.0625%

If there is no error, it means that:

D < 14.84375%

If 14.0625% < D < 14.84375%, then the Sync Field could be either consistent or inconsistent depending on dephasing between the signal on the RDI line and the LIN_CLK.

Overflow during Sync Field Measurement

This check is based on the measurement of each bit time between both edges of the Sync Field. This checks that each of these bit times is large enough (more than 12 samples) compared to the bit time of the current baud rate.

Case 2: Autosynchronization OFF (LASE bit of LINCR1 = '0')

In this case the Sync character is received as a normal character. If the received character is 0x55 then the Sync Field is OK.

On any occurrence of an inconsistent Sync Field, the receiver immediately exits from Sync_Field state and the frame is consequently discarded. The SFEF bit of LINESR is set.

Identifier Parity error(IDPEF)

There are two parity bits in the identifier field. These bits are checked against the hardware-calculated parity over the other six bits of identifier, according to the formula:

P0 = ID0 XOR ID1 XOR ID2 XOR ID4

P1 = NOT (ID1 XOR ID3 XOR ID4 XOR ID5)

This parity is checked after the ID is transferred to the BIDR register (after stop of ID has been detected properly) and upon parity mismatch, the receiver state machine exits from Identifier state immediately if the IOPE bit of LINCR2 is set.

54.4.2.5.2 Bit error

This error is flagged in transmission mode when the value read back from the bus is different from the value transmitted. Bit error checking on each bit is guaranteed if transceiver delay is less than one bit time minus 6 LIN_CPU cycles. Bit error is not checked during break field transmission.

1-bit time at 20 Kbit/s = 50 µs

6 LIN_CLK cycles at 80 MHz = 75 ns

Thus, (1-bit time) - (6 LIN_CLK cycles) = 49.925 µs

Transmission of the frame is stopped after the corrupted bit if the IOBE bit in LINCR2 is set. If IOBE is reset, the transmitter continues to transmit in spite of the bit error. An interrupt is generated if the BEIER bit is set in LINIER.

Note

If the break delimiter is not detected by the master within one bit time after delimiter transmission due to transceiver delay or error on the bus, then a train of bit error interrupts are generated. In this case, the Identifier may not be replaced in the BIDR.

Similarly, if the start of a falling edge of data is not detected by the transmitter node within one bit time after start bit transmission, then a train of bit error interrupts are generated. In this case also, data and checksum replacements in the BDR and CFR respectively are not guaranteed.

54.4.2.5.3 Framing error

This error is flagged when a dominant state is sampled on stop bit of the current received character (sync field, identifier field, data field, checksum field). LINFlexD discards the current frame and returns to Idle state. An interrupt is generated if FEIE bit is set in LINEIER.

The byte that caused framing error is also shifted to the buffer but DRF or DBFF is never set in this case.

54.4.2.5.4 Checksum error

This error is flagged when the checksum computed by hardware does not match the received checksum.

LINFlexD discards the received frame and returns to Idle state. An interrupt is generated if the CEIE bit is set in LINEIER.

54.4.2.5.5 Overrun error

Once the message buffer is full (RMB is set), the next valid message reception will lead to an overrun and the message will be lost. The hardware signals the overrun condition by setting the BOF bit. Which message is lost depends on the buffer lock function control bit RBLM.

If RBLM is cleared, the old message in the buffer is overwritten by the most recent message. If RBLM bit is set, the most recent message is discarded and the oldest message is available to the software. In the case of slave, if buffer is not released (RMB is not reset) before reception of next Identifier and if RBLM is set, then the ID along with the data is discarded.

54.4.2.5.6 Timeout error

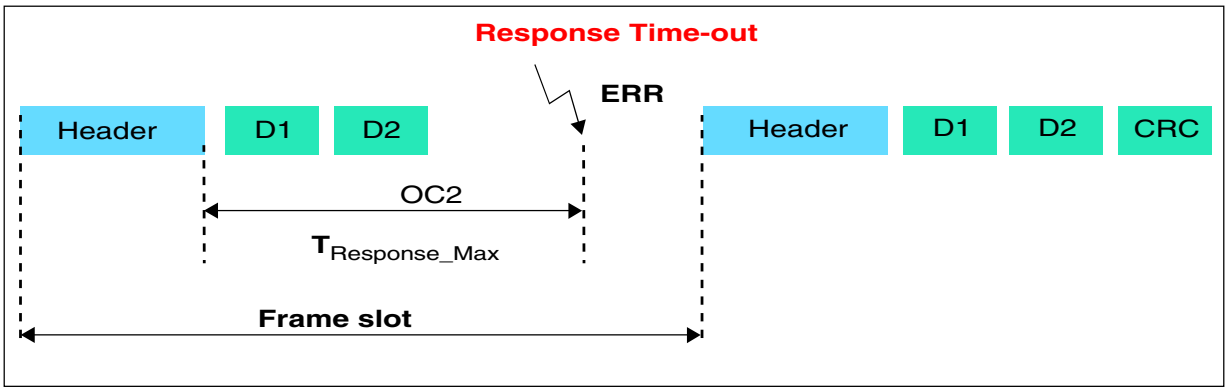

Figure 54-10. Incomplete response (for example, missing checksum)

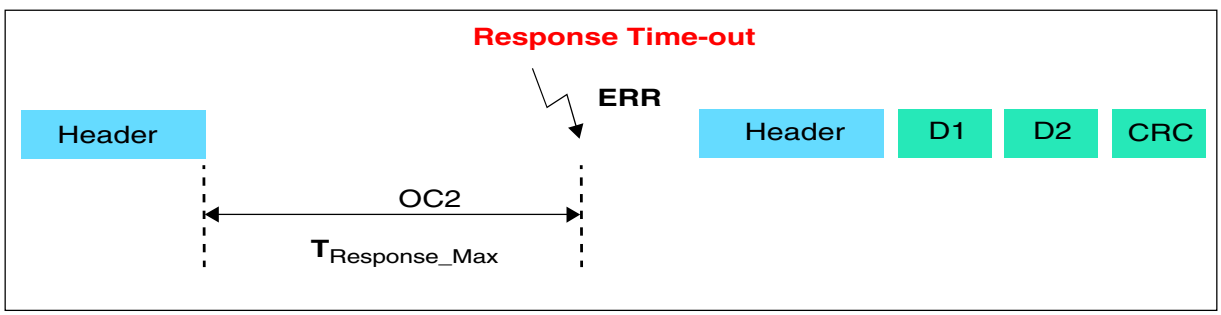

Figure 54-11. No response

Response timeout mechanism

- Master mode
  - OC2 is loaded with Nominal_time_out + LINFlexD_LINTCSR[CNT] at the end of the stop bit of the Identifier field (where nominal_time_out = 1.4 × ((DFL + 2) × 10 bit time).

    This loading takes place at the end of id field (and not at the beginning of data field). Moreover, the correct value, which depends on DFL, is loaded immediately. No further OC2 update is required.
  - In case of no response at all within this time (in other words, start of data is not received), timeout takes place when the counter reaches the OC2 value (no change compared to earlier implementation).
  - In case of an incomplete response, timeout also occurs when the counter reaches the OC2 value (no change compared to earlier implementation).
- Slave mode

- **Case 1**: The received identifier is managed by a filter. The implementation can be similar to the master mode, because the DFL value is loaded by hardware. Thus, OC2 can be loaded with Nominal_time_out + LINFlexD_LINTCSR[CNT] at the end of the stop bit of the Identifier field (where nominal_time_out = 1.4 × ((DFL + 2) × 10 bit time))
- **Case 2**: The received identifier is not managed by a filter. As the DFL value needs to be updated by software after the identifier field has been received, the implementation is the following:
  - At the end of the ID, OC2 is loaded with 36 (maximum possible response space) + LINFlexD_LINTCSR[CNT].
  - At the end of the first_data_byte it is reloaded again according to DFL
  - Before reloading, LINFlexD checks the count_val. If count value is higher than the value to be reloaded, timeout takes place immediately and no reloading occurs.

NOTE

The value of nominal_time_out (1.4 × ((DFL +2) × 10 bit time)) shown is as per the reset value of LINTOCR[RTO] and LINCR1[CFD]. It changes with change in value of LINTOCR[RTO] and LINCR1[CFD]. Here, 1.4 corresponds to (LINTOCR[RTO])/10 and 2 corresponds to (2- LINCR1[CFD])

Header timeout mechanism

- Master mode: As the header is generated by the LINFlexD, there are only two cases:
  - no error on the bus and timing is correct (nominal header length),
  - an error occurs on the bus and LINFlexD flags it in LINESR register (typically a bit error).

  Therefore there is no meaning of header timeout in master mode, so it is disabled.
- Slave mode
  - header_nominal = 13 + 2 + 10 + 10 = 35 Tbit
  - header_max = 1.4 × Header_nominal = 49 Tbit

- taking into account a possible 14% clock deviation, header_max seen by LINFlexD is 49 × 1.14 = 56 Tbit
- If the counter starts after 11 Tbit (break duration), the HTO value is 56 –11 = 45 Tbit.

The reset value of HTO is 45, and this register can only be programmed in slave mode. Counter restarts after break duration and OC1 gets loaded with the value of HTO.

As response space is not included in the response, frame timeout is no longer needed and is removed completely. Indeed, header timeout and response timeout cover all cases.

The timeout counter can be used to detect other timeouts. In this case, the MODE bit must be reset and the output compare value can be updated in the LINTOCR register by software.

Stuck at zero timeout error

If the dominant pulse lasts for a time of at least 100 bits, the SZF bit in LINESR is set. If the same dominant pulse prolongs, the subsequent SZF setting will be 87 bit times apart (instead of 100 bit times).

54.4.2.5.7 Noise

During reception each bit is sampled 16 times and the value of the bit is obtained by taking the majority value of the 8th, 9th and 10th samples. If any one of these three samples has a value different from the other two, this error is flagged.

When OSR = 8, majority of 2nd, 3rd, and 4th samples are taken into account to determine noise. Noise checking is disabled for all OSR less than eight.

This error is flagged when there is noise detected in the start bit (see LIN Error Status Register (LINFlexD_LINESR).

54.4.2.6 Identifier filtering

In LIN protocol the identifier of a message is not associated with the address of a node but is related to the content of the message. A transmitter broadcasts its message to all the receivers. Based on the header received, the receiver decides whether to receive or transmit a response (depending on the identifier value). If the message does not target the node, it should be discarded.

To fulfill this requirement, the LINFlexD provides configurable filters in order to eliminate software intervention. This hardware filtering saves CPU resources that would otherwise be required to perform filtering by software.

There are a maximum of 16 filters (depending on the generic no_of_filters) in the LINFlexD, which can be programmed by the user only during Initialization mode. In order to activate a filter the corresponding FACT bit in IFER needs to be set. There are two modes possible for each identifier depending on the corresponding IFM bit of IFMR.

Identifier list mode

If the n^{th} bit of IFMR is cleared, then filter number 2n and 2n+1 is in identifier list mode. In this mode, the maximum number of filters that can be configured for transmission/ reception equals no_of_filters, depending on the FACT bit of IFER. In this mode the identifier received should match bit by bit to the ID field of IFCR2n or IFCR2n+1 (if the corresponding FACT bit is set).

Identifier mask mode

If the number of filters required is more than no_of_filters, then filters should be configured in Mask mode. If the n^{th} bit of IFMR is set, then filter number 2n is the filter and 2n+1 acts as a mask for it. The FACT bit for filter 2n+1 has no effect in this case. In this mode, if the x^{th} bit of the mask is set, then the x^{th} bit of the received identifier must match the x^{th} bit of filter.

If there is a match of identifier with the mth filter in any mode, then m+1 is loaded in the IFMI register by hardware. No match condition is denoted by IFMI = 0.

Upon matching DFL (2:0), the CCS and DIR bits of the BIDR register are copied from the filter by hardware and from then on, the BIDR register is read-only untill the end of the frame. Now if the DIR bit of BIDR is set, then a TXI interrupt is generated if the HRIE bit of LINIER is set. In this case, software uses the IFMI register to transfer the relevant data from the RAM area to BDR, and after complete transfer the DTRQ bit of LINCR2 is set to start the transmission. If the DIR bit is cleared then an RXI interrupt is generated (provided DRIE bit of LINIER is set) when the checksum has been received and there is no checksum error.

In case of no filter match condition (IFMI = 0) and if the BF bit of LINCR1 is set, then an RXI is generated. Now it is the responsibility of software to configure BIDR and start transmission (by loading the BDR buffer and setting the DTRQ bit of LINCR2) or discard reception (by setting the DDRQ bit of LINCR2). If the BF bit is reset, then the receiver discards the received identifier and turns to Idle state in search of a new break.

Note

If one identifier matches with two filters (one is in the list and the other in Mask mode) then List mode prevails over Mask mode. In mask mode if two filters match with the identifier then the filter having the lower number prevails.

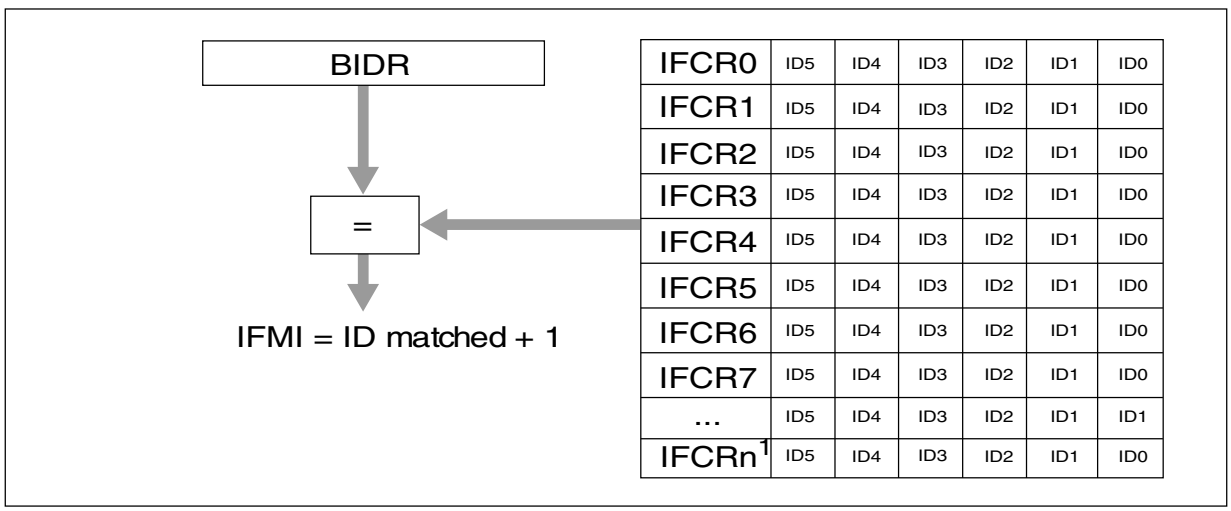

Figure 54-12. Identifier List mode

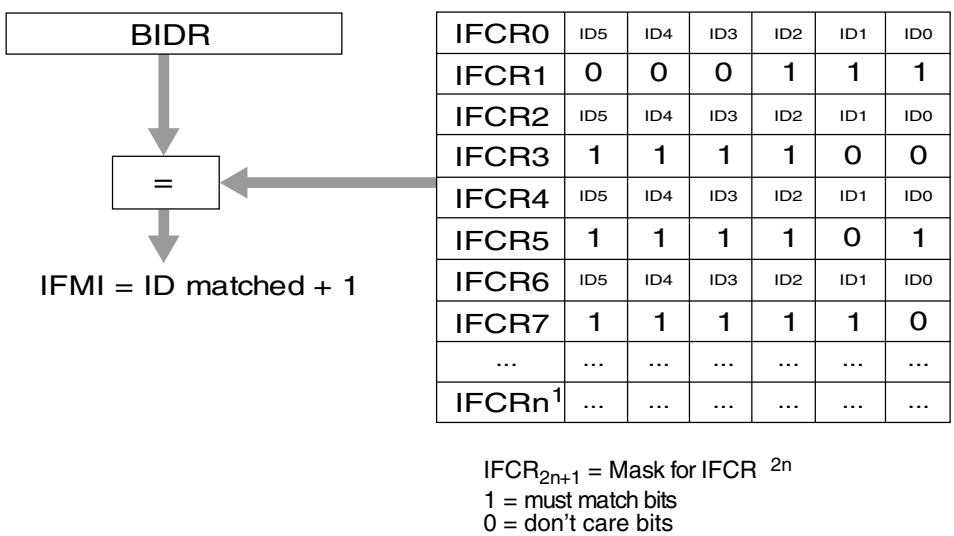

Figure 54-13. Identifier Mask mode

54.4.2.7 Start detection and break delimiter detection in receiver

There is a 10-bit-shift register sample register in the receiver that shifts signal data to the next least significant bit on each incoming sample.

Table 54-3. Start Detection and Delimiter Detection in receiver

9	8	7	6	5	4	3	2	1	0	Sample_reg
—	—	—	—	—	—	—	—	—	RT1	counter = 0
—	—	—	—	—	—	—	—	RT1	RT2	counter = 1
—	—	—	—	—	—	—	RT1	RT2	RT3	counter = 2
—	—	—	—	—	—	RT1	RT2	RT3	RT4	counter = 3
—	—	—	—	—	RT1	RT2	RT3	RT4	RT5	counter = 4
—	—	—	—	RT1	RT2	RT3	RT4	RT5	RT6	counter = 5
—	—	—	RT1	RT2	RT3	RT4	RT5	RT6	RT7	counter = 6
—	—	RT1	RT2	RT3	RT4	RT5	RT6	RT7	RT8	counter = 7
—	RT1	RT2	RT3	RT4	RT5	RT6	RT7	RT8	RT9	counter = 8
RT1	RT2	RT3	RT4	RT5	RT6	RT7	RT8	RT9	RT10	counter = 9
RT2	RT3	RT4	RT5	RT6	RT7	RT8	RT9	RT10	RT11	counter = 10
RT3	RT4	RT5	RT6	RT7	RT8	RT9	RT10	RT11	RT12	counter = 11
RT4	RT5	RT6	RT7	RT8	RT9	RT10	RT11	RT12	RT13	counter = 12
RT5	RT6	RT7	RT8	RT9	RT10	RT11	RT12	RT13	RT14	counter = 13
RT6	RT7	RT8	RT9	RT10	RT11	RT12	RT13	RT14	RT15	counter = 14
RT7	RT8	RT9	RT10	RT11	RT12	RT13	RT14	RT15	RT16	counter = 15
1	1	1	0	x	0	x	0	x	0	start detect
1	1	1	0	x	0	x	0	x	1	
1	1	1	0	x	0	x	1	x	0	
1	1	1	0	x	1	x	0	x	0	
0	0	0	1	x	1	x	1	x	1	delimiter detect
0	0	0	1	x	1	x	1	x	0	
0	0	0	1	x	1	x	0	x	1	
0	0	0	1	x	0	x	1	x	1	

Hence, a start is detected as soon as it is qualified with 1110 in the sample register and verified with at least two out of three predefined verification samples being zero. Similarly for delimiter detection, qualification samples are 0001 and at least two of the three verification samples are one. The Noise Flag is set if the start is verified with only two valid samples.

54.4.2.7.1 Start detection mechanism

The following steps are followed for detecting a start bit:

1. Refer to Table 54-3 for the status of the sample register (shift register) when count = 6
2. At this point, if RT1 (the first incoming sample) = 0 and the previous three samples already received are all ones, then it might be a start bit.
3. To make sure it is indeed a start bit, the incoming data samples in the sample register (4), sample register (2) and sample register (0) which correspond to RT3, RT5, and RT7 is verified using the steps mentioned below.
4. If the majority (i.e., 2) out of these 3 samples are equal to '0', then start bit is said to be detected.
5. These three samples RT3, RT5, and RT7 are called the "verification samples" which are checked at count = 6.
6. The sample register bits 9, 8, 7, and 6 are called "qualification samples" which are checked at count = 6.
7. At count = 9, if majority value of RT8, RT9, and RT10 is not equal to '0' then Noise flag is set.

54.4.2.7.2 Break delimiter detection mechanism

The following steps are followed for detecting a delimiter bit:

1. Refer to Table 54-3 for the status of the sample register (shift register) when count = 6
2. At this point, if RT1 (the first incoming sample) = 1 and the previous three samples already received are all zeros, then it might be a delimiter bit.
3. To make sure it is indeed a delimiter bit, the incoming data samples in the sample register (4), sample register (2) and sample register (0) which correspond to RT3, RT5, and RT7 is verified using the steps mentioned below.
4. If the majority (i.e., 2) out of these 3 samples are equal to '1', then delimiter bit is said to be detected.
5. These three samples RT3, RT5, and RT7 are called the "verification samples" which are checked at count = 6.
6. The sample register bits 9, 8, 7, and 6 are called "qualification samples" which are checked at count = 6.

Hence, a start is detected as soon as it is qualified with 1110 in the sample register and verified with at least two out of three predefined verification samples being zero. Similarly for delimiter detection, qualification samples are 0001 and at least two out of the three verification samples are one. The Noise Flag is set if the start is verified with only two valid samples.

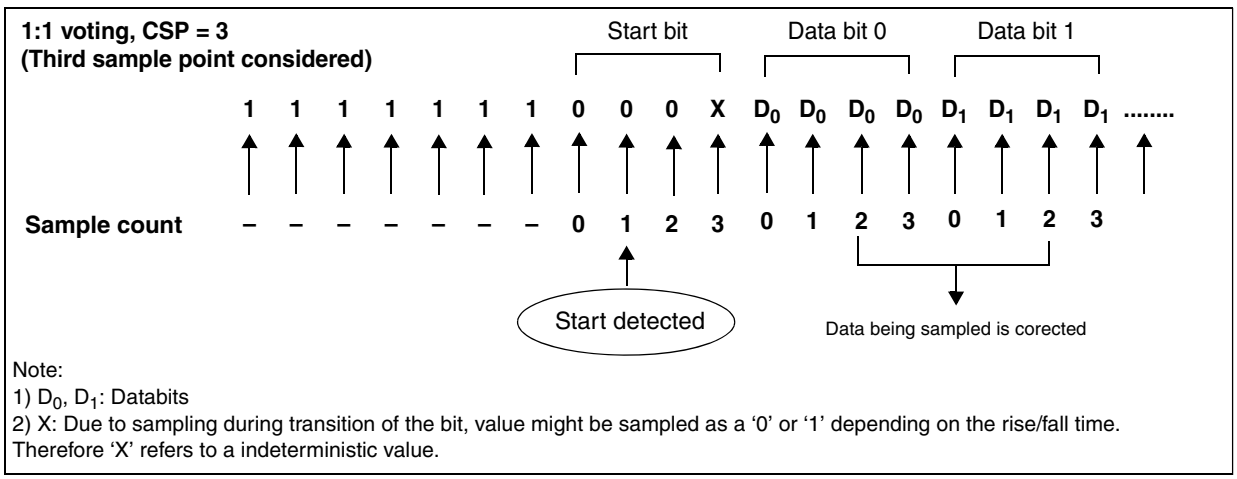

Figure 54-14. Start detection and sampling for over sampling rate = 4 (Case 1)

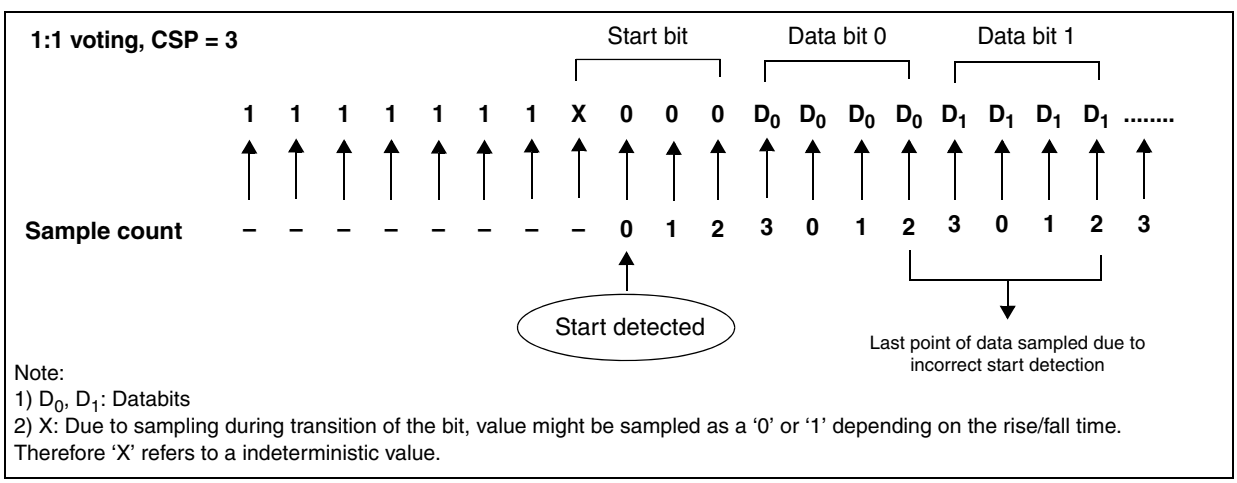

Figure 54-15. Start detection and sampling for over sampling rate = 4 (Case 2a)

The choice of the correct sample points depends on the external Rx signal quality. During the application development process, the error information indicated by the parity error can help to find the best setting for an application-specific hardware signal.

To sample at the correct point therefore, CSP has to be changed to two; resulting in the following situation:

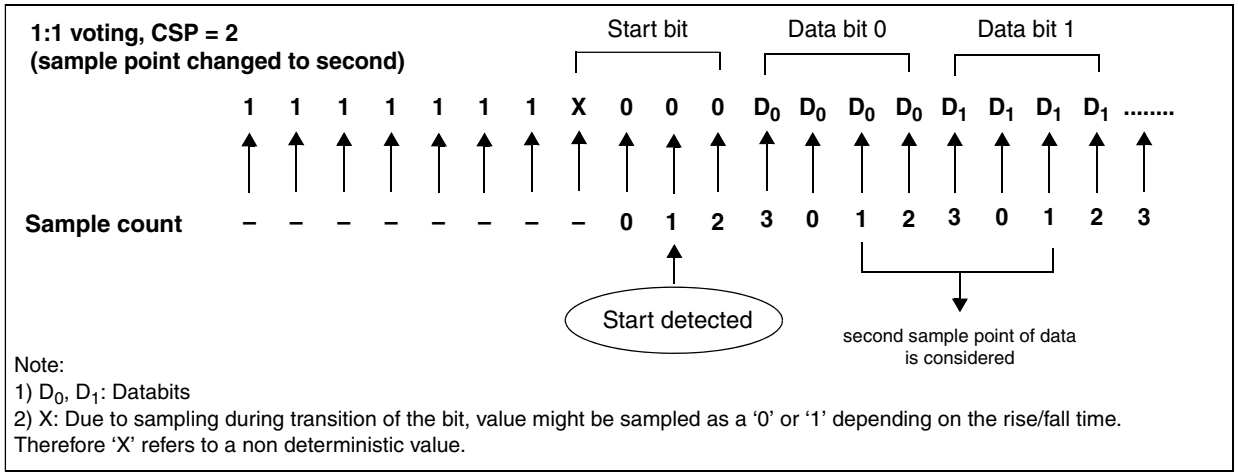

Figure 54-16. Start detection and sampling for over sampling rate = 4 (Case 2b)

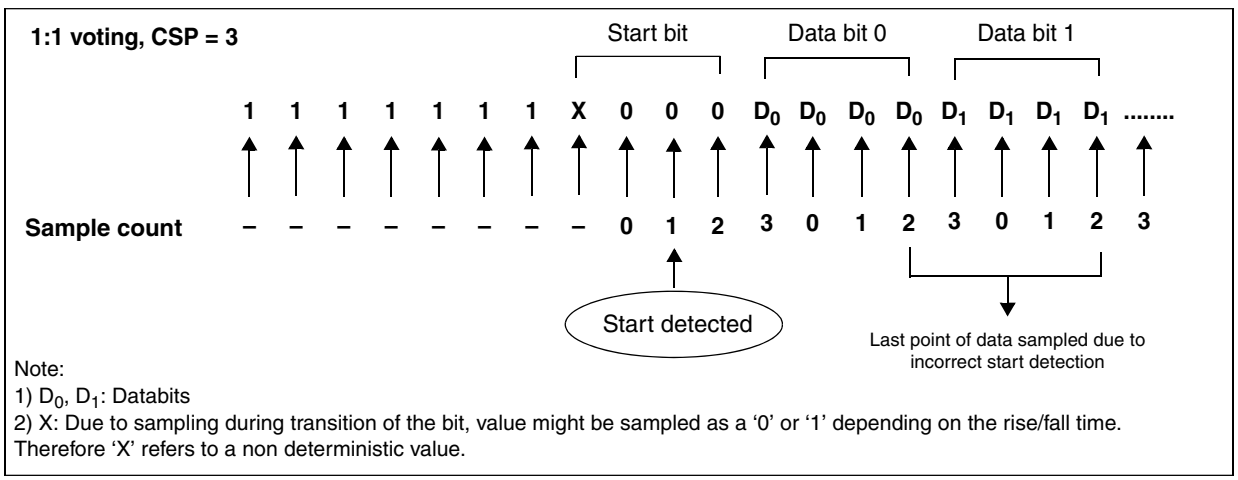

Figure 54-17. Start detection and sampling for over sampling rate = 4 (Case 3)

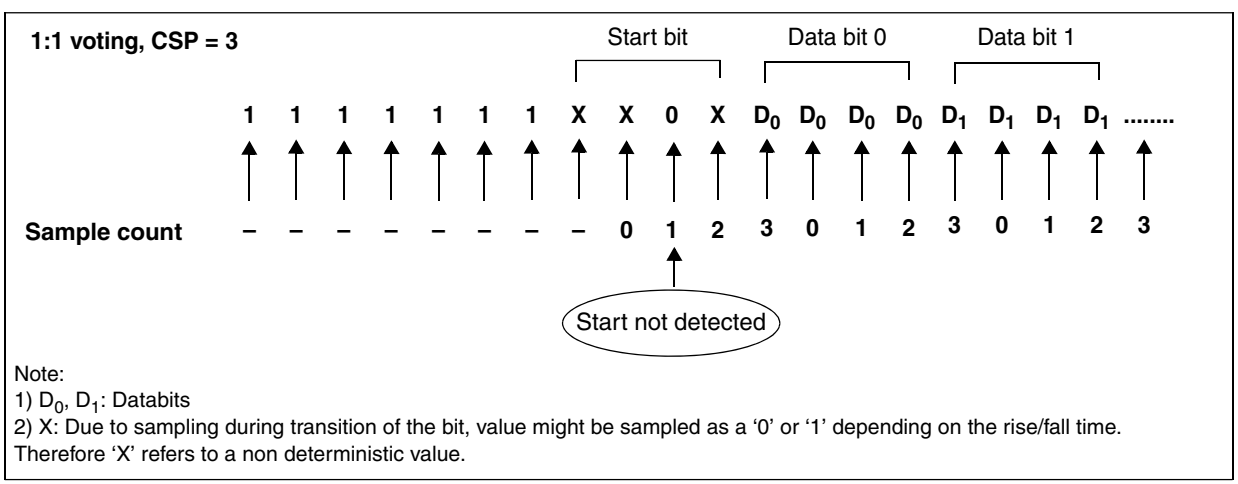

Figure 54-18. Start detection and sampling for over sampling rate = 4 (Case 4)

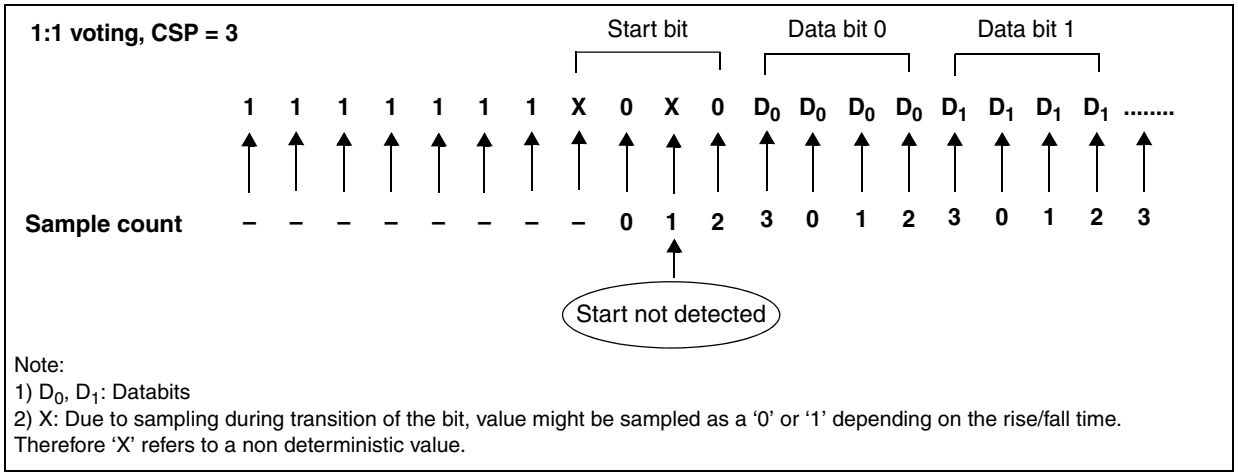

Figure 54-19. Start detection and sampling for over sampling rate = 4 (Case 5)

54.4.2.8 Baud rate generation

The LIN baud rate is programmed in two registers: the LIN Integer Baud Rate Register and the LIN Fraction baud rate register. The Baud Rate Registers can be programmed only during Initialization mode.

Baud rate is calculated with the following formula for both receiver and transmitter.

When ROSE = 1, Tx = Rx = LIN_CLK / (OSR × LDIV). When ROSE = 0, Tx = Rx = LIN_CLK / (16 × LDIV)

Where LIN_CLK is the frequency of the baud clock.

LDIV is an unsigned fixed point number. The mantissa is coded into 20 bits of LINIBRR and the fraction is coded on 4 bits of LINFBRR.

When reduced oversampling is enabled, LINFBRR should not be used and programmed to zero and LDIV contains only the integer part of LINIBRR.

For example: When ROSE = 0 (For LIN and UART mode): LDIV = 468.75 d, LIN_CLK = 36 MHz, LINIBRR = 468 d, LINFBRR = 12 *Baud rate = 36 MHz/ (16 × 468.75) = 4.8 Kbit/s*

For example: When ROSE = 1 (Only for UART mode): LDIV = 10 d, LIN_CLK = 80 MHz, LINIBRR = 4 d, OSR = 4, *Baud rate = LIN_CLK / (OSR × LDIV) = 80 MHz / (4 × 10) = 2 Mbit/s*

54.4.2.9 Automatic resynchronization

To automatically adjust the baud rate based on measurement of the LIN sync field, write the nominal Prescalar value (nominal baud rate) in LINIBRR and LINFBRR, then set the LASE bit in LINCR1 to enable automatic synchronization.

When auto synchronization is enabled, after each LIN Sync Del, the time duration between five falling edges on RDI is sampled on LIN_CLK.

54.4.2.10 Wakeup management

Any node in a sleeping LIN cluster may request a wakeup. The wakeup request is issued by forcing the bus to the dominant state for 250 μs to 5 ms. Every slave node should detect the wakeup request (a dominant pulse longer than 150 μs) and be ready to listen to bus commands within 100 ms, measured from the ending edge of the dominant pulse. The master also wakes on detecting a wakeup request and when the slaves are ready, starts sending frame headers to find out the cause of the wakeup. If the master does not issue a frame header within 150 ms from the wakeup request, then the node issuing a request may try issuing a new wakeup request.

In LINFlexD, a wakeup request can be generated by writing the wakeup character in BDR0 and setting the WURQ bit in LINCR2. On setting the WURQ bit, the character in BDR0 is transmitted. For LIN 2.0, character 0xF0 is sent as the wakeup character.

In LINFlexD, wakeup can be detected in two ways.

1. AUTOWU = 1 On detecting a falling edge in sleep mode, the SLEEP bit is cleared by hardware, the WUF flag is set, and an interrupt is generated if WUPIE is set. LINFlexD is now in normal mode and ready to receive frames.
2. AUTOWU = 0 On detecting a falling edge the WUF flag is set and an interrupt is generated (if WUPIE bit is set). It is then up to the software to clear the SLEEP bit.

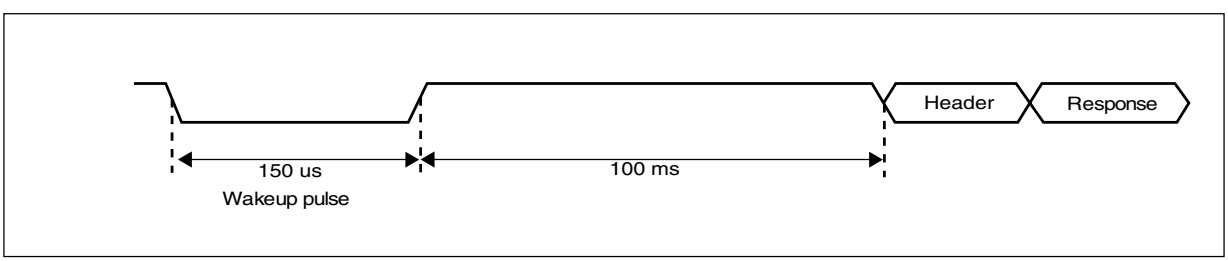

Figure 54-20. Wakeup sequence

54.4.3 Timer

There is an 8-bit counter which has different behavior in different modes as described below:

- **In Output Compare Mode (LINTCSR[MODE]= 1):**

  This counter is running even in Sleep and Initialization mode. The counter value which when matches the two software configurable output compare registers (LINOCR[OC1] or LINOCR[OC2]), generate output compare interrupt (LINESR[OCF]) provided TOCE bit in LINTCSR is set. Once an interrupt occurs subsequent interrupt is generated only when the application has reset the stuck FSM state.
- **In LIN Mode:**

  The software has no control over the TOCE bit and output compare registers are utilized for generation of LIN timeout interrupts (header, frame, response times out). In this case, if LIN moves to Sleep or Init state then this counter remains in Reset state. LIN mode has no meaning if UART is enabled, hence the counter will remain in Reset state.

54.4.4 UART mode

Main features in the UART mode are:

- Full duplex communication
- 8-bit frames, 9-bit frames, 13-bit frames, 16-bit frames, 17-bit frames
- Even/Odd/0/1 Parity
- User programmable over sampling rate to obtain the baud rate of up to 25 Mbit/s

54.4.4.1 8-bit data frames

The eighth bit can be a data or a parity bit. Even/Odd/0/1 parity can be selected by the PC[1:0] bit in the same register. An even parity will be set if the modulo-2 sum of the seven data bits is one. An odd parity will be cleared in this case.

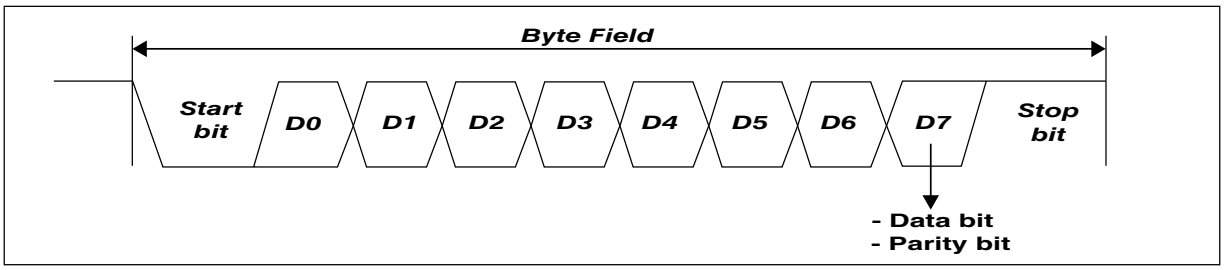

Figure 54-21. UART mode 8-bit data frame

54.4.4.2 9-bit frames

The ninth bit should be a parity bit. Even/Odd/0/1 Parity can be selected by the PC[1:0] field in the same register. An even parity will be set if the modulo-2 sum of the seven data bits is one. An odd parity will be cleared in this case. Parity 0 forces a zero logical value. Parity 1 forces a high logical value.

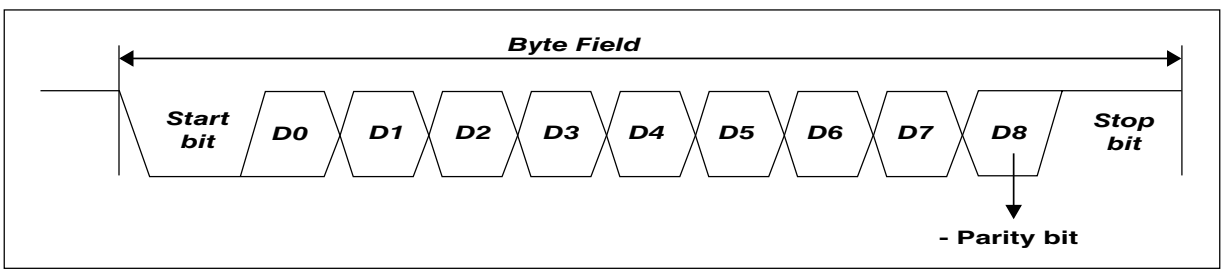

Figure 54-22. UART mode 9-bit data frame

54.4.4.3 16-bit data frames

The sixteenth bit can be a data or a parity bit. Even/Odd/0/1 Parity bit can be selected by the PC[1:0] bit in the same register. Parity 0 forces a zero logical value. Parity 1 forces a high logical value.

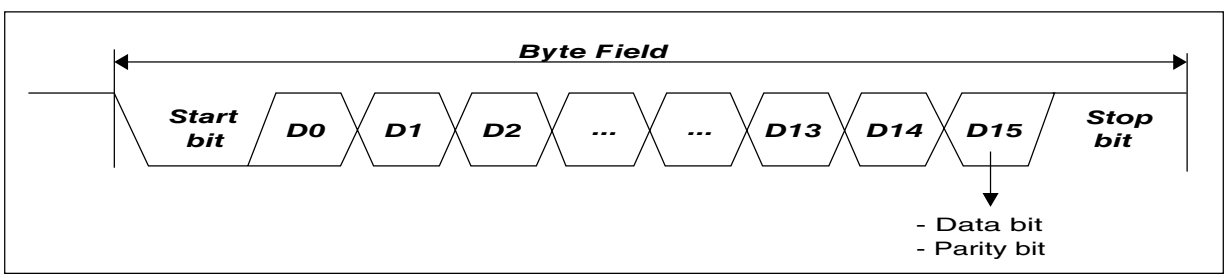

Figure 54-23. UART mode 16-bit data frame

54.4.4.4 17-bit frames

The seventeenth bit is the parity bit. Even/Odd/0/1 Parity bit can be selected by the PC[1:0] bit in the same register. Parity 0 forces a zero logical value. Parity 1 forces a high logical value.

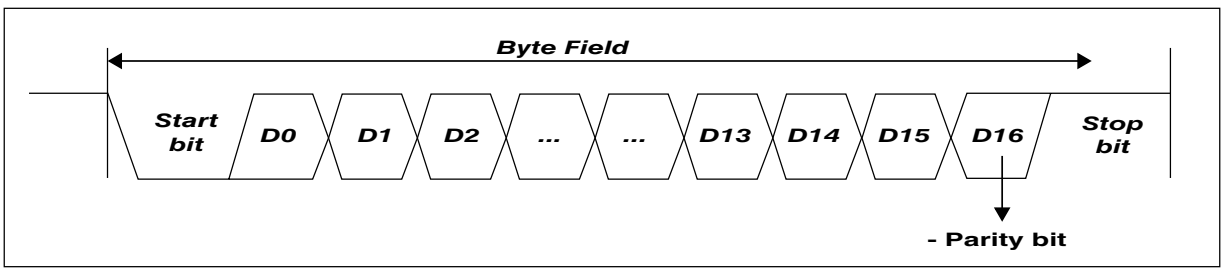

Figure 54-24. UART mode 17-bit data frame

54.4.4.5 13-bit frames

Whenever WLS is one, special word length is selected in UART mode. This bit enables 12-bit + parity bit reception only in FIFO mode.

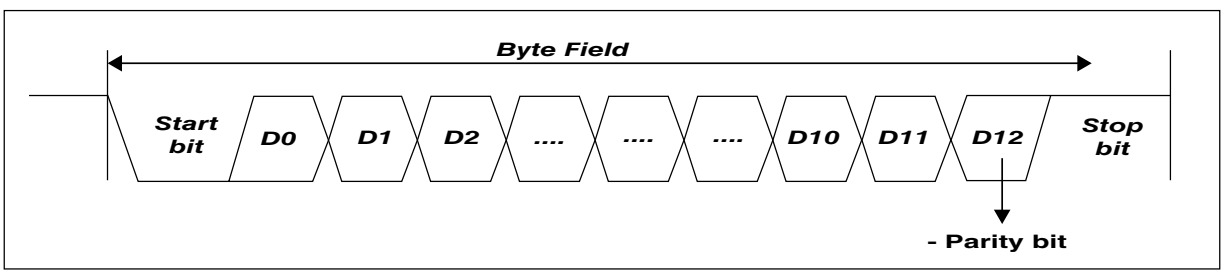

Figure 54-25. UART mode 13-bit data frame

54.4.4.6 Buffer in UART mode

The 8-byte buffer is divided into two parts: one for receiver and one for transmitter, as shown in the following figure:

Tx0	BDR0
Tx1	BDR1
Tx2	BDR2
Tx3	BDR3
Rx0	BDR4
Rx1	BDR5
Rx2	BDR6
Rx3	BDR7

Figure 54-26. Structure of 8-byte buffer

For 16-bit frames, the lower eight bits are written in BDR0 and upper eight bits in BDR1.

The same applies for reception.

54.4.4.7 UART transmitter

UART transmitter

In order to start transmission in the UART mode, UART bit should be set and the transmitter enable bit should be set. Transmission starts when the BDR0 (least significant data byte) is programmed and continues until the number of bytes/halfwords transmitted is equal to the value in the TDFL bits in UARTCR.

The transmit buffer is four bytes (when UARTCR[WL1] = 0) or two halfwords (when UARTCR[WL1] = 1), hence a maximum of four bytes (two halfwords) transmission can be triggered. Once the programmed number of bytes (halfwords) has been transmitted, the DTF flag is set in UARTSR. If the TxEn bit of UART is reset in the middle of a transmission, then the current transmission is completed and no further transmissions can be invoked.

The buffer can be configured in FIFO mode (mandatory when the DMA Tx is enabled) by setting the control bit UARTCR[TFBM].

NOTE

If TFF bit is set and a write is performed to the FIFO, the data transmitted may be erroneous.

Table 54-4. BDRL access in UART mode

IPS operation	Register	Mode (UARTCR[TFBM])	Word length (UARTCR[WL])	IPS operation result
Write Byte0	BDRL	FIFO	Byte	OK
Write Byte1-2-3	BDRL	FIFO	Byte	IPS transfer error
Write Half-word0-1	BDRL	FIFO	Byte	IPS transfer error
Write Word	BDRL	FIFO	Byte	IPS transfer error
Write Byte0-1-2-3	BDRL	FIFO	Half-word	IPS transfer error
Write Half-word0	BDRL	FIFO	Half-word	OK
Write Half-word1	BDRL	FIFO	Half-word	IPS transfer error
Write Word	BDRL	FIFO	Half-word	IPS transfer error
Read Byte0-1-2-3	BDRL	FIFO	Byte/Half-word	IPS transfer error
Read Half-word0-1	BDRL	FIFO	Byte/Half-word	IPS transfer error
Read Word	BDRL	FIFO	Byte/Half-word	IPS transfer error
Write Byte0-1-2-3	BDRL	BUFFER	Byte/Half-word	OK
Write Half-word0-1	BDRL	BUFFER	Byte/Half-word	OK

Table continues on the next page...

Table 54-4. BDRL access in UART mode (continued)

IPS operation	Register	Mode (UARTCR[TFBM])	Word length (UARTCR[WL])	IPS operation result
Write Word	BDRL	BUFFER	Byte/Half-word	OK
Read Byte0-1-2-3	BDRL	BUFFER	Byte/Half-word	OK
Read Half-word0-1	BDRL	BUFFER	Byte/Half-word	OK
Read Word	BDRL	BUFFER	Byte/Half-word	OK

In UART FIFO mode (UARTCR[TFBM] = 1), any read operation causes an IPS transfer error.

54.4.4.8 UART receiver

UART receiver

The reception of a data byte is started as soon as the user exits initialization mode, sets the RxEn bit, and detects start bit. There is a dedicated 4-byte (if UARTCR[WL1] = 0) or 2-half-words (if UARTCR[WL1] = 1) data buffer for received data. Once the programmed number (RDFL bits) of bytes have been received, the DRF flag is set in UARTSR and the current reception gets completed. RxEn bit needs to be set only to start the reception.The reception is automatically completed as soon as the programmed number (RDFL bits) of bytes have been received.

The buffer can be configured in FIFO mode (mandatory when the DMA Rx is enabled) by setting the control bit UARTCR[RFBM].

Table 54-5. BDRM access in UART mode

IPS operation	Register	Mode (UARTCR[RFBM])	Word length (UARTCR:WL)	IPS operation result
Read Byte4	BDRM	FIFO	Byte	OK
Read Byte5-6-7	BDRM	FIFO	Byte	IPS transfer error
Read Half-word2-3	BDRM	FIFO	Byte	IPS transfer error
Read Word	BDRM	FIFO	Byte	IPS transfer error
Read Byte4-5-6-7	BDRM	FIFO	Half-word	IPS transfer error
Read Half-word2	BDRM	FIFO	Half-word	OK
Read Half-word3	BDRM	FIFO	Half-word	IPS transfer error
Read Word	BDRM	FIFO	Half-word	IPS transfer error
Write Byte4-5-6-7	BDRM	FIFO	Byte/Half-word	IPS transfer error
Write Half-word2-3	BDRM	FIFO	Byte/Half-word	IPS transfer error
Write Word	BDRM	FIFO	Byte/Half-word	IPS transfer error
Read Byte4-5-6-7	BDRM	BUFFER	Byte/Half-word	OK

Table continues on the next page...

Table 54-5. BDRM access in UART mode (continued)

IPS operation	Register	Mode (UARTCR[RFBM])	Word length (UARTCR:WL)	IPS operation result
Read Half-word2-3	BDRM	BUFFER	Byte/Half-word	OK
Read Word	BDRM	BUFFER	Byte/Half-word	OK
Write Byte4-5-6-7	BDRM	BUFFER	Byte/Half-word	IPS transfer error
Write Half-word2-3	BDRM	BUFFER	Byte/Half-word	IPS transfer error
Write Word	BDRM	BUFFER	Byte/Half-word	IPS transfer error

Note

Refer to the layout of the registers BDRL and BDRM to identify the mapping between byte x and data bits of the registers BDRL/BDRM.

Note

- If the user does not know in advance how many bytes are to be received, RDFL should not be programmed in advance. The reset value of RDFL is zero. This will ensure that the reception will happen byte by byte. The state machine will move to the Idle state after each byte reception.
- If RDFL is programmed for a certain value but that number of bytes are not received, then reception will hang. In that case, software needs to take care of timeout by seeing the flag. Software has to set the sleep bit to move to Idle state.
- If a STOP request arrives in the middle of one reception, it is only acknowledged after all the programmed number of data bytes have received; it is not served immediately. If the programmed number of data bytes are not received, then software has to take care of timeout. When the state machine moves to Idle state, then only a stop request is served.
- If during reception of any byte a parity error occurs, then the corresponding PEx bit in UARTSR is set. No interrupt is generated in this case. If a framing error occurs in any byte (FE bit in UARTSR is set) then an interrupt is generated if FEIE bit in LINIER is set. As there is only one register bit for framing error, this interrupt will be helpful in identifying which byte has framing error.

- If the last received frame has not been read from the buffer (in other words, RMB is not reset by the user), then upon reception of the next byte, an overrun error occurs (BOF bit in UARTSR will be set) and one message is depending on RBLM bit of LINCR1. An interrupt is generated if the BOIE bit in LINIER is set.
- When WLS bit = 1, BDRM access depends on WL bit setting.
- When WLS bit = 1, WL = 0 or 1 should not be used, since this will lead to incorrect reception of data.
- When IPG_STOP is requested, for UART in FIFO mode, SW has to set the INIT bit in order to send the receiver to idle. This ensures that IPG_STOP_ACK is generated and IP enters STOP mode.

54.4.5 DMA interface

54.4.5.1 Main features

The LINFlexD DMA offers a parametric and programmable solution with the following distinctive features:

- LIN Master node, TX mode: single DMA channel
- LIN Master node, RX mode: single DMA channel
- LIN Slave node, TX mode: 1 to N DMA channel where N = max number of ID filters
- LIN Slave node, RX mode: 1 to N DMA channel where N = max number of ID filters
- UART node, TX mode: single DMA channel
- UART node, RX mode: single DMA channel + time-out

54.4.5.2 Definitions

Control/status register fields of the LINFlexD macrocell are described in Table 54-6 and Table 54-7.

Table 54-6. LINFlexD control/status fields description

Register	Field	Level	Description
LINCR2	DDRQ	High	Data discard request in reception mode
	DTRQ	High	Data transmission request (slave mode) of the LIN data field stored in BDRL/BDRM
	HTRQ	High	Header transmission request (master mode)
BIDR	DFL [5:0]	—	Data field length: • 1 to 8 bytes: normal frames • 1 to 64 bytes: extended frames
	DIR	—	Direction of the data field: • 0 => reception • 1 => transmission
	CCS	—	Checksum type: • 0 enhanced • 1 classic
	ID[5:0]	—	Identifier.
LINSR	RMB	—	Buffer data ready to be read via CPU/DMA. • 0 buffer data is free • 1 buffer data is ready
	DBFF	High	Data buffer full (8 bytes received) and DFL > 7. Used for the extended frames.
	DBEF	High	Data buffer empty (8 bytes have been transmitted) and DFL > 7. Used for the extended frames.
	DRF	High	Data reception completed
	DTF	High	Data transmission completed
	HRF	High	Header received. Used in slave mode in case of Tx filter match.
IFMI	IFMIx	!= zero	Filter match index (slave mode).
UARTCR	FBM	—	FIFO/Buffer mode • 0 Buffer mode • 1 FIFO mode (mandatory in DMA mode)

Table continues on the next page...

Table 54-6. LINFlexD control/status fields description (continued)

Register	Field	Level	Description
UARTSR	RFE	—	Rx FIFO empty • 0 Rx FIFO not empty • 1 Rx FIFO empty
	TFF	—	Tx FIFO full • 0 Tx FIFO not full • 1 Tx FIFO full

DMATXE[2**TX_CH_NUM][1]		High	DMA Tx channel enable (read/write). In UART or LIN master mode only the channel 0 can be programmed.
			In LIN slave mode: # DMA TX channel = IFMI[3:0] -1.
			DMATXE[x] = 0b => TX channel x disabled
			DMATXE[x] = 1b => TX channel x enabled

DMARXE[2**RX_CH_NUM][2]		High	DMA Rx channel enable (read/write). In UART or LIN master mode only the channel 0 can be programmed.
			In LIN slave mode: # DMA RX channel = IFMI[3:0] -1.
			DMARXE[x] = 0b => RX channel x disabled
			DMARXE[x] = 1b => RX channel x enabled

1. ** stands for exponentiation.
2. ** stands for exponentiation

Table 54-7. LINFlexD DMA control fields description

Field	Mode	Value	Level	Description
DMA_TEN	LIN master Tx or UART Tx	DMATXE[0]	High	Logical AND between the 2 DMA enable bits (LINFlexD and eDMA).
DMA_TEN	LIN slave Tx	DMATXE[x] x = IFMI — 1	High	
DMA_REN	LIN master Rx or UART Rx	DMARXE[0]	High	
DMA_REN	LIN slave Rx	DMARXE[x] x = IFMI — 1	High	

Control/status fields of the TCD descriptors referred to in this document are described in Table 54-8.

Table 54-8. TCD control fields description

TCD Field	Level	Description
CITER[14:0]	—	Current "major" iteration count
BITER[14:0]	—	Beginning "major" iteration count
NBYTES[31:0]	—	Inner "minor" byte transfer count. Number of bytes to be transferred in each service request of the channel.
SADDR[31:0]	—	Source address
SOFF[15:0]	—	Source address signed offset applied to the current source address as each source read is completed.
SSIZE[2:0]	—	Source data transfer size 000 => 8-bit 001 => 16-bit 010 => 32-bit 011 => 64-bit
SLAST[31:0]	—	Last source address adjustment
DADDR[31:0]	—	Destination address
DOFF[15:0]	—	Destination address signed offset applied to the current destination address as each destination write is completed.
DSIZE[2:0]	—	Destination data transfer size 000 => 8-bit 001 => 16-bit 010 => 32-bit 011 => 64-bit
DLAST_SGA[31:0]	—	Last destination address adjustment or the memory address for the next TCD to be loaded into this channel (scatter/gather)
INT_MAJ	High	Enable an interrupt when major iteration count completes
START	High	The channel is explicitly started via a software initiated service request.
DONE	High	Channel done (the DMA has completed the outer major loop).
D_REQ	High	Disable request. If this flag is set the DMA hardware automatically clears the corresponding DMAERQ bit when the current major iteration count reaches zero.

54.4.5.3 Master node –TX mode

On a master node, in TX mode the DMA interface requires a single TX channel. Each TCD controls a single frame except for the extended frames (multiple TCDs). The memory map associated with the TCD chain (RAM area and LINFlexD registers) is given in the following figure.

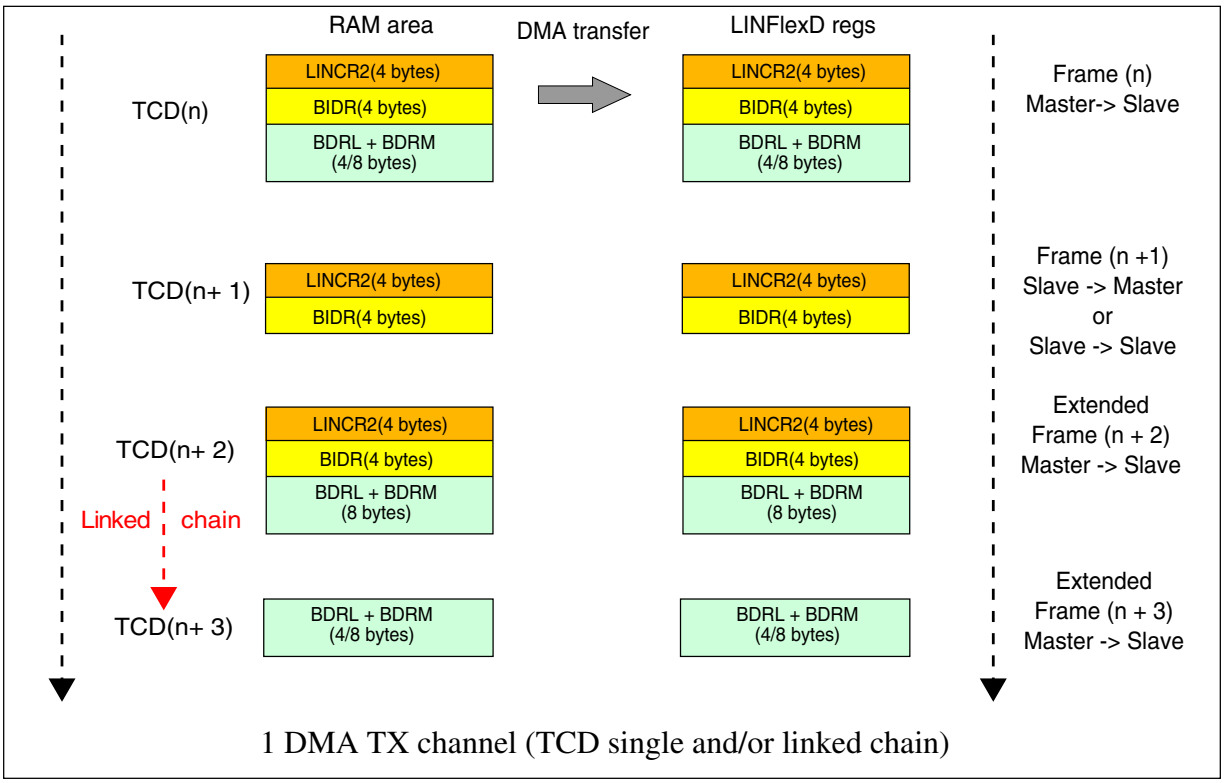

Figure 54-27. Master node –TX memory map

The TCD chain of the DMA Tx channel on a master node supports:

- Master to Slave: transmission of the entire frame (header + data)
- Slave to Master: transmission of the header; the data reception is controlled by the Rx channel on the master node
- Slave to Slave: transmission of the header

The following table provides the register settings of the LINCR2 and BIDR for each class of LIN frame.

Table 54-9. Master node – Tx mode – Register setting

LIN frame	LINCR2	BIDR
Master to Slave	DDRQ = 1	DFL = payload size
	DTRQ = 0	ID = address
	HTRQ = 0	CCS = checksum
		DIR = 1 (TX)

Table continues on the next page...

Table 54-9. Master node – Tx mode – Register setting (continued)

LIN frame	LINCR2	BIDR
Slave to Master	DDRQ = 0 DTRQ = 0 HTRQ = 0	DFL = payload size ID = address CCS = checksum DIR = 0 (RX)
Slave to Slave	DDRQ = 1 DTRQ = 0 HTRQ = 0	DFL = payload size ID = address CCS = checksum DIR = 0 (RX)

The concept FSM to control the DMA Tx interface is given in the following figure. DMA TX FSM moves to Idle state immediately at next clock edge if DMATXE[0] = 0. The TCD setting (word transfer) is given in Table 54-10. All other TCD fields = 0. TCD settings based on halfword or byte transfer are allowed.

Table 54-10. TCD setting – Master node – Tx mode

TCD Field	Value	Description
CITER[14:0]	1	Single iteration for the "major" loop
BITER[14:0]	1	Single iteration for the "major" loop
NBYTES[31:0]	[4 + 4] + 0/4/8 = N	Data buffer is stuffed with dummy bytes if the length is not word aligned. LINCR2 + BIDR + BDRL + BDRM
SADDR[31:0]	-	RAM address
SOFF[15:0]	4	Word increment
SSIZE[2:0]	2	Word transfer
SLAST[31:0]	–N	
DADDR[31:0]	-	LINCR2 address
DOFF[15:0]	4	Word increment
DSIZE[2:0]	2	Word transfer
DLAST_SGA[31:0]	–N	No scatter/gather processing
INT_MAJ	0/1	Interrupt disabled/enabled
D_REQ	1	Only on the last TCD of the chain
START	0	No SW request

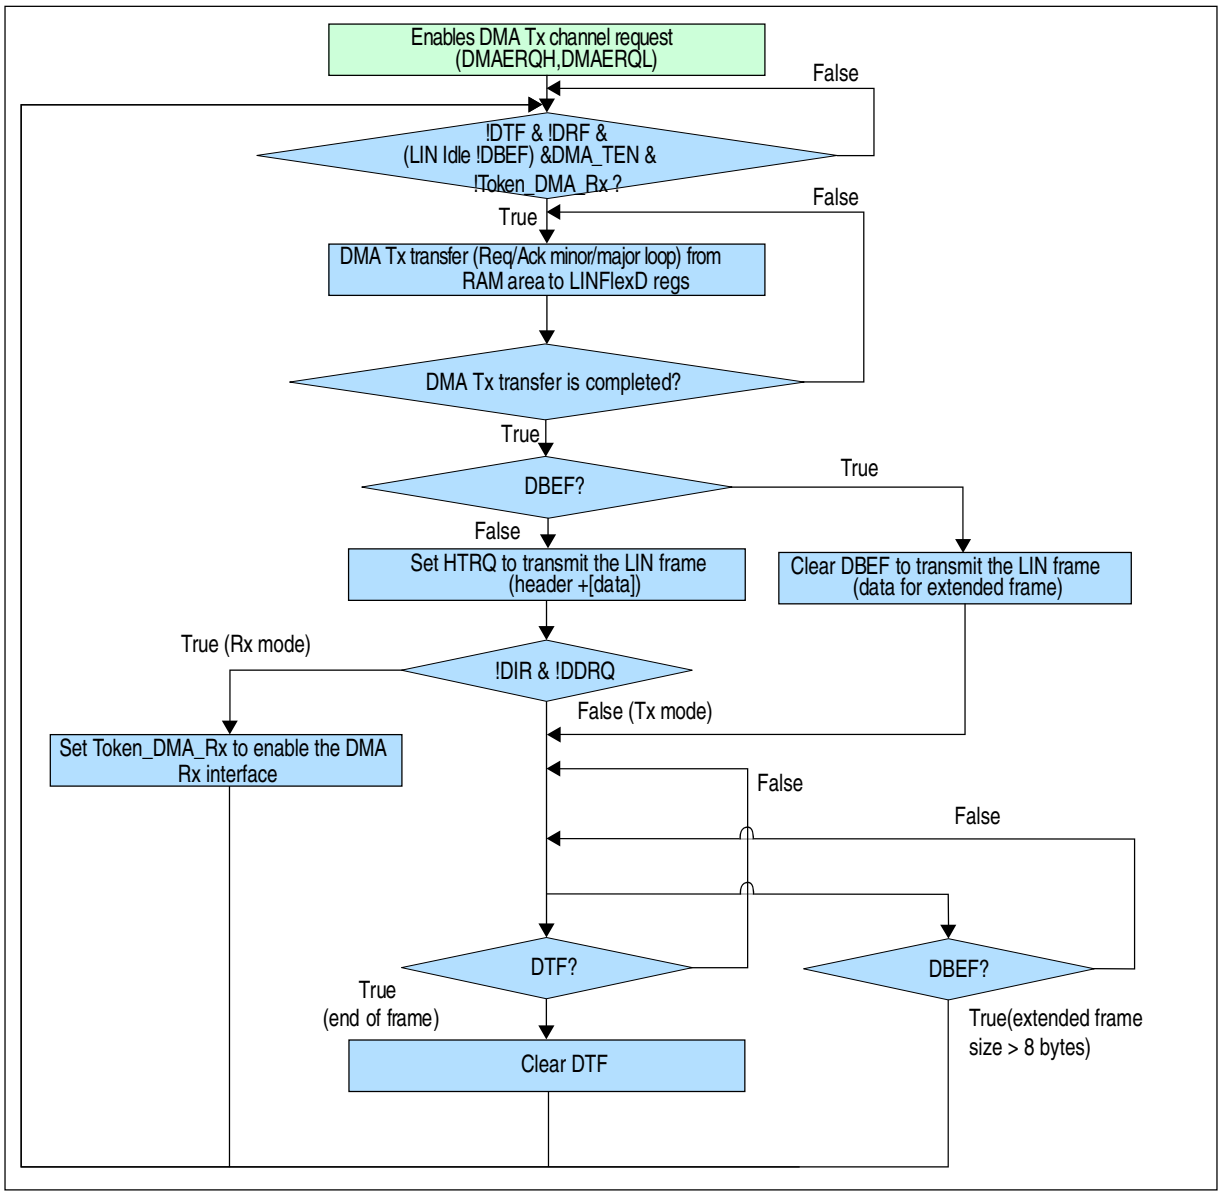

Figure 54-28. Master node – DMA Tx FSM (concept scheme)

54.4.5.4 Master node - RX mode

On a master node in RX mode, the DMA interface requires a single RX channel. Each TCD controls a single frame , except for the extended frames (multiple TCDs). The memory map associated with the TCD chain (RAM area and LINFlexD registers) is given in the following figure.

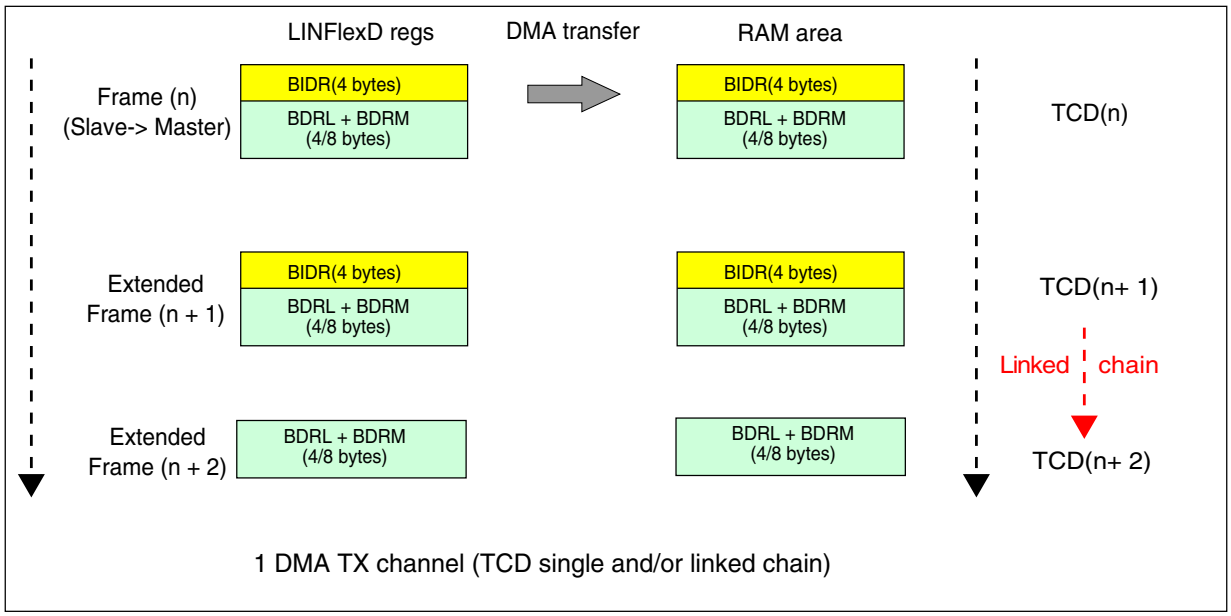

Figure 54-29. Master node – RX memory map

The TCD chain of the DMA Rx channel on a master node supports Slave to Master: reception of the data field of the header

The BIDR register is optionally copied into the RAM area. This BIDR field (part of FIFO data) contains the ID of each message, which only allows the CPU to figure out which ID the LINFlexD DMA received if the single DMA channel setup is used.

The concept FSM to control the DMA Rx interface is given in the following figure. DMA RX FSM moves to Idle state immediately at the next clock edge if DMARXE[0] = 0. The TCD setting (word transfer) is given in the next table. All other TCD fields = 0. TCD settings based on halfword or byte transfer are allowed.

Table 54-11. TCD setting – Master node – Rx mode

TCD Field	Value	Description
CITER[14:0]	1	Single iteration for the "major" loop
BITER[14:0]	1	Single iteration for the "major" loop
NBYTES[31:0]	[4] +4/8 = N	Data buffer is stuffed with dummy bytes if the length is not word aligned. BIDR + BDRL + BDRM
SADDR[31:0]	—	BIDR address
SOFF[15:0]	4	Word increment
SSIZE[2:0]	2	Word transfer
SLAST[31:0]	–N	—
DADDR[31:0]	—	RAM address
DOFF[15:0]	4	Word increment
DSIZE[2:0]	2	Word transfer

Table continues on the next page...

Table 54-11. TCD setting – Master node – Rx mode (continued)

TCD Field	Value	Description
DLAST_SGA[31:0]	–N	No scatter/gather processing
INT_MAJ	0/1	Interrupt disabled/enabled
D_REQ	1	Only on the last TCD of the chain
START	0	No SW request

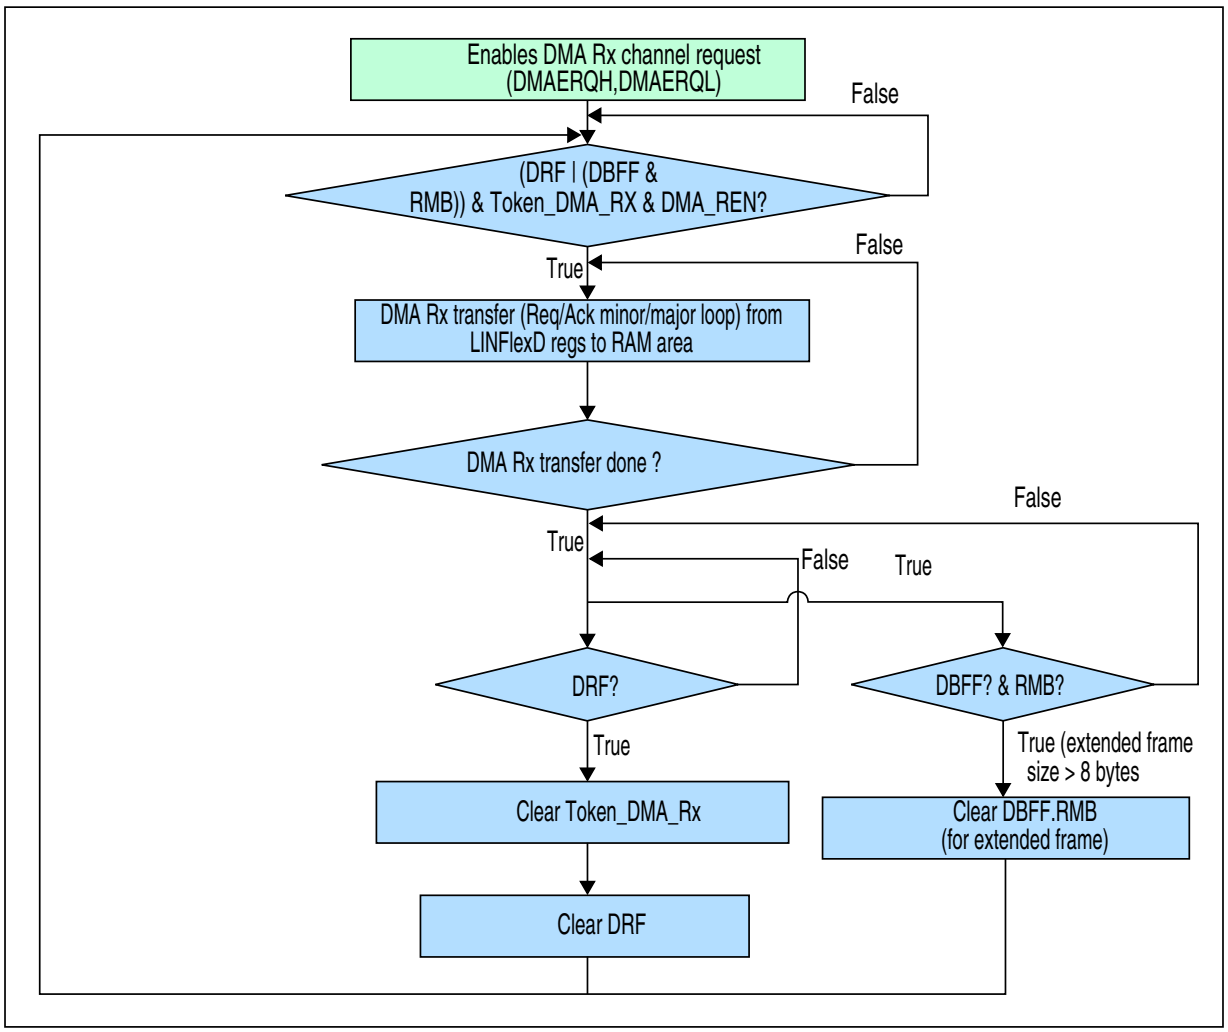

Figure 54-30. Master node – DMA Rx FSM (concept scheme)

54.4.5.5 Slave node – TX mode

On a slave node in TX mode, the DMA interface requires a DMA TX channel for each ID filter programmed in TX mode. In case a single DMA TX channel is available, a single ID field filter must be programmed in TX mode. Each TCD controls a single frame, except for the extended frames (multiple TCDs). The memory map associated with the TCD chain (RAM area and LINFlexD registers) is given in the following figure.

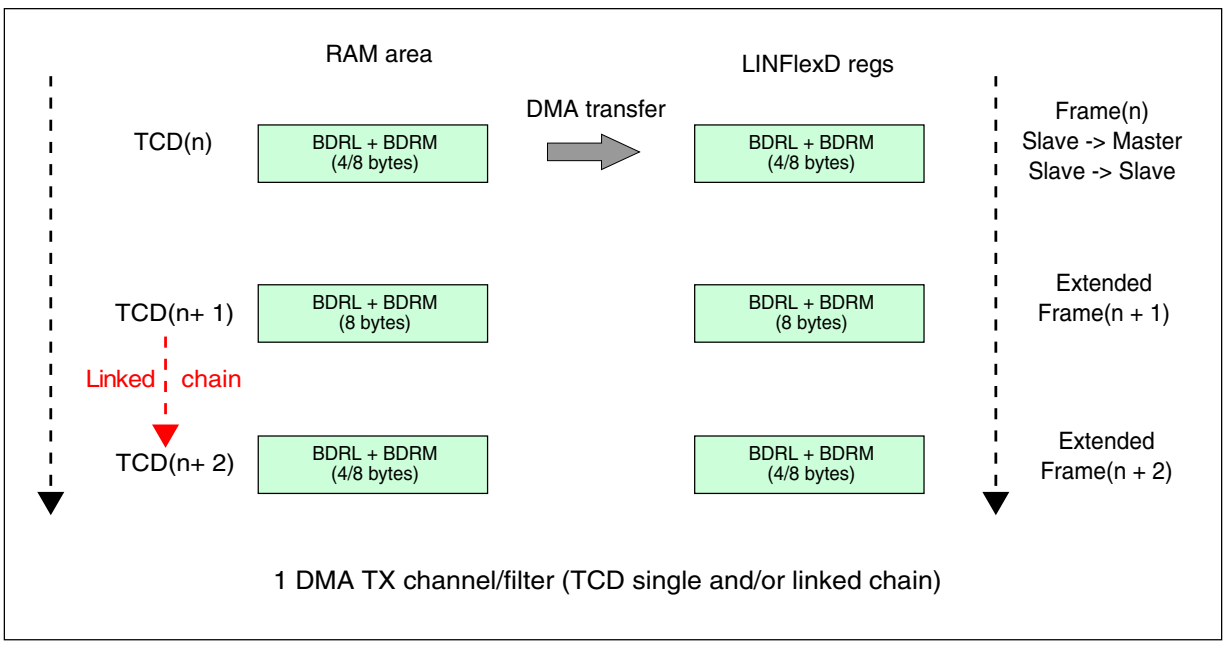

Figure 54-31. Slave node – TX memory map

The TCD chain of the DMA Tx channel on a slave node supports:

- Slave to Master: transmission of the data field
- Slave to Slave: transmission of the data field

The register setting of the LINCR2, IFER, IFMR, and IFCR registers is given in Table 54-12.

Table 54-12. Slave node – Tx mode – Register setting

LIN frame	LINCR2	IFER	IFMR	IFCR
Slave to Master or Slave to Slave	DDRQ = 0 DTRQ = 0 HTRQ = 0	To enable an ID filter (Tx mode) for each DMA TX channel	• Identifier list mode • Identifier mask mode	DFL = payload size ID = address CCS = checksum DIR = 1 (TX)

The concept FSM to control the DMA Tx interface is given in the following figure. DMA TX FSM moves to Idle state if DMATXE[x] = 0 where x = IFMI – 1.The TCD setting (word transfer) is given in Table 54-13. All other TCD fields = 0. TCD settings based on halfword or byte transfer are allowed.

Table 54-13. TCD setting – Slave node – Tx mode

TCD Field	Value	Description
CITER[14:0]	1	Single iteration for the "major" loop
BITER[14:0]	1	Single iteration for the "major" loop
NBYTES[31:0]	4/8 = N	Data buffer is stuffed with dummy bytes if the length is not word aligned. BDRL + BDRM
SADDR[31:0]	—	RAM address
SOFF[15:0]	4	Word increment
SSIZE[2:0]	2	Word transfer

DSIZE[2:0]	2	Word transfer
DLAST_SGA[31:0]	–N	No scatter/gather processing
INT_MAJ	0/1	Interrupt disabled/enabled
D_REQ	1	Only on the last TCD of the chain.
START	0	No SW request

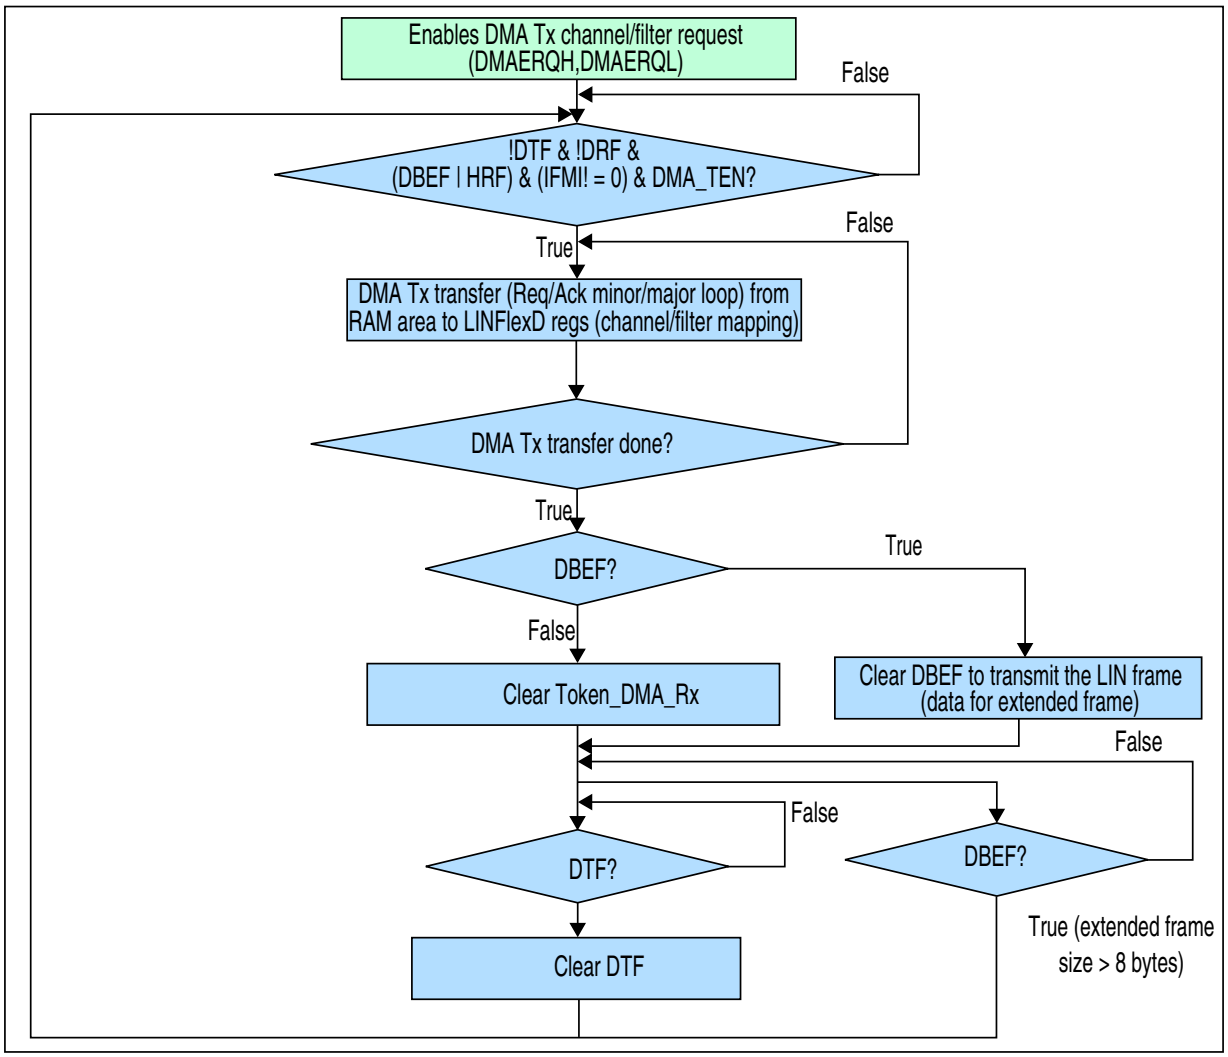

Figure 54-32. Slave node – DMA Tx FSM (concept scheme)

54.4.5.6 Slave node – RX mode

On a slave node in RX mode, the DMA interface requires a DMA RX channel for each ID filter programmed in RX mode. In case a single DMA RX channel is available, a single ID field filter must be programmed in RX mode. Each TCD controls a single frame, except for the extended frames (multiple TCDs). The memory map associated with the TCD chain (RAM area and LINFlexD registers) is given in the following figure.

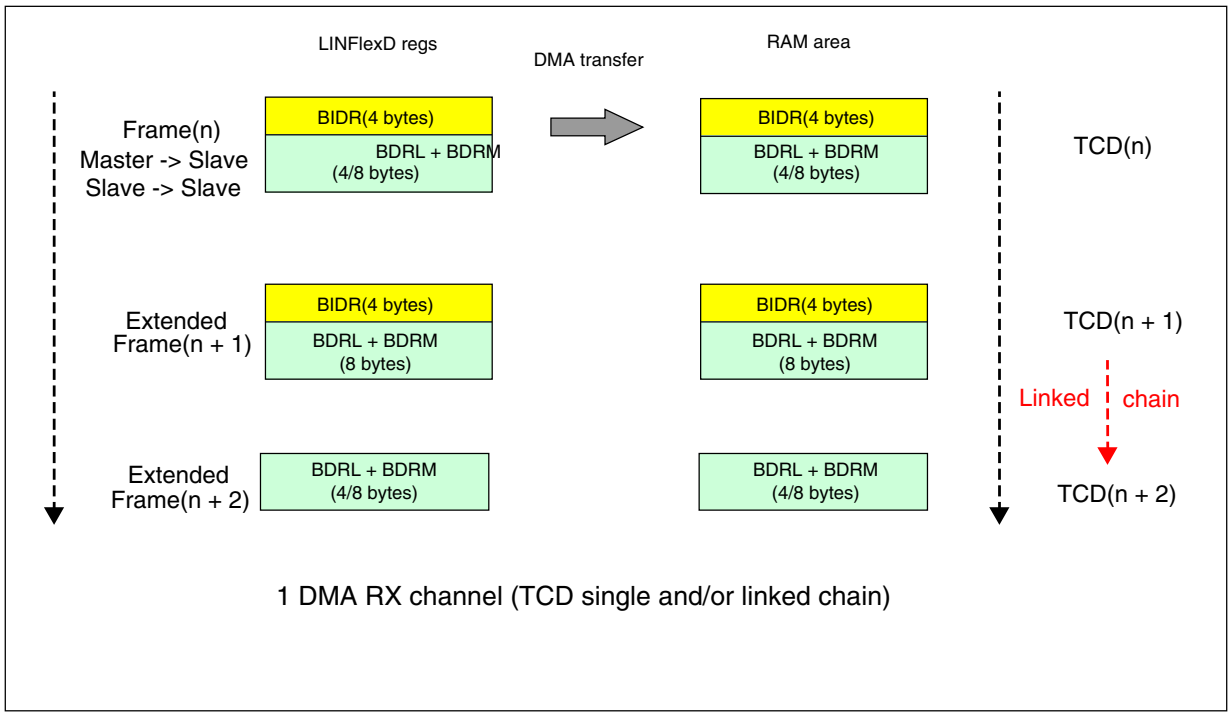

Figure 54-33. Slave node – RX memory map

The TCD chain of the DMA Rx channel on a slave node supports:

- Master to Slave: reception of the data field
- Slave to Slave: reception of the data field

The register setting of the LINCR2, IFER, IFMR, IFCR registers is given in Table 54-14.

Table 54-14. Slave node – Rx mode – Register setting

LIN frame	LINCR2	IFER	IFMR	IFCR
Master to Slave or Slave to Slave	DDRQ = 0 DTRQ = 0 HTRQ = 0	To enable an ID filter (Rx mode) for each DMA RX channel	• Identifier list mode • Identifier mask mode	DFL = payload size ID = address CCS = checksum DIR = 0 (RX)

The concept FSM to control the DMA Rx interface is given in the following figure. DMA Rx FSM moves to Idle state if DMARXE[x] = 0 where x = IFMI – 1. The TCD setting (word transfer) is given in Table 54-15. All other TCD fields = 0. TCD settings based on halfword or byte transfer are allowed.

Table 54-15. TCD setting – Slave node – Rx mode

TCD Field	Value	Description
CITER[14:0]	1	Single iteration for the "major" loop
BITER[14:0]	1	Single iteration for the "major" loop
NBYTES[31:0]	[4] + 4/8 = N	Data buffer is stuffed with dummy bytes if the length is not word aligned. BIDR + BDRL + BDRM
SADDR[31:0]	—	BIDR address
SOFF[15:0]	4	Word increment

SLAST[31:0]	–N	—
DADDR[31:0]	—	RAM address
DOFF[15:0]	4	Word increment
DSIZE[2:0]	2	Word transfer
DLAST_SGA[31:0]	–N	No scatter/gather processing
INT_MAJ	0/1	Interrupt disabled/enabled
D_REQ	1	Only on the last TCD of the chain.
START	0	No SW request

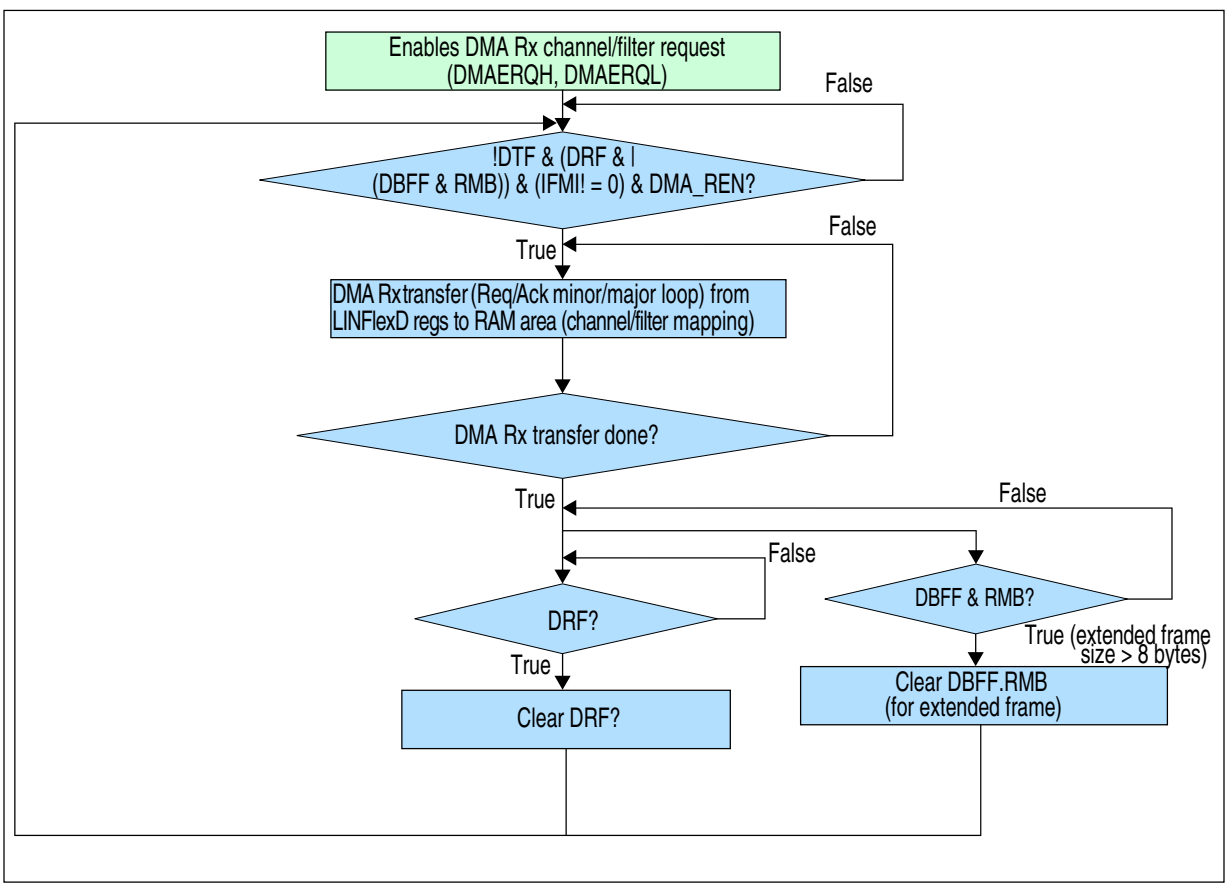

Figure 54-34. Slave node – DMA Rx FSM (concept scheme)

54.4.5.7 UART – TX mode

In UART TX mode, the DMA interface requires a DMA TX channel. A single TCD can control the transmission of an entire Tx buffer. The memory map associated with the TCD chain (RAM area and LINFlexD registers) is given in Figure 54-35.

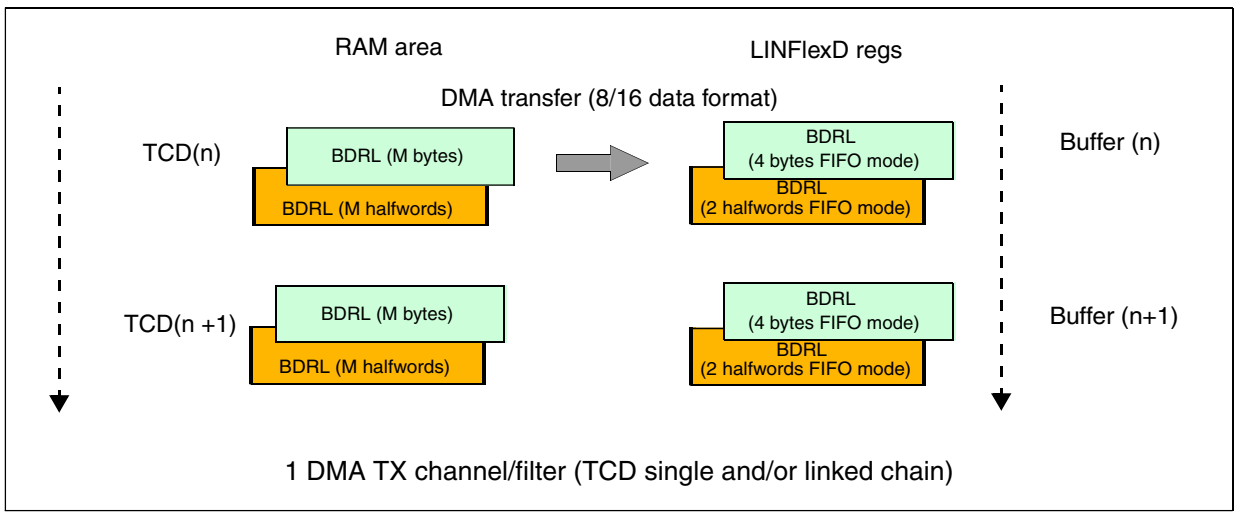

Figure 54-35. UART – TX memory map

The UART TX buffer must be configured in FIFO mode in order to:

- Allow the transfer of large data buffer by a single TCD
- Adsorb the latency, following a DMA request (due to the DMA arbitration), to move data from the RAM to the FIFO
- Use low priority DMA channels

The Tx FIFO size is:

- 4 bytes in 8 bit data format
- 2 halfwords in 16-bit data format

A DMA request is triggered by FIFO-not-full (TX) status signals.

The concept FSM to control the DMA Tx interface is given in Figure 54-36. DMA Tx FSM will move to Idle state if DMATXE[0] = 0.The TCD setting (typical case) is given in Table 54-16. All other TCD fields = 0. The minor loop transfers a single byte/halfword as soon as a free entry is available in the Tx FIFO.

Table 54-16. TCD setting – UART – Tx mode

TCD Field	Value		Description
	8 bits data	16 bits data	
CITER[14:0]	M		Multiple iterations for the "major" loop
BITER[14:0]	M		Multiple iterations for the "major" loop
NBYTES[31:0]	1	2	Minor loop transfer = 1 or 2 bytes
SADDR[31:0]	-		RAM address
SOFF[15:0]	1	2	Byte/Half-word increment
SSIZE[2:0]	0	1	Byte/Half-word transfer
SLAST[31:0]	–M	–M × 2	-
DADDR[31:0]	-		BDRL address
DOFF[15:0]	0		No increment (FIFO)
DSIZE[2:0]	0	1	Byte/Half-word transfer
DLAST_SGA[31:0]	0		No scatter/gather processing
INT_MAJ	0/1		Interrupt disabled/enabled
D_REQ	1		Only on the last TCD of the chain.
START	0		No SW request

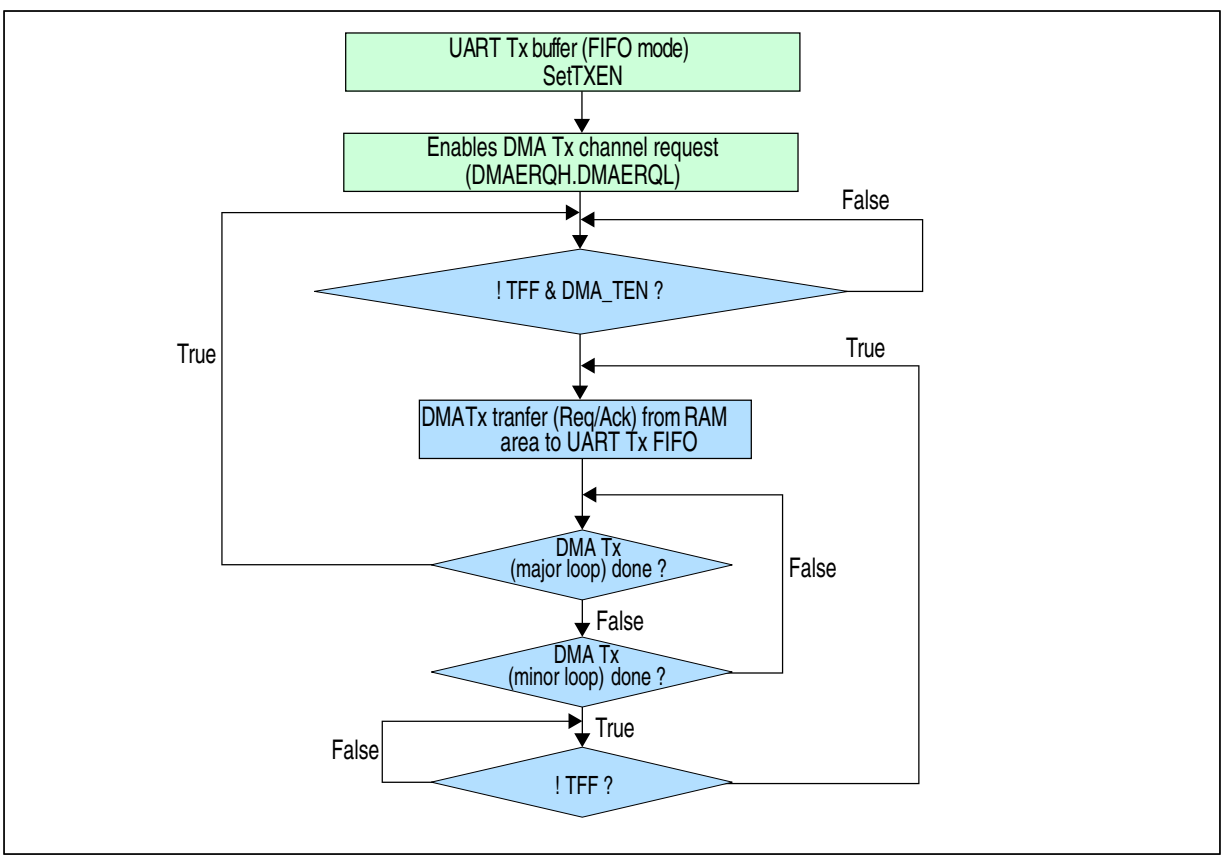

Figure 54-36. UART – DMA Tx FSM (concept scheme)

54.4.5.8 UART – RX mode

In UART RX mode, the DMA interface requires a DMA RX channel. A single TCD can control the reception of an entire Rx buffer. The memory map associated with the TCD chain (RAM area and LINFlexD registers) is given in Table 54-17.

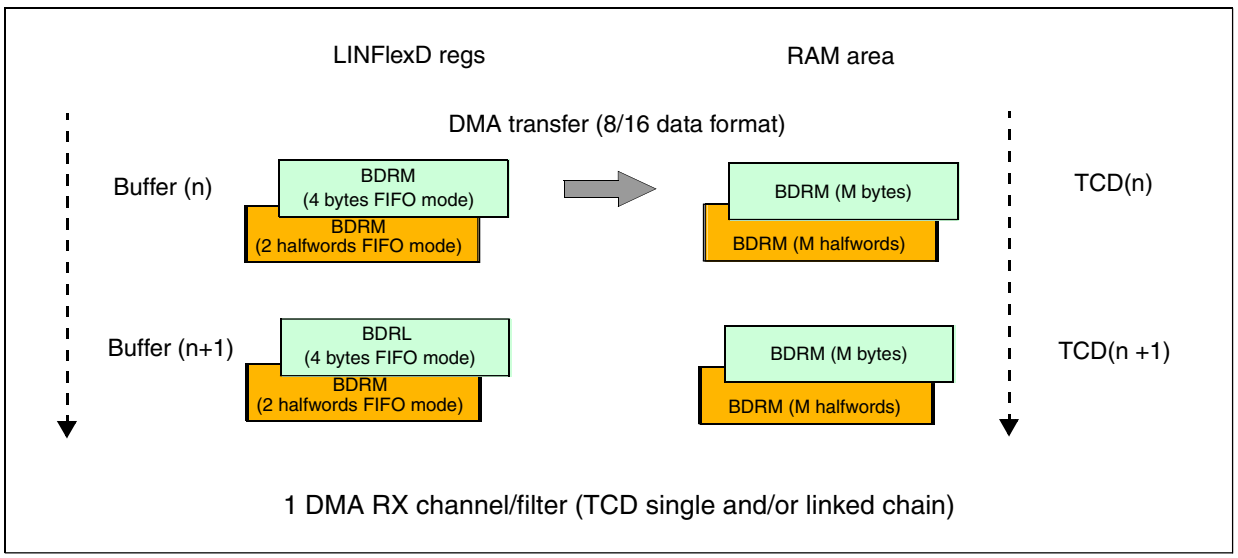

Figure 54-37. UART – RX memory map

The UART RX buffer must be configured in FIFO mode in order to:

- Allow the transfer of large data buffer by a single TCD
- Adsorb the latency, following a DMA request (due to the DMA arbitration), to move data from the FIFO to the RAM
- Use low priority DMA channels

The Rx FIFO size is:

- 4 bytes in 8-bit data format

This will sufficient because just one byte allows a reaction time of about 3.8 µs (at 2 Mbit/s) (~450 clock cycles at 120 MHz) before the transmission is affected. A DMA request is triggered by FIFO and not by empty (Rx) status signals.

The concept FSM to control the DMA Rx interface is given in Figure 54-38. DMA Rx FSM will move to Idle state if DMARXE[0] = 0.The TCD setting (typical case) is given in the next table. All other TCD fields equal zero. The minor loop transfers a single byte/ halfword as soon an entry is available in the Rx FIFO. A new software reset bit is

required that allows the LINFlexD FSMs to be reset in case this timeout state is reached or in any other case. The timeout counter can be re-written by software at any time to extend the timeout period.

Table 54-17. TCD setting – UART – Rx mode

TCD Field	Value		Description
	8 bits data	16 bits data	
CITER[14:0]	M		Multiple iterations for the "major" loop
BITER[14:0]	M		Multiple iterations for the "major" loop
NBYTES[31:0]	1	2	Minor loop transfer = 1 or 2 bytes
SADDR[31:0]	-		BDRM address
SOFF[15:0]	0		No increment (FIFO)
SSIZE[2:0]	0	1	Byte/Half-word transfer
SLAST[31:0]	0		
DADDR[31:0]	-		RAM address
DOFF[15:0]	1	2	Byte/Half-word increment
DSIZE[2:0]	0	1	Byte/Half-word transfer
DLAST_SGA[31:0]	–M	–M × 2	No scatter/gather processing
INT_MAJ	0/1		Interrupt disabled/enabled
D_REQ	1		Only on the last TCD of the chain.
START	0		No SW request

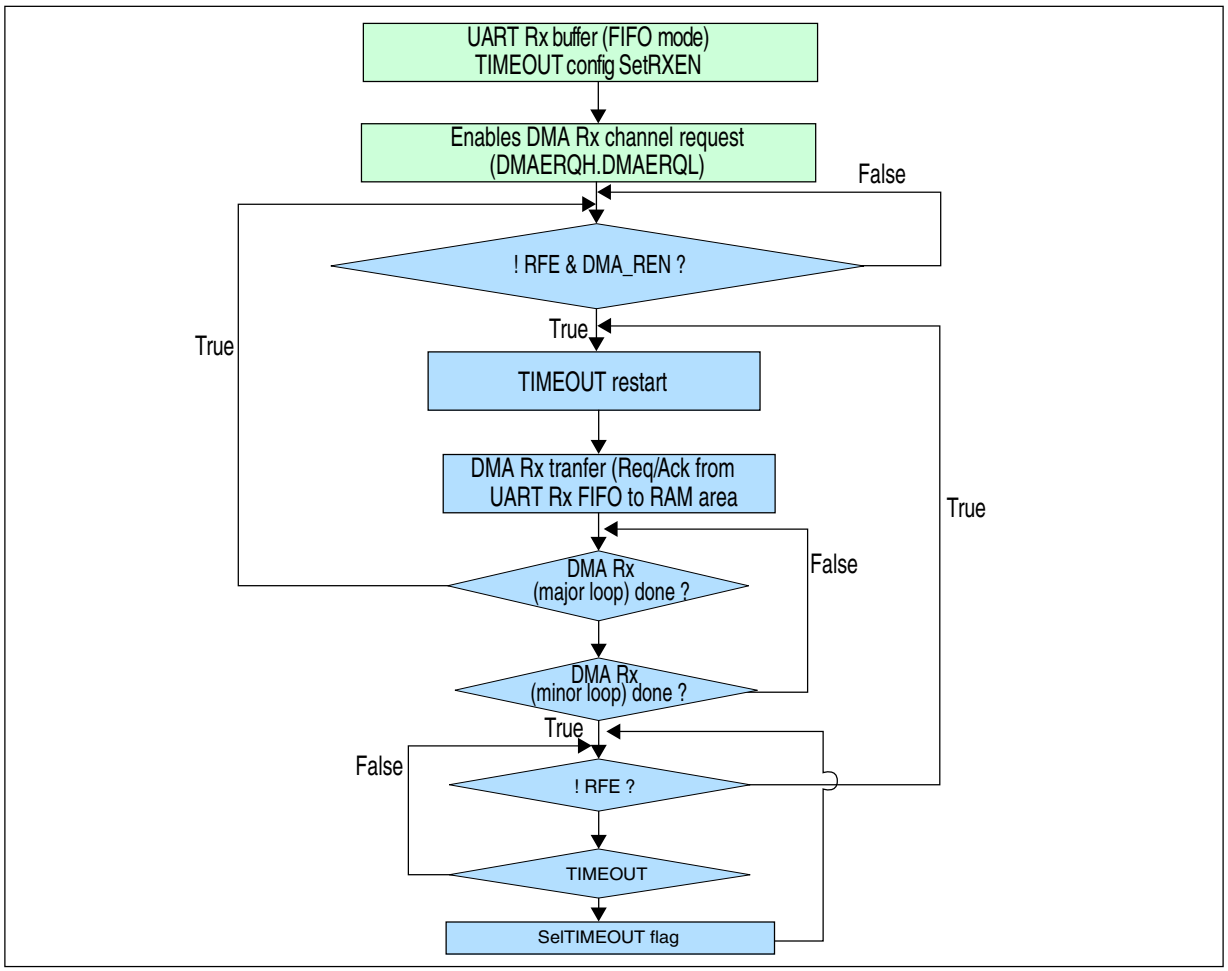

Figure 54-38. UART – DMA Rx FSM (concept scheme)

54.4.5.9 Use cases and limitations

- In LIN slave mode, the DMA capability can be used only if the ID filtering mode is activated. The number of ID filters enabled must be equal to the number of DMA channels enabled. The correspondence between channel number and ID filter is based on IFMI (identifier filter match index)
- In LIN master mode both the DMA channels (TX and RX) must be enabled in case the DMA capability is required
- In UART mode the DMA capability can be used only if the UART Tx/Rx buffers are configured as FIFOs
- DMA and CPU operating modes are mutually exclusive for the data/frame transfer on a UART or LIN node. Once a DMA transfer is finished the CPU can manage subsequent accesses

- Error management must always be executed via the CPU enabling the related error interrupt sources. DMA capability does not provide support for error management. Error management means checking status bits, handling IRQs, and potentially canceling DMA transfers
- The DMA programming model must be coherent with the TCD setting defined in this document
- When IPG_STOP is requested, SW has to first disable DMATXE/DMARXE channel registers, after the current minor loop finishes (indicated by the clearing of ACTIVE bit in DMA TCD register). This ensures that IPG_STOP_ACK is generated and IP enters STOP mode.

54.5 Memory map and register description

The following points should be considered for the below mentioned LINFlexD registers:

- Reset values are with-slave/without-slave (master only) format
- If not specified, then the bit can be configured for both master only and master/slave format; in other words, for both values of generic slave = 0 and slave = 1.

NOTE

In Master mode, the registers IFCR0-IFCR15 are not present and the corresponding absolute address of the below register changes as shown in the following table.

Table 54-19. Offsets of the register from offsets 8C to 9C

Register name	Master/slave mode	Master only mode
LINFlexD_GCR	0x8C	0x4C
LINFlexD_UARTPTO	0x90	0x50
LINFlexD_UARTCTO	0x94	0x54
LINFlexD_DMATXE	0x98	0x58
LINFlexD_DMARXE	0x9C	0x5C

NOTE

In Master Mode, read access to IFMI register and read/write access to IFER and IFMR registers would result in transfer error.

NOTE

Any access to A0 location will not generate a transfer error.

54.5.1 LIN Control Register 1 (LINFlexD_LINCR1)

LINCR1 consists of control bits used to configure features of the LINFlexD.

NOTE

When accessing the LINCR1 register, each reserved bit should be written to its original reset value.

Address: 0h base + 0h offset = 0h

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	CCD	CFD	LASE	AUTOWU	MBL				BF	0	LBKM	MME	SSBL	RBLM	SLEEP	INIT
W																
Reset	0	0	0	0	0	0	0	0	1	0	0	*	0	0	1	0

* Notes:
- MME field: If slave = 0, then MME bit is 1, else MME bit is 0

LINFlexD_LINCR1 field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 CCD	Checksum Calculation disable This bit can be written during Initialization mode only. It is read-only in Normal mode. 0 Checksum calculation is done by hardware. When this bit is reset the LINCFR register is read only. 1 Checksum calculation is disabled. When this bit is set the LINCFR register is read/write. User can program this register to sent a software calculated checksum/CRC (provided CFD is reset).
17 CFD	Checksum field disable This bit can be configured during Initialization mode only. It is read-only in Normal mode. 0 Checksum field is sent after the required number of data bytes are sent 1 No checksum field is sent in the frame
18 LASE	LIN Autosynchronization Enable This bit can be programmed in Initialization mode only. It is read-only in Normal mode. (Note: If generic auto_sync = 0, then this bit will always read a 0). 0 Autosynchronization disabled 1 Autosynchronization enabled
19 AUTOWU	Auto Wakeup This bit can be configured during Initialization mode only. This bit is utilized in UART mode also. 0 Sleep bit is cleared by software only 1 Sleep bit gets cleared by hardware whenever WUF bit of LINSR is set
20–23 MBL	Master Break Length These bits choose the length of the Sync break to be generated by the master. These bits can be programmed in Initialization mode only. They are read-only in Normal mode. 0000 10-bit break length 0001 11-bit break length 0010 12-bit break length 0011 13-bit break length 0100 14-bit break length 0101 15-bit break length 0110 16-bit break length

Table continues on the next page...

LINFlexD_LINCR1 field descriptions (continued)

Field	Description
	0111 17-bit break length 1000 18-bit break length 1001 19-bit break length 1010 20-bit break length 1011 21-bit break length 1100 22-bit break length 1101 23-bit break length 1110 36-bit (cooling) break length 1111 50-bit break length
24 BF	By-pass filter This bit can be programmed during Initialization mode only. **NOTE:** If generic slave = 0 or no_of_filters = 0, then this bit will always read a 1, and cannot be programmed. 0 No IRQ if ID does not match any filter 1 A RX IRQ is generated on ID not matching any filter
25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26 LBKM	Loop Back mode Refer to "Loop back mode" in Test mode . Note that this bit can be programmed only in Initialization mode. This bit is utilized in UART mode also. 0 Loop Back Mode disabled 1 Loop Back mode enabled
27 MME	Master mode enable This bit can be programmed in Initialization mode only. It is read-only in Normal mode. **NOTE:** If generic slave = 0, then this bit will read a '1' always, and cannot be programmed. 0 Slave Mode 1 Master Mode
28 SSBL	Slave Mode Sync Break Length This bit can be programmed in Initialization mode only. It is read only in Normal mode. 0 11 bit break length 1 10 bit break length
29 RBLM	Receiver Buffer Locked mode This bit can be programmed in Initialization mode only. It is read-only in Normal mode. This bit is utilized in UART mode also. 0 Receiver Buffer not locked, next incoming message will overwrite the old one 1 Receiver buffer locked against overrun. Once the buffer is full the next incoming message will be discarded if buffer is not released — in other words, RMB is not reset by software.
30 SLEEP	Sleep Mode Request This bit is set by software to request LINFlexD to enter Sleep mode. This bit is cleared by software or hardware (if AUTOWU bit in LINCR1 and WUF bit in LINSR are set) to exit sleep mode. This bit is utilized in UART mode also.

Table continues on the next page...

LINFlexD_LINCR1 field descriptions (continued)

Field	Description
31 INIT	Initialization Mode Request The software sets this bit to switch the hardware into Initialization mode. On clearing this bit (and if SLEEP bit is also zero) LINFlexD enters normal mode. This bit is utilized in UART mode also.

54.5.2 LIN Interrupt enable register (LINFlexD_LINIER)

Address: 0h base + 4h offset = 4h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

LINFlexD_LINIER field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 SZIE	Stuck at zero Interrupt Enable An interrupt is generated if this bit is set and the Stuck at Zero Flag (SZF) in LINESR or UARTSR is set. 0 No interrupt 1 Interrupt enabled
17 OCIE	Output Compare Interrupt Enable 0 No interrupt 1 Interrupt generated when OCF bit in LINESR or UARTSR is set
18 BEIE	Bit Error Interrupt Enable 0 No interrupt 1 Interrupt generated when BEF bit in LINESR is set
19 CEIE	Checksum Error Interrupt Enable An interrupt is generated if this bit is set and the Checksum Error Flag (CEF) is set in LINESR.

Table continues on the next page...

LINFlexD_LINIER field descriptions (continued)

Field	Description
	0 No interrupt 1 Interrupt enabled
20 HEIE	Header Error Interrupt Enable An interrupt is generated when this bit is set and either of the following flags are set SFEF, SDEF, IDPEF in LINESR are set. **NOTE:** If generic slave = 0, then this bit will always read a 0 and cannot be programmed. 0 No interrupt 1 Interrupt enabled
21–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23 FEIE	Frame Error Interrupt Enable 0 No interrupt 1 Interrupt generated if Frame Error Flag (FEF) bit is set in LINESR or UARTSR
24 BOIE	Buffer Overrun Error Interrupt Enable An interrupt is generated if this bit is set and the Buffer Overrun Flag (BOF) is set in LINESR or UARTSR. 0 No interrupt 1 Interrupt enabled
25 LSIE	LIN state Interrupt enable Interrupt is generated only when entering the above fields. This interrupt can mainly be used for debugging purposes. The interrupt has no status flag. 0 No interrupt 1 Interrupt generated on entering the following states: Sync Del, Sync Field, Identifier field, Checksum
26 WUIE	Wakeup interrupt enable If this bit is set and the WUF in LINSR or UARTSR is set then an interrupt is generated. 0 No interrupt 1 Interrupt enabled
27 DBFIE	Data Buffer Full Interrupt enable An interrupt is generated if this bit is set and the DBFF bit in LINSR is also set. 0 No interrupt 1 Interrupt enabled
28 DBEIETOIE	Data Buffer Empty Interrupt enable/Timeout Interrupt Enable An interrupt is generated if this bit is set and LINSR[DBEF] status bit is set (in LIN mode) or if this bit is set and UARTSR[TO] status bit is set (in UART mode). 0 No interrupt 1 Interrupt enabled
29 DRIE	Data Reception complete Interrupt enable An interrupt is generated when this bit is set and Data Received flag (DRF) in LINSR or UARTSR is set. 0 No interrupt 1 Interrupt enabled

Table continues on the next page...

LINFlexD_LINIER field descriptions (continued)

Field	Description
30 DTIE	Data Transmitted Interrupt enable An interrupt is generated when this bit is set and Data Transmitted flag (DTF) in LINSR or UARTSR is set. 0 No interrupt 1 Interrupt enabled
31 HRIE	Header Received Interrupt An interrupt is generated when this bit is set and the Header Received flag (HRF) in LINSR is set. **NOTE:** If generic slave = 0, then this bit will always read a 0, and cannot be programmed. 0 No interrupt 1 Interrupt enabled

54.5.3 LIN Status Register (LINFlexD_LINSR)

This register consists of status bits indicating the state of the LINFlexD hardware.

Address: 0h base + 8h offset = 8h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0												AUTOSYNC_COMP	RDC		
W													w1c			
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	LINS				0		RMB	DRBNE	RXbusy	RDI	WUF	DBFF	DBEF	DRF	DTF	HRF
W	1						w1c	w1c			w1c	w1c	w1c	w1c	w1c	w1c
Reset	0	0	0	0	0	0	0	0	0	*	0	0	0	0	0	0

* Notes:
- RDI field: Reset value of RDI reflects the RX pin state

LINFlexD_LINSR field descriptions

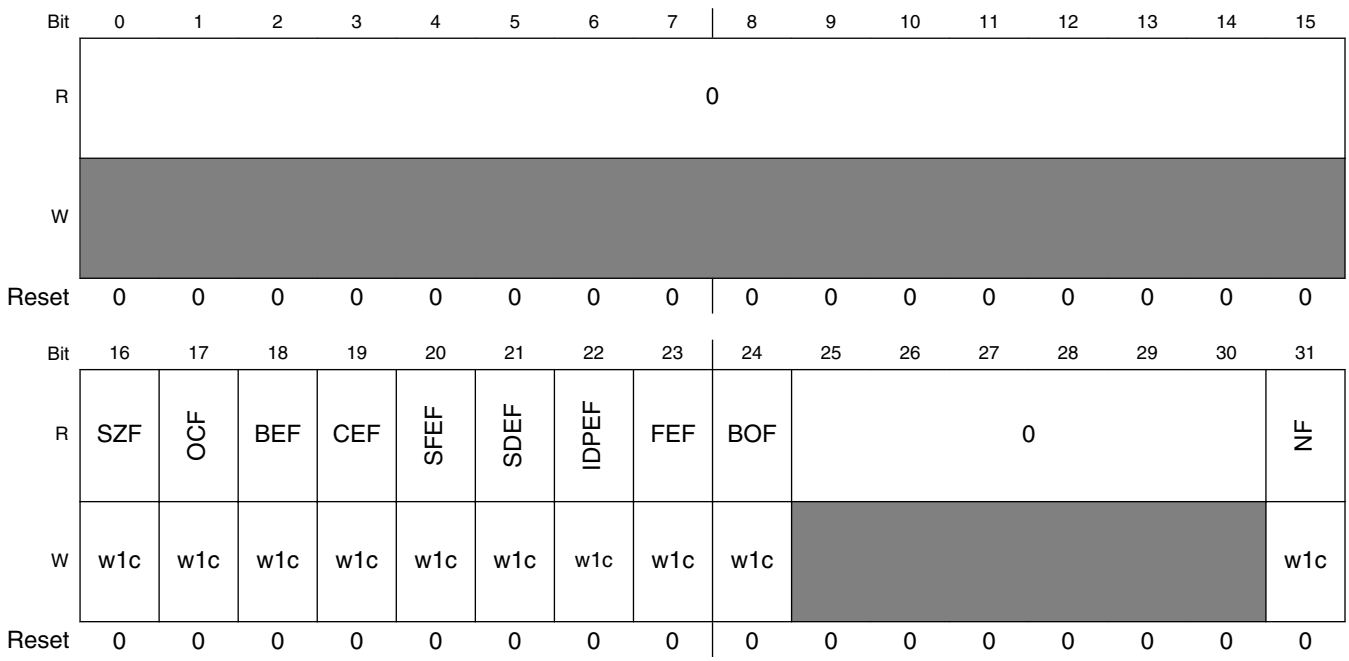
Field	Description
0–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12 AUTOSYNC_COMP	AUTOSYNC_COMP This bit is set after autosynchronization is complete and when the LASE bit in LINCR1 register is enabled. Only after this bit is set, the contents of LINIBRR and LINFBRR registers can be read in autosynchronization mode. **NOTE:** If autosynchronization is disabled, this bit is reserved.
13–15 RDC	Receive Data Byte Count RDC contains the number of entries (bytes) in the Receive data buffer in LIN mode. RDCx is a read-only field available for debug purposes. 000 1 byte 001 2 bytes 010 3 bytes 011 4 bytes 100 5 bytes 101 6 bytes 110 7 bytes 111 8 bytes

Table continues on the next page...

LINFlexD_LINSR field descriptions (continued)

Field	Description
16–19 LINS	LIN state In UART mode Idle, Init, Sleep, and Data Transmission/Reception states are flagged by the LIN status bits. **NOTE:** The value of this bit field doesn't change by any write operation to it. Writing 0xF to this bit field clears the Rx interrupt, only when set due to the LIN state event. 0000 Sleep mode: LINFlexD is in Sleep mode, to save power consumption. 0001 Init mode: This mode is entered when: SLEEP bit and INIT bit are reset by software; Wakeup pulse has been received on RX pin (AUTOWU set); Previous frame transmission/reception has been completed/aborted 0010 Idle mode: This mode is entered when: SLEEP bit and INIT bit are reset by software; Wakeup pulse has been received on RX pin (AUTOWU set); Previous frame transmission/reception has been completed/aborted 0011 Sync break: In slave mode, a falling edge followed by a dominant state has been detected. Receiving sync break. In slave mode, a falling edge followed by a dominant state has been detected. Receiving sync break. In master mode, sync break transmission ongoing. Note: In slave mode upon any error LIN state could be either Idle or Rec Break, depending on last bit detected on LIN_RX. If last bit detected is dominant then Rec_Break, otherwise Idle. 0100 Sync Del: In Slave mode, valid Sync break has been detected (10 bit or 11 bit). Waiting for a rising edge. In Master mode, Sync break transmission has been completed, sync delimiter transmission is ongoing. 0101 Sync Field: In Slave mode, a valid sync Del has been detected (recessive state for at least one bit time). Receiving sync field. In Master mode, sync field transmission ongoing. 0110 Identifier Field: In Slave mode, a valid sync field has been received. Receiving ID field. In Master mode, identifier transmission is ongoing. 0111 Header Reception/Transmission: In Slave mode, a valid header has been received and Identifier field is available in the BIDR. In Master mode, header transmitted. 1000 Data Reception/Data Transmission: In Receiver mode, reception ongoing. In Transmitter mode, response transmission ongoing. 1001 Checksum: Data transmission/reception completed, checksum transmission/reception ongoing.
20–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22 RMB	Release Message Buffer 0 Buffer data is free. Reset by hardware in when in Initialization mode 1 Buffer data ready to be read by software. This bit should be cleared by software after reading the data received in the buffer.
23 DRBNE	Data Reception Buffer Not Empty Flag This bit is set by hardware as soon as the first byte of response has been received and stored in BDRL (when there is at least one data byte in reception buffer). Software should clear it after reading all the buffers. This bit is also reset by hardware in Initialization mode. This flag could be checked by software in case of a response timeout event.
24 RXbusy	Receiver Busy flag In Slave mode after header reception, if DIR bit is reset and reception starts, then this bit is set. In this case user cannot set the DTRQ bit. 0 Receiver is idle 1 Reception ongoing

Table continues on the next page...



LINFlexD_LINSR field descriptions (continued)

Field	Description
25 RDI	LIN Receive signal This bit reflects the current status of the Rx pin. **NOTE:** After reset is released, RDI reflects the actual value of Rx pin.
26 WUF	Wakeup flag This bit is set by hardware when a falling edge is detected on the Rx pin. 1. When slave is in Sleep mode 2. When master is in Sleep mode or Idle mode It can be cleared by software. It gets reset by hardware in Initialization mode.
27 DBFF	Data Buffer full flag This bit is set by hardware when the buffer is full (8 bytes received) and DFL > 7. It should be cleared by software. This bit is also reset by hardware in Initialization mode.
28 DBEF	Data Buffer empty flag This bit is set by hardware when the buffer is empty (8 bytes have been transmitted) and DFL > 7. It should be cleared by software after data buffer is refilled by software. Transmission of next 8 bytes will not start unless this bit is reset by software. This bit is also reset by hardware in Initialization mode.
29 DRF	Data Reception Completed flag This bit is set by hardware and indicates that data reception has been completed. This flag should be cleared by software. This bit is also reset by hardware in Initialization mode. **NOTE:** In case framing error or checksum error occurs then this flag is not set.
30 DTF	Data Transmission Completed flag This bit is set by hardware and indicates that data transmission is completed. This flag should be cleared by software. This bit is also reset by hardware in Initialization mode. **NOTE:** For LIN mode, in case a bit error occurs (and IOBE is reset) then this flag is not set.
31 HRF	Header Received flag This bit is set when the header reception is completed. It should be cleared by software. This bit is set only when: a) All filters are inactive and Bypass filter (BF) bit is set b) No match in any filter and Bypass filter (BF) bit is set c) TX filter match At end of frame or frame aborted, if HRF is still set, it gets reset by hardware. This bit is also reset by hardware in Initialization mode. **NOTE:** If generic slave = 0, then this bit will always read a 0, and cannot be programmed.

54.5.4 LIN Error Status Register (LINFlexD_LINESR)

Refer to Errors for detailed description of all errors.

Address: 0h base + Ch offset = Ch

LINFlexD_LINESR field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 SZF	Stuck at Zero flag This bit is set when there is a stuck-at-zero timeout error. It should be reset by software.
17 OCF	Output Compare Flag 0: No output compare event occurred 1: In master mode, LINESR[OCF] flag is set when counter LINTCSR[CNT] has matched the content of LINOCR[OC2]. In slave mode, LINESR[OCF] is set when the content of the counter LINTCSR[CNT] has matched the content of LINOCR[OC1] or LINOCR[OC2]. This bit should be cleared by software. If this bit is set, MODE bit in LINTCSR is cleared, and the IOT bit of LINTCSR is set, then LINFlexD moves to Idle state. If the MODE bit in LINTCSR is clear, then OCF gets reset by hardware in Initialization mode; if the MODE bit is set, then OCF maintains its status irrespective of the LIN state.
18 BEF	Bit Error flag This bit is set by hardware when there is a bit error. It should be cleared by software. Reset by hardware in Initialization mode.

Table continues on the next page...

LINFlexD_LINESR field descriptions (continued)

Field	Description
19 CEF	Checksum Error flag This bit is set by hardware if the received checksum does not match the hardware-calculated checksum. It should be cleared by software. This error will never occur if CCD or CFD bit of LINCR1 is set. Reset by hardware in Initialization mode.
20 SFEF	Sync Field Error flag This bit is set by hardware when the received Sync Field is inconsistent. It should be cleared by software. Reset by hardware in Initialization mode. If generic slave = 0, then this bit will always read a 0, and cannot be programmed.
21 SDEF	Sync Delimiter Error flag This bit is set by hardware when the delimiter is too short (in other words, less than one bit time). It should be cleared by software. Reset by hardware in Initialization mode. **NOTE:** If generic slave = 0, then this bit will always read a 0, and cannot be programmed.
22 IDPEF	ID Parity Error flag This bit is set by hardware when there is an error in the ID parity. It should be cleared by software. **NOTE:** Header Error Interrupt is triggered for SFEF or SDEF or IDPEF flag is set and HEIE is set. If generic slave = 0, then this bit will always read a 0, and cannot be programmed. For generic slave = 1,this bit is reset by hardware in Initialization mode.
23 FEF	Framing Error flag This bit is set by hardware when there is a framing error (invalid stop bit). It should be cleared by software. Reset by hardware in initialization mode.
24 BOF	Buffer overrun flag This bit is set by hardware when there is a new byte received and RMB bit is not cleared. It can be cleared by software. Reset by hardware in initialization mode.
25–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 NF	Noise flag This bit is set by hardware when noise is detected in the received character. It should be cleared by software. Reset by hardware in Initialization mode.

54.5.5 UART Mode Control Register (LINFlexD_UARTCR)

NOTE

When accessing the UARTCR register, reserved bits should always be written to zero.

NOTE

- The LINFlexD module in UART mode does not support communication with Special Word Length (UARTCR[WLS] = 1) in buffer mode.
- The LINFlexD module in UART mode supports communication with Special Word Length (UARTCR[WLS] = 1) in FIFO mode only with UARTCR[WL1, WL0] = 1,1.

Address: 0h base + 10h offset = 10h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R W	MIS	CSP			OSR				ROSE	NEF			DTU_PCETX	SBUR		WLS

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	TDFL_TFC			RDFL_RFC			RFBM	TFBM	WL1	PC1	RxEn	TxEn	PC0	PCE	WL0	UART
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

LINFlexD_UARTCR field descriptions

Field	Description
0 MIS	Monitor Idle State 0 UARTCTO monitors the number of bits to be received. 1 UARTCTO monitors the idle state of the reception line.
1–3 CSP	Configurable Sample Point (i) These bits will decide the sample point during reduced over sampling. CSP can take the following range of values for a certain over sampling rate:

OSR	CSP
4	2,3
5	2, 3, 4
6	3, 4, 5
8	NA

4–7 OSR	Over Sampling Rate These bits are programmable by the user to configure the number of samples taken for a bit when reduced over sampling is enabled.

Table continues on the next page...

LINFlexD_UARTCR field descriptions (continued)

Field	Description
	Allowed values are: 4, 5, 6 and 84 and 8 .
8 ROSE	Reduced Over Sampling Enable 0 Each bit is over sampled sixteen times. 1 OSR bits decide the over sampling rate.
9–11 NEF	Number of expected frame These bits are used to configure the number of expected frames in UART reception mode. If the DTU bit is set, then the UART timeout counter will be reset after the configured number of frames have been received.
12 DTU_PCETX	Disable Timeout in UART mode This bit can be programmed in Initialization mode only when the UART bit is set. There is an internal counter that gives the number of frames received. **In Buffer mode:** This timer gets reset whenever the number of bytes received (rec_byte_cnt) is equal to RDFL. At this point the DRF bit is also set and num_of_frames (number of frames received), rec_byte_cnt are reset. When num_of_frames equals NEF, Disable Timeout is generated. But this clears num_of_frames also. Thus the timer restarts again. The value of counter is 0 when it restarts. **In FIFO mode:** When num_of_frames equals NEF, Disable Timeout is generated which clears num_of_frames and causes the timer to restart again. The value of counter is 0 when it restarts. Notes: • Disable Timeout causes only the Timer to restart which enables Timeout again. • Timer reset means it resets and starts counting again and the Timeout is enabled. 0 Timeout has to be handled by software 1 Timeout in UART mode is disabled after the configured number of data frames are received
13–14 SBUR	Stop bits in UART reception mode When the UART is used for transmission and reception we have to set the same number of stop bits in GCR and SBUR. When the UART is used only as receiver, it is enough to set SBUR bits only. This bit can be programmed in the initialization mode only, when the UART bit is set. 00 1 stop bit 01 2 stop bits 10 3 stop bits 11 reserved
15 WLS	Special Word Length in UART mode This bit can be programmed in initialization mode only when the UART bit is set. If this bit is set, setting WL and PCE bits has no effect in UART reception although parity check is enabled by default in this mode and PC0/1 bits can be used to select the parity control. This bit is given the highest priority in UART reception mode. 0 This bit is disabled. 1 This bit enables 12-bit + parity bit in reception (UART mode) for MSC (Micro Second Channel upstream frame) support.
16–18 TDFL_TFC	Transmitter Data Field Length/TX FIFO Counter

Table continues on the next page...

LINFlexD_UARTCR field descriptions (continued)

Field	Description
	TDFL defines the number of bytes to be transmitted in UART buffer mode (TFBM = 0). TDFL is a read/write field. Bit 15 is reserved and not implemented. When the UART data length is configured as halfword (WL = 10 or WL = 11), only the configurations TDFL = x01 or TDFL = x11 are allowed. x00 : 1 byte x01 : 2 bytes x10 : 3 bytes x11 : 4 bytes Register bit is a read/write field. TFC contains the number of entries (bytes) of the Tx FIFO in UART FIFO mode (TFBM = 1). TFCx is a read-only field available for debug purposes. 000 : empty 001 : 1 byte 010 : 2 bytes 011 : 3 bytes 100 : 4 bytes Others : reserved TDFLTFC can be programmed and are significative only when the UART bit is set. Register bit can be read in any mode, written only in Initialization mode. **NOTE:** When a debugger is connected, this counter will decrement if TxFIFO is being read through the debugger. **NOTE:** In case of data path is functioning normally, RFC/TFC counters will be cleared internally by HW.
19–21 RDFL_RFC	Reception Data Field Length /RX FIFO Counter RDFL defines the number of bytes to be received in UART buffer mode (RFBM = 0). RDFL is a read/write field. Bit 19 is reserved and not implemented. When the UART data length is configured as halfword (WL = 10 or WL = 11), only the configurations RDFL = x01 or RDFL = x11 are allowed. x00 : 1 byte x01 : 2 bytes x10 : 3 bytes x11 : 4 bytes RFC contains the number of entries (bytes) of the Rx FIFO in UART FIFO mode (RFBM = 1). RFCx is a read-only field available for debug purposes. 000 : Empty 001 : 1 byte 010 : 2 bytes/1.5 byte in case of WLS bit setting 011 : 3 bytes 100 : 4 bytes/2x1.5 byte in case of WLS bit setting Others - Reserved RDFLRFC can be programmed and are significative only when the UART bit is set.

Table continues on the next page...

LINFlexD_UARTCR field descriptions (continued)

Field	Description
	Register bit can be read in any mode, written only in initialization mode. 0 LIN mode 1 UART mode

54.5.6 UART Mode Status Register (LINFlexD_UARTSR)

Address: 0h base + 14h offset = 14h

LINFlexD_UARTSR field descriptions

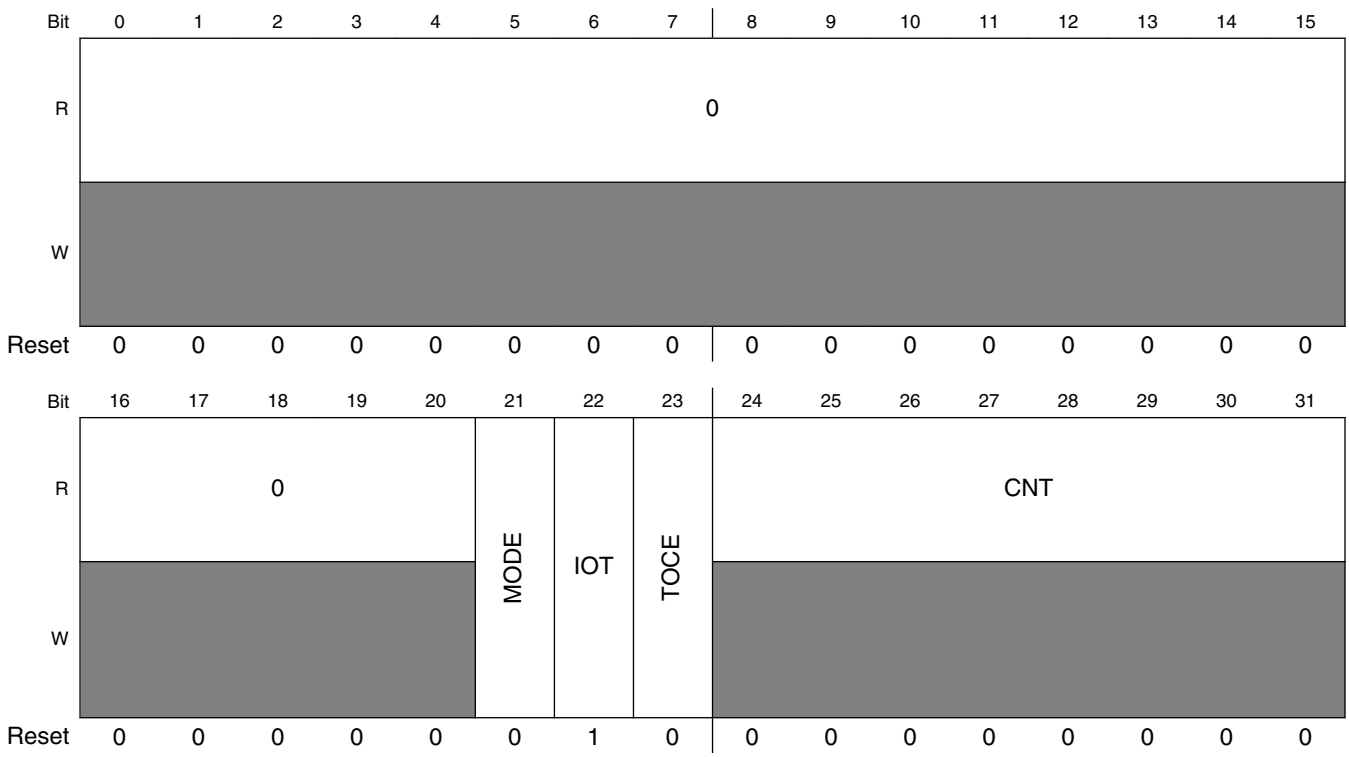
Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 SZF	Stuck at Zero flag This bit is set by hardware when 100 dominant bits are detected. It should be cleared by software. An interrupt will be generated if the SZIE bit in LINIER is set. This bit will reflect the same value as in LINESR, when in Initialization mode and the UART bit is set.

Table continues on the next page...

LINFlexD_UARTSR field descriptions (continued)

Field	Description
17 OCF	Output Compare Flag An interrupt will be generated if the OCIE bit in LINIER is set. This bit will reflect the same value as in LINESR, when in Initialization mode and the UART bit is set. **NOTE:** For Baud rate above 1 Mbit/s, this flag is not usable. 0 No output compare event occurred 1 The content of the counter has matched the content of LINOCR
18–21 PE	Parity Error flag These bits indicate if there is a Parity Error in the corresponding byte. No interrupt is generated if this error occurs. This bit will reflect the same value as in LINESR, when in initialization mode and UART bit set. **NOTE:** Parity is checked only after complete frame is received. Following are the conditions when WL bits = 01 or 11 (either PE0 or PE2 is only set). • When PE0 is set, it indicates Parity error in either first or second byte received • When PE2 is set, it indicates Parity error in either third or fourth byte received 0 No parity error 1 Parity error in the corresponding received byte
22 RMB	Release Message Buffer This bit should be cleared by software. This bit will reflect the same value as in LINSR, when in Initialization mode and the UART bit is set. 0 Buffer data is free 1 Buffer data ready to be read by software
23 FEF	Framing Error flag This bit is set by hardware when there is a framing error (invalid stop bit). It should be cleared by software. It will generate an interrupt if the FEIE bit of LINIER is set. This bit will reflect the same value as in LINESR, when in Initialization mode and the UART bit is set.
24 BOF	FIFO/Buffer overrun flag This bit is set by hardware when there is a new byte received and the RMB bit is not cleared in UART buffer mode. In UART FIFO mode this bit is set when there is a new byte and the Rx FIFO is full. In UART FIFO mode, once Rx FIFO is full, the new received message will be discarded irrespective of the new value of the RBLM bit. In UART Rx Buffer mode, if RBLM is set then the new message received will be discarded; if RBLM is reset then the new message will overwrite the buffer. It can be cleared by software writing a 1. An interrupt is generated if the BOIE bit of LINIER is set. This bit will reflect the same value as in LINESR, when in Initialization mode and the UART bit is set.
25 RDI	Receiver Data Input signal This bit reflects the current status of the RX pin.
26 WUF	Wakeup flag This bit is set by hardware when a falling edge is detected on the RX pin in sleep mode. It should be cleared by software. An interrupt will be generated if the WUIE bit in LINIER is set. This bit will reflect the same value as in LINESR when in Initialization mode and the UART bit is set.
27 RFNE	Receive FIFO Not Empty

Table continues on the next page...



LINFlexD_UARTSR field descriptions (continued)

Field	Description
	RFNE bit is set by hardware in UART FIFO mode (RFBM = 1), when there is at least one data byte present in the receive FIFO. RFNE is a read-only bit for debugging purposes. This flag can be used by software in case of a timeout event.
28 TO	Timeout This bit is set by hardware when a UART timeout occurs — in other words, the value of UARTCTO becomes equal to the preset value of the timeout (UARTPTO register setting). TO should be cleared by software. The SR bit should be used to reset the receiver fsm to Idle state in case of UART TIMEOUT for UART reception, depending on the application, in both buffer and FIFO mode. An interrupt will be generated when LINIER.DBEIE/TOIE bit is set on the Error interrupt line in UART mode.
29 DRFRFE	Data Reception Completed Flag /Rx FIFO Empty Flag DRF is set by hardware in UART buffer mode (RFBM = 0) and indicates that the number of bytes programmed in RDFL have been received. DRF should be cleared by software. An interrupt will be generated if the DRIE bit in LINIER is set. DRF bit is set when the configured number of valid stop bits are received for the last frame (number of frames is configurable by RDFL bits). DRF is set irrespective of framing error in case framing error is in the last STOP bit configured, parity error or overrun error. This bit will reflect the same value as in LINSR when in Initialization mode and the UART bit is set. Register bit can be read/cleared by software. Writing 1 clears contents. RFE is set by hardware in UART FIFO mode (RFBM = 1) when the RX FIFO is empty. RFE is a read-only bit for debugging purposes. It is internally used by the DMA RX interface.
30 DTFTFF	Data Transmission Completed Flag/ TX FIFO Full Flag DTF is set by hardware in UART buffer mode (TFBM = 0) and indicates that data transmission is completed. DTF should be cleared by software. An interrupt will be generated if the DTIE bit in LINIER is set. This bit will reflect the same value as in LINSR when in Initialization mode and the UART bit is set. Register bit can be read/cleared by software. Writing 1 clears contents. TFF is set by hardware in UART FIFO mode (TFBM = 1) when TX FIFO is full. TFF is a read-only bit for debugging purposes. It is internally used by the DMA TX interface.
31 NF	Noise flag This bit is set by hardware when noise is detected in the received character. It should be cleared by software. This bit will reflect the same value as in LINESR when in Initialization mode and the UART bit is set. During reduced oversampling (ROSE bit = 1), it is enabled only when OSR = 8.

54.5.7 LIN Time-Out Control Status Register (LINFlexD_LINTCSR)

This register contains control and status bits for timeout feature.

Address: 0h base + 18h offset = 18h

LINFlexD_LINTCSR field descriptions

Field	Description
0–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21 MODE	Time-out counter mode This bit can be configured only during initialization. Register bit can be read in any mode, written only in initialization mode. 0 LIN mode 1 Output compare mode
22 IOT	Idle on timeout Register bit can be read in any mode, written only in initialization mode. This feature is applicable only when MODE bit in LINTCSR is cleared. 0 LIN state machine does not reset to Idle on timeout 1 LIN state machine resets to Idle on timeout event

Table continues on the next page...

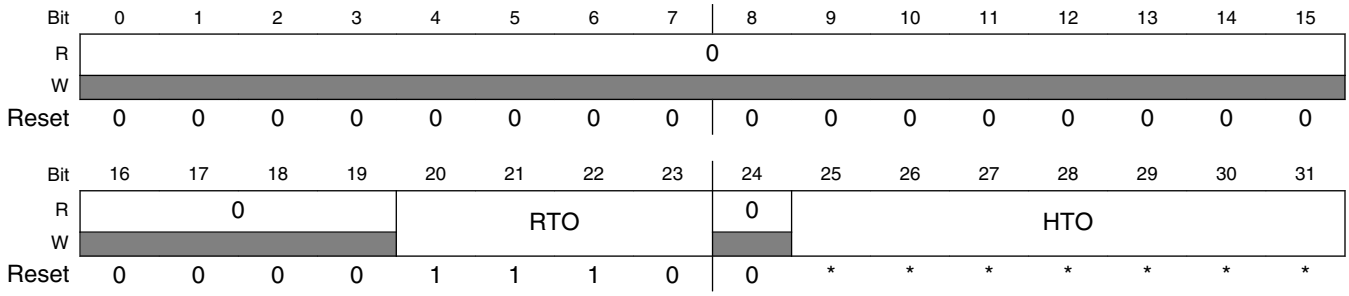
LINFlexD_LINTCSR field descriptions (continued)

Field	Description
23 TOCE	Time-out counter enable TOCE is always configurable by software in Initialization mode. If LIN state is other than INIT and if timer is configured in LIN mode, then hardware takes control of TOCE. 0 Time-out counter disable. OCF flag is not set on an output compare event. 1 Time-out counter enable. OCF flag is set if an output compare event occurs.
24–31 CNT	Counter Value These bits reflect the value of a counter used for timeout. **NOTE:** For proper functionality of this counter, LINIBRR should be >= 5.

54.5.8 LIN Output Compare Register (LINFlexD_LINOCR)

This register contains the value to be compared to the LINTCSR:CNT value. This register is writable by software only in Output Compare Mode.

Address: 0h base + 1Ch offset = 1Ch



Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0																OC2								OC1							
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

LINFlexD_LINOCR field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–23 OC2	Output compare value 2
24–31 OC1	Output compare value 1

54.5.9 LIN Time-Out Control Register (LINFlexD_LINTOCR)

Address: 0h base + 20h offset = 20h

* Notes:

- HTO field: HTO reset values:

  HTO resets to 0011100b in Master only mode, if generic slave = 0.

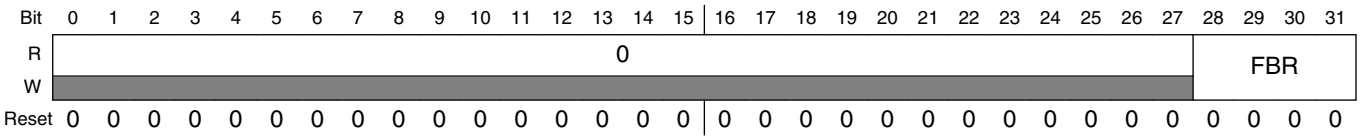
  HTO resets to 0101100b in Master/Slave mode, if generic slave = 1.

LINFlexD_LINTOCR field descriptions

Field	Description
0–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20–23 RTO	Response timeout value This is the response timeout duration (in bit time) for 1 byte. The reset value is 0Eh = 14, corresponding to $T_{Response_Maximum} = 1.4 \times T_{Response_Nominal}$
24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25–31 HTO	Header timeout value This register contains the header timeout duration (in bit time). This register can be written only for Slave mode. If Master mode is enabled then these bits will always reflect 28 (1.4 x 10 bits of sync + 1.4 x 10 bits of ID). For slave, these bits should be programmed without considering 11 bits of break.

54.5.10 LIN Fractional Baud Rate Register (LINFlexD_LINFBRR)

This register consists of bits that decide the fractional part of the LIN Baud Rate. It can be programmed only in Initialization mode.



NOTE

When LASE bit is set, this register should be read only after AUTOSYNC_COMP bit in LINSR register is set to obtain the correct value.

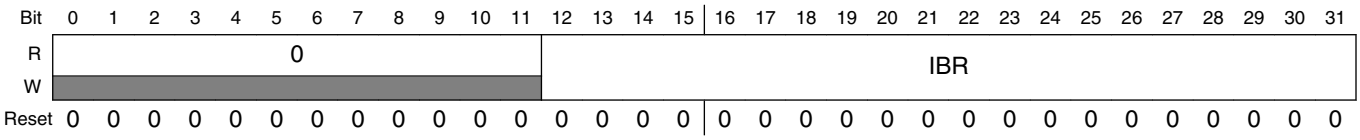
NOTE

This register cannot be used when reduced oversampling is enabled (ROSE bit = 1)

Address: 0h base + 24h offset = 24h

LINFlexD_LINFBRR field descriptions

Field	Description
0–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28–31 FBR	Fractional Baud rates Register bit can be read in any mode, written only in initialization mode. 0000 Fraction(LDIV) = 0 0001 Fraction(LDIV) = 1/16 0010 Fraction(LDIV) = 2/16 0011 Fraction(LDIV) = 3/16 0100 Fraction(LDIV) = 4/16 0101 Fraction(LDIV) = 5/16 0110 Fraction(LDIV) = 6/16 0111 Fraction(LDIV) = 7/16 1000 Fraction(LDIV) = 8/16 1001 Fraction(LDIV) = 9/16 1010 Fraction(LDIV) = 10/16 1011 Fraction(LDIV) = 11/16 1100 Fraction(LDIV) = 12/16 1101 Fraction(LDIV) = 13/16 1110 Fraction(LDIV) = 14/16 1111 Fraction(LDIV) = 15/16



54.5.11 LIN Integer Baud Rate Register (LINFlexD_LINIBRR)

This register consists of control bits that decide the baud rate along with the LINFBRR. It can be programmed only in Initialization mode.

NOTE

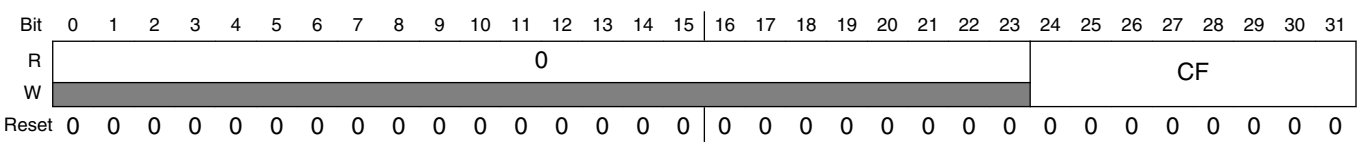
When LASE bit is set, this register should be read only after AUTOSYNC_COMP bit in LINSR register is set to obtain the correct value.

Address: 0h base + 28h offset = 28h

LINFlexD_LINIBRR field descriptions

Field	Description
0–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12–31 IBR	Integer Baud rates These bits along with the fractional baud rate bits decide the LIN baud rate. IBR = 0h: LIN clock disabled IBR = 1h: Mantissa (LDIV) = 1 ... IBR = FFFFEh: Mantissa (LDIV) = 1048574 IBR = FFFFFh: Mantissa (LDIV) = 1048575 Register bit can be read in any mode, written only in initialization mode.

54.5.12 LIN Checksum Field Register (LINFlexD_LINCFR)



NOTE

There is a delay between 4 to 6 clock cycles of PBRIDGEx_CLK for the internal checksum's value (which is clocked with LIN_CLK/16 * LDIV) to reflect on LINCFR.

This register consists of checksum bits.

CFD	CCD	LINCHKSUM Read/write	Checksum sent
1	1	read/write	None
1	0	read-only	None
0	1	read/write	Programmed checksum
0	0	read-only	Calculated checksum

Address: 0h base + 2Ch offset = 2Ch

LINFlexD_LINCFR field descriptions

Field	Description
0–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–31 CF	Checksum bits When the CCD bit is reset these bits are read-only and are calculated by hardware. When the CCD bit is set, these bits can be written by software.

54.5.13 LIN Control Register 2 (LINFlexD_LINCR2)

This register includes control status bits related to buffer operations.

NOTE

When accessing the LINCR2 register, each reserved bit should be written to its original reset value.

Address: 0h base + 30h offset = 30h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	TBDE	IOBE	IOPE	WURQ	DDRQ	DTRQ	ABRQ	HTRQ	0							
W																
Reset	0	1	*	0	0	0	0	0	0	0	0	0	0	0	0	0

* Notes:

- IOPE field: When slave = 0, this field always reads ‘0’ and cannot be programmed else this bit is programmable and reset value is 1.

LINFlexD_LINCR2 field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 TBDE	Two Bit delimiter bit This bit can be set in Initialization mode only. Register bit can be read in any mode, written only in initialization mode.

Table continues on the next page...

LINFlexD_LINCR2 field descriptions (continued)

Field	Description
	0 Delimiter length in break field is 1 bit 1 Delimiter length in break field is 2 bits
17 IOBE	Idle on Bit Error This bit can be set in Initialization mode only. Register bit can be read in any mode, written only in initialization mode. 0 Bit Error does not reset LIN state machine 1 Bit Error resets LIN state machine
18 IOPE	Idle on Identifier Parity Error This bit can be set in Initialization mode only. Register bit can be read in any mode, written only in initialization mode. If generic slave = 0, then this bit will always read a 1 else 0, and cannot be programmed. 0 Parity Error does not reset LIN state machine 1 Parity Error resets LIN state machine
19 WURQ	Wakeup Generate Request Setting this bit will generate a wakeup pulse. It is reset by hardware when the wakeup character has been transmitted. The character sent during wakeup is copied from BDRL (DATA0). Note that this bit cannot be set in Sleep mode — software has to exit Sleep mode before setting this bit. Bit Error is not checked when transmitting the wakeup request. Register bit can be read/set by software
20 DDRQ	Data Discard request Set by software to stop data reception if the frame does not concern the node. This bit is reset by hardware once LINFlexD ignores the response and moves to Idle state. For LIN slave this bit can be set only when HRF bit is set and Identifier is software-filtered. Register bit can be read/set by software
21 DTRQ	Data Transmission Request Set by software in slave mode to request the transmission of the LIN Data field stored in the Buffer data register. This bit can be set only when the HRF bit is set (to ensure that data transmission is requested only after a header reception). Cleared by hardware when the request has been completed, or on abort request or error condition. In Master mode, this bit is set by hardware when the DIR bit is set and header transmission is complete. Register bit can be read/set by software
22 ABRQ	Abort Request Set by software to abort the current transmission. Cleared by hardware when the transmission has been aborted. LINFlexD aborts the transmission at the end of the current bit. This bit can abort a wakeup request also and can be used in UART mode also. Register bit can be read/set by software Register bit can be read/set by software
23 HTRQ	Header Transmission Request Set by software to request the transmission of the LIN Header.

Table continues on the next page...

LINFlexD_LINCR2 field descriptions (continued)

Field	Description
	Cleared by hardware when the request has been completed or on abort request. This bit has no effect in UART mode. **NOTE:** In master mode, if both HTRQ and ABRQ are set at the same time then ABRQ has no effect. Similarly, in slave mode after header reception, if DTRQ and ABRQ are simultaneously set then ABRQ has no effect.
24–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

54.5.14 Buffer Identifier Register (LINFlexD_BIDR)

This register contains the bits which provide information about the identifier of the transaction and other related information.

NOTE

All the fields (ID, CSS, DIR, DFL) of the BIDR register must be updated when an ID filter (enabled) in Slave mode (Tx or Rx) matches the ID received.

Address: 0h base + 34h offset = 34h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R	DFL						DIR	CCS	0		ID					
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

LINFlexD_BIDR field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–21 DFL	Data Field Length Number of data bytes in the response part of the frame. DFL = Number of data bytes - 1 **NOTE:** DFL[5:3] is provided for extended frames. Normally LIN mode will use DFL[2:0]. Identifier filters are now compatible with DFL[5:0] also.
22 DIR	Direction This bit controls the direction of the data field. 0 LINFlexD receives the data and copy them in the BDR registers 1 LINFlexD transmits the data from the BDR registers

Table continues on the next page...

LINFlexD_BIDR field descriptions (continued)

Field	Description
23 CCS	Classic Checksum This bit controls the type of checksum applied on the current message. 0 Enhanced Checksum covering Identifier and Data fields. This is compatible with LIN specification rev. 2.0 and higher. 1 Classic Checksum covering Data filed only. This is compatible with LIN specification 1.3 and lower.
24–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26–31 ID	Identifier Identifier part of the identifier field without the identifier parity. This field can be written only in Master mode (MME = '1').

54.5.15 Buffer Data Register Least Significant (LINFlexD_BDRL)

This register is a part of an 8-byte data buffer.

Address: 0h base + 38h offset = 38h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

LINFlexD_BDRM field descriptions

Field	Description
0–7 DATA7	Data Byte 7 Data byte 7 of the data field.
8–15 DATA6	Data Byte 6 Data byte 6 of the data field.
16–23 DATA5	Data Byte 5 Data byte 5of the data field.
24–31 DATA4	Data Byte 4 Data byte 4 of the data field.

54.5.17 Identifier Filter Enable Register (LINFlexD_IFER)

This register enables/disables a particular filter.

Address: 0h base + 40h offset = 40h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

LINFlexD_IFER field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 FACT	Filter active The software sets the bit FACT[x] to activate the filter x in Identifier list mode. Register bit can be read in any mode, written only in initialization mode.

Table continues on the next page...

LINFlexD_IFER field descriptions (continued)

Field	Description
	1. In Identifier mask mode, FACT (2n+1) have no effect on the corresponding filters as they act as mask for the Identifier 2n. 2. The length of this field depends on the value of no_of_filters. 3. The register diagram depicts the maximum no_of_filters, which can be up to 16. **NOTE:** Refer to chip configuration details to see the number of filters used in the device.

54.5.18 Identifier Filter Match Index (LINFlexD_IFMI)

This register contains the index corresponding to the received ID. It can be used to read or write the data directly in RAM.

Address: 0h base + 44h offset = 44h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0																											IFMI				
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

LINFlexD_IFMI field descriptions

Field	Description
0–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27–31 IFMI	Filter match index Upon a filter match with xth filter – IFMI[4:0] = x+1. On no match IFMI is equal to 00h. This register contains the index corresponding to the received identifier. It can be used to directly write or read the data in SRAM (see Slave mode for more details).

54.5.19 Identifier Filter Mode Register (LINFlexD_IFMR)

This register configures the modes of filters.

Address: 0h base + 48h offset = 48h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

LINFlexD_IFMR field descriptions

Field	Description
0–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–31 IFM	Filter mode Register bit can be read in any mode, written only in initialization mode. 0 Filters 2n and 2n+1 are in identifier list mode 1 Filters 2n and 2n+1 are in mask mode, where filter 2n+1 is the mask for filter 2n

54.5.20 Identifier Filter Control Register (LINFlexD_IFCR*n*)

This register is read-only in normal mode and can be programmed only in Initialization mode.

Even-numbered instances (IFCR0, IFCR2, IFCR4, ...) of this register act as filters in both Identifier list and Identifier mask modes.

Odd-numbered instances (IFCR1, IFCR3, IFCR5, ...) of this register act:

- As filters in Identifier list mode
- As a mask for the preceding-numbered register in identifier mask mode

Refer to chip configuration details to see the number of filters used in the device.

Address: 0h base + 4Ch offset + (4d × i), where i=0d to 15d

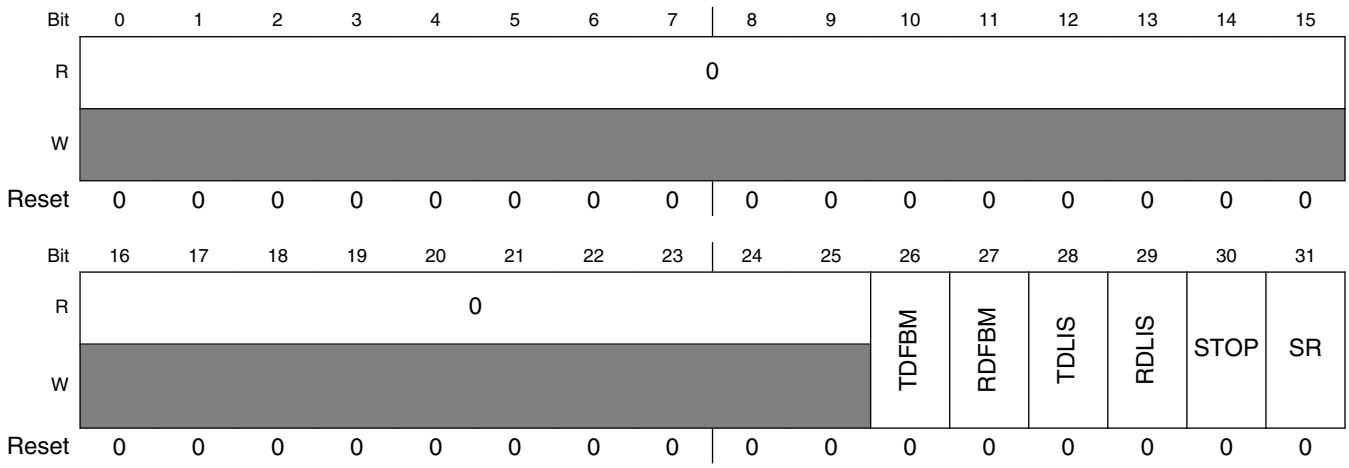
16–21 DFL	Data Field Length Number of data bytes in the response part of the frame. DFL[5:0] = Number of data bytes - 1 Register bit can be read in any mode, written only in initialization mode.

Table continues on the next page...

LINFlexD_IFCR*n* field descriptions (continued)

Field	Description
22 DIR	Direction This bit controls the direction of the data field. Register bit can be read in any mode, written only in initialization mode. 0 LINFlexD receives data and copies to the BDR registers 1 LINFlexD transmits data from the BDR registers
23 CCS	Classic Checksum This bit controls the type of checksum applied on the current message. Register bit can be read in any mode, written only in initialization mode. 0 Enhanced Checksum covering Identifier and Data fields. This is compatible with LIN specification rev. 2.0 and higher. 1 Classic Checksum covering Data field only. This is compatible with LIN specification 1.3 and lower.
24–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26–31 ID	Identifier Identifier part of the identifier field without the identifier parity. Register bit can be read in any mode, written only in initialization mode.

54.5.21 Global Control Register (LINFlexD_GCR)



This register is read-only in Normal mode and can be programmed only in Initialization mode. This is a global control register — in other words, the register configuration will be applied in LIN mode as well as in UART mode.

The address offset depends on the no_of_filters. Refer to the chip configuration details for the number of filters used in this device.

Table 54-57. Register fields reset by SR

Register	Comment
LINSR	All fields except RXbusy and AUTOSYNC_COMP are reset
LINESR	All fields are reset
LINTCSR	Only CNT[0:7] is reset
UARTSR	All fields except RFE & TFF are reset
UARTCR	Only TFC & RFC are reset
UARTCTO	All fields are reset

Address: 0h base + 8Ch offset = 8Ch

LINFlexD_GCR field descriptions

Field	Description
0–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26 TDFBM	Transmit data first bit MSB This bit controls the first bit of transmit data (payload only) as MSB/LSB in both UART and LIN modes. Register bit can be read in any mode, written only in initialization mode. 0 The first bit of transmitted data is LSB — in other words, the first bit transmitted is mapped on LSB bit (BDR (0), BDR (8), BDR (16), BDR (24)) 1 The first bit of transmitted data is MSB — in other words, the first bit transmitted is mapped on MSB bit (BDR (7), BDR (15), BDR (23), BDR (31))
27 RDFBM	Received data first bit MSB This bit controls the first bit of received data (payload only) as MSB/LSB both in UART and LIN modes. Register bit can be read in any mode, written only in initialization mode. 0 The first bit of received data is LSB — in other words, the first bit received is mapped on LSB bit (BDR (0), BDR (8), BDR (16), BDR (24)) 1 The first bit of received data is MSB — in other words, the first bit received is mapped on MSB bit (BDR (7), BDR (15), BDR (23), BDR (31))
28 TDLIS	Transmit data level inversion selection This bit controls the data inversion of transmitted data (payload only) in both UART and LIN modes. Register bit can be read in any mode, written only in initialization mode. 0 Transmitted data is not inverted 1 Transmitted data is inverted
29 RDLIS	Received data level inversion selection This bit controls the data inversion of received data (payload only) in both UART and LIN modes. Register bit can be read in any mode, written only in initialization mode. 0 Received data is not inverted 1 Received data is inverted

Table continues on the next page...

LINFlexD_GCR field descriptions (continued)

Field	Description
30 STOP	1/2 stop bit configuration This bit controls the number of stop bit transmitted data in both UART and LIN modes. The stop bit is configured for all the fields (Delimiter, Sync, ID, Checksum, Payload). Register bit can be read in any mode, written only in initialization mode. 0 1 stop bit 1 2 stop bits
31 SR	Soft reset SR executes a soft reset of the LINFlexD controller (FSMs, FIFO pointers, counters, timers, status and error registers) without modifying the configuration registers when a 1 write operation is performed. This bit should be cleared by software to perform further operations (this bit is not cleared by hardware). Register bit can be written only be software in initialization mode. Bit is always read 0 by software. Table 54-57 describes the register fields reset by SR.

54.5.22 UART Preset Timeout Register (LINFlexD_UARTPTO)

This register contains the preset value of the timeout register in UART mode and is programmed according to the number of bits to be receivedor to monitor the idle state of the reception line. This register can be written by software any time.

The address offset depends on no_of_filters. Refer to the chip configuration details to see the number of filters used in the device.

Address: 0h base + 90h offset = 90h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0																PTO															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1	1	1	1	1	1	1	1	1	1

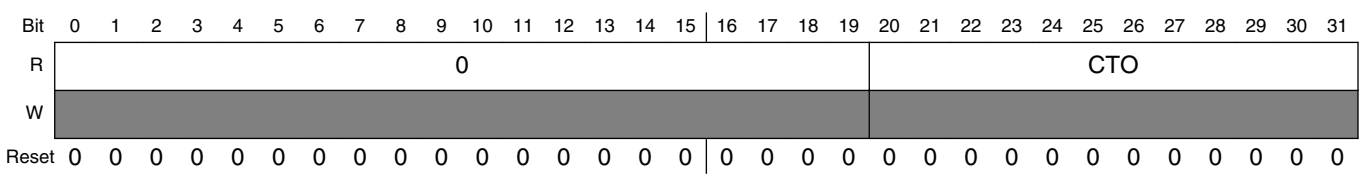
LINFlexD_UARTPTO field descriptions

Field	Description
0–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20–31 PTO	Preset Timeout PTO defines the preset value of timeout counter. A zero-value is forbidden, otherwise the UARTSR[TO] status bit is immediately set. Refer also to register UARTCTO.

54.5.23 UART Current Timeout Register (LINFlexD_UARTCTO)

This register contains the current timeout value in UART mode, and is used in conjunction with the UARTPTO register (see UART Preset Timeout Register (LINFlexD_UARTPTO) to monitor the number of bits received by UARTor to monitor the idle state of the reception line. UART timeout works in both CPU and DMA modes.

The timeout counter:



- Starts at zero and counts upward
- Is clocked with LIN_CLK / (16 * LDIV) synchronized to PBRIDGEx_CLK (when ROSE = 0)
- Is clocked with LIN_CLK / (OSR * IBRR) synchronized to PBRIDGEx_CLK (when ROSE = 1)
- Is automatically enabled when UARTCR[RXEN] = 1

It is reset when:

- Number of frames received is equal to NEF bits
- UARTCTO becomes equal to UARTPTO
- Whenever UARTPTO is written
- When DRF is set and DTU bit = 1

The address offset depends on no_of_filters. Refer to chip configuration details to see the number of filters used in the device.

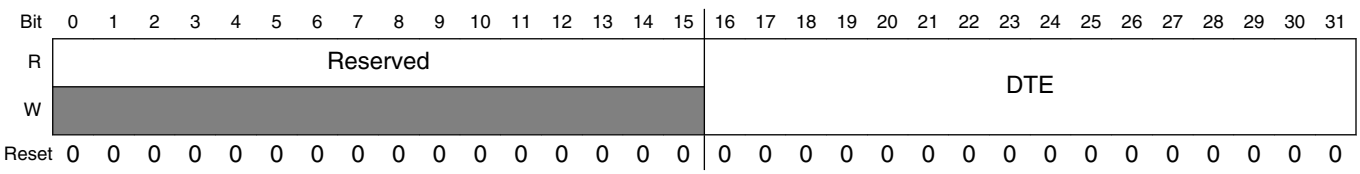
Address: 0h base + 94h offset = 94h

LINFlexD_UARTCTO field descriptions

Field	Description
0–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20–31 CTO	Current Timeout

Table continues on the next page...

LINFlexD_UARTCTO field descriptions (continued)



Field	Description
	CTO defines the current value of the timeout counter. CTO is a read-only field. CTO is reset every time UARTPTO is re-initialized, or UARTCTO = UARTPTO, or by hard/soft reset. When the CTO value matches the preset value (UARTPTO), the status bit UARTSR[TO] is set.

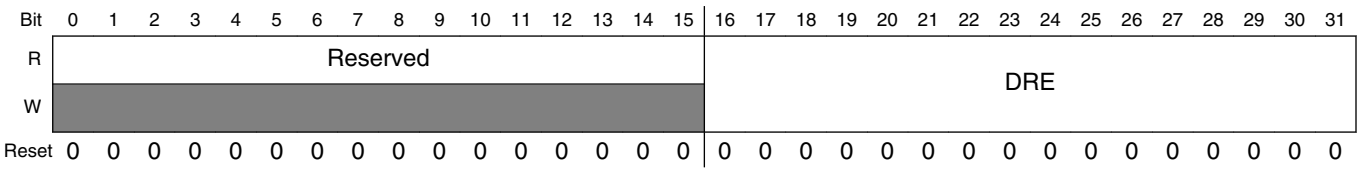
54.5.24 DMA Tx Enable Register (LINFlexD_DMATXE)

This register enables the DMA TX interface. This register can be written and read by software anytime.

The address offset depends on no_of_filters. Refer to chip configuration details to see the number of filters used in the device.

Address: 0h base + 98h offset = 98h

LINFlexD_DMATXE field descriptions



Field	Description
0–15 Reserved	This field is reserved. Reserved **NOTE:** The number of reserved bits varies, and is equal to 32 - $2^{TX_CH_NUM}$. These lies from 0 to (31 - $2^{TX_CH_NUM}$). Refer to the chip configuration details for the value of TX_CH_NUM used in this device.
16–31 DTE	DMA Tx channel Y enable **NOTE:** The actual size of the register DMATXE depends on the value of the static parameter TX_CH_NUM. The size is [$2^{TX_CH_NUM}$ - 1 : 0]. The position of these bits are (32 - $2^{TX_CH_NUM}$) to 31. When DMATXE = 0x00000000, the DMA TX interface FSM is forced (soft reset) in Idle state. **NOTE:** Refer to the chip configuration details for the value of TX_CH_NUM used in this device. 0 DMA Tx channel Y disabled 1 DMA Tx channel Y enabled

54.5.25 DMA Rx Enable Register (LINFlexD_DMARXE)

This register enables the DMA RX interface. This register can be written and read by software any time.

The address offset depends on no_of_filters. Refer to device configuration chapter to see the number of filters used in the device.

Address: 0h base + 9Ch offset = 9Ch

LINFlexD_DMARXE field descriptions

Field	Description
0–15 Reserved	This field is reserved. Reserved **NOTE:** The number of reserved bits varies, and is equal to 32 - $2^{RX_CH_NUM}$. These lies from 0 to (31 - $2^{RX_CH_NUM}$). Refer to the chip configuration details for the value of RX_CH_NUM used in this device.
16–31 DRE	DMA Rx channel Y enable **NOTE:** The actual size of the register DMARXE depends on the value of the static parameter RX_CH_NUM. The size is [$2^{RX_CH_NUM}$ -1 : 0]. The position of these bits are (32 - $2^{RX_CH_NUM}$) to 31. When DMARXE = 0x00000000, the DMA RX interface FSM is forced (soft reset) in Idle state. **NOTE:** Refer to the chip configuration details for the value of RX_CH_NUM used in this device. 0 DMA Rx channel Y disabled 1 DMA Rx channel Y enabled

54.6 Programming considerations

The next subsections describe the various configurations in which the LINFlexD module can be used.

54.6.1 Master node

LINFlexD acts as Master when the MME bit is set.

54.6.1.1 Transmitter

Transmitter Master Node - Transmitter configuration.

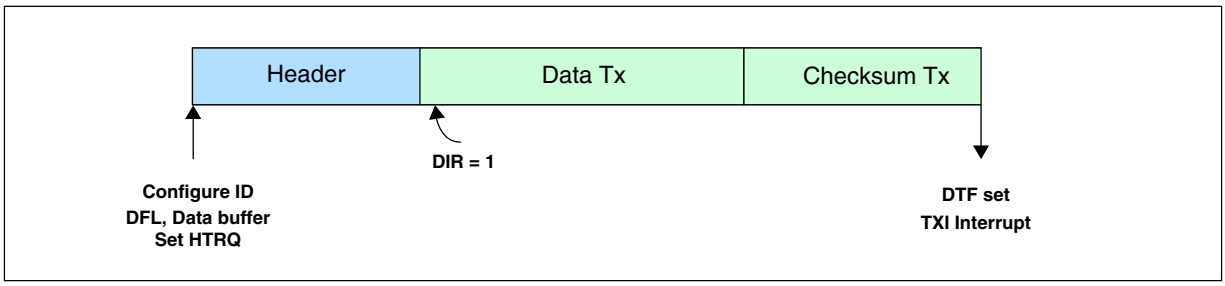


Figure 54-80. Master node – Transmitter configuration

54.6.1.2 Receiver

Receiver Master Mode - RX Configuration

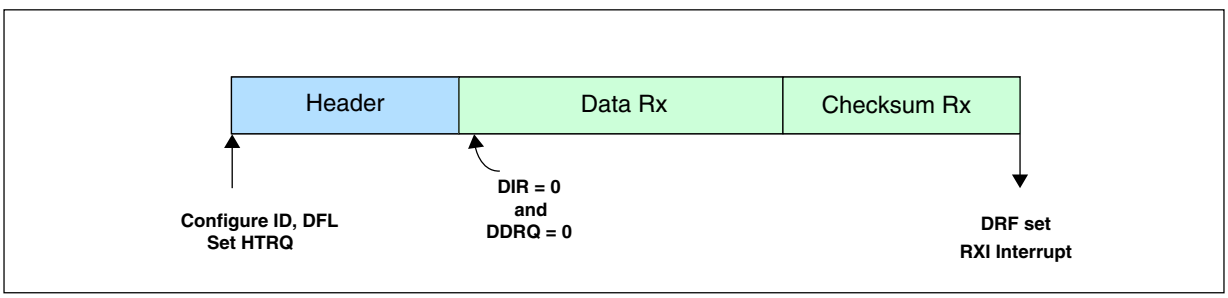

Figure 54-81. Master node – Receiver configuration

54.6.1.3 Transmitter, Bit Error

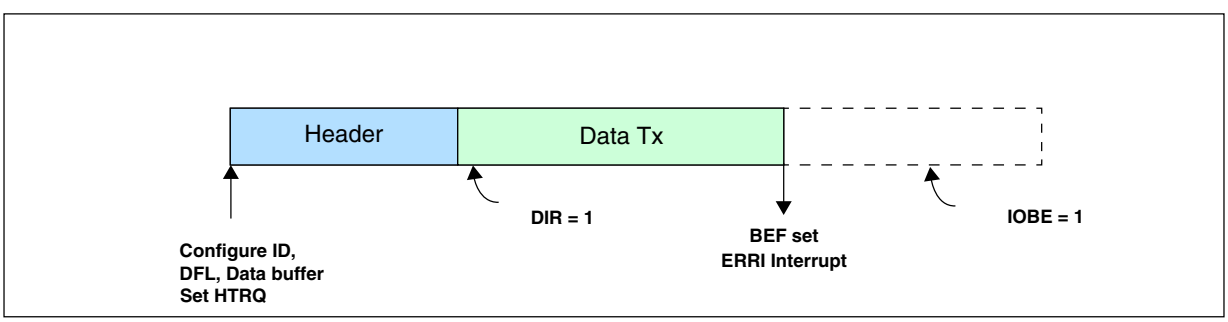

Figure 54-82. Master node – Transmitter, Bit Error configuration

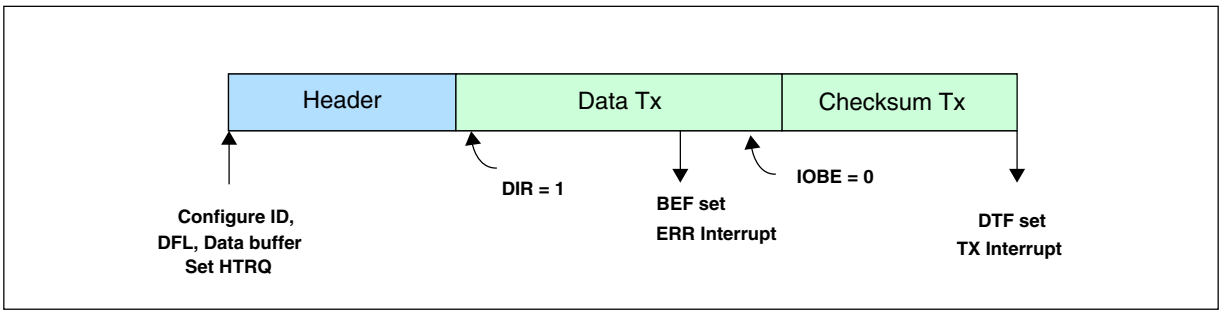

Figure 54-83. Master node – Transmitter, Checksum Error configuration

54.6.1.4 Receiver, Checksum Error

Checksum Error for Receiver.

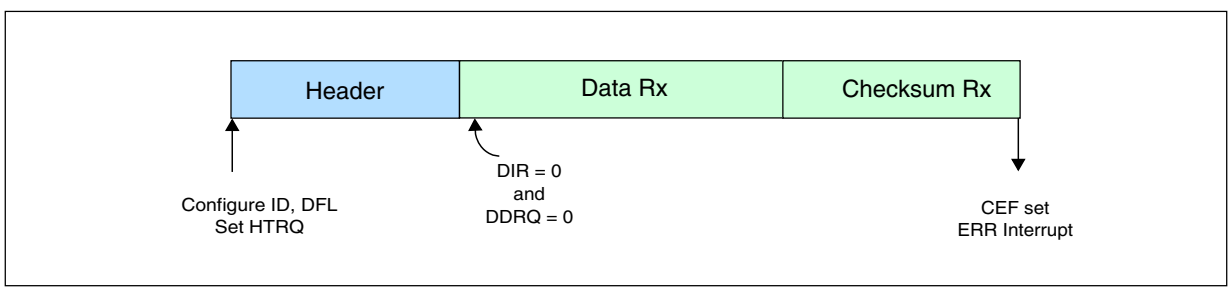

Figure 54-84. Master node – Receiver, Checksum Error configuration

54.6.2 Slave node

Slave node (transmitter).

54.6.2.1 Transmitter (no identifier filters)

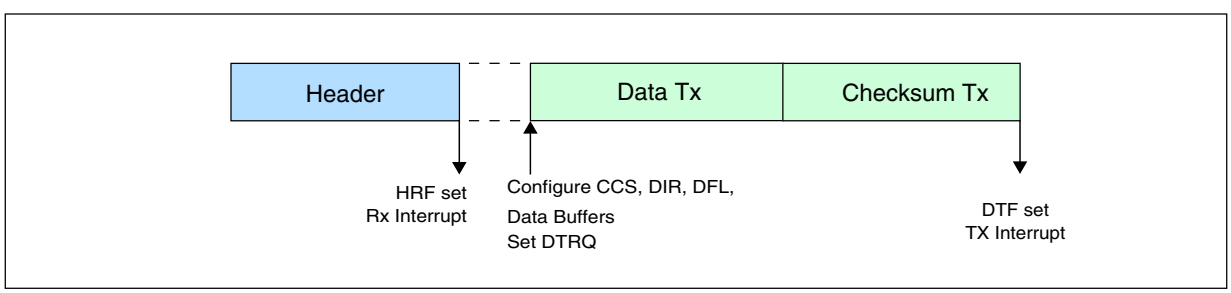

Figure 54-85. Slave node – Transmitter (no identifier filters) configuration

54.6.2.2 Receiver (no identifier filters)

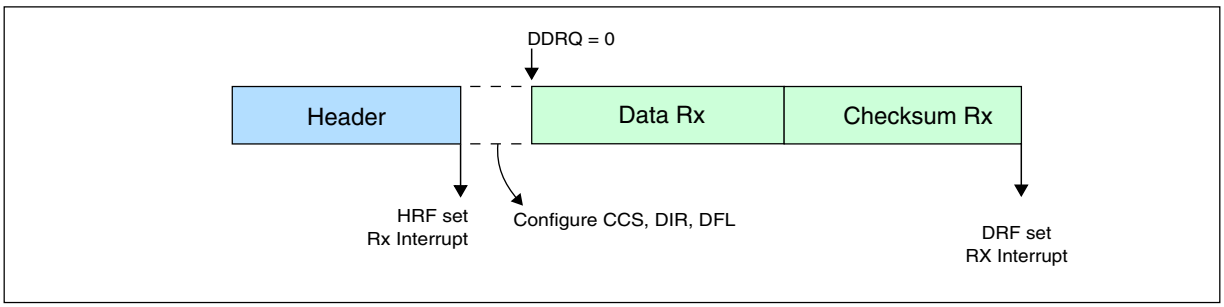

Figure 54-86. Slave node – Receiver (no identifier filters) configuration

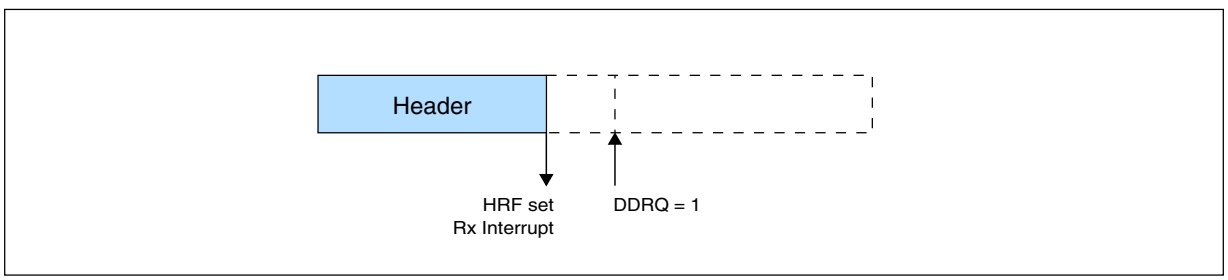

Figure 54-87. Slave node – Receiver (no identifier filters) configuration

54.6.2.3 No filters, Transmitter, Bit error

The following figure shows Slave node - No filters, Transmitter, Bit error configuration.

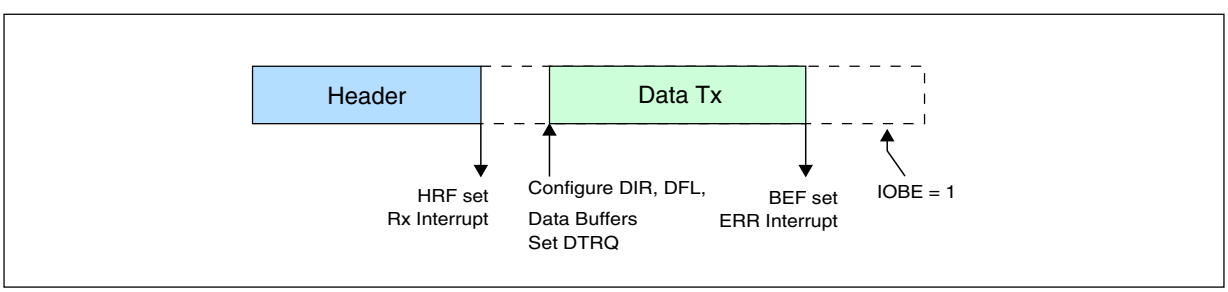

Figure 54-88. Slave node – No filters, Transmitter, Bit error configuration

54.6.2.4 No filters, Receiver, Checksum Error

The following figure shows Slave node - No filters, Receiver, Checksum error configuration.

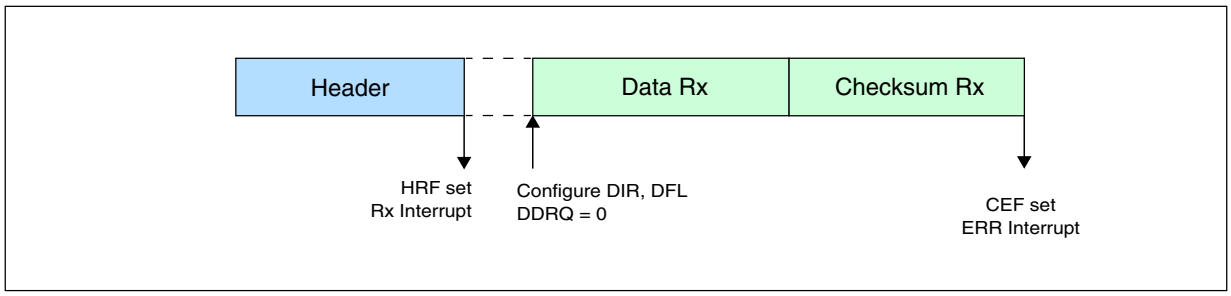

Figure 54-89. Slave node – No filters, Receiver, Checksum error configuration

54.6.2.5 At least one TX filter, BF is reset, ID matches filter

This configuration can be used in case slave never receives data, for example, sensor.

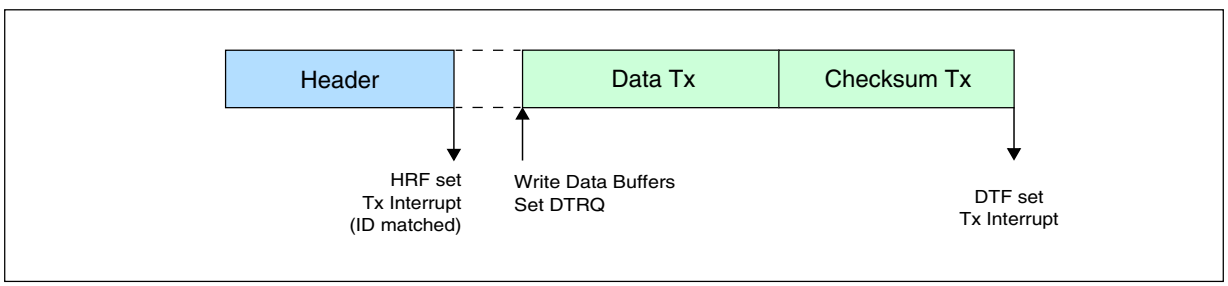

Figure 54-90. Slave node – one TX filter configuration

54.6.2.6 At least one RX filter, BF reset, ID matches filter

The following figure shows Slave node - one RX filter configuration.

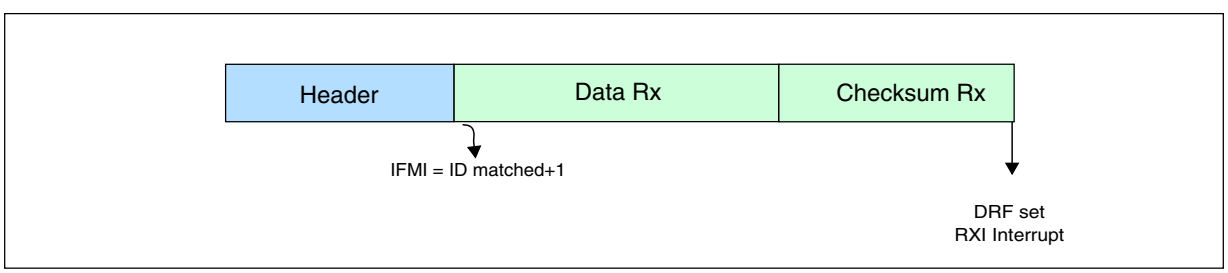

Figure 54-91. Slave node – one RX filter configuration

54.6.2.7 RX only, TX only, RX & TX filters, ID not matching filter, BF reset

The following figure shows RX only, TX only, RX and TX filters configuration.

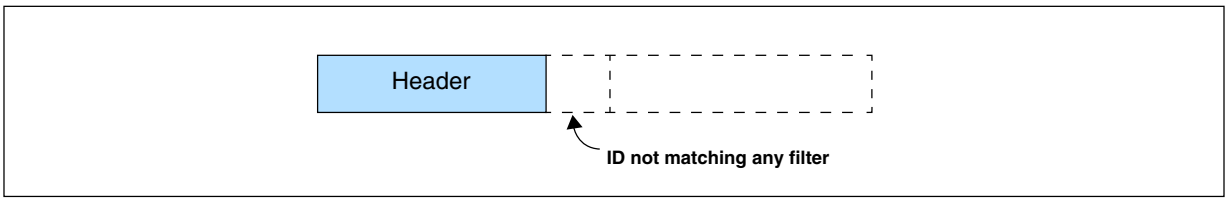

Figure 54-92. RX only, TX only, RX & TX filters configuration

54.6.2.8 TX filter, BF is set

This configuration is used when:

- All TX IDs are handled by filters.
- There are not enough other filters to handle all reception IDs.

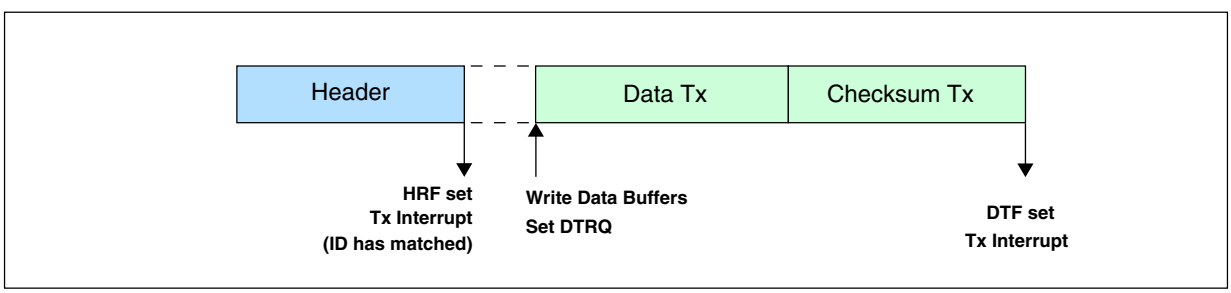

Figure 54-93. TX filter, BF is set configuration – ID has matched

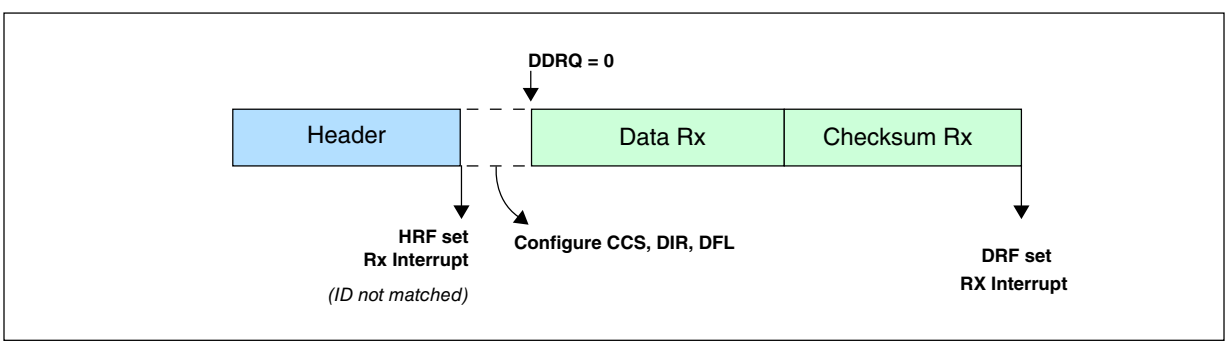

Figure 54-94. TX filter, BF is set configuration – ID not matched

54.6.2.9 RX filter, BF is set

The following figures show RX filter configurations.

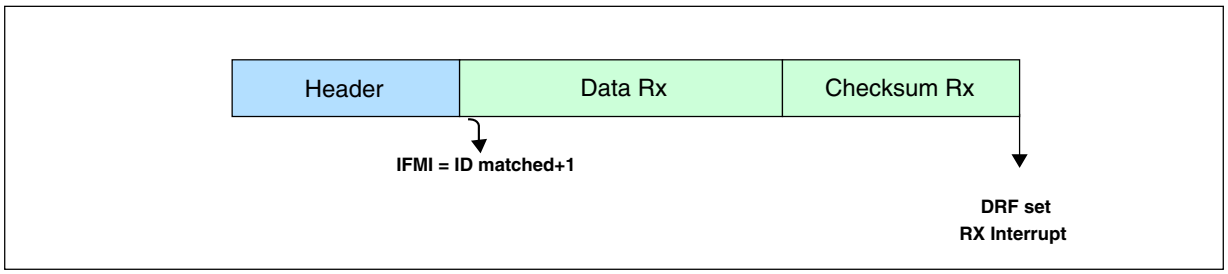

Figure 54-95. RX filter, BF is set configuration – ID matched

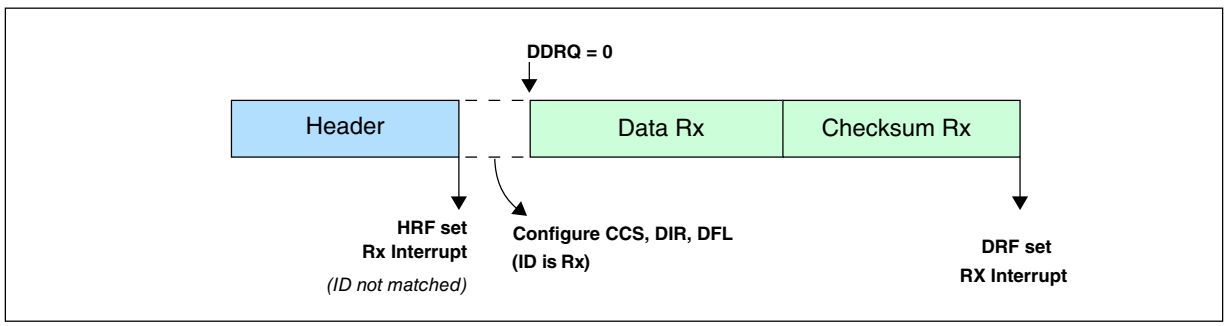

Figure 54-96. RX filter, BF is set configuration – ID not matched (ID is Rx)

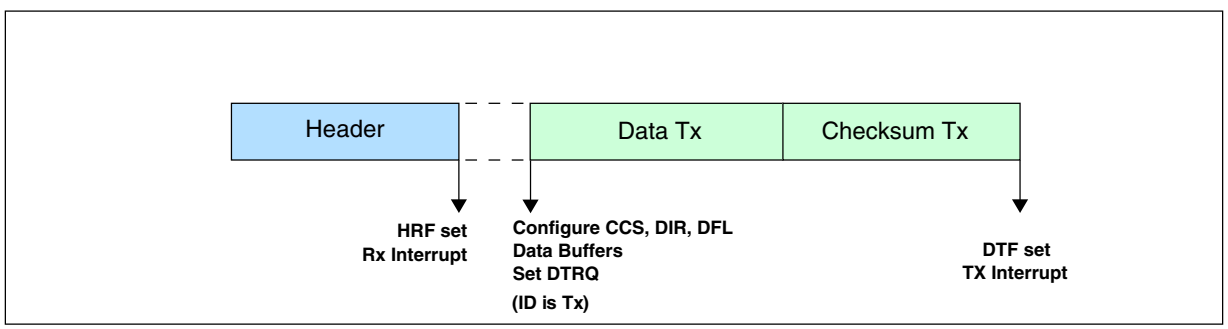

Figure 54-97. RX filter, BF is set configuration – (ID is Tx)

54.6.2.10 TX filter, RX filter, BF set

This configuration is used when:

- There are not enough filters.
- The filters are used for most frequently used IDs to reduce CPU usage.

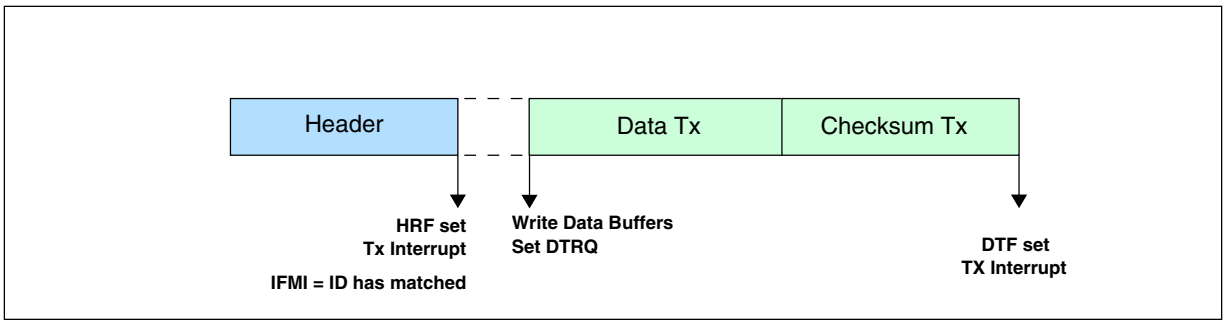

Figure 54-98. TX filter, RX filter, BF set configuration – (ID matched)

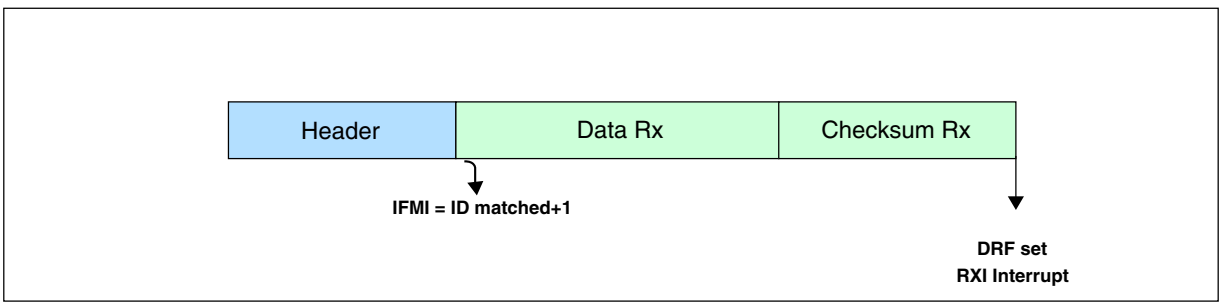

Figure 54-99. TX filter, RX filter, BF set configuration – (ID matched + 1)

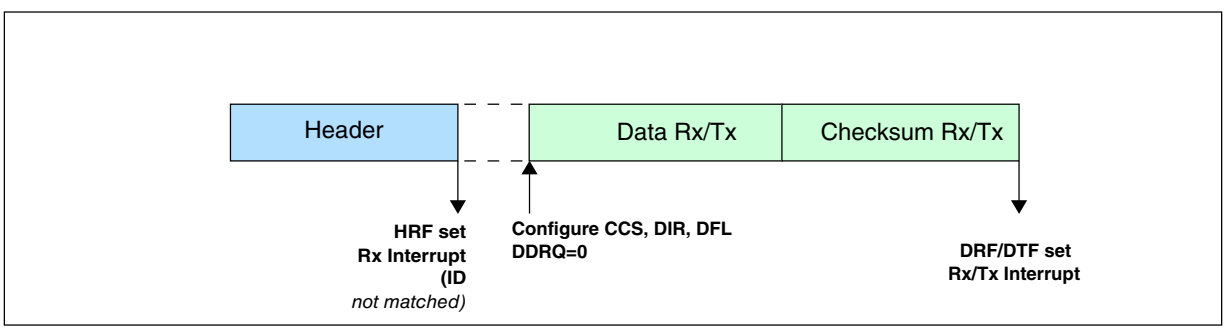

Figure 54-100. TX filter, RX filter, BF set configuration – (ID not matched, RX/TX Interrupt)

54.6.3 Extended frames

The following figure shows Extended frames (RX Interrupt).

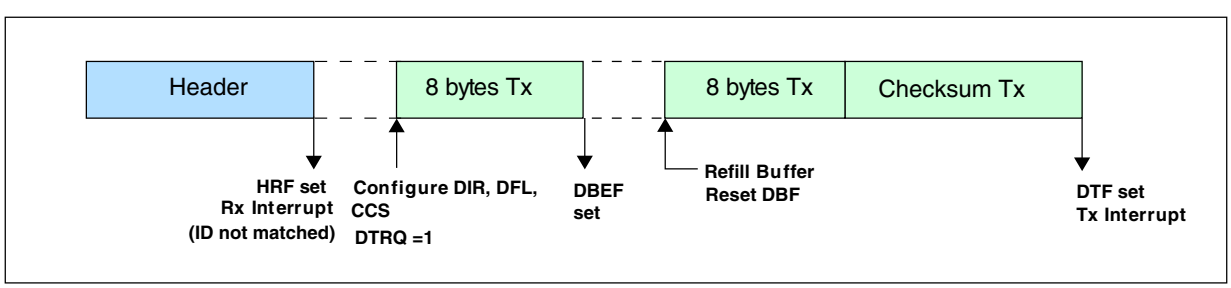

Figure 54-101. Extended frames (TX Interrupt)

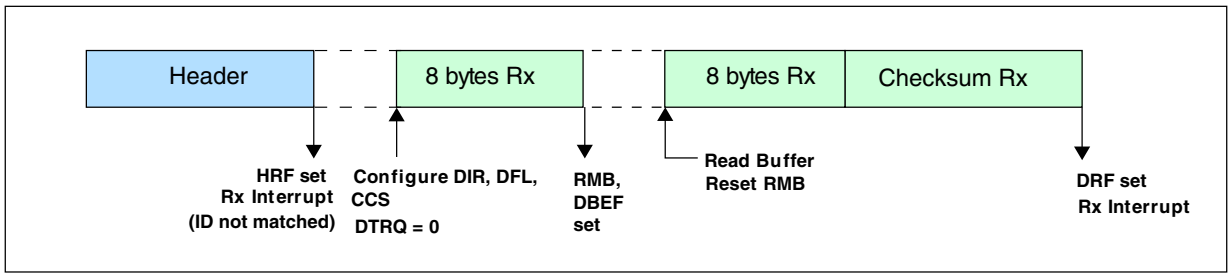

Figure 54-102. Extended frames (RX Interrupt)

54.6.4 Timeout

Master Node: Response (during reception only) and frame timeout are checked.

Slave Node: Header, Response (during reception only), and frame timeout are checked.

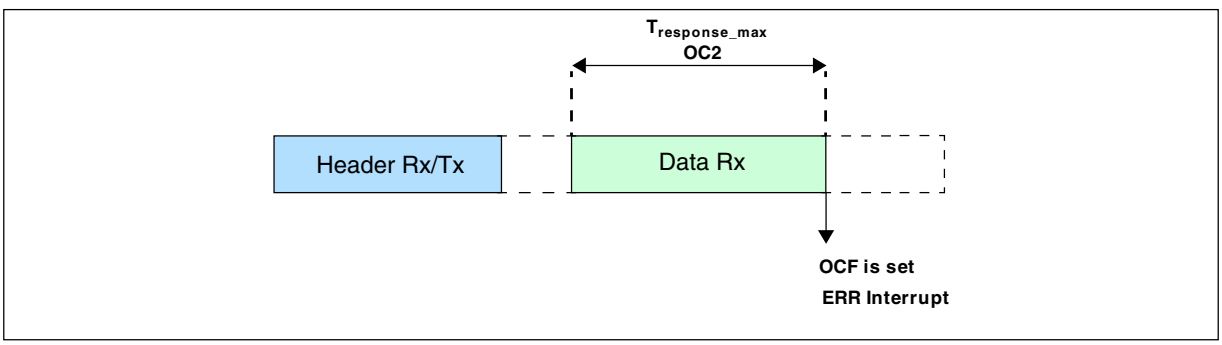

Figure 54-103. Response timeout

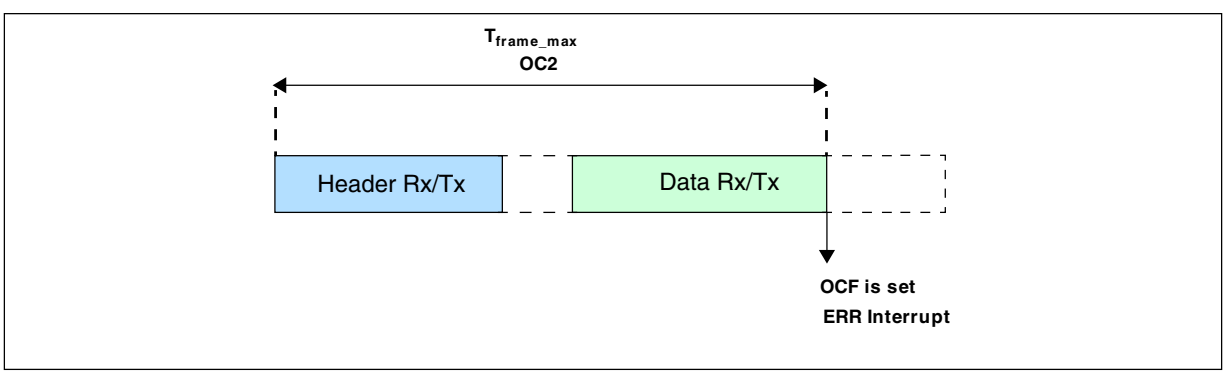

Figure 54-104. Frame timeout

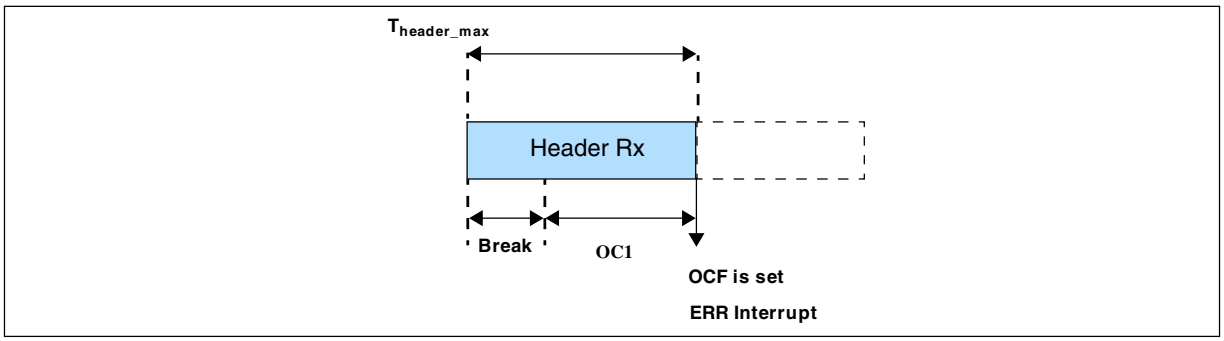

Figure 54-105. Header timeout

54.6.5 UART mode

The following figure shows UART mode configuration.

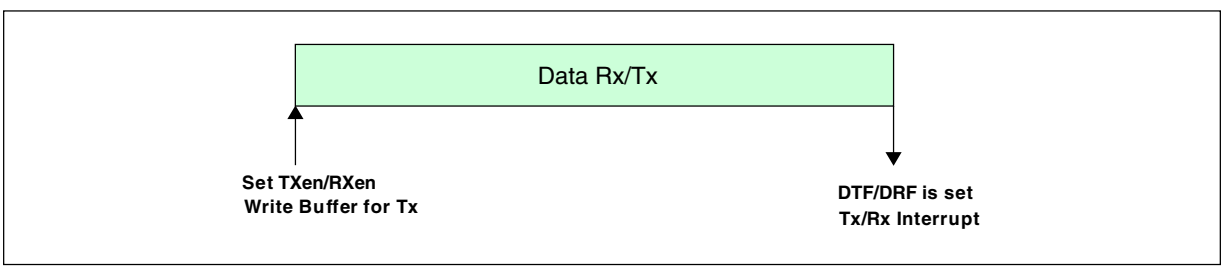

Figure 54-106. UART mode configuration

54.6.6 Interrupts

Interrupt section.

Table 54-62. Interrupts

Interrupt Event	Event flag	Enable control bit	Interrupt vector
Stuck at zero	SZF	SZIE	Error
Output compare	OCF	OCIE	Error
Bit error	BEF	BEIE	Error
Checksum error	CEF	CEIE	Error
Header error	SFEF orSDEF orIDPEF	HEIE	Error
Frame error	FEF	FEIE	Error
Buffer Overrun error	BOF	BOIE	Error
UART Timeout error	TO	TOIE	Error

Table continues on the next page...

Table 54-62. Interrupts (continued)

Interrupt Event	Event flag	Enable control bit	Interrupt vector
Lin state	Sync Del, Sync Field,Identifier field or Checksum Field	LSIE	Rx
Wakeup	WUF	WUIE	Rx
Data buffer full	DBFF	DBFIE	Rx
Data buffer empty	DBEF	DBEIE	Tx
Data Reception Complete	DRF	DRIE	Rx
Data transmitted	DTF	DTIE	Tx
Header received	HRF	HRIE	Rx
Header received	HRF	HRIE	Tx (if there is a filter match for Tx identifier)

The following figure shows an Interrupt Flow Diagram.

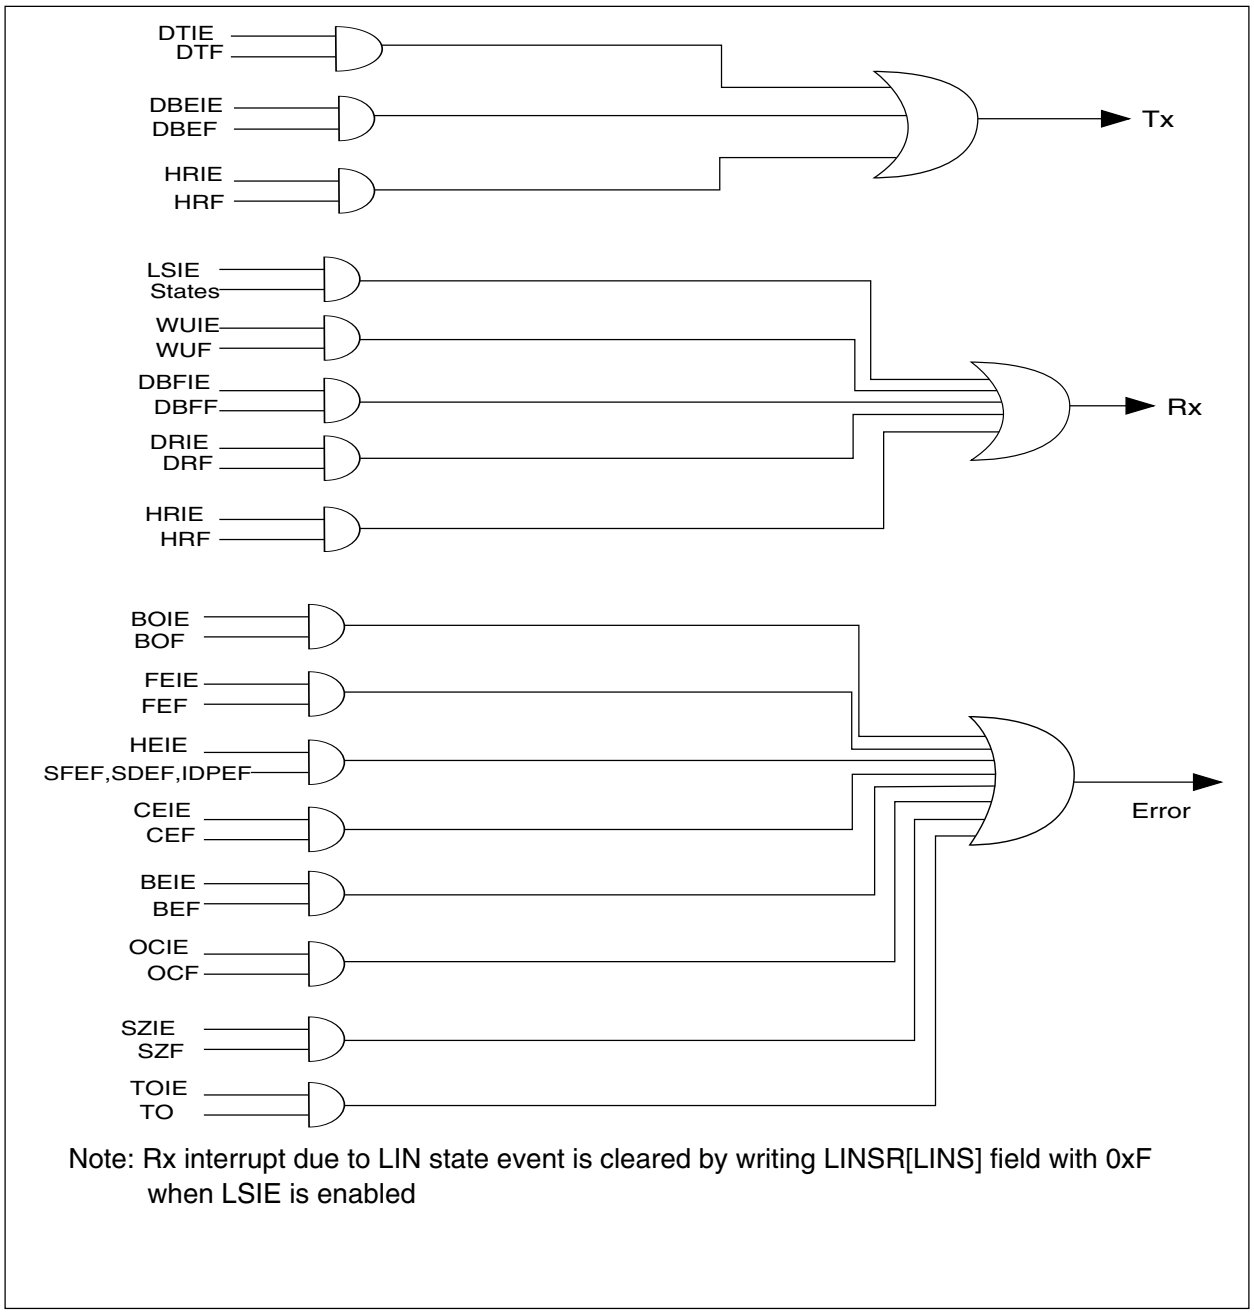

Figure 54-107. Interrupt diagram

54.6.7 LINFlexD Clock Tolerance

1. **Faster receiver tolerance:**
   In this case the receiver has a higher baud rate than the transmitter, thus the stop bit sampling starts already in the last transmitted payload bit. To ensure the correct noise and framing error free reception bit , the samples RS8, RS9, and RS10 must be located in the transmitted stop bit as shown in the following figure.

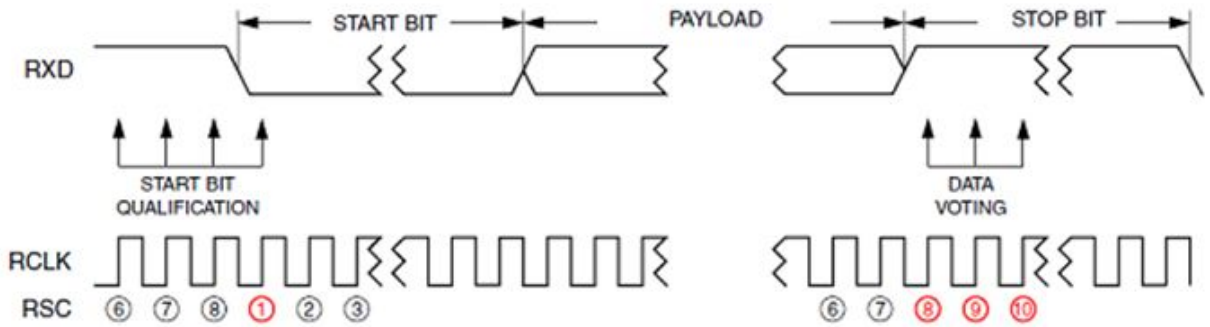

Figure 54-108. Faster receiver

2. **Slower receiver tolerance:**
   In this case the receiver has a slower baud rate than the transmitter, thus the stop bit sampling is still running while the next start bit is already transmitted. To ensure the correct noise and framing error free reception bit , the samples RS8, RS9, and RS10 must be located in the transmitted stop bit as shown in the following figure.

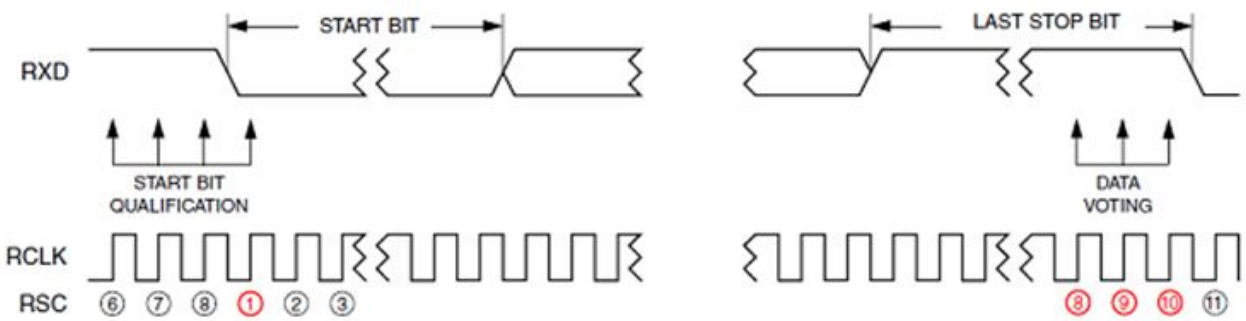

Figure 54-109. Slower receiver

Chapter 55
Reset and Boot

55.1 Introduction

The reset, boot and initialization sequences for this device provides significant new safety and security features for automotive microcontrollers and provides additional flexibility in controlling the initial configuration of the device after reset. The device must be brought out of reset with each of the system components configured for correct operation.

- Multiple processing cores, configuration and startup
- Lock step core preparation and startup
- Use of the Device Configuration Format (DCF) records
- Clock tree and PLL configuration and startup
- Configuring and entering the correct run mode

55.2 Flash memory boot overview

The device boot process uses several different blocks as it progresses. These blocks are the Power Management Controller (PMC), the Reset Generation Module (RGM), the Mode Entry Module (MC_ME), the System Status and Configuration Module (SSCM), the Boot Assist Flash (BAF), and the Self Test Configuration Unit (STCU). The reset sequence and interaction of the various blocks is illustrated at a very high level in the following figure.

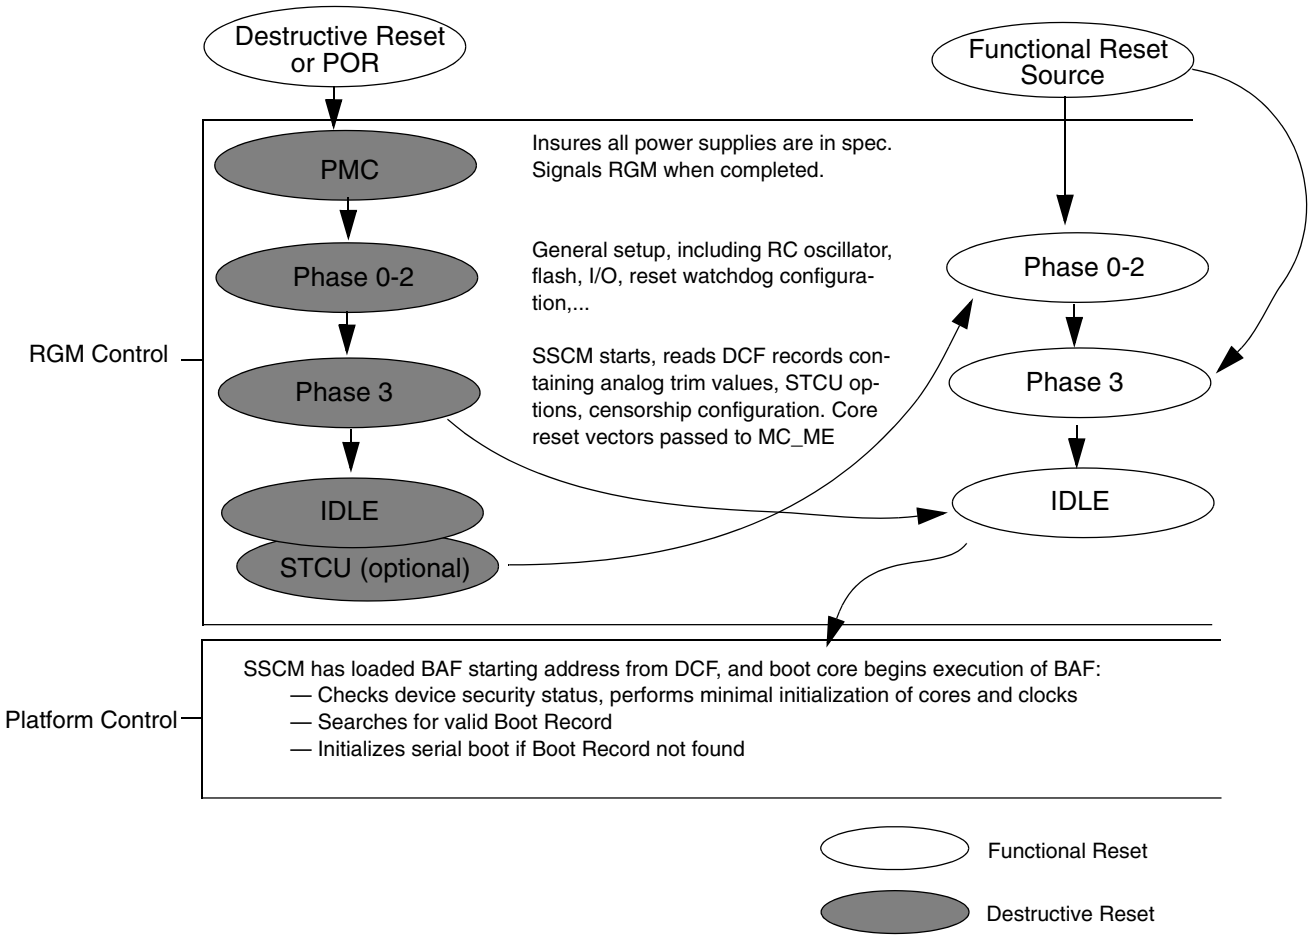

Figure 55-1. Boot sequence (high level)

See the chapter for each module for detailed descriptions of each module.

Note that the device has both destructive and functional resets. This feature allows a full system reset that is typical of a power on reset (POR), or a less destructive functional reset. The functional reset allows reset and initialization of a subset of the system resources, as opposed to a full system reset.

55.3 Device Configuration Format (DCF) records

A special area of flash memory contains programmed information in Device Configuration Format (DCF) records, which is used to control certain options at boot time. During the boot process the BAF and SSCM modules use these pre-programmed values to control certain options for device configuration. Some of these DCFs are preprogrammed at the factory and may not be modified, while others can be programmed by the end user.

The region of flash used for storing these records is called UTEST. See the DCF records chapter for details.

55.4 Reset sequence

Following section is giving an overview of the power-up sequence from power rising to the release of reset to the internal modules.

When a reset is triggered, the MC_RGM state machine is activated and proceeds through the different phases (i.e. ***PHASEn_X*** states). Each phase is associated with a particular device reset being provided to the system. A phase is completed when all corresponding phase completion gates from either the system or internal to the MC_RGM are acknowledged. The device reset associated with the phase is then released, and the state machine proceeds to the next phase up to entering the ***IDLE*** phase. During this entire process, the MC_ME state machine is held in ***RESET*** mode. Only at the end of the reset sequence, when the ***IDLE*** phase is reached, does the MC_ME enter the ***DRUN*** mode.

Alternatively, it is possible for software to configure some reset source events to be converted from a reset to either a ***SAFE*** mode request issued to the MC_ME or to an interrupt issued to the core.

The reset sequence can be observed by monitoring the *PORST* and *RESET* pins status.

The *PORST* pin is driven low by a strong internal pull-down during the ***POWERUP*** phase. It is released on ***PHASE0*** exit when all supplies have reached their specification values. After release, the PORST remains driven by a weak pull-down for safety reason, ensuring test of *PORST* pin connection. Device will not exit ***PHASE3[FUNC]*** until *PORST* is driven high.

The *RESET* pin is driven low by a strong internal pull-down during the full power-up/ reset sequence, from the ***POWERUP*** phase up to the beginning of ***PHASE3[FUNC]***. It is released during ***PHASE3[FUNC]*** when internal reset sequence is completed. Device will not exit ***PHASE3[FUNC]*** until *RESET* is driven high.

55.4.1 RSTOUT functionality

Pin PJ[5] can be configured to drive a reset signal (RSTOUT) without generating the internal reset. RSTOUT will follow the RESET pin until reconfigured in SW.

RSTOUT actively drives low during all Destructive and Functional resets and drives high at the end of reset PHASE3.

To assert RSTOUT in SW, it is necessary to reconfigure PJ[5] to be GPIO output. Writing this GPIO to '0' will assert RSTOUT without causing a reset. (If a real reset occurs while software has asserted this pin, the pin automatically switches back to RSTOUT and normal reset processing continues.

If the RSTOUT functionality is needed on PJ[5], any signal connected to PJ[5] must be able to withstand this pin driving low during reset. After reset, software can reconfigure this pin as any function available.

55.4.2 POWERUP Phase: power stabilization

The PMC module contains a set of modules for power on reset generation and supply monitoring. The device enters ***POWERUP*** phase on power on reset event. The device will remain in ***POWERUP*** phase until all supplies are in the operational range. Please refer to the PMC chapter for power on exit and details of the power supply stabilization.

55.4.3 *PHASE0* Phase: analog supply initial configuration

This phase is entered immediately from any phase on a power-on or enabled 'destructive' reset event, including PORST pin falling edge detection. The reset state machine exits ***PHASE0*** and enters ***PHASE1[DEST]*** on verification of the following:

- All enabled 'destructive' resets have been processed
- All processes that need to be done in ***PHASE0*** are completed. This includes mainly internal analog module start-up: PMC, RC-oscillator, Flash, I/Os.

During this phase, all digital modules are reset, including safety, security and test modules.

55.4.4 *PHASE1[DEST]* Phase: temporization and monitoring setup

This phase is entered either on exit from ***PHASE0*** or immediately from IDLE on an enabled, long external 'functional' reset event. The reset state machine exits ***PHASE1[DEST]*** and enters ***PHASE2[DEST]*** on verification of the following:

- All processes that need to be done in ***PHASE1[DEST]*** are completed. This includes mainly the initial configuration of the watch-dog to monitor reset process and temporization for reset signal propagation in case of reset.

55.4.5 *PHASE2[DEST]* Phase: flash initial configuration

This phase is entered on exit from ***PHASE1[DEST]***. The reset state machine exits ***PHASE2[DEST]*** and enters ***PHASE3[DEST]*** on verification of the following:

- All processes that need to be done in ***PHASE2[DEST]*** are completed

During this phase, the reset is released to the flash which can start its initial configuration. Watchdog is monitoring execution ensuring reset in case of flash configuration failure.

55.4.6 *PHASE3[DEST]* Phase: device configuration

This phase is entered on exit from ***PHASE2[DEST]***. The reset state machine exits ***PHASE3[DEST]*** and enters ***IDLE[FUNC]*** or ***IDLE[DEST]*** on verification of the following:

- All processes that need to be done in ***PHASE3[DEST]*** are completed

During this phase, the SSCM parse the DCF Records in UTEST flash and writes the data to the relevant DCF clients in the modules that require configuration. This includes:

- The trimming of the analog modules (voltage regulator, voltage detectors, I/Os, oscillator, …)
- Life cycle of the device: censorship configuration, debug security configuration, functional security configuration
- Application configuration bits: watchdog configuration, safety execution directives (self-test, LBIST/MBIST), Boot Assist Module options, Oscillator start-up during reset sequence configuration

This configuration are maintained until next internal power-on reset

At the end of ***PHASE3[DEST]***, the security status of the device has been read. If allowed by life cycle information full test mode can be entered.

In case configuration information are requesting self-test execution, the device will move to ***IDLE[DEST]***, otherwise device will directly move to ***IDLE[FUNC]***. When self-test execution is not requested, it is possible to maintain the device within ***PHASE3[DEST]*** by forcing either PORST or RESET pin low. This can be used for debug purpose to connect through JTAG to the internal debugger.

55.4.7 *IDLE[DEST]* Phase: self-test execution

This phase is entered on exit from ***PHASE3[DEST]***. The reset state machine exits ***IDLE[DEST]*** and enters ***PHASE1[FUNC]*** on verification of the following:

- Self test engine update self test completion flag and trigger associated functional reset

This phase is variable depending on self-test requirement.

During this phase, self-test control unit executes all the directives retrieved during previous phase. Dedicated watch-dog is configured to monitor self-test execution complete within expected time.

At completion of self-test, functional reset is generated and the reset state machine moves to ***PHASE1[FUNC]***.

55.4.8 *PHASE1[FUNC]* Phase: temporization and monitoring setup

This phase is entered either on exit from ***IDLE[DEST]*** or immediately from ***PHASE2[FUNC]***, ***PHASE3[FUNC]***, or ***IDLE[FUNC]*** on a non-masked external or 'functional' reset event if it has not been configured to trigger a 'short' sequence. The reset state machine exits ***PHASE1[FUNC]*** and enters ***PHASE2 [FUNC]*** on verification of the following:

- All enabled, non-shortened 'functional' resets have been processed
- All processes that need to be done in ***PHASE1[FUNC]*** are completed. This includes mainly the initial configuration of the watch-dog to monitor reset process and temporization for reset signal propagation in case of reset.

This phase is duplication of ***PHASE1[DEST]*** after self-test.

55.4.9 *PHASE2[FUNC]* Phase: flash initial configuration

This phase is entered on exit from ***PHASE1[FUNC]***. The reset state machine exits ***PHASE2[FUNC]*** and enters ***PHASE3[FUNC]*** on verification of the following:

- All processes that need to be done in ***PHASE2[DEST]*** are completed

During this phase, the reset is released to the flash which can start its initial configuration. Watchdog is monitoring execution ensuring reset in case of flash configuration failure.

This phase is duplication of ***PHASE2[DEST]*** after self-test.

55.4.10 *PHASE3[FUNC]* Phase: device configuration monitoring

This phase is entered either on exit from ***PHASE2[FUNC]*** or immediately from ***IDLE*** on an enabled, shortened external 'functional' reset event. The reset state machine exits ***PHASE3[FUNC]*** and enters ***IDLE*** on verification of the following:

- All processes that need to be done in ***PHASE3[FUNC]*** are completed. In particular PORST and RESET pin are not forced low externally.
- A minimum number of cycles have elapsed since the last enabled, shortened external 'functional' reset event

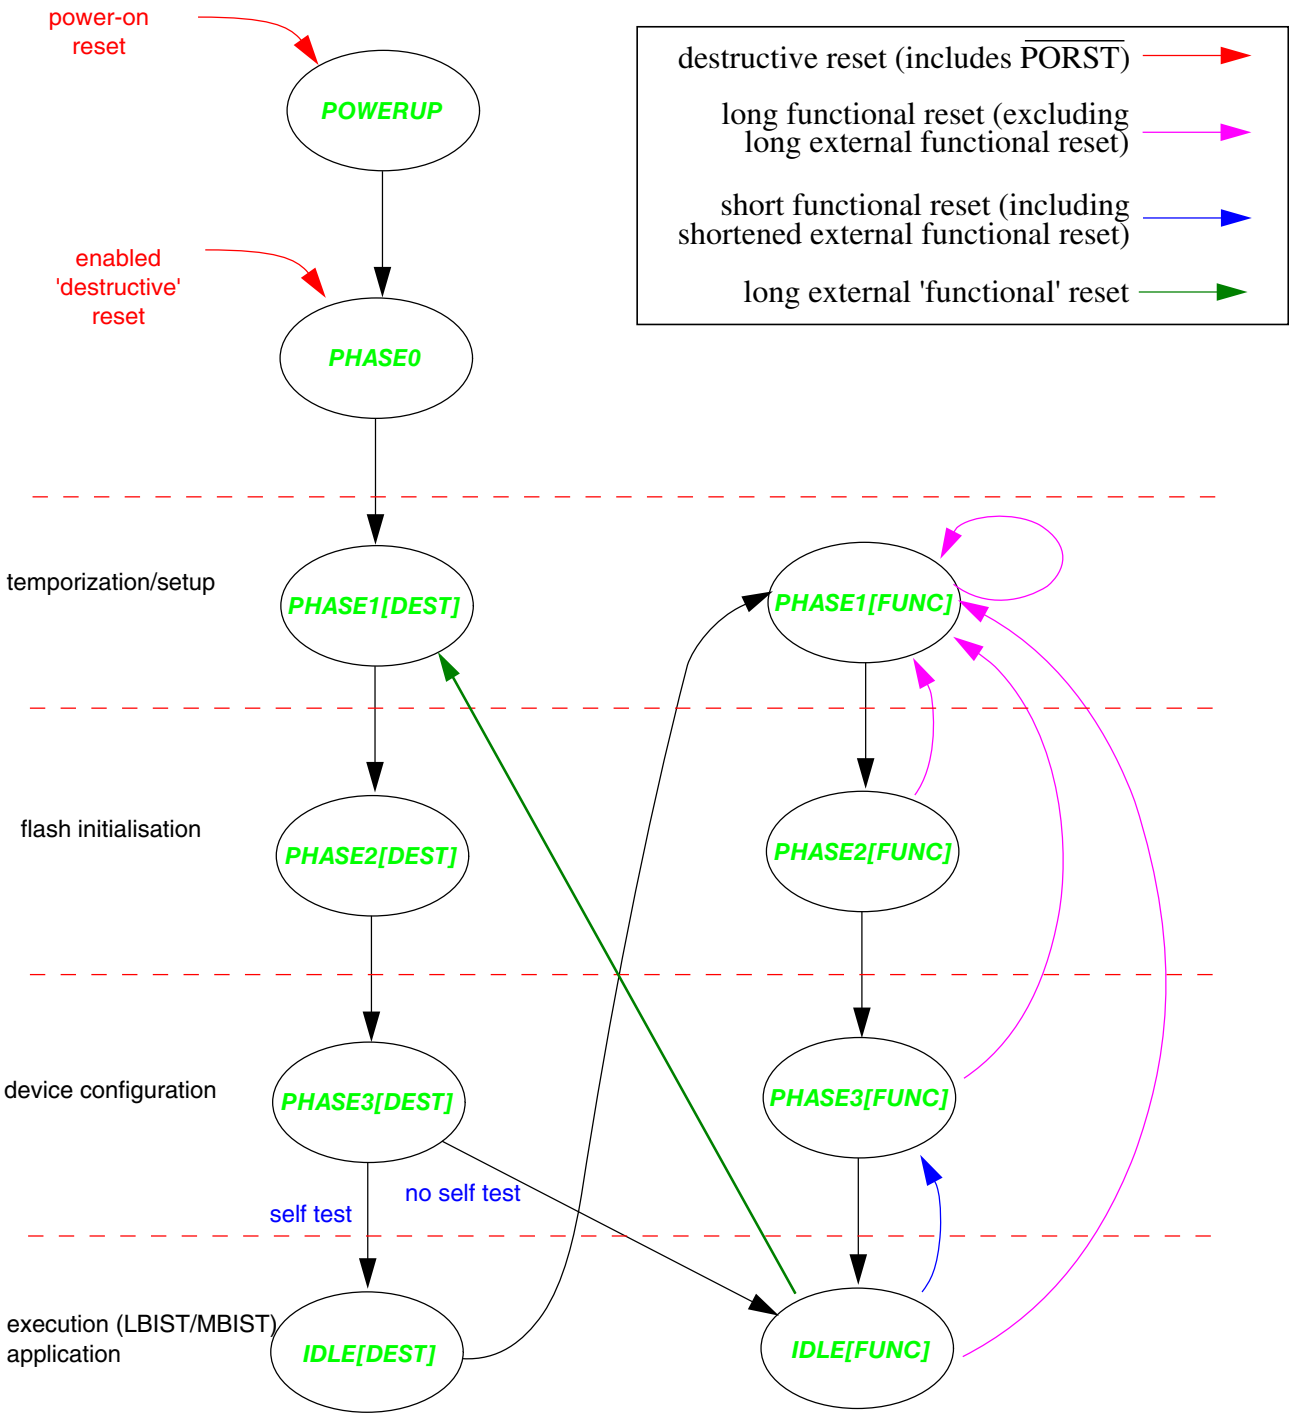
After ***PHASE3[FUNC]*** internal actions have been completed, it is possible to maintain the device within ***PHASE3[FUNC]*** by forcing either PORST or RESET pin low. This can be used for debug purpose to connect through JTAG to the internal debugger.

55.4.11 *IDLE[FUNC]* Phase

This is the final phase and is entered on exit from either ***PHASE3[DEST]*** or ***PHASE3[FUNC]***. When this phase is reached, the RGM releases control of the system to the platform and waits for new reset events that can trigger a reset sequence.

The SSCM will already have loaded the start address of the BAF code from the DCF records. As the RGM releases control of the system to the platform, CPU1 start executing at the start address of the BAF.

The state machine used to produce the reset sequence is shown in Figure 55-2.



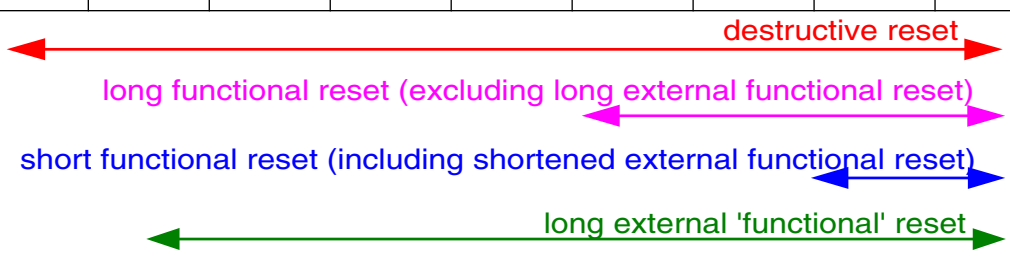


Figure 55-2. RGM state machine

55.5 Module status during reset sequence

The following table is providing status of main modules during the different reset phases:

Table 55-1. Module status during reset phases

Module	PHASE								
	P0 (RED)	P1 [DEST] (RED)	P2 [DEST] (RED)	P3 [DEST] (RED)	IDLE [DEST] (RED)	P1 [FUNC] (PURPLE)	P2 [FUNC] (PURPLE)	P3 [FUNC] (BLUE)	IDLE [FUNC] (WHITE)
Internal RCOSC	ON	ON	ON	ON	ON	ON	ON	ON	ON

Debug Modules	RESET	RESET	RESET	RESET	RESET	ON	ON	ON	ON
									

1. RESET only during POR.
2. STCU time-out monitoring LBIST/MBIST execution
3. Depending on flash configuration
4. Depending on flash configuration
5. FCCU remains ON during functional reset, it is instead reset in PHASE1[FUNC] if coming from IDLE[DEST]
6. Can be triggered by SW
7. After enabling from BAF

Chapter 56
Reset Generation Module (MC_RGM)

56.1 Introduction

56.1.1 Overview

The reset generation module (MC_RGM) centralizes the different reset sources and manages the reset sequence of the chip. It provides a register interface and a reset sequencer. Various registers are available to monitor and control the chip reset sequence. The reset sequencer is a state machine which controls the different phases (***PHASE0***, ***PHASE1***, ***PHASE2***, ***PHASE3***, and ***IDLE***) of the reset sequence and the reset signals generated in the system.

The following figure shows the MC_RGM block diagram.

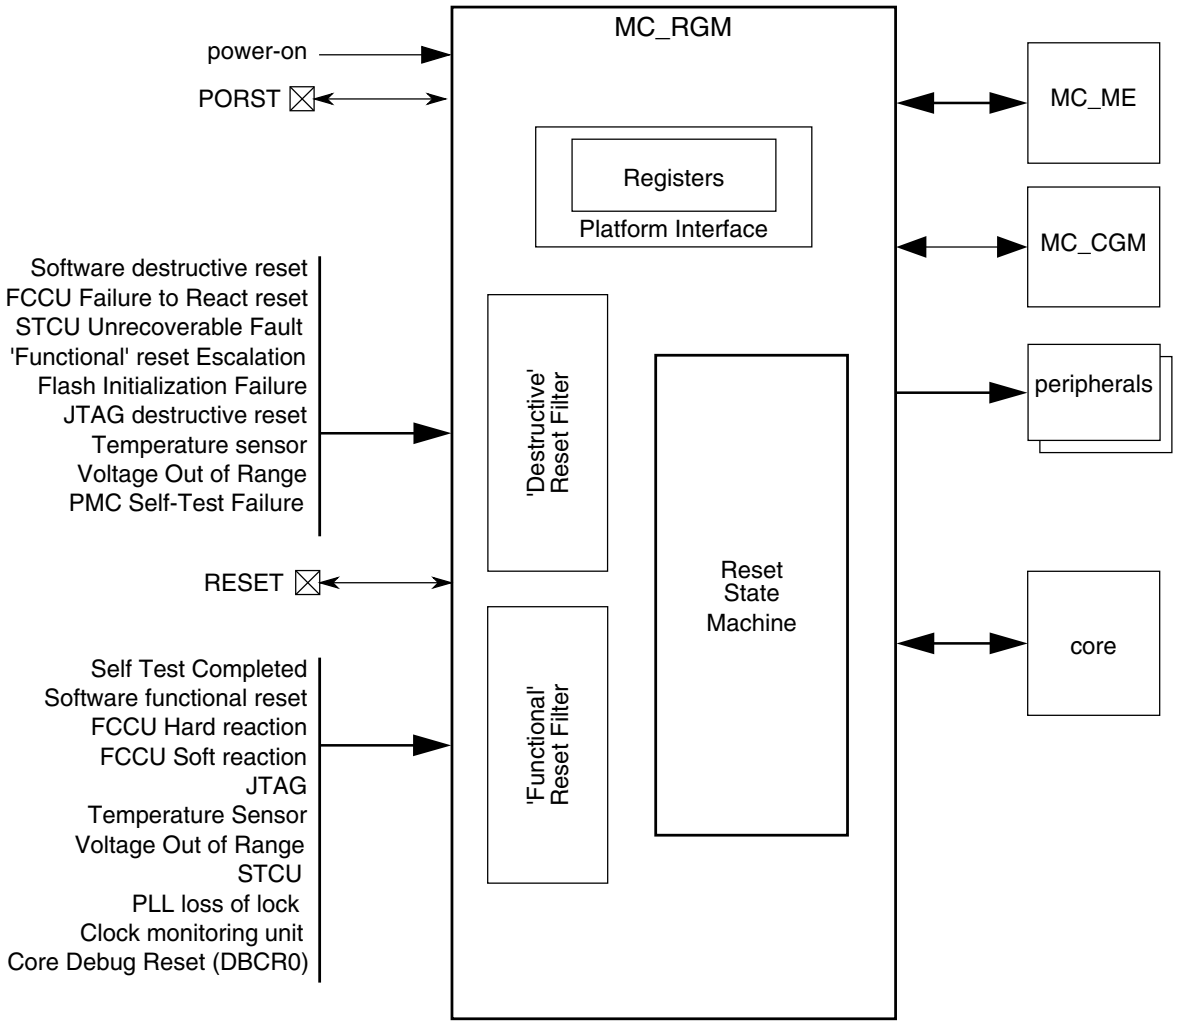

Figure 56-1. MC_RGM Block Diagram

Peripheral resets cannot be controlled individually.

56.1.2 Features

The MC_RGM contains the functionality for the following features:

- 'destructive' resets management
- 'functional' resets management
- signaling of reset events after each reset sequence (reset status flags)
- conversion of reset events to ***SAFE*** mode or interrupt request events
- short reset sequence configuration
- bidirectional reset behavior configuration

- configurable escalation of recurring 'functional' resets to 'destructive' reset
- configurable escalation of recurring 'destructive' resets to keep chip in reset state until next power-on reset

56.1.3 Reset Sources

The different reset sources are organized into two families: 'destructive' and 'functional'.

- A 'destructive' reset source is associated with an event related to a critical - usually hardware - error or dysfunction. When a 'destructive' reset event occurs, the full reset sequence is applied to the chip starting from ***PHASE0***. This resets the full chip ensuring a safe start-up state for both digital and analog modules, and the memory content must be considered to be unknown. 'Destructive' resets are
  - power-on reset
  - External PowerOn reset
  - Software destructive reset
  - FCCU Failure to React reset
  - STCU Unrecoverable Fault
  - Security reset request from SSCM
  - 'Functional' reset Escalation
  - Flash Initialization Failure
  - JTAG destructive reset
  - Temperature sensor
  - Voltage Out of Range
  - PMC self test failure reset
- A 'functional' reset source is associated with an event related to a less-critical - usually non-hardware - error or dysfunction. When a 'functional' reset event occurs, a partial reset sequence is applied to the chip starting from ***PHASE1***. In this case, most digital modules are reset normally, while the state of analog modules or specific digital modules (e.g., debug modules, flash modules) as well as the system memory content is preserved. 'Functional' resets are
  - external reset

- Self Test Completed
- Software functional reset
- FCCU Hard reaction
- FCCU Soft reaction
- JTAG functional reset
- Temperature Sensor
- Voltage Out of Range

When a reset is triggered, the MC_RGM state machine is activated and proceeds through the different phases (i.e., ***PHASEn*** states). Each phase is associated with a particular chip reset being provided to the system. A phase is completed when all corresponding phase completion gates from either the system or internal to the MC_RGM are acknowledged. The chip reset associated with the phase is then released, and the state machine proceeds to the next phase up to entering the ***IDLE*** phase. During this entire process, the MC_ME state machine is held in ***RESET*** mode. Only at the end of the reset sequence, when the ***IDLE*** phase is reached, does the MC_ME enter the ***DRUN*** mode.

Alternatively, it is possible for software to configure some reset source events to be converted from a reset to either a ***SAFE*** mode request issued to the MC_ME or to an interrupt issued to the core (see Section "'Destructive' Event Alternate Request Register (RGM_DEAR)" for 'destructive' resets and Section "'Functional' Event Reset Disable Register (RGM_FERD)" and Section "'Functional' Event Alternate Request Register (RGM_FEAR)" for 'functional' resets).

56.2 External Signal Description

The MC_RGM interfaces to the bidirectional reset pin RESET.

Table 56-1. MC_RGM Reset Phase Duration Dependency on safe_clock_busy During Functional Mode

Reset Phase Transition			Duration Counter Start
To	From	safe_clock_busy Already Deasserted During 'From' Phase	
PHASE0	power-on	-	immediate
	PHASE1	yes	immediate
		no	on safe_clock_busy deassertion
	PHASE2	-	immediate
	PHASE3	yes	immediate
		no	on safe_clock_busy deassertion
	IDLE	-	on safe_clock_busy deassertion
PHASE1	***PHASE0***	-	immediate
	PHASE2	-	immediate
	PHASE3	yes	immediate
		no	on safe_clock_busy deassertion
	IDLE	-	on safe_clock_busy deassertion
PHASE2	***PHASE1***	-	immediate
PHASE3	***PHASE2***	-	immediate
	IDLE	-	on safe_clock_busy deassertion
IDLE	***PHASE3***	-	-

56.3 MC_RGM Registers

The following subsections show the MC_RGM registers memory map and the detailed definition of each register.

The MC_ME contains registers for:

- mode selection and status reporting
- mode configuration
- mode transition interrupts status and mask control
- scalable number of peripheral sub-mode selection and status reporting
- scalable number of core enabling and disabling control and status reporting

Unless otherwise noted, all registers may be accessed as 32-bit words, 16-bit half-words, or 8-bit bytes. The bytes are ordered according to big endian. For example, the ME_RUN_PC0 register may be accessed as a word at address offset 0x0080, as a half-word at address offset 0x0082, or as a byte at address offset 0x0083.

Some fields may be read-only, and their reset value of ‘1’ or ‘0’ and the corresponding behavior cannot be changed.

MC_RGM memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	‘Destructive’ Event Status (MC_RGM_DES)	32	R/W	0000_0001h	56.3.1/2490
10	‘Destructive’ Event Reset Disable (MC_RGM_DERD)	32	R/W	0000_0000h	56.3.2/2492

56.3.1 ‘Destructive’ Event Status (MC_RGM_DES)

This register contains the status of the ‘destructive’ reset sources, including those configured to not generate a reset sequence. It can be accessed in read/write in either supervisor mode or test mode. It can be accessed in read only in user mode. Register bits are cleared by writing ‘1’.

This register is reset only on power-on.

Address: 0h base + 0h offset = 0h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

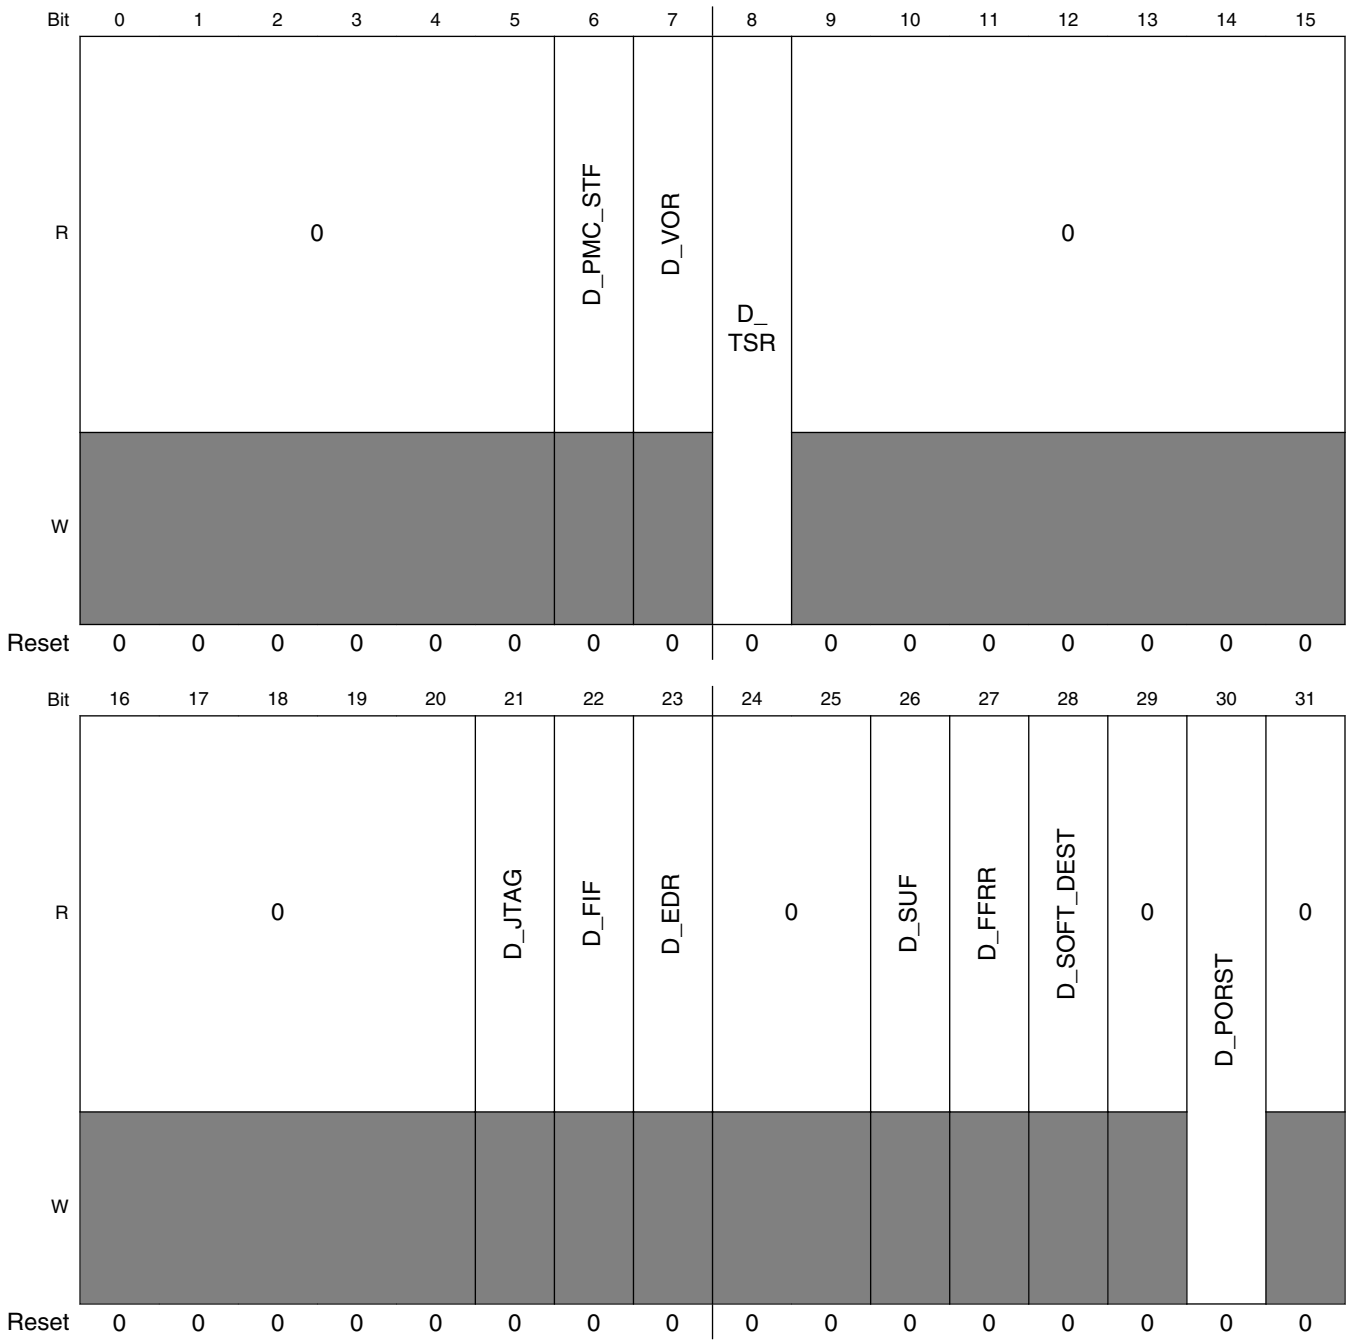
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

MC_RGM_DES field descriptions

Field	Description
0–5 Reserved	This field is reserved.
6 F_PMC	Flag for PMC self test failure after boot up (POR) This reset is generated only in case of PMC self test failure in hardware initiated self test run of PMC after boot up. This reset can be disabled by device configuration in UTEST area. 0 No Voltage Out of Range event has occurred since either the last clear or the last power-on reset assertion 1 A Voltage Out of Range event has occurred
7 F_VOR	Flag for Voltage Out of Range 0 No Voltage Out of Range event has occurred since either the last clear or the last power-on reset assertion 1 A Voltage Out of Range event has occurred
8 F_TSR	Flag for Temperature sensor 0 No Temperature sensor event has occurred since either the last clear or the last power-on reset assertion 1 A Temperature sensor event has occurred
9–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21 F_JTAG	Flag for JTAG destructive reset 0 No JTAG destructive reset event has occurred since either the last clear or the last power-on reset assertion 1 A JTAG destructive reset event has occurred
22 F_FIF	Flag for Flash Initialization Failure 0 No Flash Initialization Failure event has occurred since either the last clear or the last power-on reset assertion 1 A Flash Initialization Failure event has occurred
23 F_EDR	Flag for 'Functional' reset Escalation

Table continues on the next page...

MC_RGM_DES field descriptions (continued)



Field	Description
	0 No 'Functional' reset Escalation event has occurred since either the last clear or the last power-on reset assertion 1 A 'Functional' reset Escalation event has occurred
24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25 F_SSR	Flag for SSCM security reset Active high security reset request. Once asserted, it is deasserted only when the SSCM gets its module reset. It is asserted on ECC errors and life cycle manipulation. It is also generated on fgf_enc* signals mismatch with the flash block select if parameter EN_ENC_ERR_GEN is '1'.
26 F_SUF	Flag for STCU Unrecoverable Fault 0 No STCU Unrecoverable Fault event has occurred since either the last clear or the last power-on reset assertion 1 An STCU Unrecoverable Fault event has occurred. This reset is generated only during offline self test run, during the device initialization after POR. This can be disabled by device configuration in UTEST.
27 F_FFRR	Flag for FCCU Failure to React reset 0 No FCCU Failure to React reset event has occurred since either the last clear or the last power-on reset assertion 1 An FCCU Failure to React reset event has occurred
28 F_SOFT_DEST	Flag for Software destructive reset 0 No Software destructive reset event has occurred since either the last clear or the last power-on reset assertion 1 A Software destructive reset event has occurred
29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30 F_PORST	Flag for External PowerOn reset 0 No External PowerOn reset event has occurred since either the last clear or the last power-on reset assertion 1 An External PowerOn reset event has occurred
31 F_POR	Flag for Power-On reset 0 No power-on event has occurred since the last clear 1 A power-on event has occurred

56.3.2 'Destructive' Event Reset Disable (MC_RGM_DERD)

This register provides dedicated bits to disable particular 'destructive' reset sources. When a 'destructive' reset source is disabled, the associated 'destructive' event will trigger either a SAFE mode request or an interrupt request (see Section, 'Destructive' Event Alternate Request (RGM_DEAR)). It can be accessed in read/write in either supervisor mode or test mode. It can be accessed in read only in user mode. Each byte can be written only once after a 'destructive' or power-on reset.

This register is reset only on power-on.

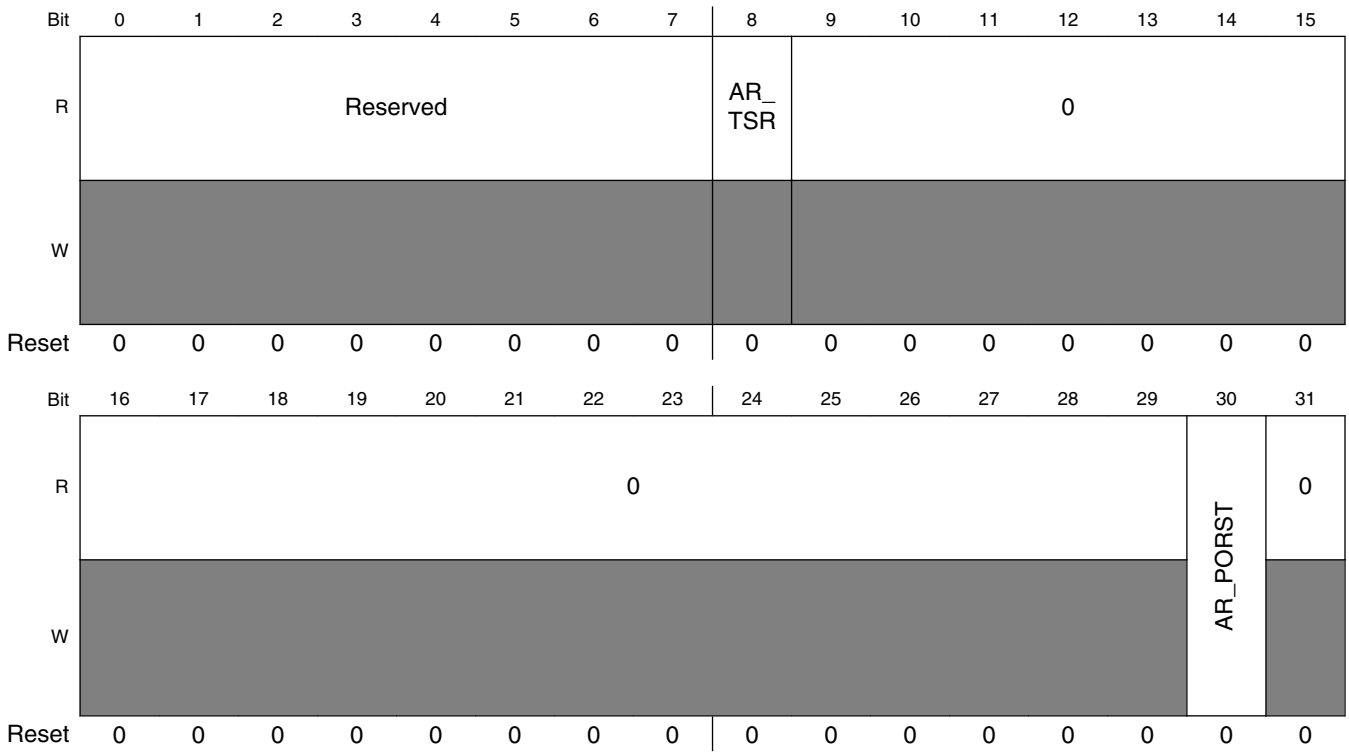
Address: 0h base + 10h offset = 10h

MC_RGM_DERD field descriptions

Field	Description
0–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6 D_PMC_STF	Disable PMC Self_Test Failure

Table continues on the next page...

MC_RGM_DERD field descriptions (continued)



Field	Description
	0 A PMC selt test failure ‘destructive’ reset event triggers a reset sequence
7 D_VOR	Disable Voltage Out of Range 0 A Voltage Out of Range ‘destructive’ reset event triggers a reset sequence
8 D_TSR	Disable Temperature sensor 0 A Tempearature sensor ‘destructive’ reset event triggers a reset sequence 1 A Temperature sensor ‘destructive’ event generates a SAFE mode
9–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21 D_JTAG	Disable JTAG destructive reset 0 A JTAG ‘destructive’ reset event triggers a reset sequence
22 D_FIF	Disable Flash Initialization Failure 0 A Flash Initialization Failure ‘destructive’ reset event triggers a reset sequence
23 D_EDR	Disable ’Functional’ reset Escalation 0 A ’Functional’ reset Escalation ‘destructive’ reset event triggers a reset sequence
24–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26 D_SUF	Disable STCU Unrecoverable Fault 0 An STCU Unrecoverable Fault ‘destructive’ reset event triggers a reset sequence
27 D_FFRR	Disable FCCU Failure to React reset 0 An FCCU Failure to React reset ‘destructive’ reset event triggers a reset sequence
28 D_SOFT_DEST	Disable Software destructive reset 0 A Software ‘destructive’ reset event triggers a reset sequence
29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30 D_PORST	Disable External PowerOn reset 0 An External PowerOn reset ‘destructive’ reset event triggers a reset sequence 1 An External PowerOn reset ‘destructive’ event generates either a SAFE mode or an interrupt request depending on the values in RGM_DEAR register
31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

56.3.3 ‘Destructive’ Event Alternate Request (MC_RGM_DEAR)

This register defines an alternate request to be generated when a reset on a 'destructive' event has been disabled. The alternate request can be either a SAFE mode request to MC_ME or an interrupt request to the system. It can be accessed in read/write in either supervisor mode or test mode. It can be accessed in read only in user mode.

This register is reset only on power-on.

Address: 0h base + 20h offset = 20h

MC_RGM_DEAR field descriptions

Field	Description
0–7 Reserved	This field is reserved.
8 AR_TSR	Alternate Requests for Temperature sensor 'Destructive' Reset 0 Generate a SAFE mode request on a Temperature sensor 'destructive' reset event if the reset is disabled.
9–29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30 AR_PORST	Alternate Requests for external POR ‘Destructive’ Reset 0 Generate a SAFE mode request on a Temperature sensor ‘destructive’ reset event if the reset is disabled 1 Generate an interrupt request on a Temperature sensor ‘destructive’ reset event if the reset is disabled
31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

56.3.4 ‘Destructive’ Bidirectional Reset Enable (MC_RGM_DBRE)

This register enables the generation of an external reset on 'destructive' reset. It can be accessed in read/write in either supervisor mode or test mode. It can be accessed in read only in user mode.

This register is reset only on power-on.

Address: 0h base + 30h offset = 30h

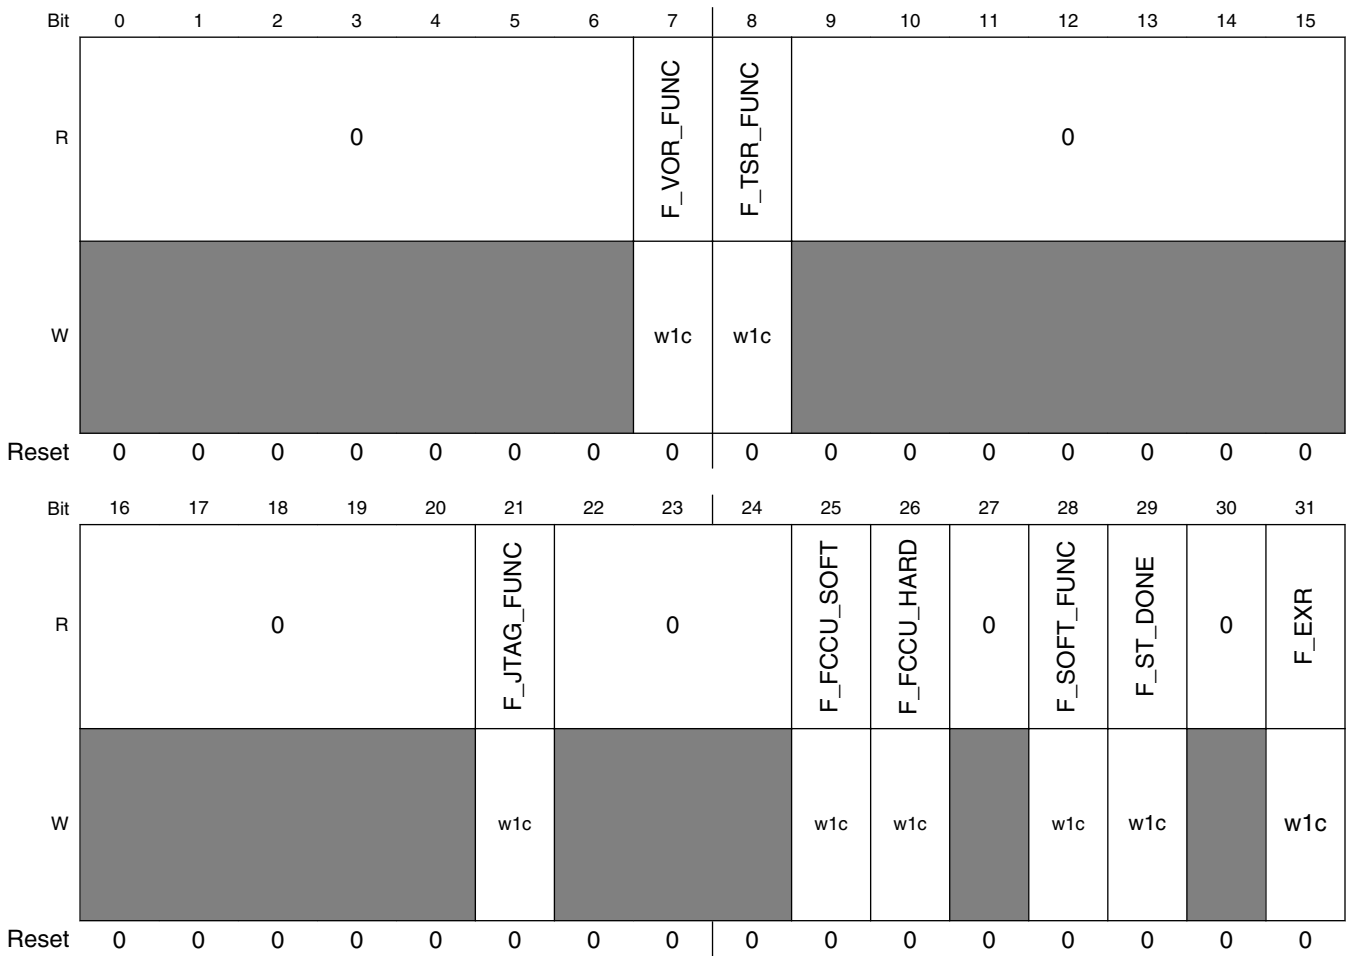
MC_RGM_DBRE field descriptions



Field	Description
0–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6 BE_PMC_STF	Bidirectional Reset Enables for PMC Selt Test Failure 'Destructive' Reset 0 RESET_B is asserted on a PMC Selt Test Failure ‘destructive’ reset event if the reset is enabled
7 BE_VOR	Bidirectional Reset Enables for Voltage Out of Range ‘Destructive’ Reset 0 RESET_B is asserted on a Voltage Out of Range ‘destructive’ reset event if the reset is enabled
8 BE_TSR	Bidirectional Reset Enables for Temperature sensor ‘Destructive’ Reset 0 RESET_B is asserted on a Temperature sensor ‘destructive’ reset event if the reset is enabled
9–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21 BE_JTAG	Bidirectional Reset Enables for JTAG destructive reset ‘Destructive’ Reset 0 RESET_B is asserted on a JTAG ‘destructive’ reset event if the reset is enabled 1 RESET_B is not asserted on a JTAG destructive reset event
22 BE_FIF	Bidirectional Reset Enables for Flash Initialization Failure ‘Destructive’ Reset 0 RESET_B is asserted on a Flash Initialization Failure ‘destructive’ reset event if the reset is enabled
23 BE_EDR	Bidirectional Reset Enables for ’Functional’ reset Escalation ‘Destructive’ Reset 0 RESET_B is asserted on a ’Functional’ reset Escalation ‘destructive’ reset event if the reset is enabled
24–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26 BE_SUF	Bidirectional Reset Enables for STCU Unrecoverable Fault ‘Destructive’ Reset 0 RESET_B is asserted on an STCU Unrecoverable Fault ‘destructive’ reset event if the reset is enabled
27 BE_FFRR	Bidirectional Reset Enables for FCCU Failure to React reset ‘Destructive’ Reset 0 RESET_B is asserted on an FCCU Failure to React reset ‘destructive’ reset event if the reset is enabled
28 BE_SOFT_DEST	Bidirectional Reset Enables for Software ‘Destructive’ Reset 0 RESET_B is asserted on a Software destructive reset ‘destructive’ reset event if the reset is enabled
29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30 BE_PORST	Bidirectional Reset Enables for External PowerOn reset ‘Destructive’ Reset 0 RESET_B is asserted on an External PowerOn reset ‘destructive’ reset event if the reset is enabled
31 BE_POR	Bidirectional Reset Enables for Power On ‘Destructive’ Reset 0 RESET_B is asserted on a Power On ‘destructive’ reset event if the reset is enabled

56.3.5 ‘Functional’ Event Status (MC_RGM_FES)

This register contains the status of the 'functional' reset sources, including those configured to not generate a reset sequence. It can be accessed in read/write in either supervisor mode or test mode. It can be accessed in read only in user mode. Register bits are cleared by writing '1' if the triggering event has already been cleared at the source.

This register is reset only on power-on.

Address: 0h base + 300h offset = 300h

MC_RGM_FES field descriptions

9–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21 F_JTAG_FUNC	Flag for JTAG ‘Functional’ Reset 0 No JTAG ‘Functional’ Reset event has occurred since either the last clear or the last ‘destructive’ reset assertion 1 A JTAG ‘Functional’ Reset event has occurred
22–24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25 F_FCCU_SOFT	Flag for FCCU Soft reaction ‘Functional’ Reset 0 No FCCU Soft reaction ‘Functional’ Reset event has occurred since either the last clear or the last ‘destructive’ reset assertion 1 An FCCU Soft reaction ‘Functional’ Reset event has occurred
26 F_FCCU_HARD	Flag for FCCU Hard reaction ‘Functional’ Reset 0 No FCCU Hard reaction ‘Functional’ Reset event has occurred since either the last clear or the last ‘destructive’ reset assertion 1 An FCCU Hard reaction ‘Functional’ Reset event has occurred
27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28 F_SOFT_FUNC	Flag for Software functional reset 0 No Software functional reset event has occurred since either the last clear or the last ‘destructive’ reset assertion 1 A Software functional reset event has occurred
29 F_ST_DONE	Flag for Self Test Completed ‘Functional’ Reset 0 No Self Test Completed event has occurred since either the last clear or the last ‘destructive’ reset assertion 1 A Self Test Completed event has occurred
30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 F_EXR	Flag for External Reset 0 No external reset event has occurred since either the last clear or the last power-on reset assertion 1 An external reset event has occurred

56.3.6 ‘Functional’ Event Reset Disable (MC_RGM_FERD)

This register provides dedicated bits to disable 'functional' reset sources.When a 'functional' reset source is disabled, the associated 'functional' event will trigger either a SAFE mode request or an interrupt request (see Section 'Functional' Event Alternate Request (RGM_FEAR)). It can be accessed in read/write in either supervisor mode or test mode. It can be accessed in read only in user mode. Each byte can be written only once after a 'destructive' or power-on reset.

This register is reset only on power-on and any ‘destructive’ reset.

Address: 0h base + 310h offset = 310h

30–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

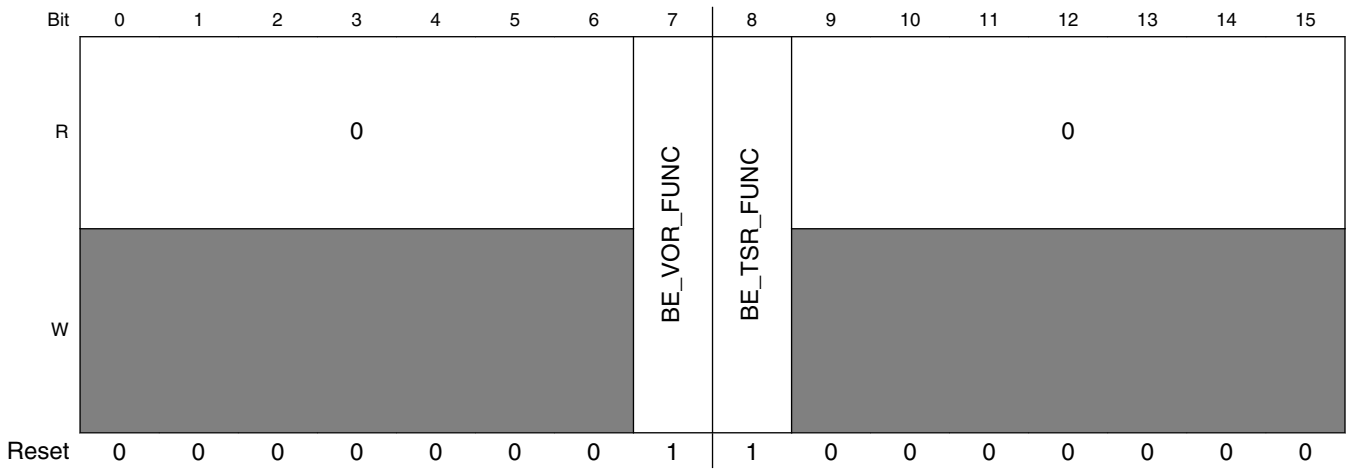
56.3.7 ‘Functional’ Event Alternate Request (MC_RGM_FEAR)

This register defines an alternate request to be generated when a reset on a 'functional' event has been disabled. The alternate request can be either a SAFE mode request to MC_ME or an interrupt request to the system. It can be accessed in read/write in either supervisor mode or test mode. It can be accessed in read only in user mode.

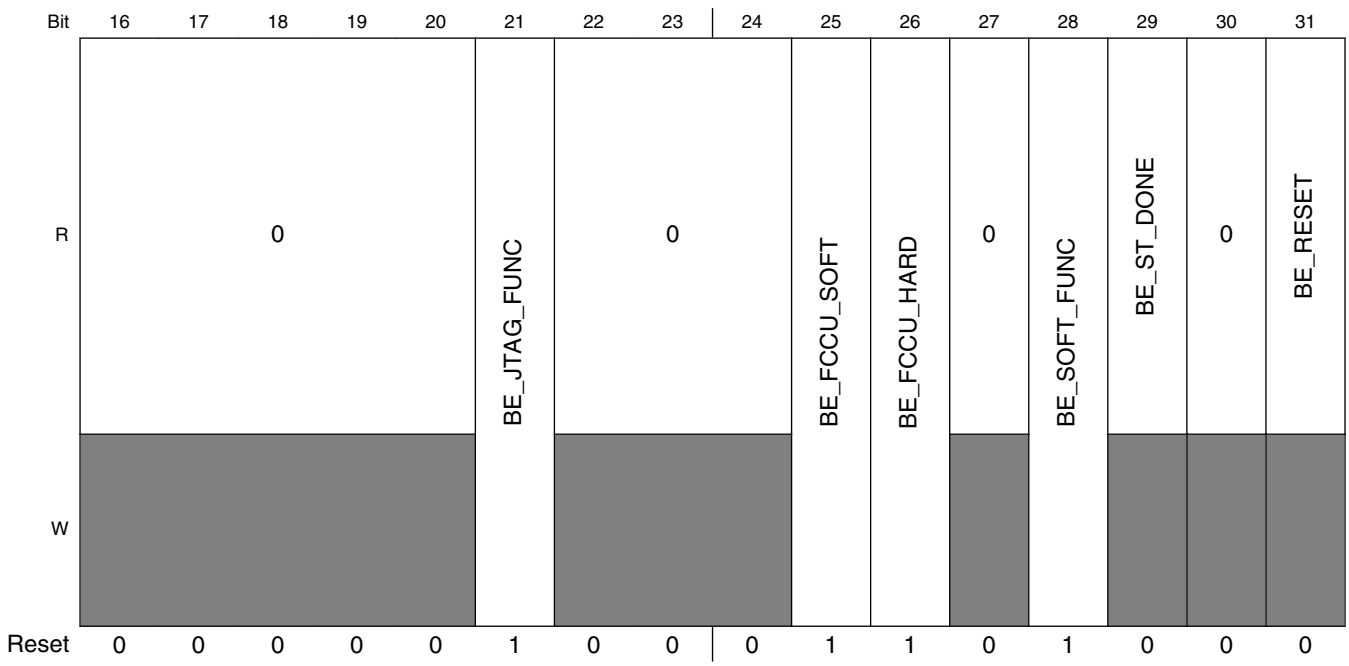
This register is reset only on power-on and any ‘destructive’ reset.

Address: 0h base + 320h offset = 320h

MC_RGM_FEAR field descriptions



Field	Description
0–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 AR_VOR_FUNC	Alternate Request for Voltage Out of Range ‘Functional’ Reset 0 Generate a SAFE mode request on a Voltage Out of Range ‘Functional’ Reset event if the reset is disabled 1 Generate an interrupt request on a Voltage Out of Range ‘Functional’ Reset event if the reset is disabled
8 AR_TSR_FUNC	Alternate Request for Temperature Sensor ‘Functional’ Reset 0 Generate a SAFE mode request on a Temperature Sensor ‘Functional’ Reset event if the reset is disabled 1 Generate an interrupt request on a Temperature Sensor ‘Functional’ Reset event if the reset is disabled
9–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.



56.3.8 ‘Functional’ Bidirectional Reset Enable (MC_RGM_FBRE)

This register enables the generation of an external reset on 'functional' reset. It can be accessed in read/write in either supervisor mode or test mode. It can be accessed in read in user mode.

This register is reset only on power-on and any ‘destructive’ reset.

Address: 0h base + 330h offset = 330h

MC_RGM_FBRE field descriptions

Field	Description
0–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 BE_VOR_FUNC	Bidirectional Reset Enable for Voltage Out of Range ‘Functional’ Reset 0 RESET_B is asserted on a Voltage Out of Range ‘Functional’ Reset event if the reset is enabled 1 RESET_B is not asserted on a Voltage Out of Range ‘Functional’ Reset event
8 BE_TSR_FUNC	Bidirectional Reset Enable for Temperature Sensor ‘Functional’ Reset 0 RESET_B is asserted on a Temperature Sensor ‘Functional’ Reset event if the reset is enabled 1 RESET_B is not asserted on a Temperature Sensor ‘Functional’ Reset event
9–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

MC_RGM_FBRE field descriptions (continued)

Field	Description
21 BE_JTAG_FUNC	Bidirectional Reset Enable for JTAG 'Functional' Reset 0 RESET_B is asserted on a JTAG 'Functional' Reset event if the reset is enabled 1 RESET_B is not asserted on a JTAG 'Functional' Reset event
22–24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25 BE_FCCU_SOFT	Bidirectional Reset Enable for FCCU Soft reaction 0 RESET_B is asserted on an FCCU Soft reaction event if the reset is enabled 1 RESET_B is not asserted on an FCCU Soft reaction event

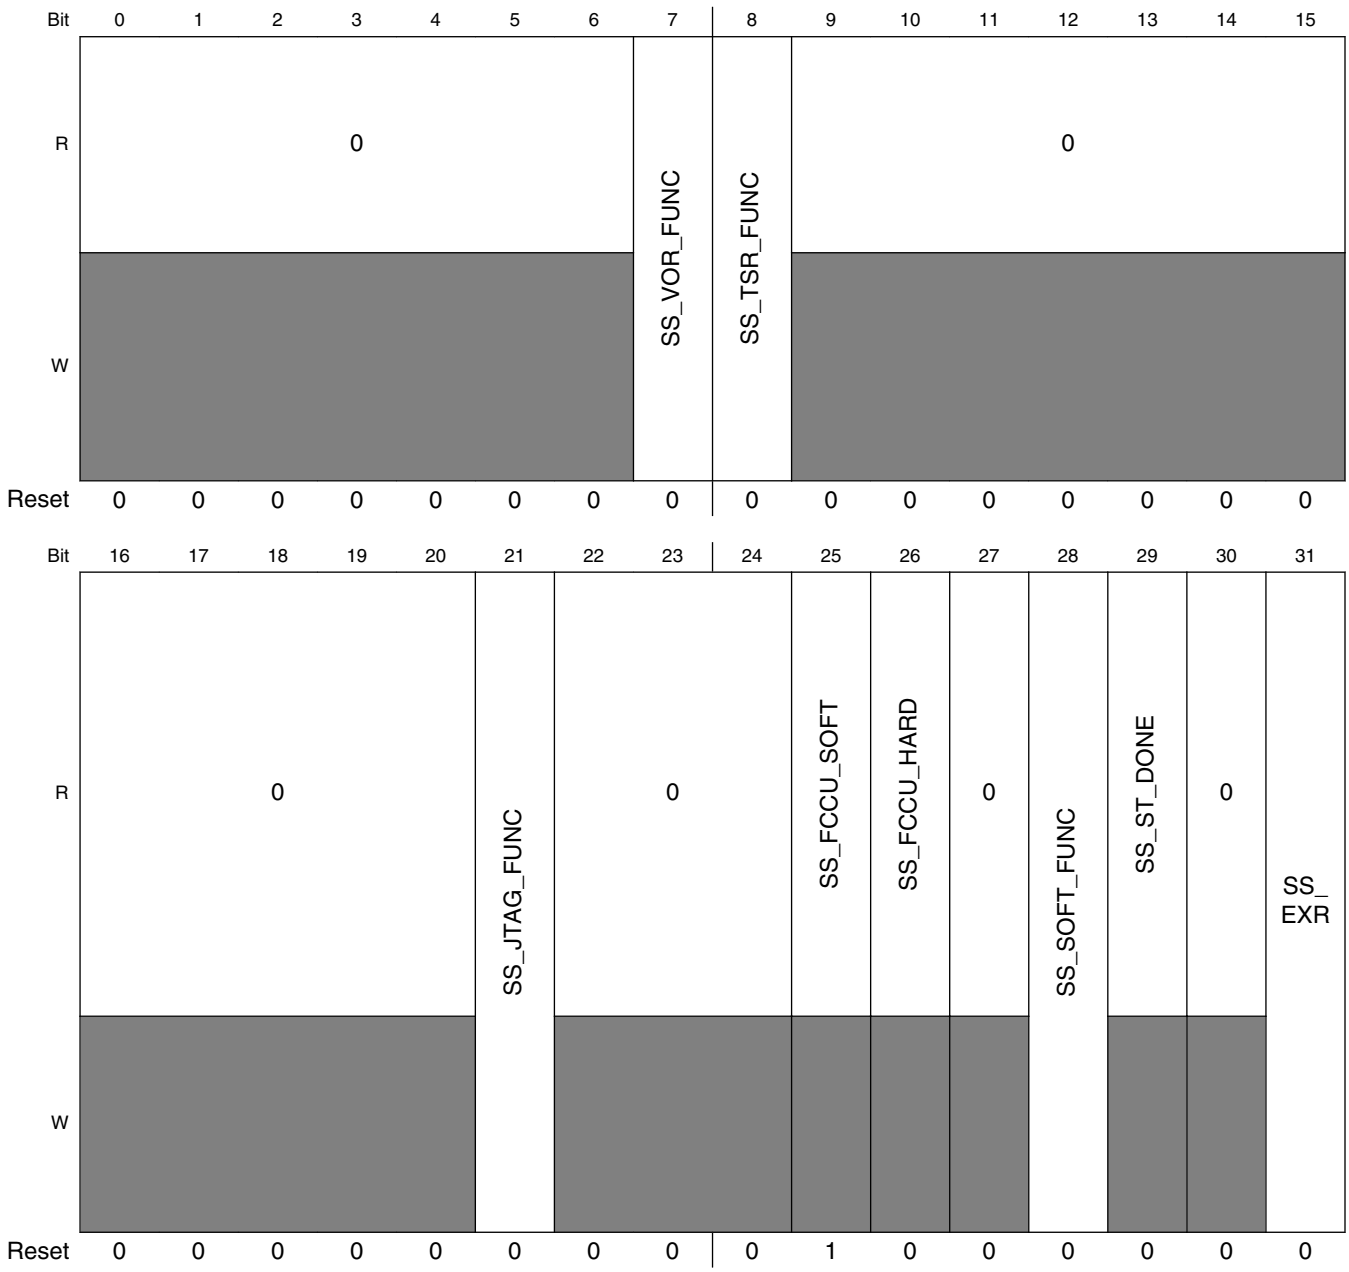
27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28 BE_SOFT_FUNC	Bidirectional Reset Enable for Software functional reset 0 RESET_B is asserted on a Software functional reset event if the reset is enabled 1 RESET_B is not asserted on a Software functional reset event
29 BE_ST_DONE	Bidirectional Reset Enable for Self Test Completed 'Functional' Reset 0 RESET_B is asserted on a Self Test Completed 'Functional' Reset event if the reset is enabled 1 RESET_B is not asserted on a Self Test Completed 'Functional' Reset event
30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 BE_RESET	Bidirectional Reset Enable for RESET External Reset 0 RESET_B is asserted on an external reset event if the reset is enabled 1 RESET_B is not asserted on an external reset event

56.3.9 'Functional' Event Short Sequence (MC_RGM_FESS)

This register defines which reset sequence will be done when a 'functional' reset sequence is triggered. The 'functional' reset sequence can either start from PHASE1 or from PHASE3, skipping PHASE1 and PHASE2.



NOTE

This could be useful for a fast reset sequence, for example to skip flash reset.

It can be accessed as read/write in either supervisor mode or test mode. It can be accessed as read-only in user mode.

This register is reset only on power-on and any 'destructive' reset.

Address: 0h base + 340h offset = 340h

MC_RGM_FESS field descriptions

Field	Description
0–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 SS_VOR_FUNC	Short Sequence for Voltage Out of Range ‘Functional’ Reset 0 The reset sequence triggered by a Voltage Out of Range ‘Functional’ Reset event will start from PHASE1 1 The reset sequence triggered by a Voltage Out of Range ‘Functional’ Reset event will start from PHASE3, skipping PHASE1 and PHASE2

Table continues on the next page...

27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28 SS_SOFT_FUNC	Short Sequence for Software functional reset 0 The reset sequence triggered by a Software functional reset event will start from PHASE1 1 The reset sequence triggered by a Software functional reset event will start from PHASE3, skipping PHASE1 and PHASE2
29 SS_ST_DONE	Short Sequence for Self Test Completed 0 The reset sequence triggered by a Self Test Completed event will start from PHASE1
30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 SS_EXR	Short Sequence for External Reset 0 The reset sequence triggered by an external reset event will start from PHASE1 1 The reset sequence triggered by an external reset event will start from PHASE3, skipping PHASE1 and PHASE2

56.3.10 Functional Reset Threshold (MC_RGM_FRET)

This register sets the threshold for 'functional' reset escalation to a 'destructive' reset. It can be accessed in read/write in either supervisor mode or test mode. It can be accessed in read only in user mode.

Writing a non-zero value to the FRET field will enable the ‘functional’ reset escalation function. Writing any value to this register will reset the ‘functional’ reset counter. See Section “‘Functional’ Reset Escalation” for details on the ‘functional’ reset escalation function.

This register is reset only on power-on and any ‘destructive’ reset.

Address: 0h base + 604h offset = 604h

Bit	0	1	2	3	4	5	6	7

Write								
Reset	0	0	0	0	1	1	1	1

MC_RGM_FRET field descriptions

Field	Description
0–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4–7 FRET	‘Functional’ Reset Escalation Threshold - If the value of this field is 0, the ‘functional’ reset escalation function is disabled. Any other value is the number of ‘functional’ resets which will cause a ‘destructive’ reset if the RGM_FRET register is not written to beforehand.

56.3.11 ‘Destructive’ Reset Threshold (MC_RGM_DRET)

This register sets the threshold for ‘destructive’ reset escalation to keep the chip in the reset state until the next power-on reset triggers a new reset sequence. It can be accessed in read/write in either supervisor mode or test mode. It can be accessed in read only in user mode.

Writing a non-zero value to the DRET field will enable the ‘destructive’ reset escalation function. Writing any value to this register will reset the ‘destructive’ reset counter. See Section “‘Destructive’ Reset Escalation” for details on the ‘destructive’ reset escalation function.

This register is reset only on power-on.

Write								
Reset	0	0	0	0	0	0	0	0

MC_RGM_DRET field descriptions

Field	Description
0–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4–7 DRET	'Destructive' Reset Escalation Threshold — If the value of this field is 0, the 'destructive' reset escalation function is disabled. Any other value is the number of 'destructive' resets which will keep the chip in the reset state until the next power-on reset triggers a new reset sequence if the RGM_DRET register is not written to beforehand.

56.4 Functional Description

56.4.1 Reset State Machine

The main role of MC_RGM is the generation of the reset sequence which ensures that the correct parts of the chip are reset based on the reset source event. This is summarized in the following table.

Table 56-14. MC_RGM Reset Implications

Source	What Gets Reset	External Reset Assertion
power-on reset	all	yes
'destructive' resets	all except some clock/reset management	programmable[1]
external reset	all except some clock/reset management and debug	programmable[2, 2]
'functional' resets	all except some clock/reset management and debug	programmable[3]
shortened 'functional' resets[3, 3]	flip-flops except some clock/reset management	programmable[3]

1. The assertion of the external reset is controlled via the **RGM_DBRE** register.
2. The assertion of the external reset is controlled via the **RGM_FBRE** register.
3. The short sequence is enabled via the **RGM_FESS** register.

Note

JTAG logic has its own independent reset control and is not controlled by the MC_RGM in any way.

The reset sequence is comprised of five phases managed by a state machine, which ensures that all phases are correctly processed through waiting for a minimum duration and until all processes that need to occur during that phase have been completed before proceeding to the next phase.

The state machine used to produce the reset sequence is shown in the following figure.

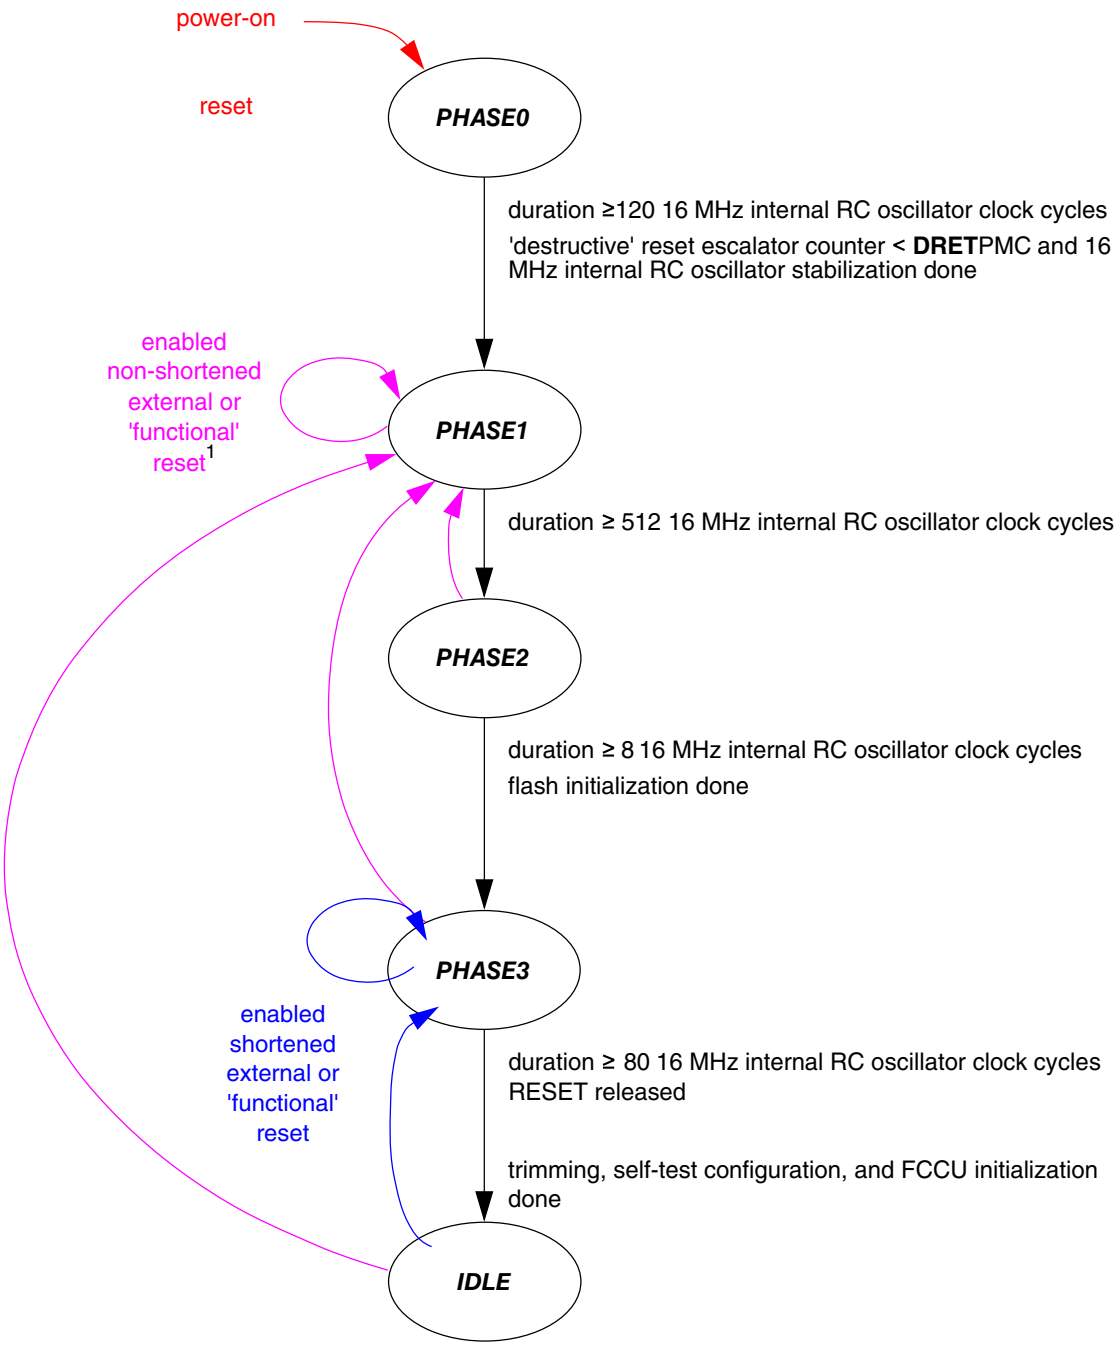

Figure 56-13. MC_RGM State Machine

56.4.1.1 *PHASE0* Phase

This phase is entered immediately from any phase on a power-on or enabled 'destructive' reset event. The reset state machine exits ***PHASE0*** and enters ***PHASE1*** on verification of the following:

- all enabled 'destructive' resets have been processed

- all processes that need to be done in ***PHASE0*** are completed
  - PMC and 16 MHz internal RC oscillator stabilization
- a minimum of 120 16 MHz internal RC oscillator clock cycles have elapsed since power-up completion and the last enabled 'destructive' reset event
- the 'destructive' reset escalator counter has not reached the value in the **DRET** field of the **RGM_DRET** resister

56.4.1.2 *PHASE1* Phase

This phase is entered either on exit from ***PHASE0*** or immediately from ***PHASE2***, ***PHASE3***, or ***IDLE*** on a non-masked external or 'functional' reset event if it has not been configured to trigger a 'short' sequence. The reset state machine exits ***PHASE1*** and enters ***PHASE2*** on verification of the following:

- all enabled, non-shortened 'functional' resets have been processed
- a minimum of 512 16 MHz internal RC oscillator clock cycles have elapsed since the last enabled external or non-shortened 'functional' reset event

56.4.1.3 *PHASE2* Phase

This phase is entered on exit from ***PHASE1***. The reset state machine exits ***PHASE2*** and enters ***PHASE3*** on verification of the following:

- all processes that need to be done in ***PHASE2*** are completed
  - flash initialization
- a minimum of 8 16 MHz internal RC oscillator clock cycles have elapsed since entering ***PHASE2***

56.4.1.4 *PHASE3* Phase

This phase is entered either on exit from ***PHASE2*** or immediately from ***IDLE*** on an enabled, shortened 'functional' reset event. The reset state machine exits ***PHASE3*** and enters ***IDLE*** on verification of the following:

- all processes that need to be done in ***PHASE3*** are completed

- trimming, self-test configuration, and FCCU initialization

- a minimum of 80 16 MHz internal RC oscillator clock cycles have elapsed since the last enabled, shortened 'functional' reset event

56.4.1.5 *IDLE* Phase

This is the final phase and is entered on exit from ***PHASE3***. When this phase is reached, the MC_RGM releases control of the system to the platform and waits for new reset events that can trigger a reset sequence.

56.4.2 'Destructive' Resets

A 'destructive' reset indicates that an event has occurred after which critical register or memory content can no longer be guaranteed.

The status flag associated with a given 'destructive' reset event (**RGM_DES.F_<destructive reset>** bit) is set when the 'destructive' reset is asserted and the power-on reset is not asserted. It is possible for multiple status bits to be set simultaneously, and it is software's responsibility to determine which reset source is the most critical for the application.

A given 'destructive' reset dest_rst[*n*] can be optionally disabled by writing bit **RGM_DERD.D_<destructive reset>**.

Note

The **RGM_DERD** register can be written only once between two 'destructive' reset events.

The chip's low-voltage detector threshold ensures that, when the reset corresponding to the core supply low-voltage detect is enabled, the supply is sufficient to have the 'destructive' event correctly propagated through the digital logic. Therefore, if a given 'destructive' reset is enabled, the MC_RGM ensures that the associated reset event will be correctly triggered to the full system. However, if the given 'destructive' reset is disabled and the voltage goes below the digital functional threshold, functionality can no longer be ensured, and the reset may or may not be asserted.

An enabled 'destructive' reset will trigger a reset sequence starting from the beginning of ***PHASE0***.

56.4.3 External Reset

The MC_RGM manages the external reset coming from RESET. The detection of a falling edge on RESET will start the reset sequence from the beginning of ***PHASE1***.

The status flag associated with the external reset falling edge event (**RGM_FES.F_EXR** bit) is set when the external reset is asserted and the power-on reset is not asserted.

An enabled external reset will normally trigger a reset sequence starting from the beginning of ***PHASE1***. Nevertheless, the **RGM_FESS** register enables the further configuring of the reset sequence triggered by the external reset. When **RGM_FESS.SS_EXR** is set, the external reset will trigger a reset sequence starting directly from the beginning of ***PHASE3***, skipping ***PHASE1*** and ***PHASE2***. This can be useful especially when an external reset should not reset the flash.

The MC_RGM may also assert the external reset if the reset sequence was triggered by one of the following:

- a power-on reset
- a 'destructive' reset event configured via the **RGM_DBRE** register to assert the external reset
- an external reset event
- a 'functional' reset event configured via the **RGM_FBRE** register to assert the external reset

In this case, RESET_B is asserted until all conditions for exiting ***PHASE3*** have been met, with the exception of the RESET assertion check.

56.4.4 'Functional' Resets

A 'functional' reset indicates that an event has occurred after which it can be guaranteed that critical register and memory content is still intact.

The status flag associated with a given 'functional' reset event (**RGM_FES.F_<functional reset>** bit) is set when the 'functional' reset is asserted and the power-on reset is not asserted. It is possible for multiple status bits to be set simultaneously, and it is software's responsibility to determine which reset source is the most critical for the application.

The 'functional' reset can be optionally disabled by software writing bit **RGM_FERD.D_<functional reset>**.

Note

The **RGM_FERD** register can be written only once between two power-on reset events.

An enabled 'functional' reset will normally trigger a reset sequence starting from the beginning of ***PHASE1***. Nevertheless, the **RGM_FESS** register enables the further configuring of the reset sequence triggered by a 'functional' reset. When **RGM_FESS.SS_<functional reset>** is set, the associated 'functional' reset will trigger a reset sequence starting directly from the beginning of ***PHASE3***, skipping ***PHASE1*** and ***PHASE2***. This can be useful especially in case a 'functional' reset should not reset the flash module.

See the MC_ME chapter for details on the ***DRUN*** modes.

56.4.5 Alternate Event Generation

The MC_RGM provides alternative events to be generated on reset source assertion. When a reset source is asserted, the MC_RGM normally enters the reset sequence. Alternatively, it is possible for some reset source events to be converted from a reset to either a ***SAFE*** mode request issued to the MC_ME or to an interrupt request issued to the core.

Alternate event selection for a given reset source is made via the **RGM_F/DERD** and **RGM_F/DEAR** registers as shown in the following table.

Table 56-15. MC_RGM Alternate Event Selection

RGM_F/DERD Bit Value	RGM_F/DEAR Bit Value	Generated Event
0	X	reset
1	0	***SAFE*** mode request
1	1	interrupt request

The alternate event is cleared by deasserting the source of the request (that is, at the reset source that caused the alternate request) and also clearing the appropriate **RGM_F/DES** status bit.

Note

SAFE mode requests are generated regardless of whether the system clock is running. Interrupt requests are generated with the system clock, and therefore, if the system clock is disabled at the time of the event, the interrupt request isn't asserted until the system clock is re-enabled.

Note

If a masked 'destructive' reset event which is configured to generate a ***SAFE*** mode/interrupt request occurs during ***PHASE0***, it is ignored, and the MC_RGM will not send any safe mode/interrupt request to the MC_ME.

Note

If a masked 'functional' reset event which is configured to generate a ***SAFE*** mode/interrupt request occurs during ***PHASE1***, it is ignored, and the MC_RGM will not send any safe mode/interrupt request to the MC_ME.

56.4.6 'Functional' Reset Escalation

'Functional' reset escalation can be used to generate a 'destructive' reset if a number of 'functional' or external resets has occurred between software writes to the **RGM_FRET** register. This function is enabled by writing a non-zero value to the **FRET** field of this register.

Once 'functional' reset escalation has been enabled, the MC_RGM increases a counter on each 'functional' or external reset which causes a reset sequence to be initiated (that is, entrance into ***PHASE1*** or ***PHASE3*** from the ***IDLE*** phase). This counter is cleared on a write of any value to the **RGM_FRET** register and on any power-on or 'destructive' reset. If the counter reaches the value in the **RGM_FRET** register's **FRET** field, the MC_RGM asserts.

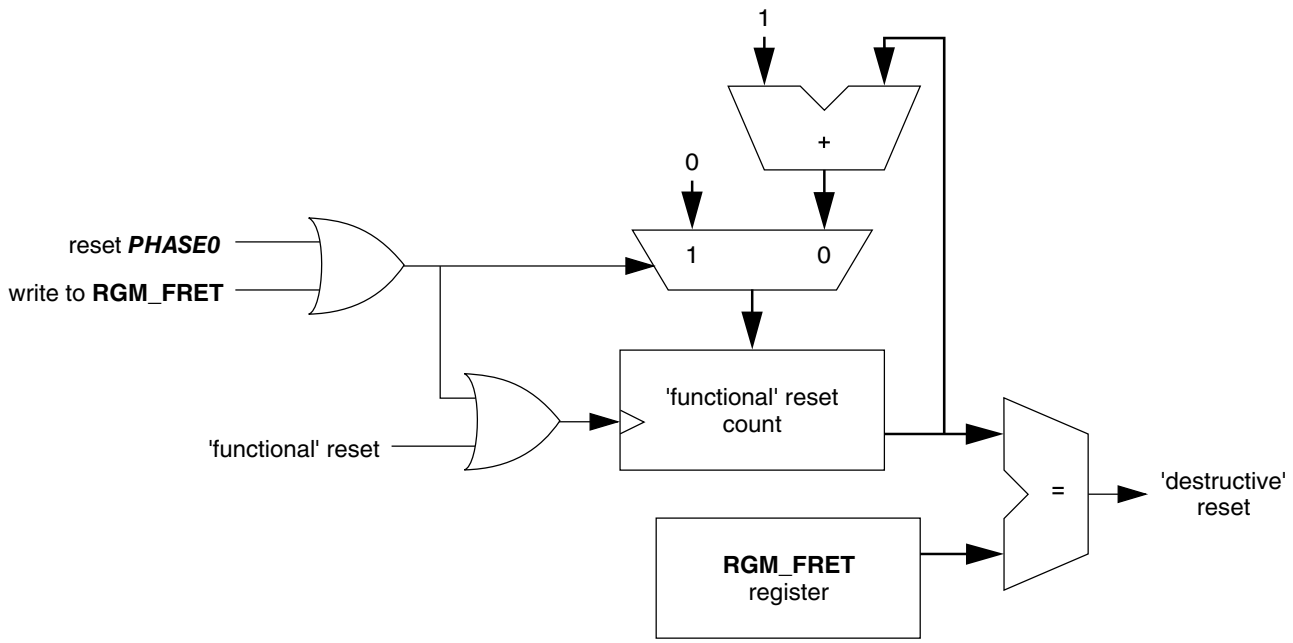

Figure 56-14. MC_RGM 'Functional' Reset Escalation to 'Destructive' Reset

56.4.7 'Destructive' Reset Escalation

'Destructive' reset escalation can be used to keep the chip in the reset state until the power-on triggers a reset sequence if a number of 'destructive' resets has occurred between software writes to the **RGM_DRET** register. This function is enabled by writing a non-zero value to the **DRET** field of this register.

Once 'destructive' reset escalation has been enabled, the MC_RGM increases a counter on each 'destructive' reset and which causes a reset sequence to be initiated (i.e., entrance into ***PHASE0*** from the ***IDLE*** phase) or an ongoing reset sequence to restart (i.e., entrance into ***PHASE0*** from ***PHASE1***, ***PHASE2***, or ***PHASE3***). This counter is cleared on a write of any value to the **RGM_DRET** register and on any power-on reset. If the counter reaches the value in the **RGM_DRET** register's **DRET** field, the MC_RGM enters reset ***PHASE0*** and stays there until the next power-on reset occurs.

On a power-on reset, the dest_rst_escalation output is deasserted. It is asserted by the MC_RGM when the counter reaches the value in the **RGM_DRET** register's **DRET** field. It is not deasserted until the next power-on reset.

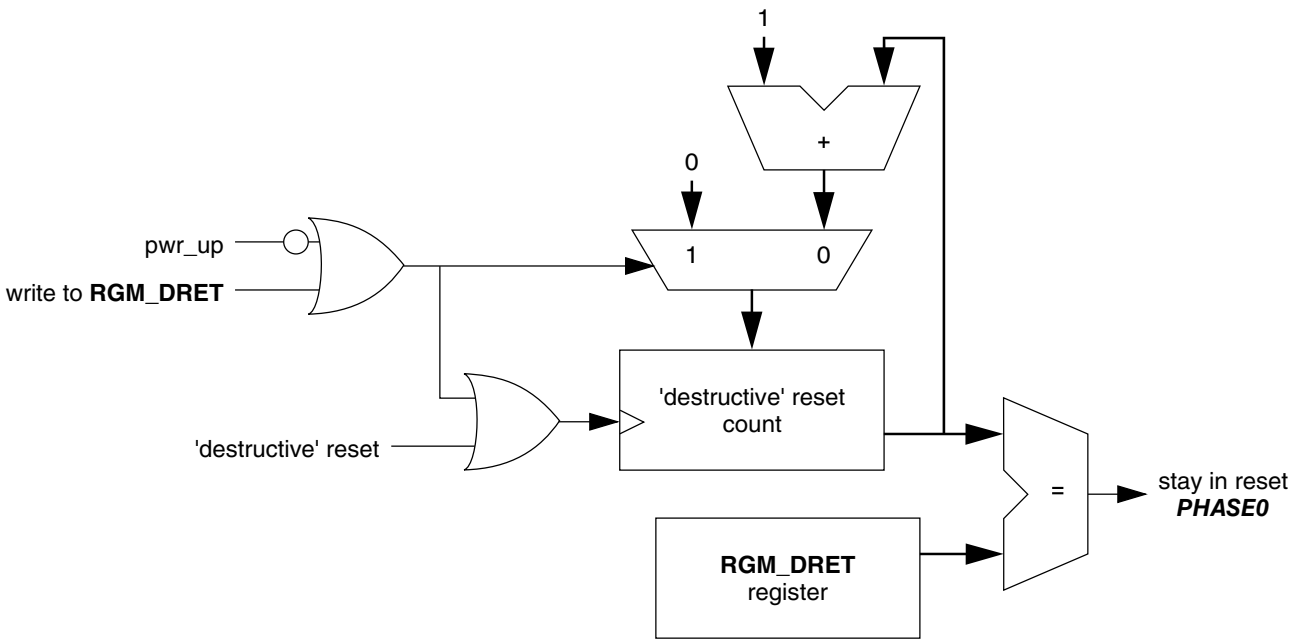

Figure 56-15. MC_RGM 'Destructive' Reset Escalation to Stay in *PHASE0*

Chapter 57
Boot Assist Flash (BAF)

57.1 BAF chip-specific module information

57.1.1 Search boot header and boot options

The BAF searches the flash memory for the boot header, checking the first word location of the 5 × 16 KB blocks, then the first of the 4 × 256 KB blocks. The blocks are searched in the order shown in Table 57-1. Once a boot header is found, no further blocks are searched.

Table 57-1. Locations of boot headers

Search order	Block	Address
1	16KB Code Flash block 0	00F9_C000h
2	16KB Code Flash block 1	00FA_0000h
3	16KB Code Flash block 2	00FA_4000h
4	16KB Code Flash block 3	00FA_8000h
5	16KB Code Flash block 4	00FA_C000h
6	256KB Code Flash block 0	0100_0000h
7	256KB Code Flash block 1	0104_0000h
8	256KB Code Flash block 2	0108_0000h
9	256KB Code Flash block 3	010C_0000h

The first header found that contains the value 005Ah in the first halfword is valid for booting. The whole header structure is shown in Table 57-2.

Table 57-2. Boot header structure

Address Offset	Contents
00h	Boot Header Configuration (see Table 57-3)
04h	Reserved for future use
08h	Reserved for future use

Table continues on the next page...

Table 57-2. Boot header structure (continued)

Address Offset	Contents
0Ch	Reserved for future use
10h	CPU0 Reset Vector
14h	CPU1 Reset Vector
18h	CPUC Reset Vector

Table 57-3. Boot header configuration

Offset 00h															
0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
0				0				5				A			
16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
0				0				0				CPU1	CPUC	CPU0	0

Table 57-4. Boot header configuration field description

Field	Description
CPU1	CPU1 is enabled (will start execution at CPU1 Reset Vector)
CPUC	CPU_SC is enabled (will start execution at CPU_SC Reset Vector, must be the same as CPU0 Reset Vector)
CPU0	CPU0 is enabled (will start execution at CPU0 Reset Vector)

The cores that are enabled in the boot header configuration field are enabled by programming MC_ME_CCTL*n*[DRUN] register to run in all DRUN modes and their reset vector is set in register MC_ME_CADDR*n*. Then, the memory area of the BAF is protected from execution for functional safety considerations. This is achieved by disabling BAF execution in PFLASH control register3 (PFLASHC_PFCR3[BAF_DIS]). Finally, a mode change (from DRUN to DRUN again) is requested from the MC_ME module to activate the new core configuration and make the cores jump to their respective reset vectors. At this point the BAF has finished its operation.

57.1.2 LinFLEXD_1 and FlexCAN_1 pin configuration

Table 57-5 shows the device pin configurations for LINFlexD_1 and FlexCAN_1 modules.

Table 57-5. FlexCAN_1 and LINFlexD_1 pin configuration

Pads	Reset Function	Initial Serial Boot mode		Serial Boot mode after valid CAN message received	Serial Boot mode after valid LINFlexD message received
		Function	Pad configuration	Function	Function
PG[6]	GPIO Input buffer off Output buffer off	CAN1TX	Output Push/Pull medium no pullup/pulldown	CAN1TX	LIN1TX
PG[5]	GPIO Input buffer off Output buffer off	LIN1RX and CAN1RX	Input pullup hystersis TTL voltage level	CAN1RX	LIN1RX

57.1.3 BAF memory map

The BAF is located in a 16 KB block of flash that is mapped adjacent to the UTEST flash memory block. It is one time programmable (OTP) and is programmed during factory test. The address space and memory used by the BAF code are shown in Table 57-6.

Table 57-6. BAF memory map

BAF component	Address
BAF address range	0040_4000h – 0040_7FFFh
BAF version number	0040_4000h
BAF code entry point	0040_4100h
BAF code exit point	5180_0080h
BAF data area and stack	5180_0000h – 5180_01FFh

Table 57-7 shows UTEST memory addresses used by the BAF.

Table 57-7. UTEST addresses

UTEST component	Address
Soft DCF Record Start Address	0040_00C0h
DCF Start Record	0040_0300h

57.1.4 Reset values on BAF exit

Table 57-8. Reset Values on BAF exit

Sl. No.	Module Name	Register	BAF Exit Reset Value
1	MC_ME	ME_IS (Interrupt status)	0x00000001
2	MC_ME	ME_DMTS (Debug mode transition status)	0x30000000
3	FCCU	FCCU_NCF_CFG_0	0xFFF7FFFF
4	LIN_Flex	LINSR	0x00000020
5	LIN_Flex	LINESR	0x00008000

57.1.5 Serial boot password behavior

Due to the SWT implementation on this chip, the serial boot password behavior described in Download 64-bit password and password check needs to be read as follows for this chip:

Table 57-9. Chip-specific serial boot password behavior

Generic module behavior described in Download 64-bit password and password check	Behavior specific to this chip
"If an incorrect password is supplied, BAF puts the device into static mode (low power safe mode)."	If an incorrect password is supplied, BAF puts the device into static mode (low power safe mode), *and causes a functional reset after 30s*.
"If 64 bits of password data is not received after approximately 30s, BAF causes a destructive reset of the MCU."	If 64 bits of password data is not received after approximately 30s, BAF causes a *functional* reset of the MCU.

57.2 Introduction

The MCU is booted through a collaboration of several blocks, hardware, and firmware. The first boot phases are performed by a state machine inside the System Status and Configuration Module (SSCM). Once completed, SSCM send reset vector to boot core, which sets PC to BAF start address.

The BAF code then checks the life cycle of the device. If the life cycle is FAIL_ANALYSIS, the BAF enters a loop in which it services the watchdog and CSE initialization is enabled. The BAF does not execute further since the read access to flash memory boot sectors for the cores may be disabled if the device life cycle is FAIL_ANALYSIS. Otherwise, it searches for a boot header and boots the application code in internal flash memory.

If no boot header is found in internal flash memory, it downloads application code serially using the LINFlexD or FlexCAN modules (see Serial boot configuration for configuration details).

57.3 BAF image header

BAF image contains a 256-byte header starting from the BAF version number (see table "BAF memory map" table in the "BAF Configuration" section of this chapter). The header contains important information such as BAF version. The BAF header is explained in Table 57-10.

Table 57-10. BAF image header

Address offset	Size (bits)	Field description
0000h	32	BAF image version
0004h – 00FFh	Reserved	

57.3.1 BAF image version

The BAF version is a 32-bit field in the image header at the BAF starting address (see the "BAF memory map" table in the "BAF Configuration" section of this chapter). The 32-bit field is explained in Table 57-11.

Table 57-11. BAF image version

Field	Description
[0:7]	Major Number: This field contains the major version number for the BAF image
[8:15]	Minor Number: This field contains the minor version number for the BAF image
[16:23]	BAF Type: This field contains customer specific information.
[24:31]	Reserved

57.4 Functional description

A functional description of the BAF modes is contained in the following sections.

57.4.1 Boot modes

Depending on the state and the content of its flash memory the device can enter one of three different boot modes:

- Boot from internal flash – If the internal flash contains application code with a valid boot header, the application is booted. The boot header contains flags that enable/ disable individual cores and their reset vectors.
- Serial boot – If no valid boot header is found and the current life cycle phase of the device is CUST_DEL (Customer Delivery) or JDP/FSL Production, an attempt is made to download the application by a serial protocol over LINFlexD or FlexCAN physical interface. The downloaded code is then executed by the initial boot core.
- Static mode – The device enters power safe mode and waits for an external reset.

57.4.2 Device initialization

The BAF performs a minimal initialization of core registers and clocks required to enter the above described boot modes, then attempts to interact with the buddy device[1] in the following way:

1. Buddy device: If the device is an emulation device (buddy device present) and the calibration RAM content is valid, then this RAM is automatically remapped over the calibration flash memory. This is intended to assist with cold-start calibration.
2. BAF sets up the exception vector table to catch machine check exceptions, which may occur if there are any uncorrectable ECC errors. In the event of an uncorrectable ECC error, the BAF issues a destructive reset from the machine check exception handler if the exception is due to the reading of instructions from the BAF region. If an exception occurs during reading of the Boot header, the BAF ignores the ECC error and jumps to next boot header. If an ECC error occurs during reading of D-MEM, the BAF will still issue a destructive reset. BAF programs the Mode Entry module’s MC_ME_MCTL[TARGET_MODE] to issue a destructive reset.
3. BAF uses memory of the Core_1 D-MEM area as in the 'BAF memory map' table (at the beginning of this chapter) for its stack, data and any code that executes from volatile memory. During the BAF start-up procedure, it initializes this section of memory so that there is no ECC error when BAF accesses this memory area.

1. "Buddy device" refers to a companion device that is used only for system development and debug activities. It is not used in production systems.

57.4.3 Flow of control

Figure 57-1 shows the overall flow of control in the BAF. The individual steps are explained in the following sections.

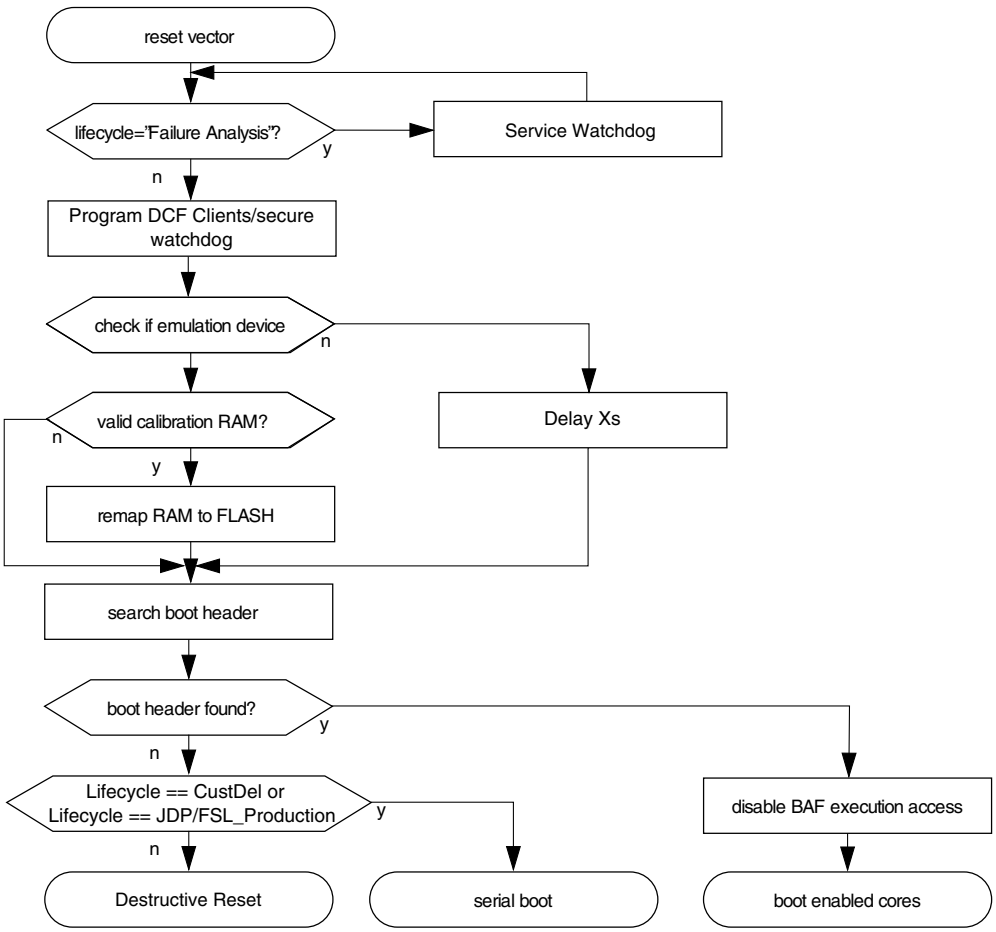

Figure 57-1. Flow of control

57.4.4 Optionally remap calibration RAM

If the device is an emulation device (buddy device present, SIUL2_MIDR1[ED] = 1), and the external overlay RAM has a valid content, then this RAM is automatically remapped over the selected flash memory regions. The details of the mapping are defined by a 400-byte configuration table at the beginning of the external overlay RAM. The layout of the table is depicted in Table 57-12.

The content of the overlay RAM is assumed valid if all of the following are true:

- The BD_INIT flag in the initialization status register of the buddy device (BD_SIUL2_ISR) is set.
- A CRC calculation over the configuration table yields the correct result.
- The version of the calibration data matches the version of the application software in flash memory (*((uint64_t*)ADDR_SWID) = DATID).

In this case, all 32 calibration remap descriptors (PFCRDs) are setup with the values contained in the configuration table. Finally, the PFCRDE field is copied to the enable register in the PFLASH controller.

Table 57-12. Remap configuration table

Address Offset	Name	Contents
00h	CRC_REF	CRC reference value
04h	ADDR_SWID	Address of 64 bit ID value in SW FLASH
08h	DATID	64 bit ID value of the calibration data
0Ch		
10h	PFCRDE	CRD enable flags
14h	LSTARTADDR0	PFCRD0 (logical start address)
18h	PSTARTADDR0	PFCRD0 (physical start address)
1Ch	CRDSize0	PFCRD0 (Master Mask, size)
20h	LSTARTADDR1	PFCRD1 (logical start address)
24h	PSTARTADDR1	PFCRD1 (physical start address)
28h	CRDSize1	PFCRD1 (Master Mask, size)
…	…	…
188h	LSTARTADDR31	PFCRD31 (logical start address)
18Ch	PSTARTADDR31	PFCRD31 (physical start address)
190h	CRDSize31	PFCRD31 (Master Mask, size)

The CRC calculation is performed using the CRC unit applying the CRC-32 (Ethernet protocol) polynomial. The calculation is initialized with a seed of 0000h. Then, the 100 32-bit words starting at table address offset 04h are moved to the CRC_INP register by the CPU. Finally, the content of the CRC_OUTP register is compared to the CRC_REF value.

57.4.5 BAF SAFE mode event handling

BAF executes under different conditions viz. Power-On-Reset (POR), Destructive Reset or any Functional Reset (Long or Short).

Due to device configuration, the device mode can be SAFE or DRUN during BAF execution. BAF issues a DRUN Mode transition to enable any peripheral or transfer control to application. If the device mode is SAFE or changes to SAFE during ongoing DRUN mode transition, then BAF issues an additional SAFE mode transition. After BAF execution when the control is transferred to the application, the device mode can be either SAFE or DRUN. It is recommended that the application (in its bootstrap) should take necessary action after idenitifying the current mode.

NOTE

Safe mode handling is only available in Flash Boot use case. Serial boot mode does not support SAFE mode handling as XOSC is disabled in SAFE mode.

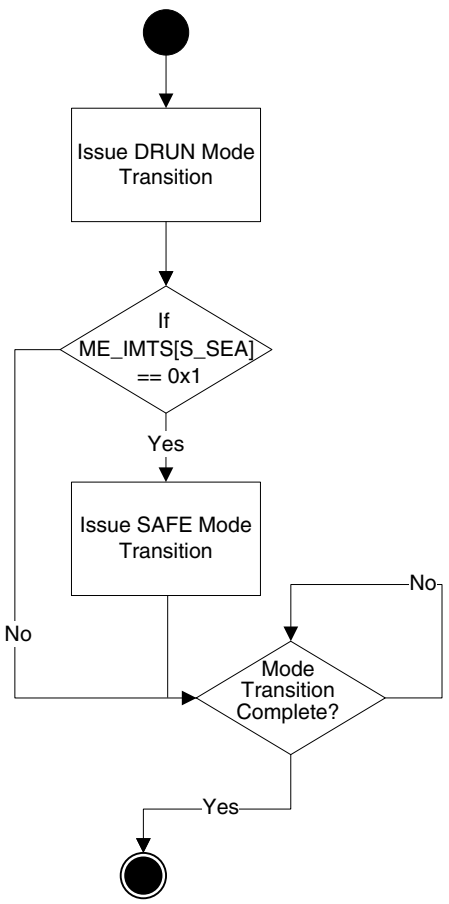

Figure 57-2. SAFE Mode Handling

57.4.6 BAF NMI Event Handling

BAF executes under different conditions viz. Power-On-Reset (POR), Destructive Reset or any Functional Reset (Long or Short). Due to device configuration, there can be a case where pending FCCU NMI events are latched in the device. These NMI events are

masked as described in NMI/WKPU interface. When BAF issues device mode transition to transfer control to application (MC_ME_CADDR*x*[RMC] = 1), the FCCU NMI event gets un-masked causing exception till RMC take effect and resets the core. The exception to CPU0 causes an additional fault (CPU0 Machine check) to be latched in the FCCU. Reset to the core also masks FCCU NMI Reaction.

As a workaround, the application can install a CALLBACK – BAF callback DCF client to initialize FCCU fault reaction to default state (No reaction for NMI Faults). This ensures that NMI faults occurring (during the BAF execution) are logged in the system. Application can then in its boot code can take corrective action and re-initialize FCCU.

As a best practice, application must check for any pending FCCU events and clear them.

57.4.7 Initialization of BAF DCF clients

57.4.7.1 Soft DCF clients

DCF clients are 32-bit hardware registers that are written by the SSCM during reset with data that is stored in DCF record format in UTEST region of flash memory. These DCF records are used to configure module registers, and select device operating modes.

The BAF extends the DCF record concept by implementing soft DCF clients. The 64-bit DCF records include:

- 32-bits of data
- 15-bit chip select field (selects the module which implements the DCF clients)
- 15-bit address field (selects a specific DCF client within the selected module)
- Parity bit (not used with UTEST DCF records)
- Stop bit (to indicate the end of DCF record has been reached)

As part of its execution flow, BAF searches through the list of DCF records in UTEST flash to determine if any of the records are to be processed by BAF.

The search starts at one of two addresses: either the start address of DCF records in UTEST (DCF Start Record), or the address specified in UTEST (Soft DCF Record Start Address). If either of the two least significant bits of the 32-bit address stored at the Soft DCF Record Start Address is set, the default start address at the DCF Start Record is used. If the two least significant bits are clear, this 32-bit value is assumed to be the start address of the search.

The default setting of the two least significant bits is 11b (erased value of flash memory is FFFF_FFFFh). A user may intentionally program a dummy address with the least two significant bits set in order to disable the search for an alternate address (as the UTEST block is OTP). Valid search start address must start on a 4-byte boundary.

The DCF record search finishes when a DCF record is read with a STOP bit set. The STOP bit may be set because that memory location is not programmed yet (so the list can be added to) or it can be an intentionally programmed STOP record to indicate that no more records are added to the list. BAF does not execute the DCF record with STOP bit set. BAF parses the STOP bit before parsing the rest of the records.

BAF uses Chip Select 14 (CS14) for BAF DCF clients. For records with CS14 asserted, the BAF uses the address field (address[14:0]) in DCF records to determine how to process the 32-bits of data. The soft DCF clients programmed by BAF are listed in Table 57-13.

The DCF clients which are used for initialization of security watchdog are explained in Security watchdog configuration.

A group of four Soft DCF clients is used to provide a mechanism to write configuration information to address locations. The first DCF client receive 32-bit address information. The next three DCF Clients receive the data that is to be written to the address contained in the first client. The three data clients allow 32-bit, 16-bit and 8-bit data to be written to the address in the first client. These four clients can be accessed repeatedly to write whole string of data to memory.

The serial boot DCF client provides a mechanism which can configure the BAF to perform serial boot or boot from internal flash. Details can be viewed in SER_BOOT_CBACK – BAF serial boot DCF client.

Table 57-13. BAF DCF client list

Address	Name	Label	Description
0000h	Security Watchdog Control register	SEC_SWT_CR	Data to write to SWT Control Register.
0001h	Security Watchdog Timeout register	SEC_SWT_TO	Security watchdog counter value.
0002h	Security Watchdog service address	SEC_IAC8	Instruction Address compare register value - Code present at this address services the watchdog.
0003h	Security watchdog CPU select	SEC_SWT_CPU	Determines which CPU is to use the security watchdog.
0004h – 01FFh	Reserved	—	Reserved for future use
0200h	Address	ADDR	The address to which DATA*n* is written.
0201h	32-bit data	DATA32	The 32-bit data that is written to ADDR.
0202h	16-bit data	DATA16	The 16-bit data that is written to ADDR.

Table continues on the next page...

Table 57-13. BAF DCF client list (continued)

Address	Name	Label	Description
0203h	8-bit data	DATA8	The 8-bit data that is written to ADDR.
0204h – 020Fh	Reserved	—	Reserved for future use.
0210h	Callback Address	CALLBACK	The address of a callback function.
0211h	Serial boot Callback address	SER_BOOT_CBACK	The address of serial boot callback function.
0212h – 0213h	Reserved	—	Reserved for future use.
0214h	Enable Calibration Delay Loop	CALIBRATION_PD_DELAY_ENABLE	Enables calibration remap equivalent delay loop on PD.
0215h	LIN_CLK Domain Select	BAF_DCF_CLIENT_LIN_CLK_DOMAIN	Selects LIN_CLK domain in A-synchronous mode.
0216h	IVPR1 for CPU1	IVPR1_CPU1	Programs the IVPR1 for CPU1.
0217h – 7FFF	Reserved	—	Reserved for future use.

NOTE

BAF boots with a watchdog timeout window set to 16ms. Parsing more and more DCF Records may increase boot time. But it should be taken care that number of DCF records should not be very high as it can cause watchdog window timeout.

57.4.7.2 Security watchdog configuration

BAF initializes the security watchdog before it jumps to the HOST CPU application. BAF implements four DCF clients for security watchdog initialization. The BAF parses the DCF records and looks for configuration data to be used to program the security watchdog registers. BAF first collects all information required to program the security watchdog from DCF records and then programs the security watchdog registers. BAF configures only SWT1 as security watchdog for the CPU1 (Core_1) core. Configuration of the Security watchdog for other cores has to be performed by the application running on that core as BAF cannot program other core's IAC8 register. Security watchdog detailed configuration steps are explained in the section below.

57.4.7.2.1 Security Watchdog Control Register (SEC_SWT_CR)

BAF parses the DCF records. If BAF finds a record with CS14 set and address field as 0000h while parsing, BAF programs the DCF client "Security watchdog control register" with the 32-bit value present in the DATA section of the DCF records. Once written, any subsequent writes to this DCF Client are ignored by BAF.

57.4.7.2.2 Security Watchdog Timeout (SEC_SWT_TO)

The BAF parses the DCF records. While parsing, if the BAF finds a DCF record with CS14 set and address field as 0001h, the BAF programs the security watchdog timeout DCF Clients. This is the security watchdog timeout register. The BAF checks the value obtained from DCF records. If the value yields a timeout greater than 30 seconds, then the BAF changes this value to 30 seconds. Once written, any subsequent writes to this DCF client are ignored.

57.4.7.2.3 Security Watchdog Service Address (SEC_IAC8)

BAF configures the security watchdog in 'fixed address execution service mode'. In this mode, the watchdog is serviced by executing code at the address loaded into the designated IAC8 (Instruction Address Compare) register. If BAF finds a DCF record with CS14 set and address field as 0002h while parsing the DCF records, BAF programs the DCF clients for SEC_IAC8. This DCF client can only be written once. Subsequent writes are ignored.

NOTE

To program the core IAC8 special purpose register, the ownership of this register should be with software. If Hardware has its ownership software will not be able to write to it using mtspr instruction.

57.4.7.2.4 Security Watchdog CPU select (SEC_SWT_CPU)

This DCF client indicates to the BAF which Core will use the security watchdog. The BAF parses the DCF record and if it finds a record with CS14 set and an address field of 0003h, the BAF programs this DCF client. This means that the BAF uses the two least significant bits out of the 32-bit data in the DCF record to find the CPU number which will use the security watchdog. Table 57-15 and Table 57-14 shows the data layout for this client in the DCF record. This client may only be written once during reset. Subsequent writes are ignored.

NOTE

Due to the limitation that only the IAC8 on the CPU running the BAF code can be accessed, the BAF can only configure the Security Watchdog to operate on CPU1. If another CPU is selected, the Security watchdog is NOT configured.

Writing this client causes the BAF to configure the security watchdog based on data written to the three previous DCF clients. If any of the three previous DCF clients were not written, data is configured erroneously.

If security watchdog is assigned to CPU0, relevant CPU IAC8 register is programmed along with other debug configuration registers to enable IAC8 as watch point.

During normal BAF operation, SWT1 is configured to perform a conventional task watchdog function (cause reset if not regularly serviced). To assign the security watchdog to the CPU1, first SWT3 is configured to perform the watchdog function task. The timeout value, configuration, and current time is read from SWT1 and copied to SWT3. Then SWT1 is unlocked with current sequence and enabled as security watchdog.

Table 57-14. Security Watchdog Core select bit configuration

DCF Client Address 0003h															
0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
0				0				0				0			
16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
0				0				0				0	0	SC1	SC0

Table 57-15. Security Watchdog CPU select bit description

Field	Description
[31:2]	Reserved
SC[1:0]	These bits select the CPU which will use the security watchdog. 00 Reserved 01 CPU1 10 Reserved 11 Reserved

NOTE

BAF programs FCCU for enabling SWT2 and SWT3 as fault source and makes them hardware recoverable. This is done to ensure that fault latched in FCCU get cleared on reset and on next SWT timeout FCCU can again trigger reset. BAF does not clear the faults latched in FCCU as they can be of interest for application.

NOTE

Currently, only the boot Core (CPU1) can be configured by the BAF to use the security watchdog. Future versions of the BAF may support other Cores, or customer code can configure other Cores to use the Security Watchdog.

57.4.7.3 BAF DCF client - ADDRESS

BAF parses the DCF records. If BAF finds a DCF record with CS14 set and Address field as 0200h while parsing, BAF programs this DCF client. This client is written with a 32-bit address from the Data section of DCF record. This 32-bit address is used in conjunction with any one of the DATA32, DATA16 or DATA8 DCF Data clients. BAF does not immediately use the ADDRESS information, but it is stored and used later in conjunction with a DATAX DCF client (DATA32, DATA16 or DATA8). Then BAF writes the data to the address in memory specified by this ADDRESS DCF client.

The user can create a series of data writes to memory by programming a series of DCF records consisting of pairs of records. The first DCF record of the pair writes to ADDR to provide the address. The second DCF record of the pair writes to the DATA client (DATAX) to provide the data. Subsequent pairs of DCF records can be programmed to write to more memory locations. The number of pairs of DCF records that can be programmed is only limited by the amount UTEST space set aside for DCF records.

Table 57-16. BAF DCF ADDR client configuration

DCF Client Address 0200h															
0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Table 57-17. BAF DCF ADDR client description

Field	Description
ADDR[0:31]	32-Bit Address DCF client. This Address value is used in conjunction with a DATAX value. The BAF writes DATAX value to ADDRESS value in the memory space of the MCU

57.4.7.4 BAF DCF client - DATAX

CAUTION

While using DATAX DCF records, it should be taken in account that BAF does not take care of ECC scheme and can generate ECC, if write is performed in memory locations which are protected by ECC and are not pre-initialized as required.

57.4.7.4.1 DATA32 – 32-bit data DCF client

BAF parses the DCF records. If BAF finds a record with CS14 set and address field set as 0201h while parsing, BAF programs this 32-bit DCF client. BAF takes the memory address provided by the ADDR client, masks the least significant 2-bits to '0' (Only 32-bit aligned writes are supported) and writes this 32-bit data to the address.

Table 57-18. DATA32 DCF client configuration

DCF Client Address 0201h															
0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Table 57-19. DATA32 DCF client description

Field	Description
DATA[0:31]	32-Bit DCF Data

57.4.7.4.2 DATA16 – 16-bit data DCF client

BAF parses the DCF records. If BAF finds a record with CS14 set and address field set as 0202h while parsing, BAF programs this 16-bit DCF client. BAF takes the memory address provided by the ADDR client, masks the least significant bits to '0' (Only 16-bit aligned writes are supported) and writes least significant 16-bit data to the address. Data in the 16 most significant bits are ignored.

Table 57-20. DATA16 DCF client configuration

Field	Description
DATA[0:15]	32-Bit DCF Data

57.4.7.4.3 DATA8 – 8-bit data DCF client

The BAF parses the DCF records. During parsing, if the BAF finds a record with CS14 set and address field equal to 0203h, the BAF programs this 8-bit DCF client. The BAF takes the memory address provided by the ADDR client, and writes least significant 8-bit data to the address. Data in the 24 most significant bits are ignored.

Table 57-22. DATA8 DCF client configuration

Field	Description
DATA[0:7]	8-Bit DCF Data

57.4.7.5 CALLBACK – BAF callback DCF client

BAF parses the DCF records. If BAF finds a record with CS14 set and address field as 0210h while parsing, BAF programs this callback DCF client. This client is written with a 32-bit start address of a function which is invoked by BAF. The BAF code checks the start address is within the UTEST or within the BAF flash memory blocks, and then passes program flow to this address. If the address is found to be outside the UTEST and BAF flash memory blocks, no function call is executed. The callback is aborted and BAF moves on to the next DCF records. The function that is called is expected to comply with Power.org EABI and to terminate in an orderly manner. An incorrectly written function causes unpredictable operations in BAF. No parameters are passed to this function and no return value is expected.

Warning

Excessively long callback functions could cause the watchdog timer to time-out and cause a reset.

BAF executes the callback function as the DCF records are parsed. Therefore several callback functions maybe executed by writing several DCF records that write to the callback DCF clients. The callback functions are executed in the same order as the DCF records.

57.4.7.6 SER_BOOT_CBACK – BAF serial boot DCF client

The BAF parses DCF records. If it finds a record with CS14 set and an address field of 0211h during parsing, the BAF programs this serial boot DCF client. This DCF client is written with a 32-bit start address of a function which is invoked by the BAF. The BAF code checks to see if the start address is within the UTEST or BAF flash memory blocks, then program flow is passed to this address if it is within either of these blocks. If the address is outside the the UTEST and BAF flash memory blocks, no function call is executed. The DCF client execution is aborted, and the BAF moves to the next DCF record. The function that is called is expected to comply with Power.org EABI and to terminate in an orderly manner. An incorrectly written function causes unpredictable operations in the BAF.

Warning

No parameters are passed to the function invoked by the BAF.

Excessively long callback functions could cause the watchdog timer to time-out and cause a reset.

The serial boot callback function returns a character value. The return value informs BAF if serial or normal internal flash boot should be executed (see Table 57-24 for details).

Table 57-24. Serial boot callback function return value definition

Return values	Description
00h	Boot from internal flash using standard search for boot record (see "Search boot header and boot options" at the beginning of this chapter).
01h	Serial boot using both FlexCAN and LINFlexD (in UART mode). See Optionally perform serial boot for details.
02h – FFh	Reserved

57.4.7.7 CALIBRATION_PD_DELAY_ENABLE – BAF calibration PD delay enable DCF client

The BAF parses DCF records. If it finds a record with CS14 set and an address field of 0214h during parsing, the BAF programs this Calibration PD delay DCF client. This DCF client is written with a 32-bit key in DATA section of this DCF record. BAF supports Calibration Remap over external overlay ram on Emulation Device. On Production Device, this feature is not present but an equivalent delay loop can be activated. This is used if same BAF boot time is required on PD and ED. This delay can be activated using this DCF Client, if key present in DATA section of DCF record is

0x000055AA. For all other values, if DCF client itself is not present then delay is not activated. This DCF record can be programmed multiple times, but only the last instance of the DCF Record will be effective.

57.4.7.8 LINCLK_DOMAIN_SELECTION - BAF LINCLK Synch/Asynch Clock domain selection DCF Client

The BAF parses DCF records. If it finds a record with CS14 set and an address field of 0215h during parsing, BAF selects LINCLK (Linflex Baud Clock) domain according to user setup.

If DCF record is not present or if the DATA section of this DCF record is set to anything other than 0xA5A5, LINCLK must be Synchronous to Linflex System Clock (PBRIDGEx) and will be switched to System Clock Selector, Clock Divider 1 (MC_CGM_SC_DC1). Refer to the Clocking Chapter for more details.

If the DATA section of this DCF record is set to 0xA5A5, LINCLK must be Asynchronous to Linflex System Clock (PBRIDGEx) and will be switched to Auxiliary Clock Selector 0, Clock Divider 4 (MC_CGM_AC0_DC4). Refer to the Clocking Chapter for more details.

57.4.7.9 IVPR1_CPU1 - BAF set IVPR1 for CPU1 DCF Client

The BAF parses DCF records. If it finds a record with CS14 set and an address field of 0216h during parsing, the BAF programs the IVPR1 for CPU1. This DCF client is written with a 32-bit value in DATA section of this DCF record. BAF parses this data value and programs it to IVPR1 for CPU1 just before jumping to application. If this DCF client is not present, then IVPR1 will contain address of BAF vector table. This DCF record can be programmed multiple times, but only the last instance of the DCF Record will be effective.

57.4.8 Optionally perform serial boot

If no boot header is found in any of the locations mentioned above, the BAF determines the Life Cycle status of the device. If the Life Cycle is in CUST_DELIV (Customer Delivery) or JDP/FSL Production, it attempts a serial boot. Otherwise, the boot has failed and BAF issues a destructive reset.

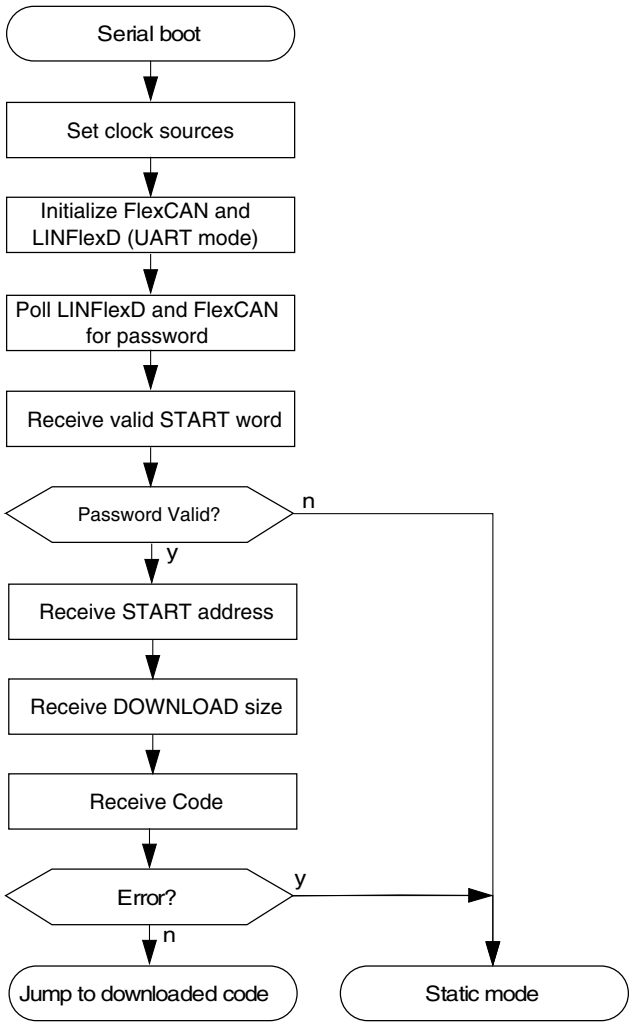

Figure 57-3. Flow of control during serial boot

The clock source in the MC_CGM module is configured and the PADs are set up for LINFlexD and FlexCAN signals (see Serial boot configuration for details), then the code is downloaded using LINFlexD or FlexCAN in Serial Boot mode. In the absence of errors causing the device to be placed in Static mode, the device state is restored to resemble the out-of-reset state and the downloaded code is executed.

Serial boot allows the download of application to internal SRAM via the LINFlexD or FlexCAN interface. After downloading the application image to SRAM, the BAF jumps to the start address provided as part of download protocol mentioned below and executes the downloaded application.

At the start of the process, both LINFlexD and FlexCAN are configured in passive listening mode, connected to the same pair of pads. As soon as the interface receives a valid message, the receiving interface is configured in full Tx and Rx mode. The interface that is not receiving is switched back to its reset state and does not participate further in the serial boot process.

If a CAN message of 8 bytes with ID 11h is received on the or FlexCAN controller first, the BAF program:

- Disables LINFlexD.
- Configures LINFlexD RXD input mux back to reset state.
- Transitions to CAN serial download protocol routine.

If a CAN message is received that does not contain 8 bytes or does not have an ID 11h by the FlexCAN controller, or the FlexCAN controller generates a CAN error, it is probable that the tool is sending a LIN frame. Under such circumstances the BAF program:

- Ignores the CAN message, if a message arrived.
- Clear any pending CAN error.
- Continue monitoring for valid CAN messages.

If any byte from LINFlexD is received first, the BAF program:

- Checks if the first byte is FEh of the password. If not, continue polling. The data may be a valid CAN message.
- If it is first byte of the password (FEh) then disable FlexCAN controller and restore to its reset state.
- Configures FlexCAN pads to their reset state.
- Transition to LINFlexD serial boot (UART mode).

57.4.8.1 Serial boot mode protocol

From a high-level perspective, the download protocol over CAN and LIN interfaces follows steps below:

1. Host transmits the 64-bit password to MCU.
2. Host transmits start address, size of downloaded code in bytes, NO_ECHO bit and VLE bit to MCU.
3. Host transmits a sequence of data bytes that are to be executed.
4. CPU1 executes code from start address provided in 2

NO_ECHO bit signifies if actual download data to be echoed or not. If NO_ECHO bit is set, then data will not be echoed otherwise if NO_ECHO bit is clear, then data will be echoed.

Each step must be complete before the next step starts.

The exact protocol between LinFlex and FlexCAN differs slightly.

57.4.8.2 LINFlexD download protocol

The communication is performed in half-duplex mode, Any transmission from the host is followed by the MCU transmission:

1. The host sends data to the MCU and starts waiting.
2. The MCU echoes the received 8-byte of password, 4-byte of load address and 4-byte of VLE-bit, NO_ECHO bit and 30-bit of download size to the host. The MCU echoes actual download data depending upon NO_ECHO bit.
3. The host verifies whether the echo is correct.
   - If the data is correct, the host can send the next byte of data.
   - If data is not correct, it is assumed the MCU has not correctly received the data and the only practical option is for the Host to reset the MCU and start again.

A more detailed description of these steps follows.

All multi-byte data structures are sent with MSB first.

The tool sends data in the following order:

1. 8 bytes that represent the password.
2. 4 bytes that represent the start address where the code is to be downloaded.
3. 4 bytes that represent the number of bytes to be downloaded, NO_ECHO bit and the VLE bit.
4. x bytes of code that is downloaded to SRAM and executed, (x must match the value specified in 3).

57.4.8.3 FlexCAN download protocol

The FlexCAN download protocol uses very similar structure to the LINFlexD protocol, but it makes use of the message ID's provided by CAN.

The tool sends data packed into standard CAN message in the following manner:

1. A message with 11h as the ID and 8-byte length to send the password. The MCU transmit the same message but with an ID of 1h.
2. A message with 12h as the ID and 8-byte length to send the start address, size of the code, NO_ECHO bit and VLE mode bit. The MCU transmit back the same data but with an ID of 2h.
3. A message with 13h as the ID is used to send data that is to be downloaded to SRAM. The MCU transmit the same data with an ID of 3h.

57.4.8.4 Download 64-bit password and password check

The first 64 bits received represent the password. The MCU only supports public passwords. The received password is always compared with the public password FEED_FACE_CAFE_BEEFh.

- If the correct password is received, BAF continues its task.
- If an incorrect password is supplied, BAF puts the device into static mode(low power safe mode).
- If 64 bits of password data is not received after approximately 30s, BAF causes a destructive reset of the MCU.

57.4.8.5 Download start address, VLE bit, NO_ECHO bit and code size

After the password, the next 8 bytes received by the MCU contains a 32-bit start address, the VLE mode bit, NO_ECHO bit and 30-bit code length as shown in Table 57-25.

The VLE bit (Variable Length Encoding) is used to indicate for which instruction set the downloaded code is compiled. The UART serial boot protocol supports download of VLE Code (VLE = 1) and BookE Code (VLE = 0).

The MCU only supports VLE code, i.e VLE=1.

The NO_ECHO bit is used to indicate if download data should be echoed by the MCU. If the NO_ECHO bit is set (for example, NO_ECHO = 1), then only 8 bytes of password, 4 bytes of download address, and 4 bytes of download size are echoed, but download data is not echoed. If the NO_ECHO bit is clear, then every byte sent to the MCU must be echoed.

The start address defines where the received data is stored and where the MCU branches after the download is finished. BAF ignores the three LSB bits of download address to avoid ECC on download address. But BAF does not align the address while jumping to application for executing. So, download address should be passed as 64-bit aligned for proper execution.

The Length defines how many data bytes have to be loaded.

Table 57-25. Start address, VLE bit, NO_ECHO bit and download size in bytes

Bytes 0-3															
0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Table continues on the next page...

16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
CODE_LENGTH[15:0]															

57.4.8.6 Download data

Each byte of data received is downloaded into device SRAM starting from the address specified in the previous protocol step. It is not verified whether the provided address is a valid address in SRAM or is writable.

The address increments until the number of bytes of data received matches the code length specified in the previous protocol step.

Since the SRAM is protected by 64-bit wide Error Correction Code (ECC), BAF always writes to SRAM grouped in 64-bit double-words. If the last byte does not fall into a 64-bit boundary, the BAF fills it with zero's and renders the data aligned on a 64-bit boundary. After the last data is written to SRAM, the BAF writes a dummy double-word (0000_0000_0000_0000h) to the next address location. This is written to avoid possible ECC error during core prefetch.

57.4.8.7 Execute code

The BAF program waits for the last echo message transmission being completed. Then it restores the initial MCU configuration and jumps to the loaded code at Start Address which was received in step 2 of the protocol. At this point the BAF has finished its tasks and MCU is controlled by new code executing from SRAM.

57.4.9 Serial boot configuration

57.4.9.1 LINFlexD configuration

Boot using UART protocol is implemented by the LINFlexD module.

NOTE

See the pin configuration table at the beginning of this chapter for pins used by the LINFlexD module.

When Serial Boot mode is started the LINFlexD_Rx pin is configured as an input and muxed to the LINFlexD module. The LINFlexD_Tx pin remains in a passive input state until the first byte of protocol is received. It is then configured as an output and muxed to LINFlexD module. The application may not be using the Serial Boot Mode function, and may be using the pin used by LINFlexD_Tx as an input, which may have some external hardware driving the pin. Inadvertently driving this pin as an output would cause contention and possible damage.

The LINFlexD module operates in half-duplex mode. The interface is either transmitting a byte or receiving a byte, but never both at the same time. It is expected that LINFlexD pins are connected to a physical layer bus driver/receiver (PHY). Many PHYs enforce half-duplex mode by using a single data channel for both transmitting and receiving data (such as LIN or CAN). The side effect of this is that all data transmitted on the Tx pin is also received on the Rx pin. To prevent the LINFlexD module from receiving its own transmission, the Rx pin is blocked during transmission.

The LINFlexD controller is configured to operate at a baud rate of f_{XOSC} / 833, using an 8-bit data frame with no parity bit and 1 stop bit.

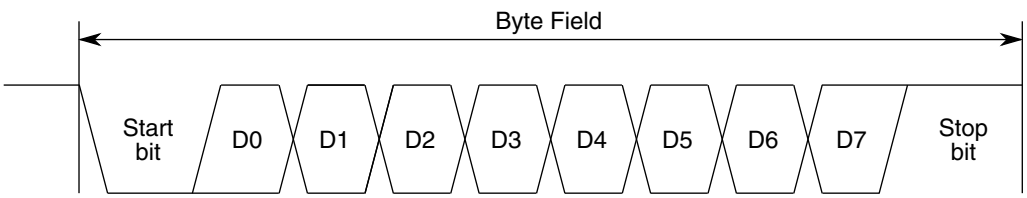

Figure 57-4. LINFlexD bit timing in UART mode

57.4.9.2 FlexCAN configuration

The FlexCAN controller is configured to operate at a baud rate equal to crystal frequency divided by 40, using the standard 11-bit identifier format detailed in CAN 2.0B specification (see Table 57-26 for baud rates).

NOTE

See the pin configuration table at the beginning of this chapter for pins used by the FlexCAN module.

The Bit timing is configured as shown in Figure 57-5.

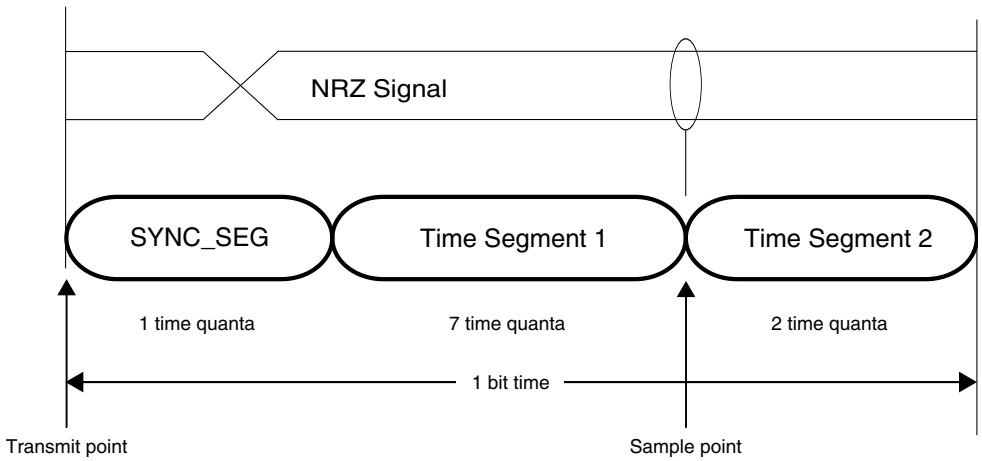

Figure 57-5. FlexCAN bit timing

57.4.9.3 LINFlexD and FlexCAN pin configuration

Please see the BAF configuration at the beginning of this chapter for pin details.

57.4.9.4 Baud rates

The LINFlexD baud rate is set by the frequency of an external crystal oscillator / 833.333. Table 57-26 shows some possible baud rates.

The FlexCAN baud rate is set by the frequency of the external crystal / 40.

Table 57-26. LINFLexD and FlexCAN baud rates

Crystal frequency	LINFlexD baud rate	FlexCAN baud rate
8 MHz	9600 baud	200 kbaud
12 MHz	14,400 baud	300 kbaud
16 MHz	19,200 baud	400 kbaud
20 MHz	24,000 baud	500 kbaud
40 MHz	48,000 baud	1000 kbaud

57.4.9.5 Protocol summary

Table 57-27 summarizes the LINFlexD protocol and BAF action during this boot mode.

Table 57-27. LINFlexD serial boot mode download protocol

Protocol steps	Host message sent	BAF response message	Action
1	64-bit password (MSB first)	64-bit password (MSB first)	Password checked for validity and compared with stored password.
2	32-bit store address	32-bit store address	Load address is stored for future use.
3	VLE bit + NO_ECHO bit + 30 bits of download data size in bytes (MSB first)	VLE bit + NO_ECHO bit + 30 bits of download data size in bytes (MSB first)	Size of download is stored for future use. Verify VLE bit.
4	8 bits of raw binary data	If NO_ECHO bit is set, data is echoed, otherwise data is not echoed.	8 x 8 bits of data are packed into 64-bit double-words. These double-words are stored in SRAM starting from the Load address. The Load address increments until the number of data received and stored matches the size as specified in the previous steps.
5	none	none	Branch to downloaded code

Table 57-28 shows the FlexCAN serial boot protocol.

Table 57-28. FlexCAN serial boot mode download protocol

Protocol step	Host message sent	BAF response message	Action
1	CAN ID 011h + 64-bit password	CAN ID 001h + 64-bit password	Password checked against fixed password (FEED_FACE_CAFE_BEEFh). Watchdog timer is refreshed if the password check is successful.
2	CAN ID 012h + 32-bit store address + 32-bit (1 VLE bit, 1 NO_ECHO bit and 30 bits of download data size in bytes)	CAN ID 002h + 32-bit store address + 32-bit (1 VLE bit, 1 NO_ECHO bit and 30 bits of download data size in bytes)	Load address and size of download are stored for future use.
3	CAN ID 013h + 8 to 64 bits of raw binary data	CAN ID 003h + 8 to 64 bits of raw binary data	Each byte of data received is store in MCU memory, starting at the address specified in the previous step and incrementing until the amount of data received and stored, matched the size as specified in the previous step.
4	None	None	The BAF returns IO pins and CAN module to their reset state, then branches to the first address the data was stored to (As specified in step 2)
5	none	none	Branch to downloaded code

57.5 Resources

- Clocks

    - Several clock configurations are made depending on the boot mode of the BAF. All settings are restored before execution of the application code (in flash memory or received via serial download).

- LINFlexD and FlexCAN
    - The LINFlexD and FlexCAN modules are used if serial boot mode is entered. This can be through failing to find a valid boot header, or from the SER_BOOT_CBACK callback function. All settings are restored before the application code in system RAM is executed.
- CRC
    - The CRC module is used to validate external overlay contents, if and only if the device is an emulation device and the buddy device has been initialized.
- PFLASH
    - PFLash module is used to disable BAF execution.
- Interrupts
    - No interrupts/exceptions are used or enabled, except the Machine Check exception, to handle ECC errors.
- Security watchdog
    - When SWT1 is chosen as security watchdog, SWT3 is used for task monitoring purpose.
- FCCU
    - FCCU is used to configure Fault Reaction of SWT1 and SWT3.

Chapter 58
System Status and Configuration Module (SSCM)

58.1 System Status and Configuration Module (SSCM) chip-specific module information

This section summarizes the System Status and Configuration Module (SSCM) configuration. There is one instance of the SSCM module on the MCU.

The SSCM reads the DCF records during boot, and parses this data to see if valid boot code exists. If the flash memory data from the DCF record is not valid, the boot sequence will automatically switch to the Boot Assist Flash (BAF) and search for serial boot modes.

The device specific reset value for the SSCM_MEMCONFIG register are shown in the table Table 58-1.

Table 58-1. SSCM_MEMCONFIG reset value

Field	Field Definition	Value
JPIN	JTAG Part ID	0346h
MREV	Minor Revision	0001b

Table 58-2 shows the address locations that the SSCM uses to search for startup information.

Table 58-2. SSCM startup information addresses

Description	Address
The location at which the SSCM will look for the UTEST DCF records (UTEST_OFFSET).	0040_0300h
Location of the Boot Assist code in flash memory (BAF)	0040_4000h

Table continues on the next page...

Table 58-2. SSCM startup information addresses (continued)

Description	Address
Locations that are checked for valid Reset Configuration Halfword (RCHW)	0100_0000h 0104_0000h 0108_0000h 010C_0000h 00F9_C000h 00FA_0000h 00FA_4000h 00FA_8000h

The SSCM module has a built-in register protection mechanism that affects the behavior of write operations to one or more registers. After software has activated the protection for a register, writes can only be performed in supervisor mode until the protection is either deactivated by software or the device undergoes reset.

See the Register Protection (REG_PROT) chapter for a detailed description of the register protection mechanism, and SSCM protected registers for the affected SSCM registers.

For the STCU transfer errors that can be indicated by SSCM_STATUS[CER], see the STCU2 chapter section IPS bus interface.

NOTE

The SSCM_STATUS[NXEN1] and [NXEN] fields can only be cleared by asserting JCOMP low (disabling Core Nexus) through the debug tool once Nexus3 access is enabled.

58.2 Introduction

58.2.1 Overview

The System Status and Configuration Module (SSCM) is pictured in the figure below.

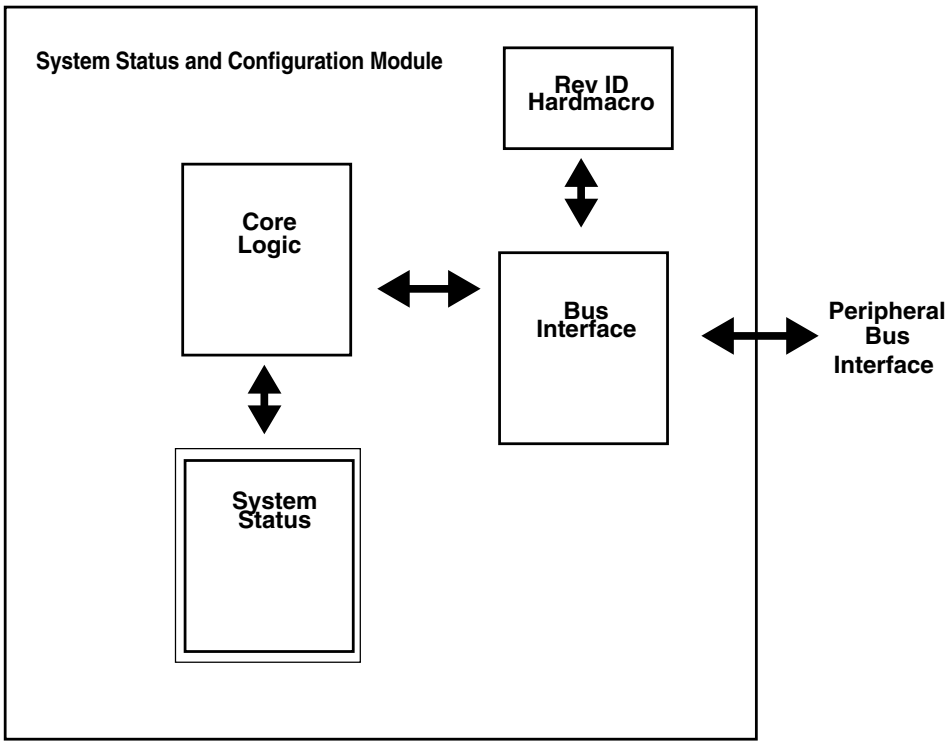

Figure 58-1. SSCM block diagram

58.2.2 Glossary

The table below shows a glossary of terms used through out the text.

Table 58-3. Glossary

Term	Definition
0011b	Binary numbers
0Fh	Hexadecimal numbers
Pin	External physical connection.
Signal	Electronic construct whose state or change in state conveys information.
X	In certain contexts, such as a signal encoding, this indicates a don't care. For example, if a field is binary coded X001b, the state of the first bit is a don't care.
y	y is used for a place holder of 1 hex digit for unknown values.

58.2.3 Features

The SSCM includes these distinct features:

- System Configuration and Status

- Device Mode and System Status
- Determine primary boot vector
- Decodes the Device Life Cycle

- Bus abort enable/disable
- Peripheral abort enable/disable

58.2.4 Modes of operation

The SSCM operates identically in all system modes.

58.3 External signal description

The SSCM has no external pins.

58.4 Memory map and register definition

This section provides a detailed description of all memory-mapped registers in the SSCM.

The table below shows the memory map for the SSCM. Note that all addresses are offsets; the absolute address may be calculated by adding the specified offset to the base address of the SSCM.

NOTE

All registers are accessible via 8-bit, 16-bit or 32-bit reads and/or writes. However, 16-bit accesses must be aligned to 16-bit boundaries, and 32-bit accesses must be aligned to 32-bit boundaries. As an example, the STATUS register is accessible by a 16-bit read or write, SSCM Base + 02h, but performing a 16-bit access to SSCM Base + 0003h is illegal (that is, you should not make any transfer that is not aligned to burst size boundary).

NOTE

SSCM does not generate transfer errors in all memory holes.

SSCM memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	SSCM System Status (SSCM_STATUS)	16	R	See section	58.4.1/2549
2	SSCM System Memory and ID Register (SSCM_MEMCONFIG)	16	R	See section	58.4.2/2551
28	Processor Start Address Register (SSCM_PSA)	32	R	See section	58.4.3/2551
34	Life Cycle Status Register (SSCM_LCSTAT)	32	R	See section	58.4.4/2552

58.4.1 SSCM System Status (SSCM_STATUS)

The System Status register reflects the current state of the system.

Address: 0h base + 0h offset = 0h

Bit	0	1	2	3	4	5	6	7
Read	0	CER	CERS	NXEN1	NXEN	1	Reserved	0
Write		w1c	w1c					
Reset	0	0	0	*	*	1	*	0

Bit	8	9	10	11	12	13	14	15
Read	BMODE			VLE	0	0	0	
Write								
Reset	*	*	*	*	0	0	0	0

* Notes:
- VLE field: Reset value depends on the associated option bits in flash memory.
- BMODE field: Reset value depends on the device status after leaving reset.
- Reserved field: This field can reset to 0 or 1.
- NXEN field: Reset value depends on the device status after leaving reset.
- NXEN1 field: Reset value depends on the device status after leaving reset..

SSCM_STATUS field descriptions

Field	Description
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 CER	Configuration Error This field indicates that the SSCM has detected a configuration error during reset while loading initial device configuration. See the chip-specific SSCM information for details about sources of the error. If a non-permanent error is detected, this bit can be cleared by writing a 1. Refer to CERS-DCF Mechanism section. 0 No configuration problem detected by the SSCM 1 Device configuration is not correct

Table continues on the next page...

SSCM_STATUS field descriptions (continued)

Field	Description
2 CERS	Configuration Error for Safe DCF Clients This field indicates that the SSCM has detected a configuration error during reset while loading the Safe DCF Clients (DCF client with SPRD ADDR enabled, Triple Voting Enabled). If a non-permanent error is detected, this bit can be cleared by writing a 1. Refer to CERS-DCF Mechanism section. 0 No configuration problem detected by the SSCM 1 Device configuration is not correct
3 NXEN1	Processor 1 Nexus enable status 0 Processor 1 Nexus disabled. 1 Processor 1 Nexus enabled
4 NXEN	Processor 0 Nexus enable status 0 Processor 0 Nexus disabled. 1 Processor 0 Nexus enabled
5 Reserved	This field is reserved. This read-only field is reserved and always has the value 1.
6 Reserved	This field is reserved. This field is for internal use. Users should ignore read values and should not attempt to write the field.
7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8–10 BMODE	Device Boot Mode This field is only updated during reset. 101 Boot from BootFlash
11 VLE	Variable Length Instruction Mode When booting in SC mode, this field indicates that the code stored in the flash memory is using the VLE instruction set. The value of this field is determined by the RCHW field of the flash memory boot sector. **NOTE:** Reset value depends on the associated option bits in flash memory. 0 SC Boot Location contains standard PPC code 1 SC Boot Location contains VLE code
12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

58.4.2 SSCM System Memory and ID Register (SSCM_MEMCONFIG)

The System Memory and ID register is a read-only register which reflects the memory configuration of the system. It also contains the JTAG ID.

Address: 0h base + 2h offset = 2h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	JPIN										1	MREV				0
Write																
Reset	*	*	*	*	*	*	*	*	*	*	1	*	*	*	*	0

* Notes:
- MREV field: Reset value can be found in the SSCM Configuration section.
- JPIN field: Reset value reflects the JTAG ID of the device.

SSCM_MEMCONFIG field descriptions

Field	Description
0–9 JPIN	JTAG Part ID Number **NOTE:** Reset value reflects the JTAG ID of the device.
10 Reserved	This field is reserved. This read-only field is reserved and always has the value 1.
11–14 MREV	Minor Mask Revision
15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

58.4.3 Processor Start Address Register (SSCM_PSA)

Address: 0h base + 28h offset = 28h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	SADR																															
W																																
Reset	*	*	*	*	*	*	*	*	*	*	*	*	*	*	*	*	*	*	*	*	*	*	*	*	*	*	*	*	*	*	*	*

* Notes:
- SADR field: Reset value is the start address

SSCM_PSA field descriptions

Field	Description
0–31 SADR	Processor Start Address The boot processor will start executing application code from this address.In SC mode this indicates the location determined by the RCHW search. In BAF mode this will show the start address of the BAF code.

58.4.4 Life Cycle Status Register (SSCM_LCSTAT)

Address: 0h base + 34h offset = 34h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0						Reserved		0					LC		
W																
Reset	0	0	0	0	0	0	*	*	0	0	0	0	0	*	*	*

* Notes:
- LC field: Reset value is the Life Cycle of the device, and is unaffected by reset.
- Reserved field: Reset Value is '11' for a valid secured part.

SSCM_LCSTAT field descriptions

Field	Description
0–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22–23 Reserved	This field is reserved.
24–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29–31 LC	Life Cycle Determined by the SSCM by reading the LC slots. The encoding is: 000 Failure Analysis 001 Reserved 010 OEM Production 011 Customer Delivery 100 Reserved 101 Reserved 110 Freescale Production 111 In Field

58.5 Functional description

The primary purpose of the SSCM is to provide information about the current state and configuration of the system that may be useful for configuring application software and for debug of the system.

58.5.1 CERS-DCF Mechanism

The figure below shows that a faulty DCF record has been loaded between the original DCF record set and the final DCF record set. When a faulty DCF record is encountered, the SSCM_STATUS[CERS] field indicates that the device configuration is not correct. In a situation like the one shown below, CERS can be cleared by writing 1 to it, as long as the final DCF record set is correct.

If there is an error in the final set of loaded DCF records, CERS cannot be cleared. This situation indicates that the final DCF record set has at least one error. To fix this, the user should update flash memory after the faulty DCF record with a correct DCF record of the same type. For example, if the faulty DCF record is DCF2, then the correct DCF record should also be DCF2.

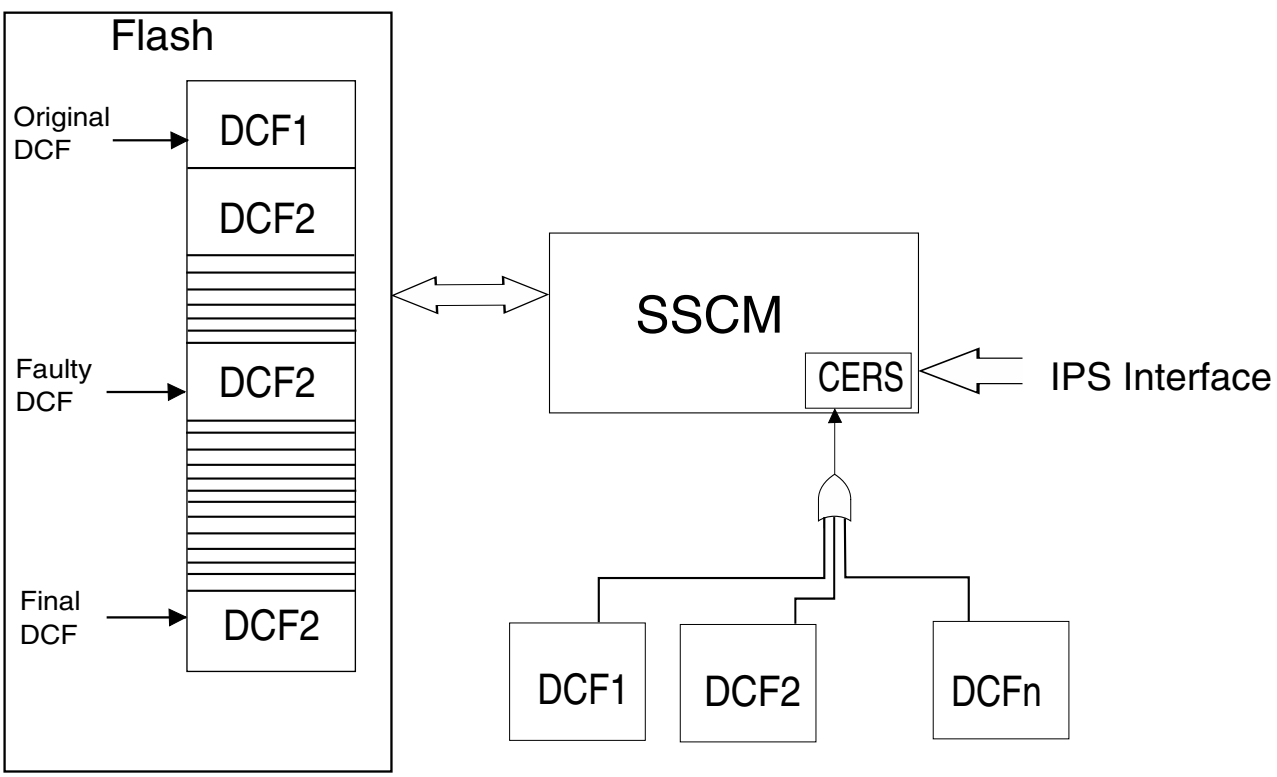

Figure 58-6. DCF Error and CERS Handling

58.5.2 ECC error monitoring

During flash memory scanning (such as Life Cycle or DCF records), the SSCM will monitor the flash memory status signals for ECC and other unexpected access errors. If such an error occurs, the SSCM will:

- Request a destructive reset
- Signal the FCCU or MEMU.

NOTE

For differential region, if any valid DCF records are programmed then there will be checked for ECC and stop record for DCF would not be checked for ECC.

58.5.3 Boot mode functionality

The device supports the following boot modes for the main boot core:

- Boot Assisted by Flash (BAF) - The device will boot from UTest NVM Flash Block, and perform device setup.

If booting is not possible with the selected configuration (for example, no Boot ID is found in the selected boot location) then the device will enter static mode.

58.5.4 BAF configuration

By default the device will boot from BAF.

In BAF mode (SSCM_STATUS[BMODE]=101b), the boot core will start executing BAF code at the location shown in the configuration section of the “Boot Assist Flash (BAF)” chapter.

58.5.5 Life Cycle

The SSCM will determine the Life Cycle (LC) of the device by reading the LC slots from the UTEST flash memory. The read operation is done during the reset phase with normal timings and it is protected by operating monitors and ECC check. In addition, a set of sanity checks executed over the LC read data guarantee the integrity of the final LC value.

At the end of the reset phase, the LC can have one of the following values:

- Freescale Production
- Customer Delivery
- OEM Production
- In Field
- Failure Analysis

Life cycle can only be moved in the direction shown below:

Figure 58-7. Life cycle sequence

The LC is written into 5 slots, 128 bits each, at fixed locations in the UTEST flash memory block. Each LC slot is read in one single atomic operation and it is organized into two fields:

- the valid field
- the invalid field

Depending on the possible combination of the data programmed into these fields, each LC slot can have one of the possible 4 statuses as seen in Table 58-9.

Table 58-9. LC slot status

LC slots		LC slot value
Valid field (64 bits)	Invalid field (64 bits)	
Erased	Erased	Erased
Marked	Erased	Active
Marked	Marked	Inactive
Any other values		Illegal

"Marked" in this case means that the value has been programmed with the bit pattern 55AA_50AF_55AA_50AFh. "Erased" is detected by the bit pattern FFFF_FFFF_FFFF_FFFFh. Table 58-10 shows how the slots are arranged in memory.

Table 58-10. LC slots in memory

Offset	LC slot word
00h	Valid[31:0]
04h	Valid[63:32]
08h	Invalid[31:0]
0Ch	Invalid[63:32]

The Life Cycle is determined as shown in Table 58-11. The priority of the entries is from top to bottom, so the first row that applies determines the resulting Life Cycle.

NOTE

"Erased" means the slot returns all 1s.

Table 58-11. LC slots

LC slot 0 Freescale Production	LC slot 1 Customer Delivery	LC slot 2 OEM Production	LC slot 3 In Field	LC slot 4 Failure Analysis	Resulting life cycle
Active	Erased	Erased	Erased	Erased	Freescale Production
Inactive	**Active**	Erased	Erased	Erased	Customer Delivery
Inactive	Inactive	**Active**	Erased	Erased	OEM Production
Inactive	Inactive	Inactive	**Active**	Erased	In Field
Inactive	Inactive	Inactive	Inactive	**Active**	Failure Analysis
Erased	Erased	Erased	Erased	Erased	System Reset
Invalid[1]	Invalid	Invalid	Invalid	Erased	In Field
Invalid	Invalid	Invalid	Invalid	Not Erased	System Reset

1. Any value programmed other than shown in table above for Erased, Active, and Inactive would be treated as illegal.

NOTE

When programming Life Cycle, ensure that programming is not interrupted and can complete without error.

58.6 Initialization and application information

58.6.1 Reset

The reset state of each individual bit appears in the detailed register descriptions.

58.7 Additional safety measures

58.7.1 Spurious reset protection

The SSCM implements protection against spurious module resets (for example, resets which only effect the SSCM, but not other modules) by gating the state machines status with the expected status of the MC_RGM. If a spurious reset occurs, the SSCM will not interfere with the flash memory bus or overwrite configuration registers. However, internal SSCM status will be lost.

Chapter 59
Power Management

59.1 Overview

The MPC5746R microcontroller includes a robust power management infrastructure that enables applications to select among various operational modes and to monitor internal voltages for high- and low-voltage conditions. The monitoring capability is also used to ensure supply voltages and internal voltages are within the required ranges before the microcontroller can exit RESET. This chapter gives an overview of the built-in power management features.

The power management infrastructure comprises the following modules:

- Power Control Unit (MC_PCU)
- Power Management Controller (PMC)

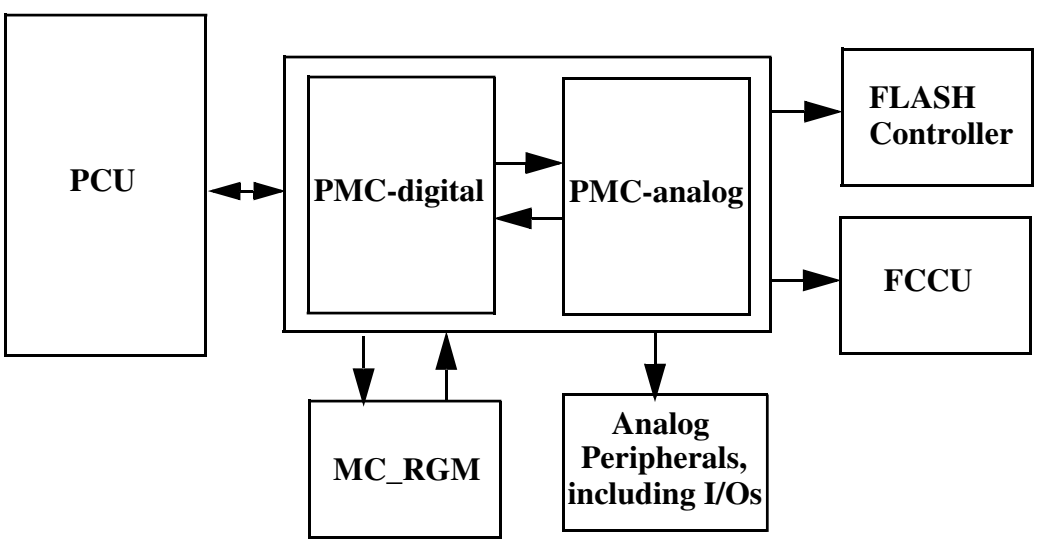

Figure 59-1. Power Management Overview

This chapter describes the module interaction in brief. For complete details, see the respective module chapters.

59.1.1 Power Management Controller (PMC)

The Power Management Controller implements a linear voltage regulator to generate the internal 1.25V digital supply from an external 3.5V to 5.5V supply and monitors various supply voltages of the MPC5746R chip for functional safety purposes. An additional regulator for the flash block is also within the PMU to provide the necessary 3.3V source to the FLASH module. Another internal regulator is present and generates a clean 1.26V supply for the LFAST PLL, as shown in the diagram in the next section. Depending on the supply voltages, power-on-reset (POR) and destructive/functional resets may be generated.

The PMC connects to the Reset Generation Module (MC_RGM), the Fault Collection Control Unit (FCCU) and the flash memory controller. The on-chip ADC receives signals from the PMC for diagnostic purposes.

59.1.2 Supply Concept

MPC5746R provides an on-chip regulator to derive the core supply from the external supply. A power transistor must be added on the PCB. See the MPC5746R Data Sheet for specifics on this device. Alternatively, an external linear or switching regulator can be used. The analog supply needs to be protected from noise on the digital supply at least by means of a decoupling capacitor. Better filters can be used if they do not affect regulator stability. A separate regulator for the analog supply is preferred.

Each of the PMC monitors supply voltage and release the resets when they are within the limits of operating conditions. The power-on-reset can be generated on-chip or can be provided from an external source, such as a brownout device.

Some supplies may already be connected internally inside the package depending on the package type, mainly in order to save pins in low pin count packages.

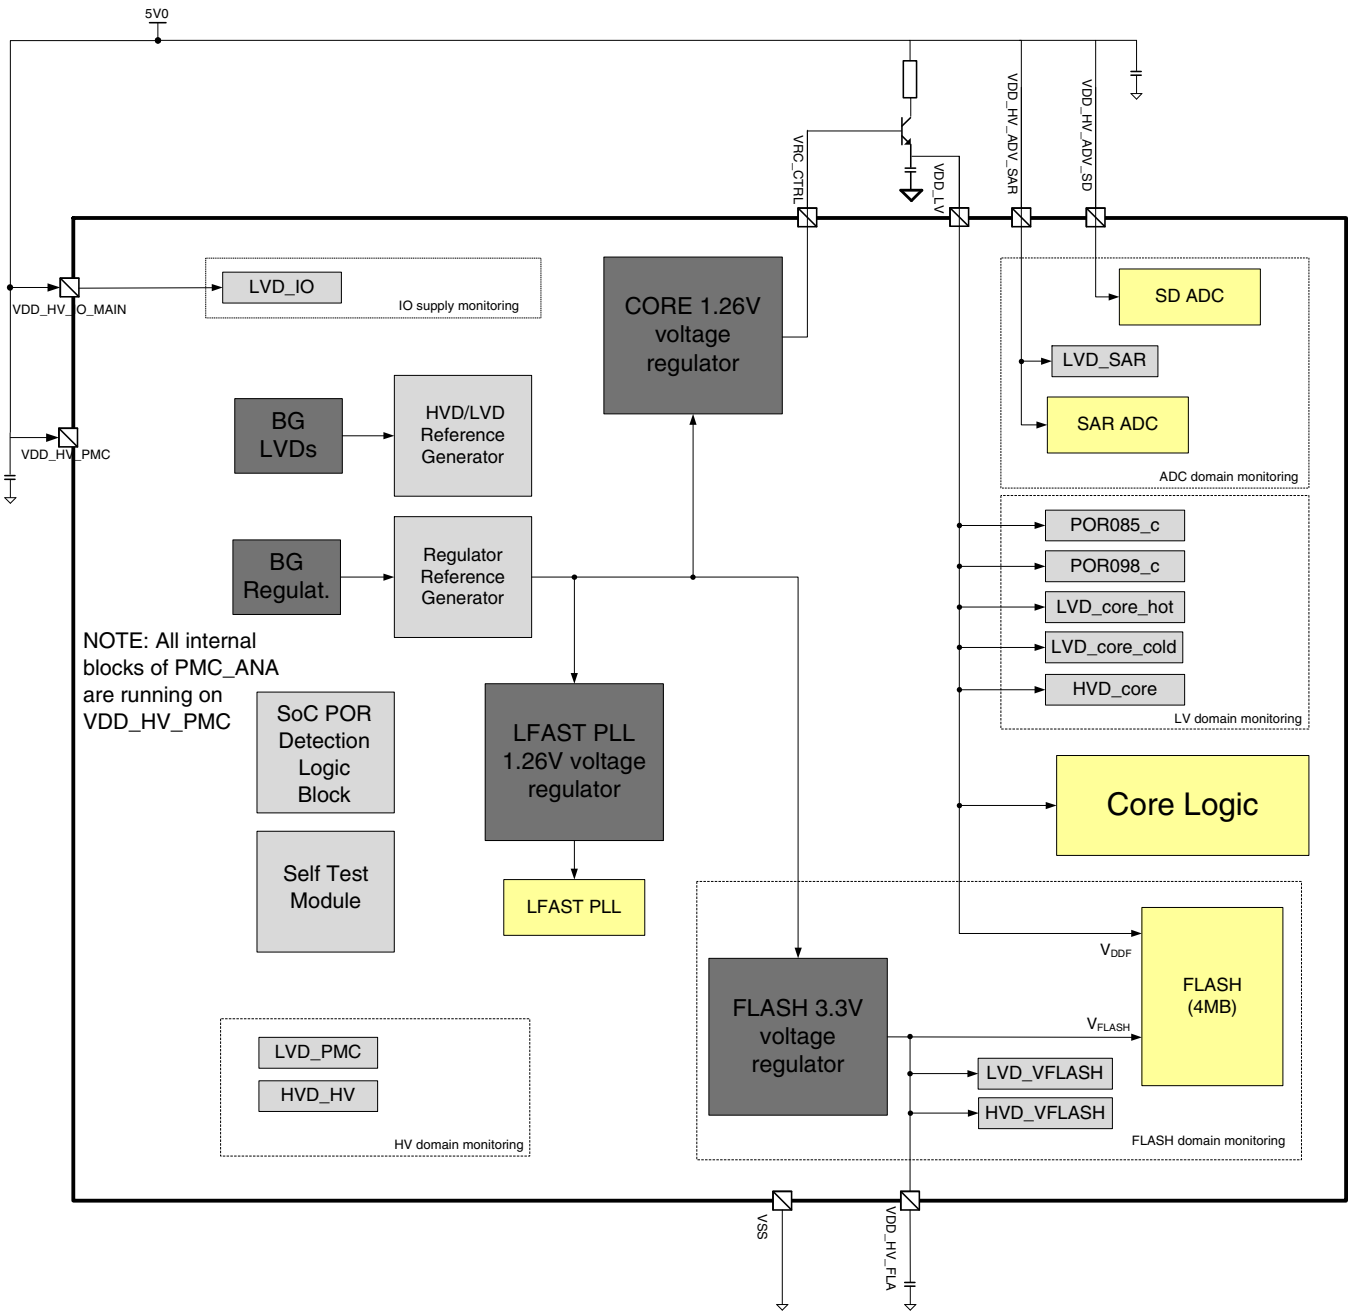

Figure 59-2. Supply concept

59.1.3 Power Modes

MPC5746R does not support ultra low-power modes that require power gating or separate power domains. The core logic implements STOP and low frequency power saving modes. A sudden transition to these low power modes from RUN mode (or vice versa) may result in de-stabilization of the core supply voltage regulator, which may

trigger LVD/HVD. It is therefore recommended to use PCFS (refer to MC_CGM chapter) to gradually change the system clock frequency and avoid sharp changes in the current load on the regulators.

59.1.4 External Supply

If an external regulator is used for VDD_LV supply, the Bipolar Junction Transistor (BJT) should be removed from the board. In that case, writing to the UTEST bit is required to disable the internal voltage regulator driver, which will remain active until RGM phase 3 (where the UTEST configuration is read). The VRC_CTRL pin may be left floating when using an external voltage regulator on VDD_LV supply.

59.1.5 Voltage Monitoring

The PMC senses the supply voltages continuously to keep the chip in safe operating range. Destructive or functional reset, depending on the PMC_RES register, or alternatively interrupts, are triggered when the voltage exceeds or falls below the limits defined by recommended electrical operating conditions. Please refer to the PMC_REE and PMC_RES register descriptions in the PMC_dig chapter for more details.

59.1.5.1 Core Supply Monitor

The digital core supply range is compared with a low and high voltage limit.

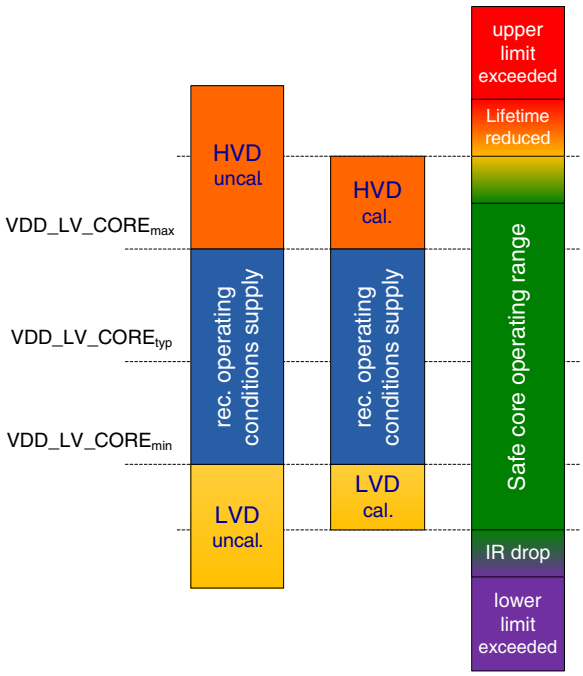

Figure 59-3. Core Supply Monitoring

The digital core is able to operate between the limits given by the MPC5746R Data Sheet. The lower limit is reduced by the amount of on-chip IR drop, that must be granted. The upper limit is defined by the beginning of lifetime degradation.

The available range for external supply voltage is further restricted by the tolerance of high (HVD) and low voltage monitors (LVD). See the MPC5746R Data Sheet for exact values. To ensure safe operating conditions for the core, the LVDs/HVDs are calibrated. Calibration of LVD/HVD takes places after the core is in the functionally safe operating range. It is performed in a way that LVD/HVD cover the allowed core operating range, i.e. by increasing the minimum value for LVD and decreasing the maximum value for HVD.

If LVD and HVD are disabled, the external core supply can have an extended operating range. External voltage monitors shall be used in that case to ensure functional safety. LVDs can be disabled using REE configuration in the UTEST area, and this is applied in RGM phase 3, before which the LVDs are still enabled (by default).

The LVD on the core supply is duplicated to monitor two points in the design: the maximum IR drop point (LVD_CORE_HOT) and the input voltage on the device point (LVD_CORE_COLD).

The core LVD/HVDs shall provide sufficient hysteresis or low-pass characteristic to prevent bouncing in case of short duration core supply over/undershoot.

59.1.5.2 IO, REG and other High Voltage Supplies Monitor

All 5 V supplied modules must remain fully functional in an extended operating range that includes the LVD calibrated tolerance. Calibration takes place when the core supply is within a safe operating range. After calibration, the typical LVD value is centered within the recommended operating conditions low limit and the safe operating conditions low limit to provide margins for supply undershoots.

If LVDs are disabled, external voltage monitors shall be used to ensure functional safety. The LVDs shall provide sufficient hysteresis or low-pass characteristic to prevent bouncing in case of short duration 5 V supply undershoots.

NOTE

All voltage monitors cannot be disabled; some of them are always active. Refer to "Voltage monitor electrical characteristics" in the Data Sheet for more details.

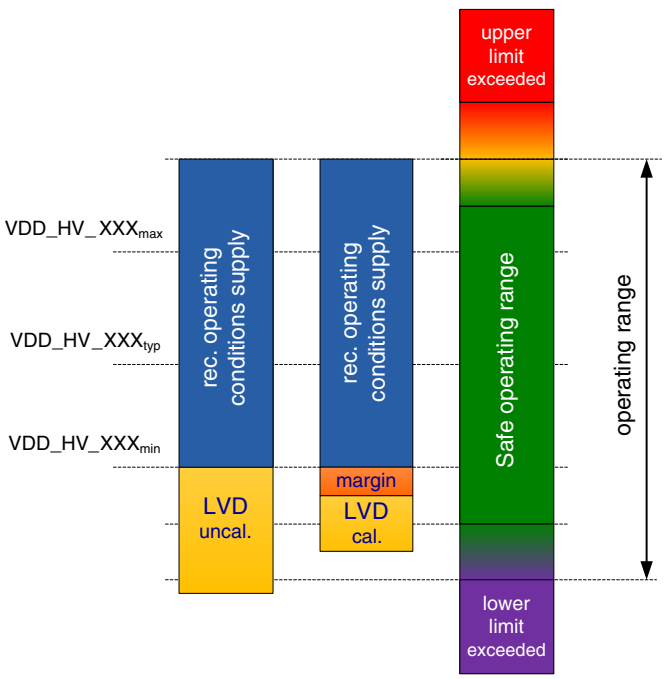

Figure 59-4. High Voltage Supply Monitoring

59.1.6 PMC Power-on Reset

The Power-on Reset (POR) Generator is required to initialize the chip during supply rise. It is a voltage monitor which detects if a supply exceeds a defined threshold voltage level. The POR checks the core voltage supply VDD_LV and the regulator supply VDD_HV_PMC. When both supplies have reliable levels for operation of the PMC and RESET generator, the internal PMC blocks, including LVD/HVD, are activated.

The POR watches the rising edge of the supply before the recommended operating conditions are reached. The POR shall function correctly even if the supply voltage is non-monotonic. It includes sufficient hysteresis to avoid bouncing in case of slow supply ramps. Within the safe operating conditions, the LVDs/HVDs take control over reset generation.

59.1.7 SoC Power-on Reset

The POR needs to hold the device in reset regardless of how slow the supply rise time is, until the point at which the soc_por is designed to release.

The figure below explains the logic for the generation of soc_por_b to the RGM, where soc_por_b is the combination of all of the PORs and auxiliary PORs from the analog PMC block and combinations of essential LVDs.

LVDs:

1. LVD_IO_MAIN for IRC and PORST / RESET pads
2. LVD_HV for PMC
3. LVD_FLASH for Flash

SOC_POR_MASK is the PMC self-test mode that overrides all POR/LVDs, and hence voltage monitoring will be disabled during LVD/HVD self-test.

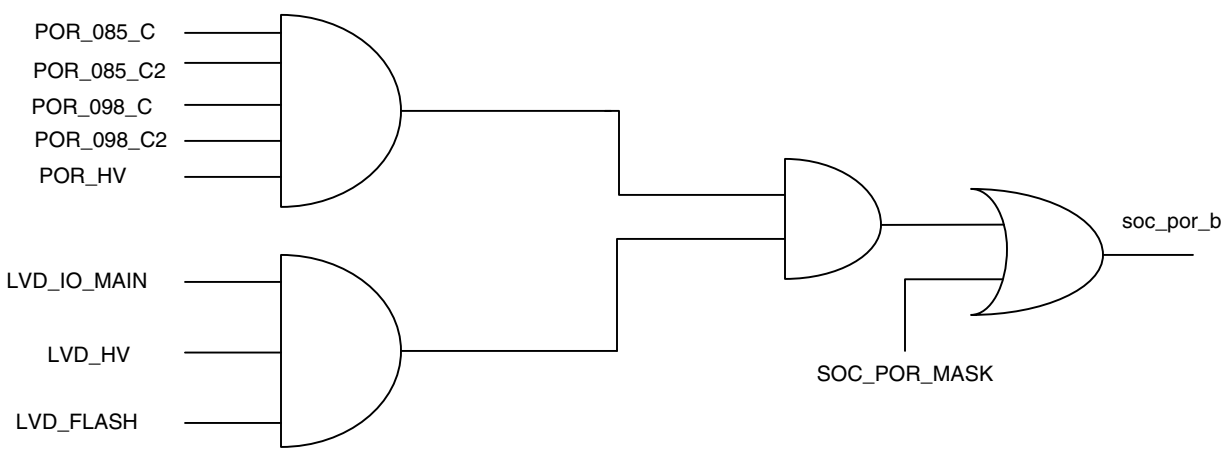

Figure 59-5. SoC POR Logic

59.1.8 Power-up Sequence

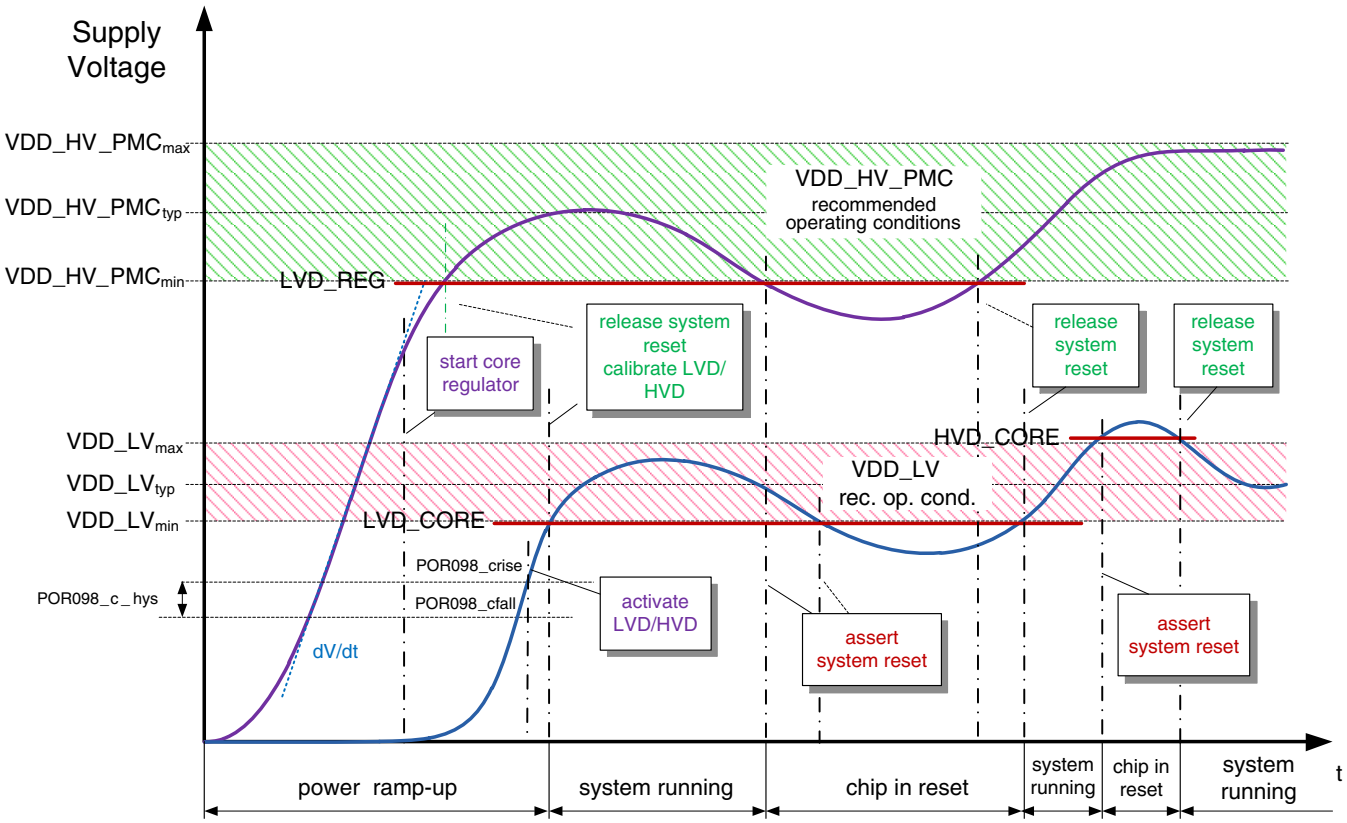

Figure 59-6. Chip Power-on RESET sequence timing diagram

The power-up sequence runs whenever the system will get through a power cycle or external reset.

When the VDD_HV_PMC voltage exceeds the POR_HV rising edge threshold, all HV LVDs are reset to their uncalibrated state and armed. The core voltage regulator CORE_REG starts to work and the core supply voltage rises.

When the core voltage crosses the POR098_c rising edge threshold, the core LVDs and HVDs are reset to their uncalibrated state and armed.

When the core supply and the regulator voltage reach their minimum value according to the recommended operating conditions, the system reset is released and the system boot process starts. The LVDs/HVDs are now calibrated during RGM phase 3 to provide tighter limits for voltage overshoot/undershoot detection.

As soon as the core or any supply (on which voltage monitoring is enabled) falls below the limit of the corresponding LVD thresholds, a reset is triggered; the type of reset is determined by the configuration. The system is held in reset state until all LVD threshold

levels are exceeded again. If the voltage exceeds the threshold of the HVD (on VDD_LV, VDD_HV_PMC or ADC supplies, which have HVD monitoring), a destructive reset is asserted. It is released when the voltage falls below the HVD threshold.

When core or regulator supply fall below the POR098_c or LVD_PMC falling edge limit, respectively, the system is reset and core supply is disabled. The chip will restart with a complete power-up cycle. The chip goes into a power-up cycle if any of the PORs or essential LVDs are triggered. These are:

1. All PORs and auxiliary PORs

2. LVDs:

-a. IO_MAIN for IRC and PORST / RESET pads

-b. PMC

-c. CORE_HOT

-d. Flash

59.1.9 ADC Interface

The ADC interface provides the PMC internal voltages for diagnostic purposes. The analog multiplexer and the buffer is inside the PMC. The SAR ADC0 converts the selected voltage, which can then be evaluated by the CPU. Refer to the PMC_dig chapter, PMC_ADC_CS register description for details.

Table 59-1. ADC interface

S.No.	pmc_adc_ch_sel[5:0]	ADC Channel Output	Expected Value
0	6'b000000	ADC Channel OFF

59.1.10 Safety Measures

The PMC implements a self-test architecture. In this test, all LVD/HVD voltage comparators are checked for stuck-at level faults by artificially triggering them to trip and checking that the comparator trips in both directions. Self-test is triggered automatically on each POR/destructive reset, and can be triggered by the user's software. The self-test will generate non-critical faults, which are collected in the FCCU module. There is also a UTEST bit which, if enabled, will cause a destructive reset if PMC self-test fails. The default state of the UTEST bit is "disabled".

Parts of the PMC design that can act as a single point of failure are replicated, such as the analog voltage reference generation circuits.

Various internal voltages can be monitored during PMC operation, with assistance of the ADC.

The PMC provides a signal that keeps the I/O pads in a reset condition if any of the voltage monitors is triggered, and the system goes into the destructive reset state.

Chapter 60
Power Management Controller digital interface (PMC_dig)

60.1 PMC_dig chip-specific module information

The Power Management Unit (PMU) implements a linear voltage regulator to generate the internal 1.25V digital supply from an external 3.5V to 5.5V supply. It also contains an option to bypass this regulator and instead use an externally supplied 1.25V input.

An additonal regulator for the flash block is also within the PMU to provide the 3.3V source necessary to the FLASH module.

Various voltage monitors also reside within the PMU, allowing the visibility of internal regualting points and external supplies. Other functional blocks such as the Power On reset (POR) are also available.

60.1.1 PMC registers whose reset values can be defined by DCF clients

Reset values for the following PMC registers are defined by the corresponding DCF clients:

- **PMC_REE_TD**: DCF_PMC_REE_TD DCF client
- **PMC_REE**: DCF_PMC_REE_CTRL DCF client
- **PMC_RES**: DCF_PMC_RES_CTRL DCF client

60.1.2 PMC registers with chip-specific reset values

The following PMC registers have chip-specific register values:

- **PMC_REE_TD**: 0x0000_0000 with DCF_PMC_REE_TD at default value
- **PMC_REE**: 0x0000_4052 with DCF_PMC_REE_CTRL at default value

- **PMC_RES**: 0x0000_0000 with DCF_PMC_RES_CTRL at default value
- **PMC_ADC_CS**: 0x0000_0100

60.1.3 Self test bit definition

The PMC_SELF_TEST_UM_VD_REG[VD_ST_CTRL] field is defined as follows for this chip.

Table 60-1. PMC_SELF_TEST_UM_VD_REG[VD_ST_CTRL] field bit definition

Field Value	Tested LVD/HVD
000000	Functional mode
000001	por085_core comparator test
000010	por098_core comparator test
000011	por085_core2 comparator test
000100	por098_core2 comparator test
000101	lvd_core_cold comparator test
000110	lvd_core_hot comparator test
000111	hvd_core comparator test
001000	por260_core comparator test
001001	por260_core2 comparator test
001010	lvd_pmc comparator test11
001011	hvd600_core comparator test
001100	lvd_flash comparator test
001101	hvd_flash comparator test
001110	lvd_io comparator test
001111 to 010001	Reserved
010010	lvd_sar_adc comparator test
010011 to 111111	Reserved

60.2 PMC introduction

The power management controller (PMC) consists of two blocks: an analog power management block (and a digital controller for the analog block).

The PMC_dig block contains all of the registers and digital logic to generate all of the enable signals, trim control bits, reset generation, and test mode logic for the analog block. The PMC digital logic also contains the controls for PMC analog outputs to be sensed with the ADC module.

In addition, the PMC digital logic contains the enable signals, trim bits and other registers for the temperature sensor. There are also several custom interfaces to various other blocks: The Reset Generation Module (RGM) block receives the LVD values during POR to use for phase transition conditions.

60.2.1 Features

The PMC module provides:

- Configuration and control information to the analog PMC block.
- An interface with Flash memory for retrieval of trim/control information, during POR, for HVDs, LVDs, regulators, and voltage bandgap.
- Configuration and monitoring of the two temperature sensors.
- Interrupt or reset generation for HVDs and LVDs (based on the configuration).
- Host access, via the IPS bus, to all register controls, configurations, and status.
- Self test logic for the LVDs and HVDs.
- Software triggered fault injection to the FCCU for LVDs, HVDs, temperature sensors, and LVD self test.
- 50MHz ipg clock frequency.
- Status and Control Register: LVD (Low-voltage detection) and HVD (high-voltage detection) for:-
  - PMC voltage supply (VDD_HV_PMC) - LVD
  - VDD core voltage supply - POR/LVD/HVD
  - VDD ADC voltage supply - LVD/HVD
  - Flash memory voltage supply - LVD
  - Oscillators/PLL voltage supply - LVD
  - VDDIO I/O voltage supply - LVD
- Status and control Register for Bandgap voltage reference:
  - LVDs and HVDs
  - ADC voltage reference channel
- DCF Client interface: An interface with Flash memory for retrieval of PMC configuration information from UTEST

60.3.1 Temperature Sensor Interrupt Enable Register (PMC_TS_IER)

This configuration register contains a set of Interrupt Enable bits that correspond to each of the Temperature Sensor Event Status Registers (TS_ESR). These bits indicate whether an interrupt occurs when the voltage event is seen. A '0' indicates that no interrupt is to be sent, and a '1' indicates that an interrupt will occur when the voltage detect event occurs. These bits are enabled via a write of one to the MSB of this register (IE_EN). After this, these bits can be read or written at any time.

Address: 0h base + A4h offset = A4h

PMC_TS_IER field descriptions

Field	Description
31 TS_EN	Temperature Sensor interrupts Enable 0 Temperature sensor interrupts are not enabled. 1 Enable temperature sensor interrupts.
30–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4 TS1_2IE	Temperature Sensor 1 input 2 Interrupt Enable. This bit determines whether an interrupt is seen by the system when the temperature rises above its corresponding threshold (flag1). 0 No interrupt. 1 Interrupt occurs.
3 TS1_0IE	Temperature Sensor 1 input 0 Interrupt Enable.

Table continues on the next page...

PMC_TS_IER field descriptions (continued)

Field	Description
	This bit determines whether an interrupt is seen by the system when the temperature falls below its corresponding threshold. 0 No interrupt. 1 Interrupt occurs.
2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 TS0_2IE	Temperature Sensor 0 input 2 Interrupt Enable. This bit determines whether an interrupt is seen by the system when the temperature rises above its corresponding threshold (flag1). 0 No interrupt. 1 Interrupt occurs.
0 TS0_0IE	Temperature Sensor 0 input 0 Interrupt Enable. This bit determines whether an interrupt is seen by the system when the temperature falls below its corresponding threshold. 0 No interrupt. 1 Interrupt occurs.

60.3.2 Temperature Event Status register (PMC_ESR_TD)

This Event Status Register indicates the past state of the two temperature sensor signals. If the temperature event has ever passed the trigger event since the last clearing event, the flag bit is set. In order to clear the flag, a one must be written to the flag bit that needs to be cleared.

Address: 0h base + A8h offset = A8h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

PMC_ESR_TD field descriptions

Field	Description
31–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4 TEMP1_2	Temperature sensor 1 status flag 2. This bit is the temperature status flag associated with the temperature for the temperature sensor 1 point (150C). It is asserted when the temperature exceeds its corresponding threshold. It gets cleared by writing one to this same bit location, even if the temperature is still above the threshold.

Table continues on the next page...

PMC_ESR_TD field descriptions (continued)

Field	Description
	If the IER[TS1_2IE] bit is also asserted, an interrupt is sent to the CPU. If REE_TD[TEMP1_2} is also asserted, a system reset is generated, which clears IER[TS1_2IE] and negate the interrupt request. If REE_TD[TEMP1_2] is asserted and a destructive reset is selected (via RES_TD[TEMP_2] being 0), then a destructive reset is generated. If RES_TD[TEMP1_2] is set, then a functional reset is generated. 0 Currently no occurrence. 1 Temperature occurrence detected.
3 TEMP1_0	Temperature sensor 1 status flag 0. This bit is the temperature status flag associated with the temperature for the cold temperature sensor 1 point. It is asserted when the temperature gets below its corresponding threshold. It gets cleared by writing one to this same bit location, even if the temperature is still below the threshold. If the IER[TS1_0IE] bit is also asserted, an interrupt is sent to the CPU. If REE_TD[TEMP1_0] is also asserted, a system reset is generated, which clears IER[TS1_0IE] and negate the interrupt request. If REE_TD[TEMP1_0] is asserted and a destructive reset is selected (via RES_TD[TEMP_0] being 0), then a destructive reset is generated. If RES_TD[TEMP1_0] is set, then a functional reset is generated. 0 Currently no occurrence. 1 Temperature occurrence detected.
2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 TEMP0_2	Temperature sensor 0 status flag 2. This bit is the temperature status flag associated with the temperature for the temperature sensor point (150C). It is asserted when the temperature exceeds its corresponding threshold. It gets cleared by writing one to this same bit location, even if the temperature is still above the threshold. If the IER[TS0_2IE] bit is also asserted, an interrupt is sent to the CPU. If REE_TD[TEMP0_2 is also asserted, a system reset is generated, which clears IER[TS0_2IE] and negate the interrupt request. If REE_TD[TEMP0_2] is asserted and a destructive reset is selected (via RES_TD[TEMP0_2] being 0), then a destructive reset is generated. If RES_TD[TEMP_2] is set, then a functional reset is generated. 0 Currently no occurrence. 1 Temperature occurrence detected.
0 TEMP0_0	Temperature sensor 0 status flag 0. This bit is the temperature status flag associated with the temperature for the cold temperature sensor point. It is asserted when the temperature gets below its corresponding threshold. It gets cleared by writing one to this same bit location, even if the temperature is still below the threshold. If the IER[TS0_0IE] bit is also asserted, an interrupt is sent to the CPU. If REE_TD[TEMP0_0] is also asserted, a system reset is generated, which clears IER[TS0_0IE] and negate the interrupt request. If REE_TD[TEMP0_0] is asserted and a destructive reset is selected (via RES_TD[TEMP0_0] being 0), then a destructive reset is generated. If RES_TD[TEMP0_0] is set, then a functional reset is generated. 0 Currently no occurrence. 1 Temperature occurrence detected.

60.3.3 Temperature Reset Event Enable register (PMC_REE_TD)

This Reset Event Enable Register controls whether the temperature detect signal event causes a reset. If the desired flag bit is enabled, the temperature detect event causes a reset to be generated when the selected temperature passes the trigger event.

These bits are loaded from the flash during the boot sequence. If the flash loaded bits are programmed to be enabled (set), these bits cannot be disabled (cleared). If the flash loaded bits are programmed to be disabled (clear), these bits cannot be enabled (set).

Address: 0h base + ACh offset = ACh

PMC_REE_TD field descriptions

Field	Description
31–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4 TEMP1_2	Temperature sensor 1 detect assertion reset enable 2. This bit defines whether a temperature detect assertion generates a system reset. The RES_TD[TEMP1_2] bit determines whether the reset is functional or destructive. 0 Disabled. Temperature Sensor detect does not cause system reset. 1 Enabled. Temperature Sensor detect causes system reset.
3 TEMP1_0	Temperature sensor 1 detect assertion reset enable 0.

Table continues on the next page...

PMC_REE_TD field descriptions (continued)

Field	Description
	This bit defines whether a temperature detect assertion generates a system reset. The RES_TD[TEMP1_0] bit determines whether the reset is functional or destructive. 0 Disabled. Temperature Sensor detect does not cause system reset. 1 Enabled. Temperature Sensor detect causes system reset.
2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 TEMP0_2	Temperature sensor 0 detect assertion reset enable 2. This bit defines whether a temperature detect assertion generates a system reset. The RES_TD[TEMP0_2] bit determines whether the reset is functional or destructive. 0 Disabled. Temperature Sensor detect does not cause system reset. 1 Enabled. Temperature Sensor detect causes system reset.
0 TEMP0_0	Temperature sensor 0 detect assertion reset enable 0. This bit defines whether a temperature detect assertion generates a system reset. The RES_TD[TEMP0_0] bit determines whether the reset is functional or destructive. 0 Disabled. Temperature Sensor detect does not cause system reset. 1 Enabled. Temperature Sensor detect causes system reset.

60.3.4 Temperature Reset Event Selection register (PMC_RES_TD)

This Reset Event Select Register controls whether the temperature sensor detect signal event causes a destructive or functional reset. If the desired flag bit is enabled, the temperature sensor event causes either a destructive or functional reset to be generated when the selected temperature passes the trigger event.

Address: 0h base + B0h offset = B0h

PMC_CTL_TD field descriptions (continued)

Field	Description
0 Reserved	This field is reserved. **NOTE:** Always write the reset value to this field.

60.3.6 Temperature Fault Injection Register (PMC_TS_FIR)

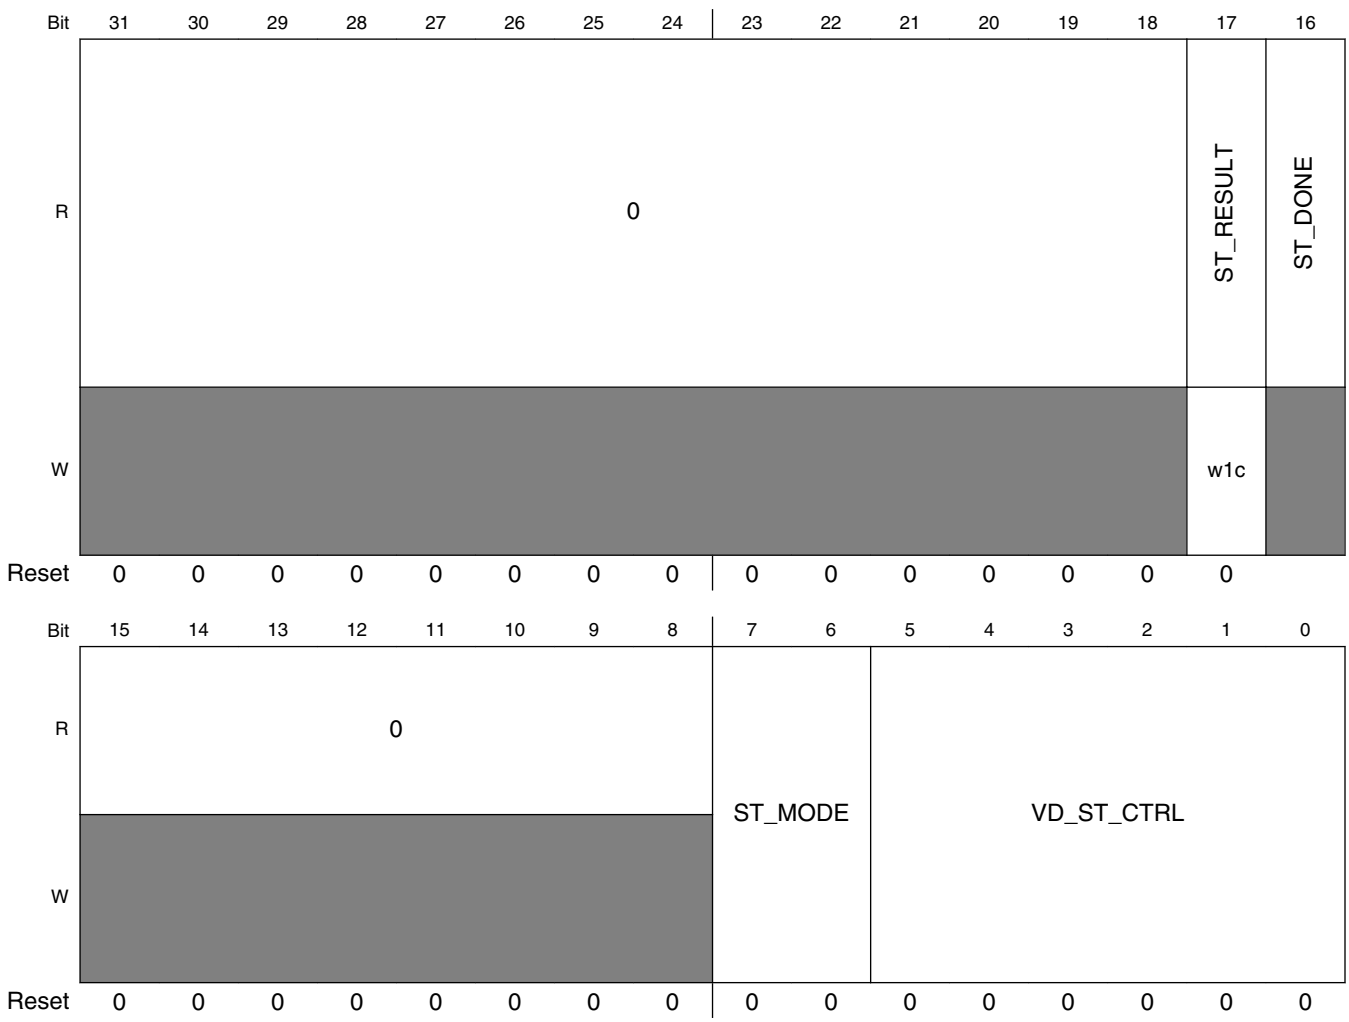
This FCCU Fault Injection register enables the user s/w to artificially generate FCCU faults corresponding to TEMP SENS. A write ‘1’ to these bits generates a single cycle pulsed fault to the FCCU block, this bit automatically gets cleared in the next cycle.

Address: 0h base + C0h offset = C0h

PMC_TS_FIR field descriptions

Field	Description
31–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...



PMC_TS_FIR field descriptions (continued)

Field	Description
0 TSNS_FAULT	Temperature Sensor Fault injection. A write to this bit sends a FCCU fault (single cycle) for TEMP SENSOR. 0 No fault is sent. 1 Single cycle fault injected.

60.3.7 Voltage Detect User Mode Test Register (PMC_SELF_TEST_UM_VD_REG)

This register is used for testing of the LVDs and HVDs during user mode.

Address: 0h base + D0h offset = D0h

PMC_SELF_TEST_UM_VD_REG field descriptions

Field	Description
31–18 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
17 ST_RESULT	ST_RESULT. Self Test result status. (Valid only when ST_DONE is High). This bit indicates whether self test has passed or failed. Logic 0 means self test has failed. Logic High menas self test has passed. It is cleared on reset or writing ‘1’ by the host. 0 Self Test Failed 1 Self Test Passed
16 ST_DONE	Self Test Done status. Self Test completed indication status. If this bit is set to logic high, iit indicates that self test is completed. Logic High on this bit doesn't indicate whether self test has passed or failed. This bit gets clear auotmatically every time the self test gets triggered. 0 Self test running 1 Self test completed.
15–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7–6 ST_MODE	Self Test mode bits for testing of LVDs and HVDs. 00 Default 01 S/W triggered self test. 10 Single VD test as indicated by the VD_ST_CTRL bits. 11 Reserved
5–0 VD_ST_CTRL	Voltage Detect Self Test Control. User mode Test bits for testing of LVDs and HVDs. See the chip-specific module information at the beginning of this chapter for the test bit definition.

60.3.8 FCCU Fault Injection Register (PMC_FIR)

This FCCU Fault Injection register enables the user s/w to artificially generate FCCU faults corresponding to various Events, namely LVD, HVD, TEMP SENS and Self Test. A write '1' to these bits generates a single cycle pulsed fault to the FCCU block, this bit automatically gets cleared in the next cycle.

Address: 0h base + D4h offset = D4h

PMC_FIR field descriptions

Field	Description
31–4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3 STEST_FAULT	A write to this bit sends a FCCU fault (single cycle) for LVD SELF TEST. This is self Clearing bit 0 No fault is sent 1 Single cycle fault injected.
2 Reserved	This field is reserved.
1 HVD_FAULT	High Voltage Detect Fault injection. A write to this bit sends a FCCU fault (single cycle) for HVD. This is self clearing bit. 0 No fault is sent 1 Single cycle fault injected.
0 LVD_FAULT	Low Voltage Detect Fault injection. A write to this bit sends a FCCU fault (single cycle) for LVD. This is self clearing bit. 0 No fault is sent 1 Single cycle fault injected.

60.3.9 LVD HVD Interrupt Enable Control Register (PMC_LVD_HVD_INTR_ENB)

This Register contains the various control bits of PMC block.

Address: 0h base + D8h offset = D8h

PMC_LVD_HVD_INTR_ENB field descriptions

Field	Description
31 PMC_ENABLE	PMC Enable Control This bit determines whether any of the PMC bits can be written or not. 0 No control bit can be written in this(PMC enable control) register.To do a write on this register, first enable this bit and then start writing on other control bits. 1 This control register can be written.
30–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0. 0 Interrupt is disabled. 1 Interrupt is enabled.
14 LVD_PMC	LVD_PMC Control This bit controls the enable/disable on this supply. 0 Interrupt is disabled. 1 Interrupt is enabled.
13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0. 0 Interrupt is disabled. 1 Interrupt is enabled.
12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0. 0 Interrupt is disabled. 1 Interrupt is enabled.
11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0. 0 Interrupt is disabled. 1 Interrupt is enabled.
10 LVD_SAR_ADC	LVD_SAR_ADC Control This bit controls the enable/disable on this supply. 0 Interrupt is disabled. 1 Interrupt is enabled.
9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0. 0 Interrupt is disabled. 1 Interrupt is enabled.
8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0. 0 Interrupt is disabled. 1 Interrupt is enabled.

Field	Description
7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0. 0 Interrupt is disabled. 1 Interrupt is enabled.
6 LVD_IO	LVD_IO Control This bit controls the enable/disable on this supply. 0 Interrupt is disabled. 1 Interrupt is enabled.
5 HVD_FLASH	HVD FLASH Control This bit controls the enable/disable on the LVD PLL supply. 0 Interrupt is disabled. 1 Interrupt is enabled.
4 LVD_FLASH	LVD FLASH Control This bit controls the enable/disable on this supply. 0 Interrupt is disabled. 1 Interrupt is enabled.
3 HVD_HV	HVD HV Control This bit controls the enable/disable on this supply. 0 Interrupt is disabled. 1 Interrupt is enabled.
2 HVD_CORE	HVD Core Control This bit controls the enable/disable on this supply. 0 Interrupt is disabled. 1 Interrupt is enabled.
1 LVD_CORE_ HOT	LVD Core Hot Control This bit controls the enable/disable on this supply. 0 Interrupt is disabled. 1 Interrupt is enabled.
0 LVD_CORE_ COLD	LVD Core Cold Control This bit controls the enable/disable on this supply. 0 Interrupt is disabled. 1 Interrupt is enabled.

60.3.10 LVD HVD Event Status Register (PMC_LVD_HVD_EVENT_STATUS)

This status register contains the latched status of the Voltage detect events. These bits indicates the state of the voltage detect events including whether a voltage level event has occurred at any time in the past but has not been cleared (via the writing '1'). These bits are read only, and they are cleared by writing a one to the corresponding ESR register bit.

NOTE

This register is cleared on POR.

Field	Description
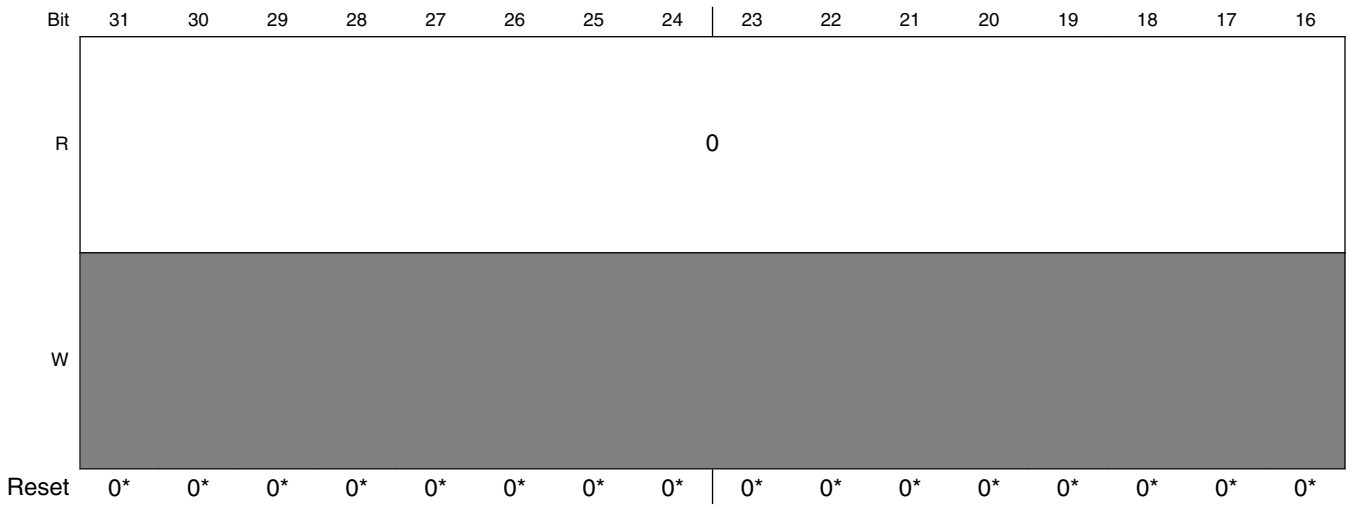
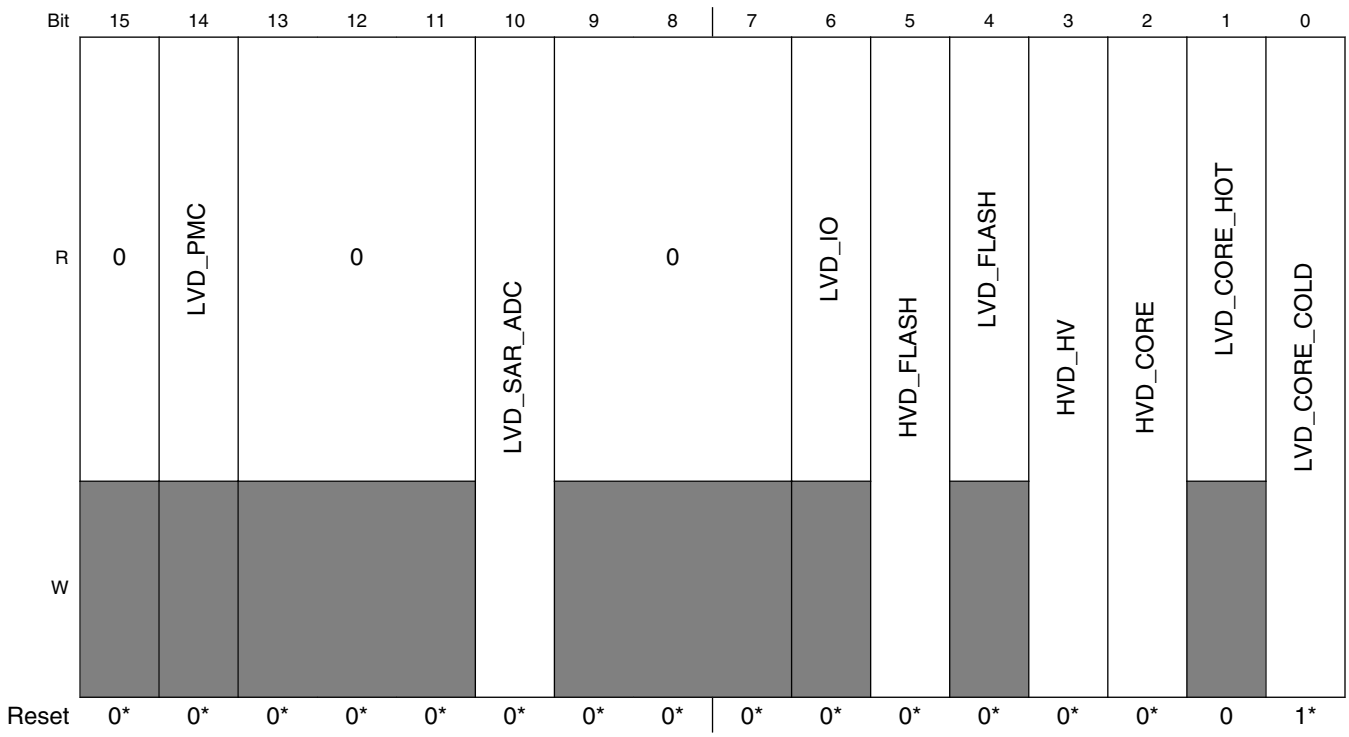
	0 No occurrence has happened. 1 An occurrence has happened.
6 LVD_IO	Indicates whether an occurrence has happened on this supply. 0 No occurrence has happened. 1 An occurrence has happened.
5 HVD_FLASH	Indicates whether an occurrence has happened on this supply. 0 No occurrence has happened. 1 An occurrence has happened.
4 LVD_FLASH	Indicates whether an occurrence has happened on this supply. 0 No occurrence has happened. 1 An occurrence has happened.
3 HVD_HV	Indicates whether an occurrence has happened on this supply. 0 No occurrence has happened. 1 An occurrence has happened.
2 HVD_CORE	Indicates whether an occurrence has happened on this supply. 0 No occurrence has happened. 1 An occurrence has happened.
1 LVD_CORE_ HOT	Indicates whether an occurrence has happened on this supply. 0 No occurrence has happened. 1 An occurrence has happened.
0 LVD_CORE_ COLD	Indicates whether an occurrence has happened on this supply. 0 No occurrence has happened. 1 An occurrence has happened.



60.3.11 Reset Enable Control Register (PMC_REE)



This Reset Event Enable Register controls whether the voltage detect signal event will cause a reset or not. If the desired flag bit is enabled, the voltage detect event causes a reset to be generated when the selected voltage passes the trigger event. These bits are loaded from the flash during the boot sequence. If the flash loaded bits are programmed to be enabled (set), these bits cannot be disabled (cleared).

NOTE

This register is cleared on POR.

Address: 0h base + E0h offset = E0h

* Notes:
- The reset value is chip-specific. Refer to the PMC_dig chip-specific module information for the reset value.

PMC_REE field descriptions

Field	Description
31–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14 LVD_PMC	This bit enable/disable the generation of Reset.

Table continues on the next page...

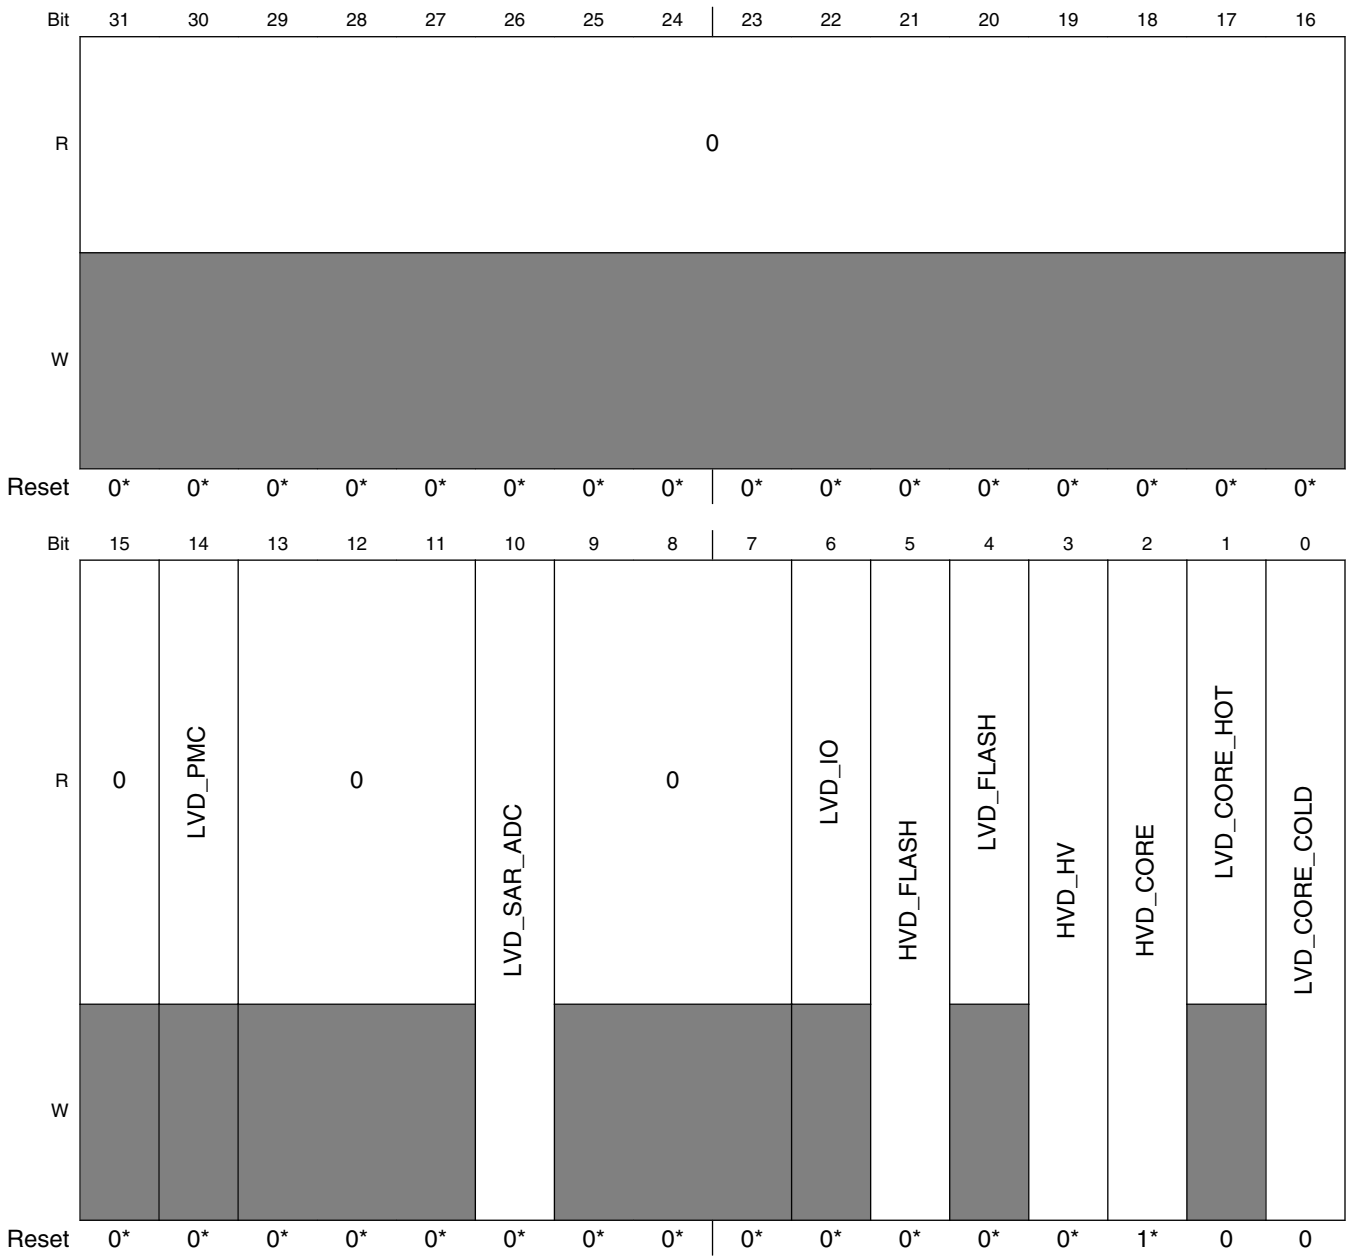
PMC_REE field descriptions (continued)

Field	Description
	0 Reset is disabled. NO reset either functional or destructive, will be generated if an event is detected on this supply 1 Reset is enabled. A reset either functional or destructive, will be generated if an event is detected on this supply
13–11 Reserved	Reserved. Read only zero. This field is reserved. This read-only field is reserved and always has the value 0. 0 Reset is disabled, no reset will be generated even if this event occurred. 1 Reset is enabled. A reset either functional or destructive, will be generated if an event is detected on this supply
10 LVD_SAR_ADC	Reset Enable/Disable Control This bit enable/disable the generation of Reset. **NOTE:** Reset value is defined by the DCF_PMC_REE_CTRL DCF client. 0 Reset is disabled, no reset will be generated even if this event occurred. 1 Reset is enabled. A reset either functional or destructive, will be generated if an event is detected on this supply
9–7 Reserved	Read This field is reserved. This read-only field is reserved and always has the value 0. 0 Reset is disabled, no reset will be generated even if this event occurred. 1 Reset is enabled. A reset either functional or destructive, will be generated if an event is detected on this supply
6 LVD_IO	This bit enable/disable the generation of Reset. 0 Reset is Disabled. NO reset either functional or destructive, will be generated if an event is detected on this supply 1 Reset is enabled. A reset either functional or destructive, will be generated if an event is detected on this supply
5 HVD_FLASH	Reset Enable/Disable Control This bit enable/disable the generation of Reset. **NOTE:** Reset value is defined by the DCF_PMC_REE_CTRL DCF client. 0 Reset is disabled, no reset will be generated even if this event occurred. 1 Reset is enabled. A reset either functional or destructive, will be generated if an event is detected on this supply
4 LVD_FLASH	Reset Enable/Disable Control 0 Reset is Disabled. NO reset either functional or destructive, will be generated if an event is detected on this supply 1 Reset is enabled. A reset either functional or destructive, will be generated if an event is detected on this supply
3 HVD_HV	Reset Enable/Disable Control This bit enable/disable the generation of Reset.

Table continues on the next page...

PMC_REE field descriptions (continued)

Field	Description
	NOTE: Reset value is defined by the DCF_PMC_REE_CTRL DCF client. 0 Reset is disabled, no reset will be generated even if this event occurred. 1 Reset is enabled. A reset either functional or destructive, will be generated if an event is detected on this supply
2 HVD_CORE	Reset Enable/Disable Control This bit enable/disable the generation of Reset. **NOTE:** Reset value is defined by the DCF_PMC_REE_CTRL DCF client. 0 Reset is disabled, no reset will be generated even if this event occurred. 1 Reset is enabled. A reset either functional or destructive, will be generated if an event is detected on this supply
1 LVD_CORE_ HOT	Reset Enable/Disable Control This bit enable/disable the generation of Reset. **NOTE:** Reset value is defined by the DCF_PMC_REE_CTRL DCF client. 0 Reset is disabled, no reset will be generated even if this event occurred. 1 Reset is enabled. A reset either functional or destructive, will be generated if an event is detected on this supply
0 LVD_CORE_ COLD	Reset Enable/Disable Control This bit enable/disable the generation of Reset. **NOTE:** Reset value is defined by the DCF_PMC_REE_CTRL DCF client. 0 Reset is disabled, no reset will be generated even if there is event occurred on this supply. 1 Reset is enabled. A reset either functional or destructive, will be generated if an event is detected on this supply.



60.3.12 Reset Type (Destructive / Functional) Selection Register (PMC_RES)

This Reset Event Select Register controls whether the voltage detect signal event causes a destructive or functional reset. If the desired flag bit is enbaled in REE regsiter, the voltage detect event causes either a destructive or functional reset, when the selected voltage passes the trigger event. These bits are loaded from the flash during the boot sequence.

NOTE

This register is cleared on POR.

Address: 0h base + E4h offset = E4h

* Notes:

- The reset value is chip-specific. Refer to the PMC_dig chip-specific module information for the reset value.

PMC_RES field descriptions

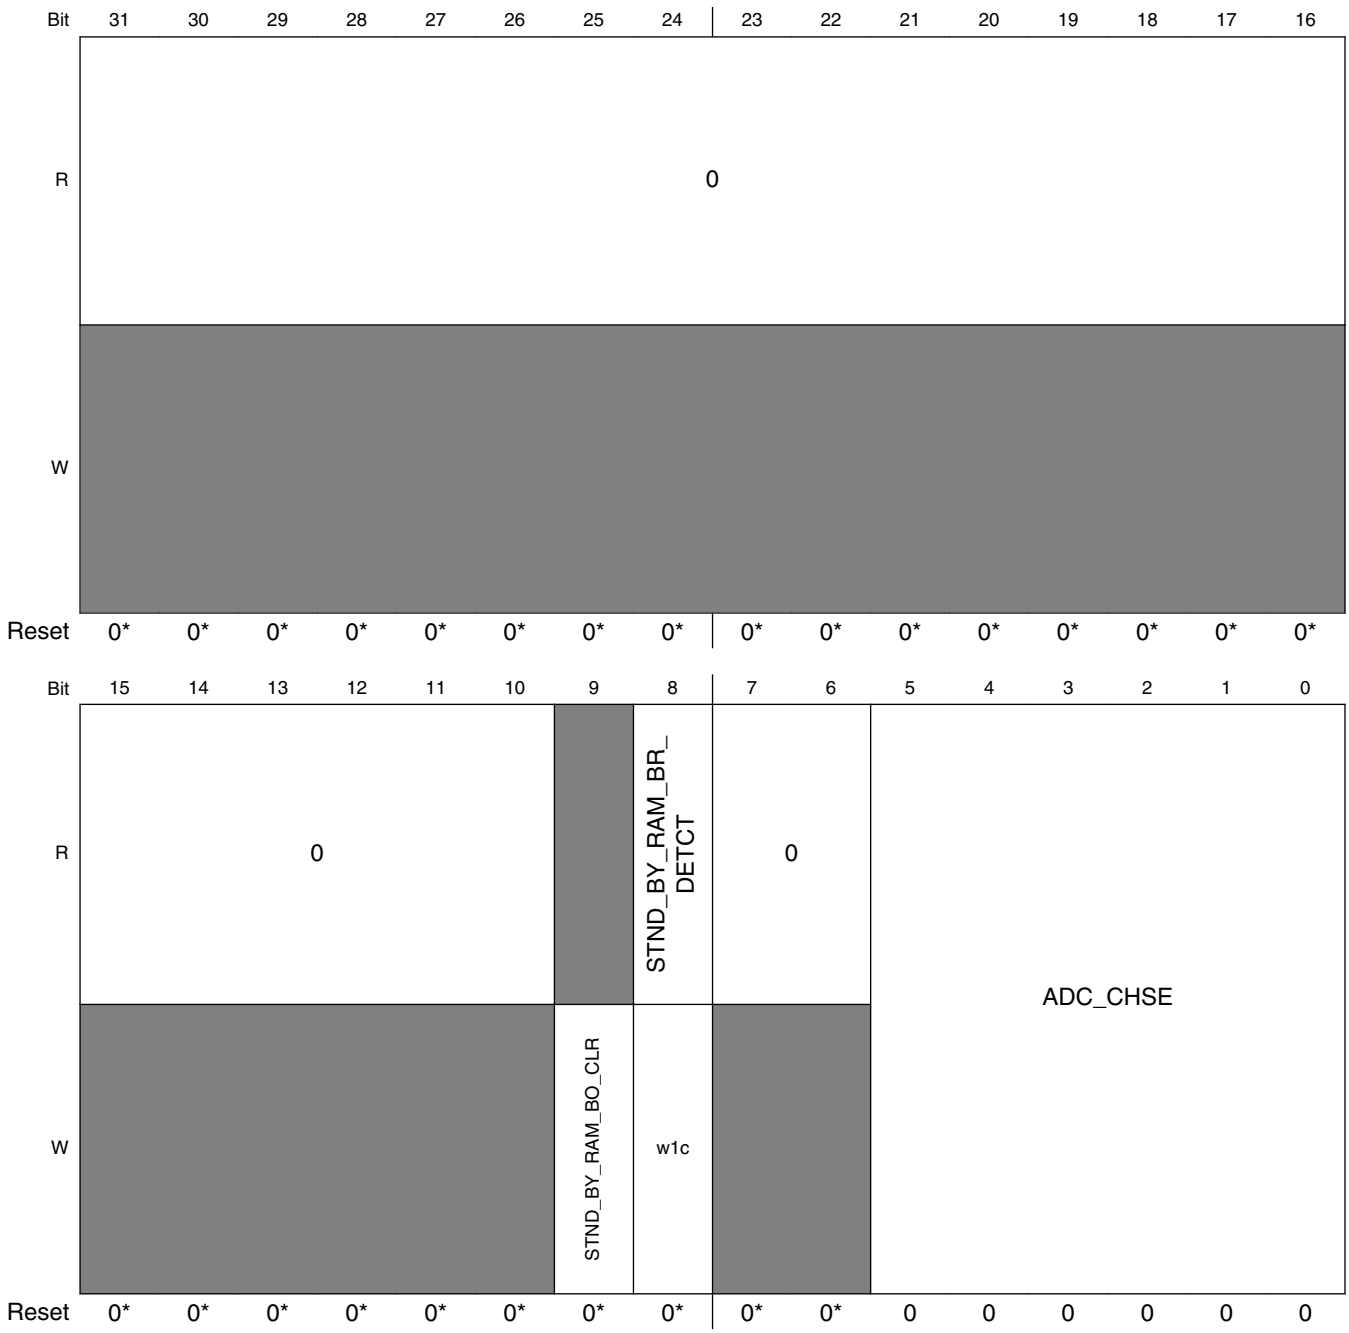
Field	Description
31–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14 LVD_PMC	Reset enabled/disabled.

Table continues on the next page...

PMC_RES field descriptions (continued)

Field	Description
	0 Reset is Disabled. NO reset either functional or destructive, will be generated if an event is detected on this supply 1 Reset is enabled. A reset either functional or destructive, will be generated if an event is detected on this supply
13–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0. 0 If the corresponding reset is enabled, then a Destructive Reset will be generated. 1 If the corresponding reset is enabled, then a Functional Reset will be generated.
10 LVD_SAR_ADC	This bit controls the enable/disable on the LVD SAR ADC supply. **NOTE:** Reset value is defined by the DCF_PMC_RES_CTRL DCF client. 0 If the corresponding reset is enabled, then a Destructive Reset will be generated. 1 If the corresponding reset is enabled, then a Functional Reset will be generated.
9–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0. 0 If the corresponding reset is enabled, then a Destructive Reset will be generated. 1 If the corresponding reset is enabled, then a Functional Reset will be generated.
6 LVD_IO	This bit enable/disable the generation of Reset. 0 If the corresponding reset is enabled, then a Destructive Reset will be generated. 1 If the corresponding reset is enabled, then a Functional Reset will be generated.
5 HVD_FLASH	This bit controls the enable/disable on the HVD FLASH supply. **NOTE:** Reset value is defined by the DCF_PMC_RES_CTRL DCF client. 0 If the corresponding reset is enabled, then a Destructive Reset will be generated. 1 If the corresponding reset is enabled, then a Functional Reset will be generated.
4 LVD_FLASH	This bit enable/disable the generation of Reset. 0 If the corresponding reset is enabled, then a destructive Reset will be generated. 1 If the corresponding reset is enabled, then a Functional Reset will be generated.
3 HVD_HV	This bit controls the enable/disable on the VDD_HV_PMC supply. **NOTE:** Reset value is defined by the DCF_PMC_RES_CTRL DCF client. 0 If the corresponding reset is enabled, then a Destructive Reset will be generated. 1 If the corresponding reset is enabled, then a Functional Reset will be generated.
2 HVD_CORE	This bit controls the enable/disable on the HVD Core supply. **NOTE:** Reset value is defined by the DCF_PMC_RES_CTRL DCF client. 0 If the corresponding reset is enabled, then a Destructive Reset will be generated. 1 If the corresponding reset is enabled, then a Functional Reset will be generated.
1 LVD_CORE_ HOT	This bit enable/disable the generation of Reset. 0 If the corresponding reset is enabled, then a destructive Reset will be generated. 1 If the corresponding reset is enabled, then a Functional Reset will be generated.

Table continues on the next page...



PMC_RES field descriptions (continued)

Field	Description
0 LVD_CORE_ COLD	LVD Core Enable Disable Bit This bit controls the enable/disable on the LVD Core supply. **NOTE:** Reset value is defined by the DCF_PMC_RES_CTRL DCF client. 0 If the corresponding reset is enabled, then a Destructive Reset will be generated. 1 If the corresponding reset is enabled, then a Functional Reset will be generated.

60.3.13 ADC Channel Select Register (PMC_ADC_CS)

This register contains the SRAM Brownout control and the analog channel mux of the analog PMC module.

Address: 0h base + E8h offset = E8h

* Notes:

- The reset value is chip-specific. Refer to the PMC_dig chip-specific module information for the reset value.

PMC_ADC_CS field descriptions

Field	Description
31–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
9 STND_BY_ RAM_BO_CLR	Standby RAM Brownout clear bit. A write on this bit will generate one clock wide pulse. It is self clear pulse.
8 STND_BY_ RAM_BR_ DETCT	Standby RAM Brownout Detection register bit. This bit is W1C type. To clear this field, first write 1 to STND_BY_RAM_BO_CLR and then write 1 to this field (STND_BY_RAM_BR_DETCT). These two writes need to be separate write instructions.
7–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5–0 ADC_CHSE	Analog-to-Digital Converter Channel Select. These bits are used to control the analog PMC's test mux going to the ADC. This is to probe the internal node voltages of the PMC for testing, calibration and characterization purposes by one of the ADCs of the SoC. To see what voltages are output from PMC in this ADC interface, please refer to Table 60-16. **NOTE:** While changing internal PMC signal exposed on ADC interface for diagnostics, it is required to change mux select lines to '000000' before changing to next valid combination. This is needed to avoid transient short circuit b/w internal nodes in PMC and a false LVD / HVD / POR assertion. This must be handled through software.

60.4 Functional description

60.4.1 Analog PMC interface

The digital block uses the analog PMC interface to configure trim values for the regulators and LVDs that are in the analog block.

60.4.2 Temperature sensor interface logic

The digital PMC block provides control and configuration information to the two temperature sensors. A user adjustable trim control is also provided to fine tune the trimming (for more detail, see the detailed description of the Temperature Sensor module).

60.4.3 POR RGM phase gates

The interface with the RGM block is used during the power on sequence and startup. It provides various phase gates, thereby enabling the MC-RGM to properly complete the reset sequence.

It also provides functional and destructive reset sources, based on the configuration. Two types of resets are generated, based on LVD and HVD faults and the corresponding REE(reset event enable) and RES (Reset event status) enables:

- functional
- destructive

The temperature sensor provides another reset source, based on the under/over temperature faults and the corresponding REE and RES enables.

60.4.4 Flash interface to DCF

During power up, trim values for the regulators, LVDs, and HVDs are read from Flash memory by the SSCM, and are then provided to the digital PMC via the DCF interface.

The reset event enable (REE) configurations that are stored in Flash memory are also provided to the PMC via the DCF interface. These REEs configurations are used, by default, to generate various resets to the RGM.

60.4.5 FCCU interface

The digital block generates various fault indications to the FCCU block:

- Separate corresponding, active-high, fault indications are generated whenever an LVD or HVD defect is detected in the analog block.
- A fault indication is generated when a self test task results in a failure.
- A fault condition is generated whenever over-temperature or under-temperature events occur in the temperature sensor.

The figure below shows the exact logic for the generation of faults to FCCU block.

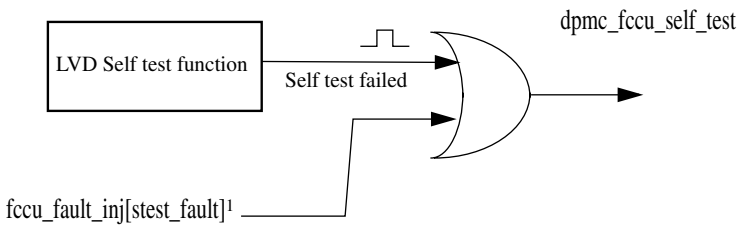


Figure 60-14. FCCU_fault_gen_LVD_Self_Test

[1] See FCCU Fault Injection Register 0(FIR) for details.

60.4.6 LVD-HVD self test mechanism

The PMC implements an LVD/HVD self test mechanism for use in satisfying safety goals. The digital block assists and controls the analog block during it's performance of the self test.

Currently, three self test modes (described in the following sections) are supported by the analog block (based on the mode specified by the VD_UTST[ST_MODE] register bit).

The self test status and result are provided in the VD_UTST[ST_DONE, ST_RESULT] register fields, respectively.

60.4.6.1 Default mode

The self test is always performed during start up (i.e power on). The self test starts during the phase 3 RGM state, when the SSCM has completed reads from the Flash memory. A counter is provided that starts from zero and increments by one after an 8 µs time gap. The counter value is the source for the output “pmc_lvd_self_test” signal, which is provided to the analog block.

Meanwhile, the LVD/HVD indication from the analog block is latched in the VD_UTST register. At the end of the self test (i.e. when all of the LVDs/HVDs have been tested), the VD_UTST[ST_DONE] status bit is set to '1' and all of the bits in the VD_UTST register are checked for ‘1’. One or more bits not set to '1' generates a fault indication to the FCCU block, and the VD_UTST[ST_RESULT] register bit is set to ‘0’. In the case

where all of the register bits are set to '1', the test is considered to be PASSED, the VD_UTST[ST_RESULT] register bit is set to ‘1’, and no fault indications are provided to the FCCU.

This startup self test function also provides gating of the reset phase3 exit in RGM. This means the RGM will not be able to exit from phase3 until the self test is successfully completed.

NOTE

The total run time of the LVD self test is equal to: ‘time required per LVD (20 µs)’ times 'number of LVDs (23)' = 460 µs.

60.4.6.2 Software-triggered self test

This mode is entered by software by writing '01' to the VD_UTST[ST_MODE] register 2-bit field. The complete self test, as is performed in default mode, is repeated. The difference is that the self test in this mode is initiated by the host while the self test in default mode is started automatically during power on.

60.4.6.3 Single voltage detect test

This mode is entered by software writing '10' to the VD_ST_CTRL[ST_MODE] register 2-bit field, which results in the assertion of the “pmc_lvd_self_test” input. The test completes after the prescribed time gap has elapsed. The PASS/FAIL result is then updated based on the corresponding LVD output tripping, or not.

NOTE

During the running of the LVD self test, all of the LVD and HVD outputs are masked including some PORs that are also under self test. Therefore, they will have no effect on POR generation, or in any reset and/or fault generation.

60.4.6.4 ADC Interface

ADC Interface is to probe the internal node voltages of PMC for testing, calibration and characterization purpose by one of the ADCs of the SoC. There will be a dedicated ADC channel for this interface.

PMC signals are buffered to ensure correct ADC sampling.

Node to be probed through ADC can be selected using bit "pmc_adc_ch_sel[5:0]".

Table 60-16. ADC Interface

S.No.	pmc_adc_ch_sel[5:0]	ADC Channel Output	Expected Value
0	6'b000000	ADC Channel OFF

Chapter 61
Power Control Unit (MC_PCU)

61.1 Introduction

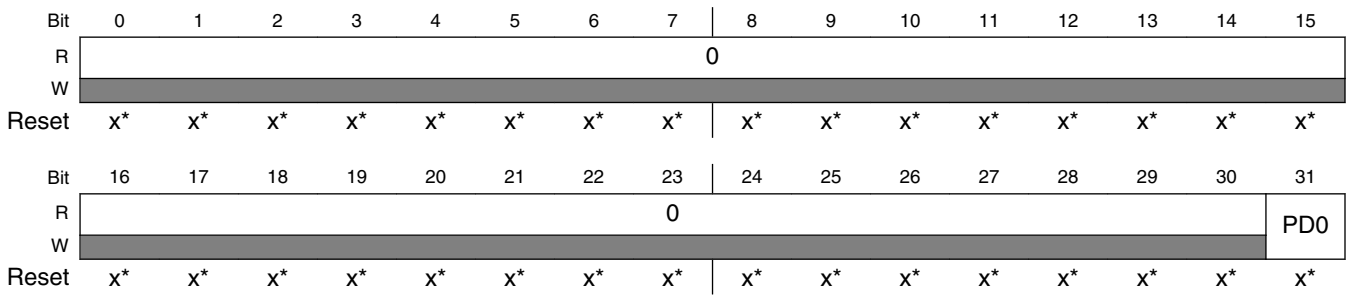
The function of this module is simply to map the PMC digital interface IP into its address space.

The MC_PCU module plays a different role in this microcontroller than it does in other microcontrollers. Instead of directly providing an interface to configure and control power distribution to various segments ("power domains") of the chip, the MC_PCU acts as an integration module.

This microcontroller has a single power domain, Power Domain 0, which is managed by an analog Power Management Controller (PMC) and a PMC digital interface (PMC_dig). The 16K address space consists of a single MC_PCU power domain status register and the PMC_dig registers used to configure and control the analog PMC.

61.2 Memory map and register definition

All registers may be accessed as 32-bit words, 16-bit half-words, or 8-bit bytes. The bytes are ordered according to big endian. For example, the PD0 field of the PCU_PSTAT register may be accessed as a word at offset 0x0040, as a half-word at offset 0x0042, or as a byte at offset 0x0043.



MC_PCU memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
40	Power Domain Status Register (MC_PCU_PSTAT)	32	R	Undefined	61.2.1/2608

61.2.1 Power Domain Status Register (MC_PCU_PSTAT)

This register reflects the power status of all available power domains.

Address: 0h base + 40h offset = 40h

* Notes:
- x = Undefined at reset.

MC_PCU_PSTAT field descriptions

Field	Description
0–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 PD0	Power status for power domain 0 0 Power domain is inoperable 1 Power domain is operable

61.3 Functional description

Please see the PMC_dig chapter for specific details on the PMC control registers.

Chapter 62
Mode Entry Module (MC_ME)

62.1 Introduction

This chapter describes the Mode Entry module.

62.1.1 Overview

The MC_ME controls the chip mode and mode transition sequences in all functional states. It also contains configuration, control, and status registers accessible for the application.

The purpose of the MC_ME is to minimize the current consumption of device modules by:

- Switching clocks on/off
- Switching clock sources on/off
- Enabling system clock progressive switching when changing to a different power level configuration

The following figure shows the MC_ME block diagram.

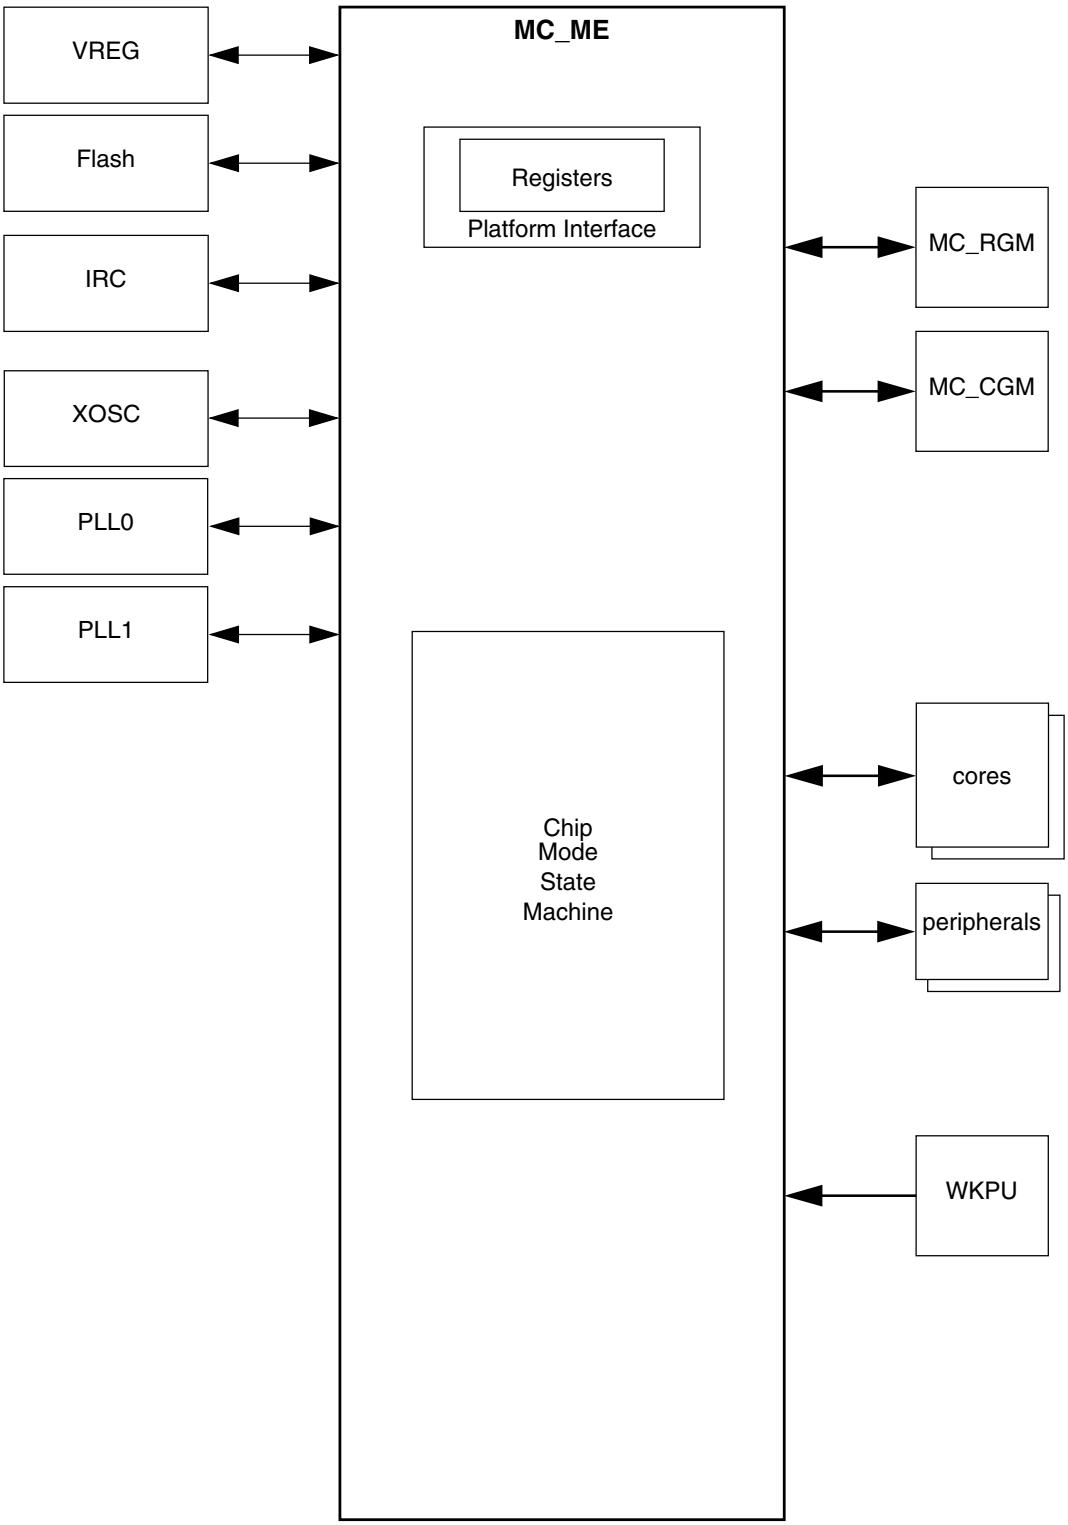


Figure 62-1. MC_ME Block Diagram

62.1.2 Features

The MC_ME includes the following features:

- control of the available modes by the **ME_ME** register
- definition of various chip mode configurations by the **ME_<mode>_MC** registers
- control of the actual chip mode by the **ME_MCTL** register for
  - switching between software-running modes
  - switching from software-running modes to low-power modes
  - switching to a mode to run diagnostics after a failure has been detected
  - triggering a device 'functional' reset which does not cause a start-up self test to run
  - triggering a device 'destructive' reset which may cause a start-up self test to run
- capture of the current mode and various resource status within the contents of the **ME_GS** register
- optional generation of various mode transition interrupts
- status bits for each cause of invalid mode transitions
- peripheral clock gating control based on the **ME_RUN_PC0…7**, **ME_LP_PC0…7**, and **ME_PCTL*n*** registers
- capture of current peripheral clock gated/enabled status
- core clock gating and boot control based on the **ME_CCTL*n*** and **ME_CADDR*n*** registers
- progressive system clock switching when transitioning from a lower power consumption mode to a higher power consumption mode, and vice versa
- capture of current core clock gated/enabled status

NOTE

It is possible to wake up from Stop/Halt mode through an interrupt even if it is not enabled at INTC level but just enabled at the module generating it.

62.1.3 Modes of Operation

The MC_ME is based on several chip modes corresponding to different usage models of the chip. Each mode is configurable and can define a policy for energy and processing power management to fit particular system requirements. An application can easily switch from one mode to another depending on the current needs of the system. The operating modes controlled by the MC_ME are divided into system and user modes. The system modes are modes such as ***RESET***, ***DRUN***, ***SAFE***, and ***TEST***. These modes aim to ease the configuration and monitoring of the system. The user modes are modes such as ***RUN0…3***, ***HALT0***, and ***STOP0*** which can be configured to meet the application requirements in terms of energy management and available processing power. The modes ***DRUN***, ***SAFE***, ***TEST***, and ***RUN0…3*** are the chip software running modes.

The following table describes the MC_ME modes.

Table 62-1. MC_ME Mode Descriptions (Continued)

Name	Description	Entry	Exit
RESET	This is a chip-wide virtual mode during which the application is not active. The system remains in this mode until all resources are available for the embedded software to take control of the chip. It manages hardware initialization of chip configuration, voltage regulators, clock sources, and flash modules.	system reset assertion from MC_RGM	system reset deassertion from MC_RGM
DRUN	This is the entry mode for the embedded software. It provides full accessibility to the system and enables the configuration of the system at startup. It provides the unique gate to enter user modes. BAM is executed in ***DRUN*** mode.	system reset deassertion from MC_RGM, software request from ***SAFE***, ***TEST*** and ***RUN0…3***	system reset assertion, ***RUN0…3***, ***TEST*** via software, ***SAFE*** via software or hardware failure.
SAFE	This is a chip-wide service mode which may be entered on the detection of a recoverable error. It forces the system into a pre-defined safe configuration from which the system may try to recover.	hardware failure, software request from any mode except ***RESET***	system reset assertion, ***DRUN*** via software
TEST	This is a chip-wide service mode which is intended to provide a control environment for chip software testing.	software request from ***DRUN***	system reset assertion, ***DRUN*** via software
RUN0…3	These are software running modes where most processing activity is done. These various run modes allow to enable different clock & power configurations of the system with respect to each other.	software request from ***DRUN*** or other ***RUN0…3***, interrupt event from ***HALT0***, interrupt or wakeup event from ***STOP0***	system reset assertion, ***SAFE*** via software or hardware failure, other ***RUN0…3*** modes, ***HALT0***, ***STOP0*** via software
HALT0	This is a reduced-activity low-power mode during which the clock to the core is disabled. It can be configured to switch off analog peripherals like clock sources, flash, main regulator, etc. for efficient power management at the cost of higher wakeup latency.	software request from ***RUN0…3***	system reset assertion, ***SAFE*** via software or hardware failure, ***RUN0…3*** on interrupt event

Table continues on the next page...

Table 62-1. MC_ME Mode Descriptions (Continued) (continued)

Name	Description	Entry	Exit
STOP0	This is an advanced low-power mode during which the clock to the core is disabled. It may be configured to switch off most of the peripherals including clock sources for efficient power management at the cost of higher wakeup latency.	software request from ***RUN0...3***	system reset assertion, ***SAFE*** via software or hardware failure, ***RUN0...3*** on interrupt event or wakeup event

62.2 External Signal Description

The MC_ME has no connections to any external pins.

62.3 MC_ME Registers

The following subsections show the MC_ME registers memory map and the detailed definition of each register.

The MC_ME contains registers for:

- mode selection and status reporting
- mode configuration
- mode transition interrupts status and mask control
- scalable number of peripheral sub-mode selection and status reporting
- scalable number of core enabling and disabling control and status reporting

Unless otherwise noted, all registers may be accessed as 32-bit words, 16-bit half-words, or 8-bit bytes. The bytes are ordered according to big endian. For example, the ME_RUN_PC0 register may be accessed as a word at address offset 0x0080, as a half-word at address offset 0x0082, or as a byte at address offset 0x0083.

Some fields may be read-only, and their reset value of '1' or '0' and the corresponding behavior cannot be changed.

MC_ME memory map

27 S_IRC	16 MHz internal RC oscillator status 0 16 MHz internal RC oscillator is not stable 1 16 MHz internal RC oscillator is providing a stable clock
28–31 S_SYSCLK	System clock switch status - These bits specify the system clock currently used by the system. 0000 16 MHz int. RC osc. 0001 external osc. 0010 PLL0 0011 reserved 0100 PLL1 0101 reserved 0110 reserved 0111 reserved 1000 reserved 1001 reserved 1010 reserved 1011 reserved 1100 reserved 1101 reserved 1110 reserved 1111 system clock is disabled

62.3.2 Mode Control (MC_ME_MCTL)

This register is used to trigger software-controlled mode changes. Depending on the modes as enabled by ME_ME register bits, configurations corresponding to unavailable modes are reserved and access to ME_<mode>_MC registers must respect this for successful mode requests.

NOTE

Byte and half-word write accesses are not allowed for this register as a predefined key is required to change its value.

Address: 0h base + 4h offset = 4h

MC_ME_MCTL field descriptions

Field	Description
0–3 TARGET_MODE	Target chip mode -These bits provide the target chip mode to be entered by software programming. The mechanism to enter into any mode by software requires the write operation twice: first time with key, and second time with inverted key. These bits are automatically updated by hardware while entering SAFE on hardware request. Also, while exiting from the HALT0 and STOP0 modes on hardware exit events, these are updated with the appropriate RUN0-3 mode value. 0000 RESET (triggers a 'functional' reset event) 0001 TEST 0010 SAFE 0011 DRUN 0100 RUN0 0101 RUN1 0110 RUN2 0111 RUN3 1000 HALT0 1001 reserved 1010 STOP0 1011 reserved 1100 reserved 1101 reserved 1110 reserved 1111 RESET (triggers a 'destructive' reset event)
4–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 KEY	Control key -These bits enable write access to this register. Any write access to the register with a value different from the keys is ignored. Read access will always return inverted key. KEY: 0101101011110000 (0x5AF0) INVERTED KEY: 1010010100001111 (0xA50F)

62.3.3 Mode Enable (MC_ME_ME)

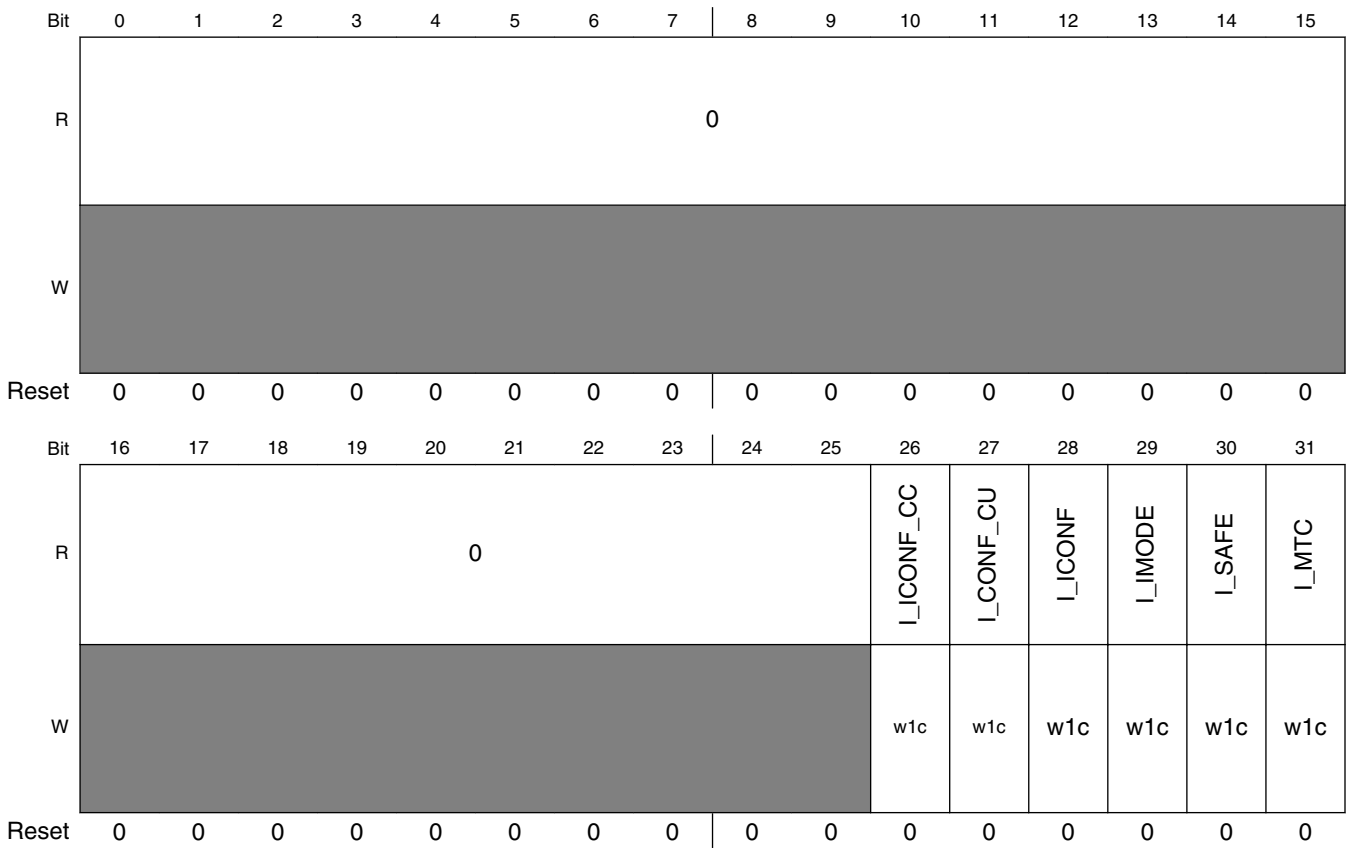
This register allows a way to disable the chip modes which are not required for a given chip. RESET, SAFE, DRUN, and RUN0 modes are always enabled.

Address: 0h base + 8h offset = 8h

MC_ME_ME field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 RESET_DEST	'Destructive' RESET mode enable 0 'Destructive' RESET mode is disabled

Table continues on the next page...



MC_ME_ME field descriptions (continued)

Field	Description
	1 'Destructive' RESET mode is enabled
17–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21 STOP0	STOP0 mode enable 0 STOP0 mode is disabled 1 STOP0 mode is enabled
22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23 HALT0	HALT0 mode enable 0 HALT0 mode is disabled 1 HALT0 mode is enabled
24 RUN3	RUN3 mode enable 0 RUN3 mode is disabled 1 RUN3 mode is enabled
25 RUN2	RUN2 mode enable 0 RUN2 mode is disabled 1 RUN2 mode is enabled
26 RUN1	RUN1 mode enable 0 RUN1 mode is disabled 1 RUN1 mode is enabled
27 RUN0	RUN0 mode enable 1 RUN0 mode is enabled
28 DRUN	DRUN mode enable 1 DRUN mode is enabled
29 SAFE	SAFE mode enable 1 SAFE mode is enabled
30 TEST	TEST mode enable 0 TEST mode is disabled 1 TEST mode is enabled
31 RESET_FUNC	'functional' RESET mode enable 0 'functional' RESET mode is disabled 1 'functional' RESET mode is enabled

62.3.4 Interrupt Status (MC_ME_IS)

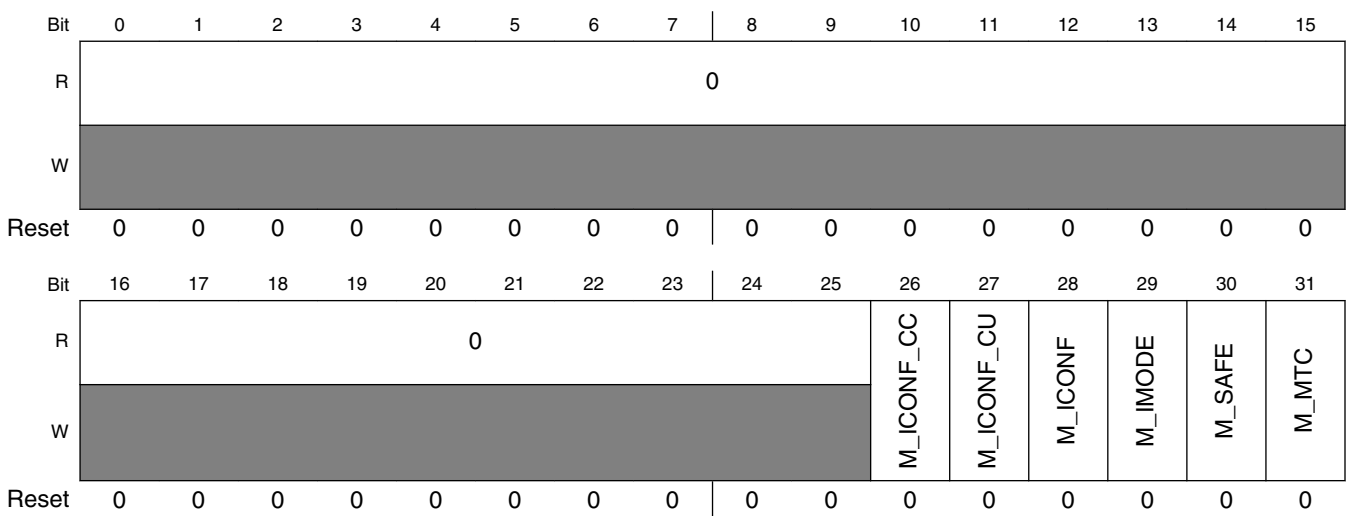
This register provides the current interrupt status.

Address: 0h base + Ch offset = Ch

MC_ME_IS field descriptions

Field	Description
0–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26 I_ICONF_CC	Invalid mode configuration interrupt (core configuration) - This bit is set if a write access to one of the ME_CADDRn registers is attempted while a mode transition is in progress. 0 No write to an ME_CADDRn register was attempted during an ongoing mode transition 1 A write to an ME_CADDRn register was attempted during an ongoing mode transition
27 I_CONF_CU	Invalid mode configuration interrupt (clock usage) - This bit is set during a mode transition if a clock which is required to be on by an enabled peripheral is configured to be turned off. It is cleared by writing a '1' to this bit. 0 No invalid mode configuration (clock usage) interrupt occurred 1 Invalid mode configuration (clock usage) interrupt is pending
28 I_ICONF	Invalid mode configuration interrupt - This bit is set whenever a write operation to ME_<mode>_MC registers with invalid mode configuration is attempted. It is cleared by writing a '1' to this bit.

Table continues on the next page...



MC_ME_IS field descriptions (continued)

Field	Description
	0 No invalid mode configuration interrupt occurred 1 Invalid mode configuration interrupt is pending
29 I_IMODE	Invalid mode interrupt - This bit is set whenever an invalid mode transition is requested. It is cleared by writing a '1' to this bit. 0 No invalid mode interrupt occurred 1 Invalid mode interrupt is pending
30 I_SAFE	SAFE mode interrupt - This bit is set whenever the chip enters SAFE mode on hardware requests generated in the system. It is cleared by writing a '1' to this bit. 0 No SAFE mode interrupt occurred 1 SAFE mode interrupt is pending
31 I_MTC	Mode transition complete interrupt - This bit is set whenever the mode transition process completes (S_MTRANS transits from 1 to 0). It is cleared by writing a '1' to this bit. This mode transition interrupt bit will not be set while entering low-power modes HALT0, or STOP0. 0 No mode transition complete interrupt occurred 1 Mode transition complete interrupt is pending

62.3.5 Interrupt Mask (MC_ME_IM)

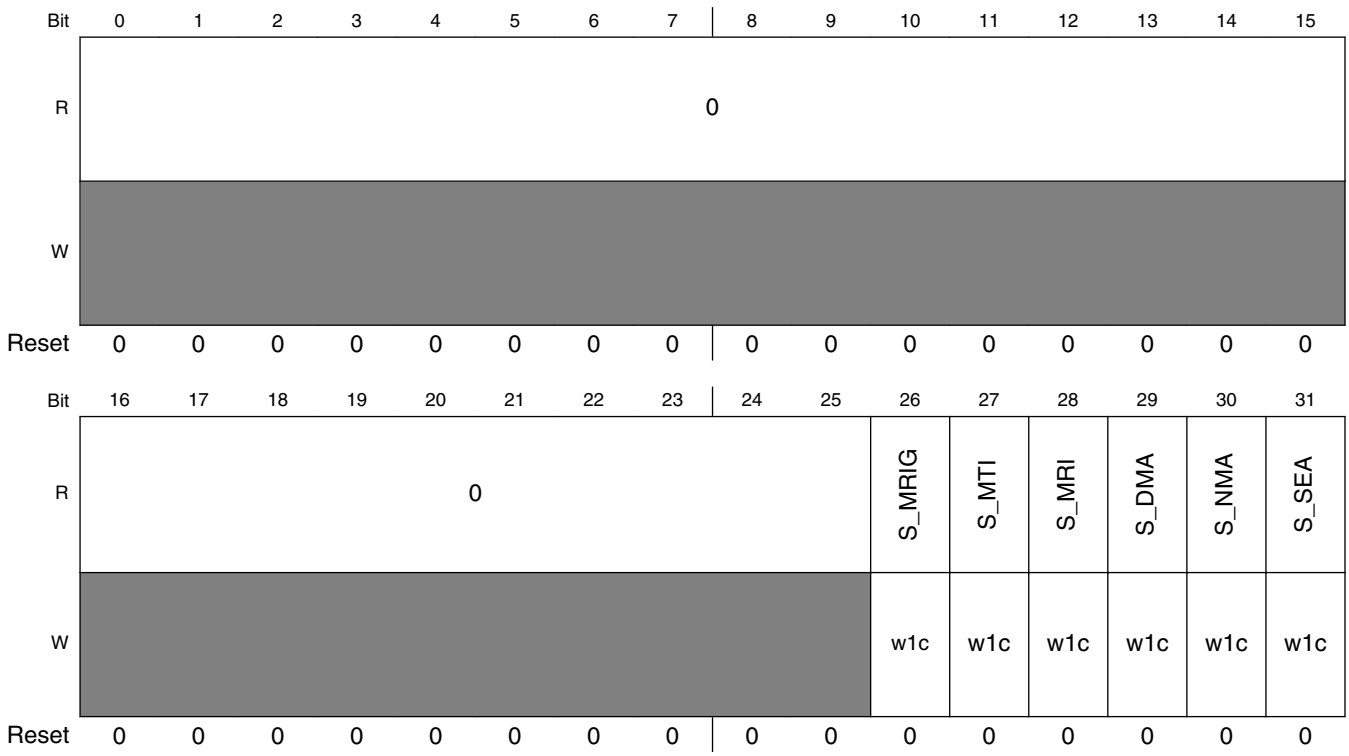
This register controls whether an event generates an interrupt or not.

Address: 0h base + 10h offset = 10h

MC_ME_IM field descriptions

Field	Description
0–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...



MC_ME_IM field descriptions (continued)

Field	Description
26 M_ICONF_CC	Invalid mode configuration (core configuration) interrupt mask 0 Invalid mode interrupt is masked 1 Invalid mode interrupt is enabled
27 M_ICONF_CU	Invalid mode configuration (clock usage) interrupt mask 0 Invalid mode interrupt is masked 1 Invalid mode interrupt is enabled
28 M_ICONF	Invalid mode configuration interrupt mask 0 Invalid mode interrupt is masked 1 Invalid mode interrupt is enabled
29 M_IMODE	Invalid mode interrupt mask 0 Invalid mode interrupt is masked 1 Invalid mode interrupt is enabled
30 M_SAFE	SAFE mode interrupt mask 0 SAFE mode interrupt is masked 1 SAFE mode interrupt is enabled
31 M_MTC	Mode transition complete interrupt mask 0 Mode transition complete interrupt is masked 1 Mode transition complete interrupt is enabled

62.3.6 Invalid Mode Transition Status (MC_ME_IMTS)

This register provides the status bits for the possible causes of an invalid mode interrupt.

Address: 0h base + 14h offset = 14h

MC_ME_IMTS field descriptions

Field	Description
0–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26 S_MRIG	Mode Request Ignored status - This bit is set whenever a new mode is requested while a transition to the SAFE mode is in progress. This bit is also set when a transition to STOP0/HALT0 mode is made when a wakeup is active. It is cleared by writing a '1' to this bit. 0 Mode transition requested is not illegal 1 Mode transition requested is illegal
27 S_MTI	Mode Transition Illegal status - This bit is set whenever a new mode is requested while some other non-SAFE mode transition process is active (S_MTRANS is '1' . Please refer to Section "Mode Transition Interrupts" for the exceptions to this behavior. It is cleared by writing a '1' to this bit. 0 Mode transition requested is not illegal 1 Mode transition requested is illegal
28 S_MRI	Mode Request Illegal status - This bit is set whenever the target mode requested is not a valid mode with respect to current mode. It is cleared by writing a '1' to this bit. 0 Target mode requested is not illegal with respect to current mode 1 Target mode requested is illegal with respect to current mode

Table continues on the next page...

MC_ME_IMTS field descriptions (continued)

Field	Description
29 S_DMA	Disabled Mode Access status - This bit is set whenever the target mode requested is one of those disabled modes determined by ME_ME register. It is cleared by writing a '1' to this bit. 0 Target mode requested is not a disabled mode 1 Target mode requested is a disabled mode
30 S_NMA	Non-existing Mode Access status - This bit is set whenever the target mode requested is one of those non existing modes determined by ME_ME register. It is cleared by writing a '1' to this bit. 0 Target mode requested is an existing mode 1 Target mode requested is a non-existing mode
31 S_SEA	SAFE Event Active status - This bit is set whenever the chip is in SAFE mode, SAFE event bit is pending and a new mode requested other than RESET/SAFE modes. It is cleared by writing a '1' to this bit. 0 No new mode requested other than RESET/SAFE while SAFE event is pending 1 New mode requested other than RESET/SAFE while SAFE event is pending

62.3.7 Debug Mode Transition Status (MC_ME_DMTS)

This register provides the status of different factors which influence mode transitions. It is used to give an indication of why a mode transition indicated by ME_GS[S_MTRANS] may be taking longer than expected.

NOTE

The ME_DMTS register does not indicate whether a mode transition is ongoing. Therefore, some ME_DMTS bits may still be asserted after the mode transition has completed.

Address: 0h base + 18h offset = 18h

MC_ME_DMTS field descriptions

Field	Description
0–3 PREVIOUS_ MODE	Previous chip mode - These bits show the mode in which the chip was prior to the latest change to the current mode. 0000 RESET 0001 TEST 0010 SAFE 0011 DRUN 0100 RUN0 0101 RUN1 0110 RUN2 0111 RUN3 1000 HALT0 1001 reserved 1010 STOP0 1011 reserved 1100 reserved 1101 reserved 1110 reserved 1111 reserved
4–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8 MPH_BUSY	MC_ME/MC_PCU Handshake Busy indicator - This bit is set if the MC_ME has requested a mode change from the MC_PCU and the MC_PCU has not yet completed its power-up/down sequencing. It is cleared when the MC_PCU has completed power-up/down sequencing. 0 Handshake is not busy 1 Handshake is busy
9–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11 PMC_PROG	MC_PCU Mode Change in Progress indicator - This bit is set if the MC_PCU is in the process of powering up or down power domains. It is cleared when all power-up/down processes have completed. 0 Power-up/down transition is not in progress 1 Power-up/down transition is in progress
12 DBG_MODE	Debug mode indicator - This bit is set while the chip is in debug mode. 0 The chip is not in debug mode 1 The chip is in debug mode
13 CCKL_PROG	Core Clock Enable/Disable in Progress - This bit is set while any core's clock is in the process of being enabled or disabled. 0 No core clock is being enabled or disabled 1 A core clock is being enabled or disabled
14 PCS_PROG	Progressive System Clock Switching in Progress - This bit is set when PCS is in progress, peripheral clock switching is ongoing, core clock switching is ongoing, or power sequence process is ongoing.

Table continues on the next page...

MC_ME_DMTS field descriptions (continued)

Field	Description
	0 PCS is not in progress 1 PCS is in progress
15 SMR	SAFE mode request from MC_RGM is active indicator - This bit is set if a hardware SAFE mode request has been triggered. It is cleared when the hardware SAFE mode request has been cleared. 0 A SAFE mode request is not active 1 A SAFE mode request is active
16 CDP_PRPH_0_255	Clock Disable Process Pending status for Peripherals 0-255 - This bit is set when any peripheral appearing has been requested to have its clock disabled. It is cleared when all the peripherals which have been requested to have their clocks disabled have entered the state in which their clocks may be disabled. 0 No peripheral clock disabling is pending 1 Clock disabling is pending for at least one peripheral
17 VREG_CSRC_SC	Main VREG dependent Clock Source State Change during mode transition indicator - This bit is set when a clock source which depends on the main voltage regulator to be powered-up is requested to change its power up/down state. It is cleared when the clock source has completed its state change. 0 No state change is taking place 1 A state change is taking place
18 CSRC_CSRC_SC	(Other) Clock Source dependent Clock Source State Change during mode transition indicator - This bit is set when a clock source which depends on another clock source to be powered-up is requested to change its power up/down state. It is cleared when the clock source has completed its state change. 0 No state change is taking place 1 A state change is taking place
19 IRC_SC	IRC State Change during mode transition indicator - This bit is set when the 16 MHz internal RC oscillator is requested to change its power up/down state. It is cleared when the 16 MHz internal RC oscillator has completed its state change. 0 No state change is taking place 1 A state change is taking place
20 SCSRC_SC	Secondary Clock Sources State Change during mode transition indicator - This bit is set when a secondary clock source is requested to change its power up/down state. It is cleared when all secondary system clock sources have completed their state changes. (A secondary clock source is a clock source other than IRC.) 0 No state change is taking place 1 A state change is taking place
21 SYSCLK_SW	System Clock Switching pending status 0 No system clock source switching is pending 1 A system clock source switching is pending
22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23 FLASH_SC	FLASH State Change during mode transition indicator - This bit is set when the FLASH is requested to change its power up/down state. It is cleared when the DFLASH has completed its state change. 0 No state change is taking place 1 A state change is taking place

Table continues on the next page...

MC_ME_DMTS field descriptions (continued)

Field	Description
24 CDP_PRPH_ 244_255	Clock Disable Process Pending status for Peripherals 224 - 2552 - This bit is set when any peripheral appearing in ME_PS7 has been requested to have its clock disabled. It is cleared when all the peripherals which have been requested to have their clocks disabled have entered the state in which their clocks may be disabled. 0 No peripheral clock disabling is pending 1 Clock disabling is pending for at least one peripheral
25 CDP_PRPH_ 192_223	Clock Disable Process Pending status for Peripherals 192 - 223 - This bit is set when any peripheral appearing in ME_PS6 has been requested to have its clock disabled. It is cleared when all these peripherals which have been requested to have their clocks disabled have entered the state in which their clocks may be disabled. 1 Clock disabling is pending for at least one peripheral
26 CDP_PRPH_ 160_191	Clock Disable Process Pending status for Peripherals 160 - 191 - This bit is set when any peripheral appearing in ME_PS5 has been requested to have its clock disabled. It is cleared when all these peripherals which have been requested to have their clocks disabled have entered the state in which their clocks may be disabled. 1 Clock disabling is pending for at least one peripheral
27 CDP_PRPH_ 128_159	Clock Disable Process Pending status for Peripherals 128 - 159 - This bit is set when any peripheral appearing in ME_PS4 has been requested to have its clock disabled. It is cleared when all these peripherals which have been requested to have their clocks disabled have entered the state in which their clocks may be disabled. 0 No peripheral clock disabling is pending 1 Clock disabling is pending for at least one peripheral
28 CDP_PRPH_96_ 127	Clock Disable Process Pending status for Peripherals 96 - 127 - This bit is set when any peripheral appearing in ME_PS3 has been requested to have its clock disabled. It is cleared when all these peripherals which have been requested to have their clocks disabled have entered the state in which their clocks may be disabled. 0 No peripheral clock disabling is pending 1 Clock disabling is pending for at least one peripheral
29 CDP_PRPH_64_ 95	Clock Disable Process Pending status for Peripherals 64 - 95 - This bit is set when any peripheral appearing in ME_PS2 has been requested to have its clock disabled. It is cleared when all these peripherals which have been requested to have their clocks disabled have entered the state in which their clocks may be disabled. 0 No peripheral clock disabling is pending 1 Clock disabling is pending for at least one peripheral
30 CDP_PRPH_32_ 63	Clock Disable Process Pending status for Peripherals 32 - 63 - This bit is set when any peripheral appearing in ME_PS1 has been requested to have its clock disabled. It is cleared when all these peripherals which have been requested to have their clocks disabled have entered the state in which their clocks may be disabled. 0 No peripheral clock disabling is pending 1 Clock disabling is pending for at least one peripheral
31 CDP_PRPH_0_ 31	Clock Disable Process Pending status for Peripherals 0 - 31 - This bit is set when any peripheral appearing in ME_PS0 has been requested to have its clock disabled. It is cleared when all these peripherals which have been requested to have their clocks disabled have entered the state in which their clocks may be disabled. 0 No peripheral clock disabling is pending

Table continues on the next page...

MC_ME_DMTS field descriptions (continued)

Field	Description
	1 Clock disabling is pending for at least one peripheral

62.3.8 RESET Mode Configuration (MC_ME_RESET_MC)

This register configures system behavior during RESET mode.

Address: 0h base + 20h offset = 20h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Field	Description
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

MC_ME_RESET_MC field descriptions (continued)

Field	Description
1–3 PWRLVL	Power level - These bits indicate the relative power consumption level of this mode with respect to that of other modes. When switching between two modes with differing power levels, system clock progressive switching is enabled.
4–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8 PDO	I/O output power-down control - This bit controls the output power-down of I/Os. 0 No automatic safe gating of I/Os used and pads power sequence driver is enabled 1 In SAFE/TEST modes, outputs of pads are forced to high impedance state and pads power sequence driver is disabled. The inputs are level unchanged. In STOP0 mode, only the pad power sequence driver is disabled, but the state of the output remains functional.
9–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11 MVRON	Main voltage regulator control - This bit specifies whether main voltage regulator is switched off or not while entering this mode.
12–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14–15 FLAON	Flash power-down control - This bit specifies the operating mode of the code flash after entering this mode. 00 reserved 01 reserved 10 reserved 11 Flash is in normal mode
16–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24 PLL1ON	secondary PLL control 0 secondary PLL is switched off 1 secondary PLL is switched on
25 PLL0ON	system PLL control 0 system PLL is switched off 1 system PLL is switched on
26 XOSCON	4-40 MHz crystal oscillator control 0 4-40 MHz crystal oscillator is switched off 1 4-40 MHz crystal oscillator is switched on
27 IRCON	16 MHz internal RC oscillator control 0 16 MHz internal RC oscillator is switched off 1 16 MHz internal RC oscillator is switched on
28–31 SYSCLK	System clock switch control - These bits specify the system clock to be used by the system. 0000 16 MHz int. RC osc. 0001 external osc. 0010 PLL0 0011 reserved

W																
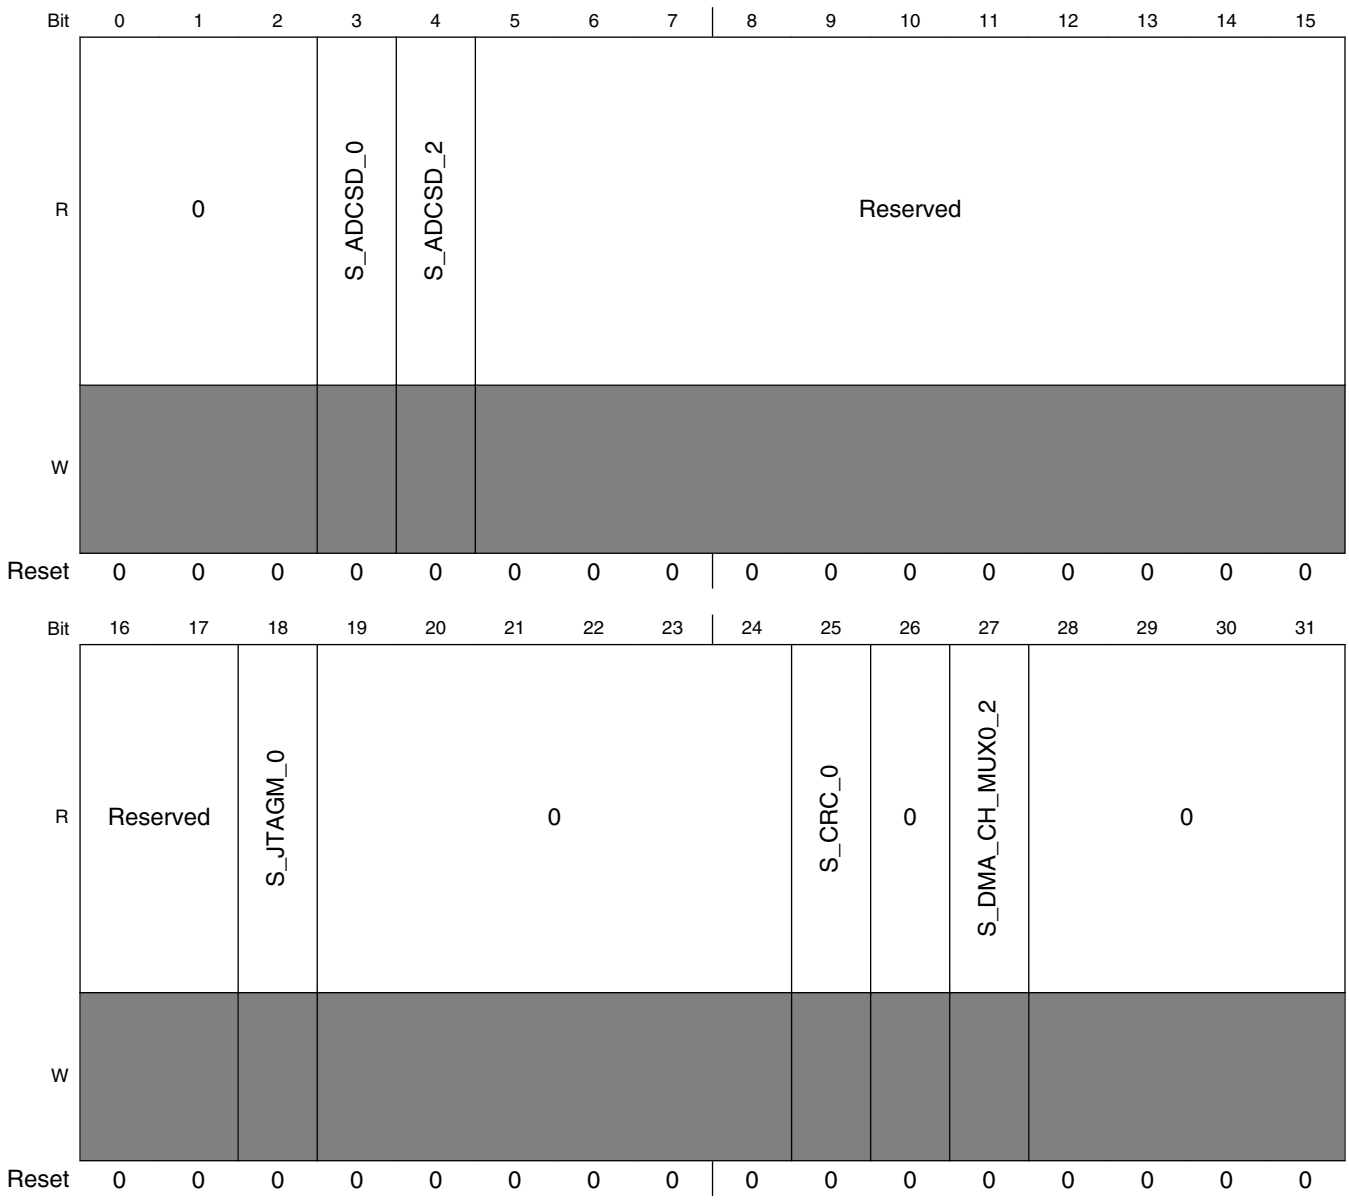
Reset	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0



MC_ME_PS0 field descriptions

Field	Description
0 S_PIT_RTI_1	Peripheral status - These bits specify the current status of each peripheral which is controlled by the MC_ME 0 Peripheral is frozen 1 Peripheral is active
1 S_PIT_RTI_0	(See the Description for the S_PIT_RTI_1 bit.)
2 S_DECFILT_0	(See the Description for the S_PIT_RTI_1 bit.)
3 S_DECFILT_1	(See the Description for the S_PIT_RTI_1 bit.)
4–15 reserved	This field is reserved.
16 S_SIUL2_0	SIUL2 is always on.
17–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20 S_SIPI_0	(See the Description for the S_PIT_RTI_1 bit.)
21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22 S_LFAST_0	(See the Description for the S_PIT_RTI_1 bit.)
23–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

62.3.19 Peripheral Status 1 (MC_ME_PS1)

This register provides the status of the peripherals.

Address: 0h base + 64h offset = 64h

MC_ME_PS1 field descriptions

Field	Description
0–2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3 S_ADCSD_0	(See the Description for the ME_PS0[S_PIT_RTI_1] register.)

Table continues on the next page...

MC_ME_PS1 field descriptions (continued)

Field	Description
4 S_ADCSD_2	(See the Description for the ME_PS0[S_PIT_RTI_1] register.)
5–17 Reserved	This field is reserved.
18 S_JTAGM_0	(See the Description for the ME_PS0[S_PIT_RTI_1] register.)
19–24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25 S_CRC_0	(See the Description for the ME_PS0[S_PIT_RTI_1] register.)
26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 S_DMA_CH_ MUX0_2	(See the Description for the ME_PS0[S_PIT_RTI_1] register.) This controls only DMAMUX0, 1, and 2.
28–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

62.3.20 Peripheral Status 2 (MC_ME_PS2)

This register provides the status of the peripherals.

Address: 0h base + 68h offset = 68h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

MC_ME_PS2 field descriptions

Field	Description
0–2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3 S_LINFLEX_0	(See the Description for the ME_PS0[S_PIT_RTI_1] register.)
4 S_LINFLEX_2	(See the Description for the ME_PS0[S_PIT_RTI_1] register.)
5–9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
10 S_LINFLEX_M0	(See the Description for the ME_PS0[S_PIT_RTI_1] register.)
11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12 S_FLEXCAN_0	(See the Description for the ME_PS0[S_PIT_RTI_1] register.)
13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14 S_FLEXCAN_2	(See the Description for the ME_PS0[S_PIT_RTI_1] register.)
15–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24 S_ADCSAR_0	(See the Description for the ME_PS0[S_PIT_RTI_1] register.)
25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26 S_ADCSAR_2	(See the Description for the ME_PS0[S_PIT_RTI_1] register.)
27–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

62.3.21 Peripheral Status 3 (MC_ME_PS3)

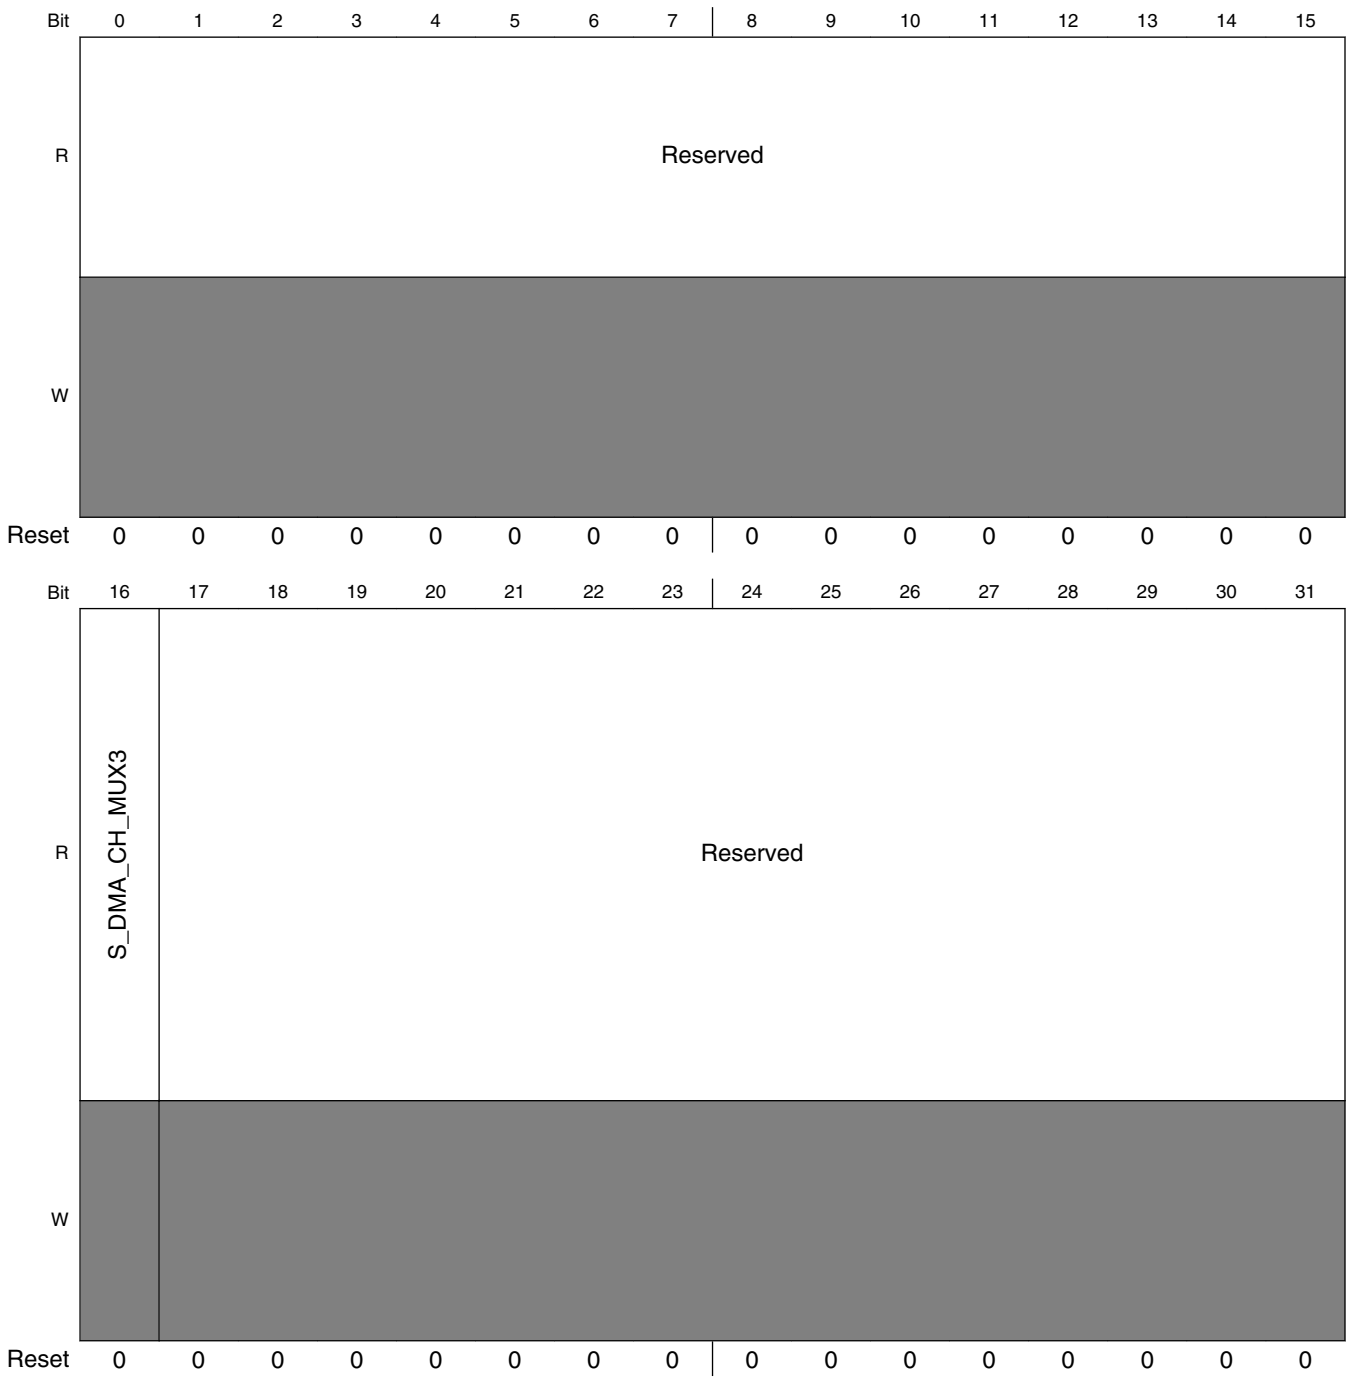
This register provides the status of the peripherals.

Address: 0h base + 6Ch offset = 6Ch

MC_ME_PS3 field descriptions

Field	Description
0–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23 S_SENT_0	(See the Description for the ME_PS0[S_PIT_RTI_1] register.)
24 Reserved	This field is reserved.
25 S_EMIOS_0	(See the Description for the ME_PS0[S_PIT_RTI_1] register.)

Table continues on the next page...



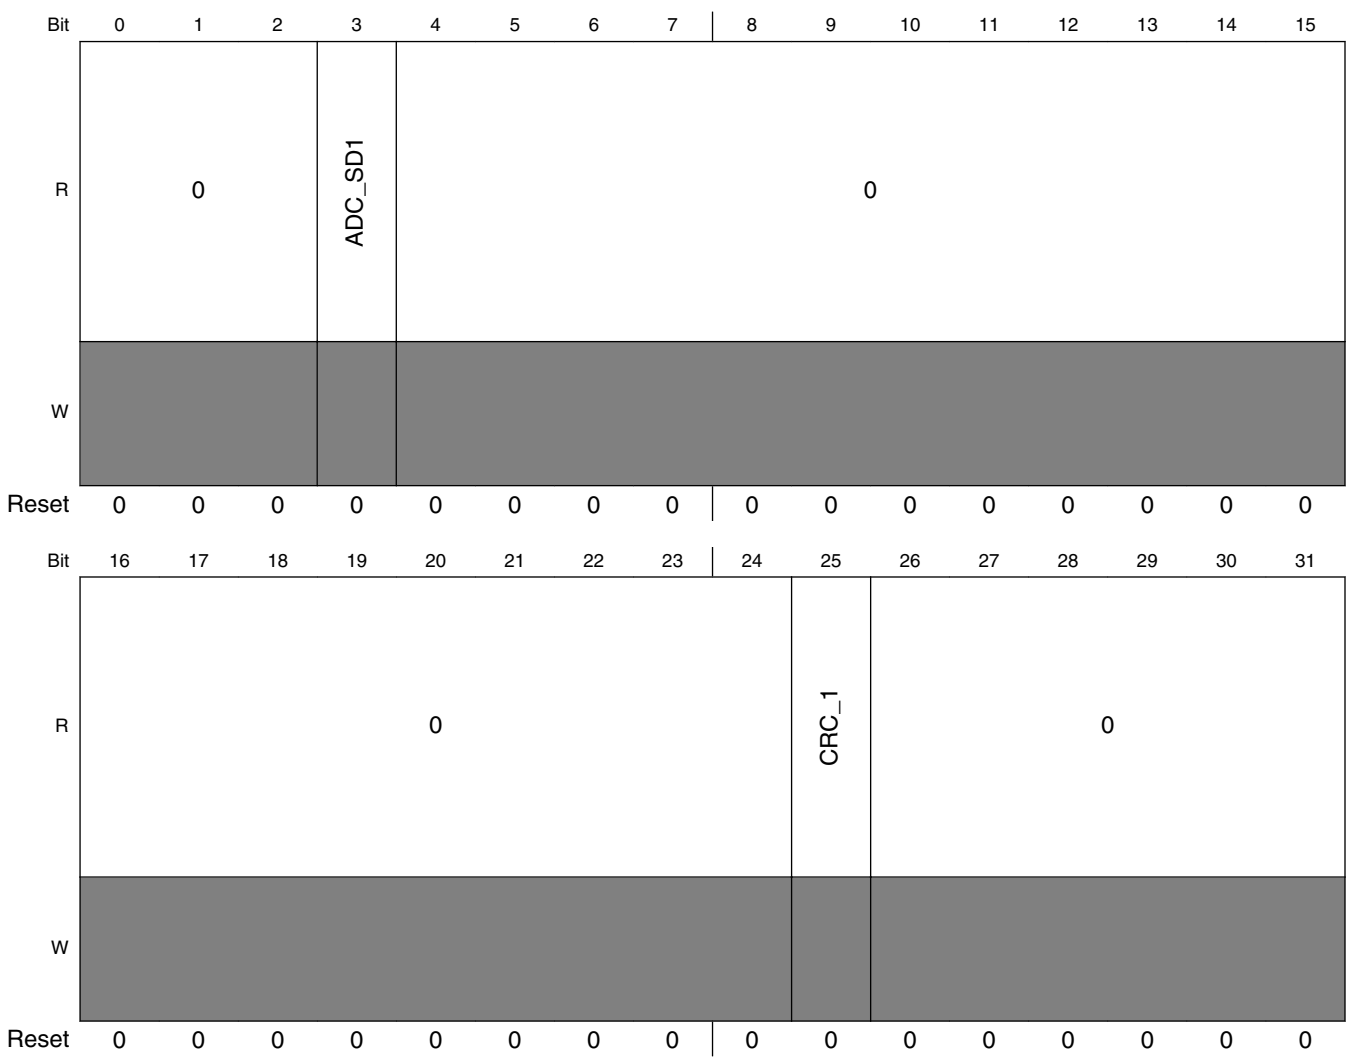
MC_ME_PS3 field descriptions (continued)

Field	Description
26–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28 S_DSPI_0	(See the Description for the ME_PS0[S_PIT_RTI_1] register.)
29 S_DSPI_2	(See the Description for the ME_PS0[S_PIT_RTI_1] register.)
30 S_DSPI_4	(See the Description for the ME_PS0[S_PIT_RTI_1] register.)
31 S_DSPI_M0	(See the Description for the ME_PS0[S_PIT_RTI_1] register.)

62.3.22 Peripheral Status 4 (MC_ME_PS4)

This register provides the status of the peripherals.

Address: 0h base + 70h offset = 70h



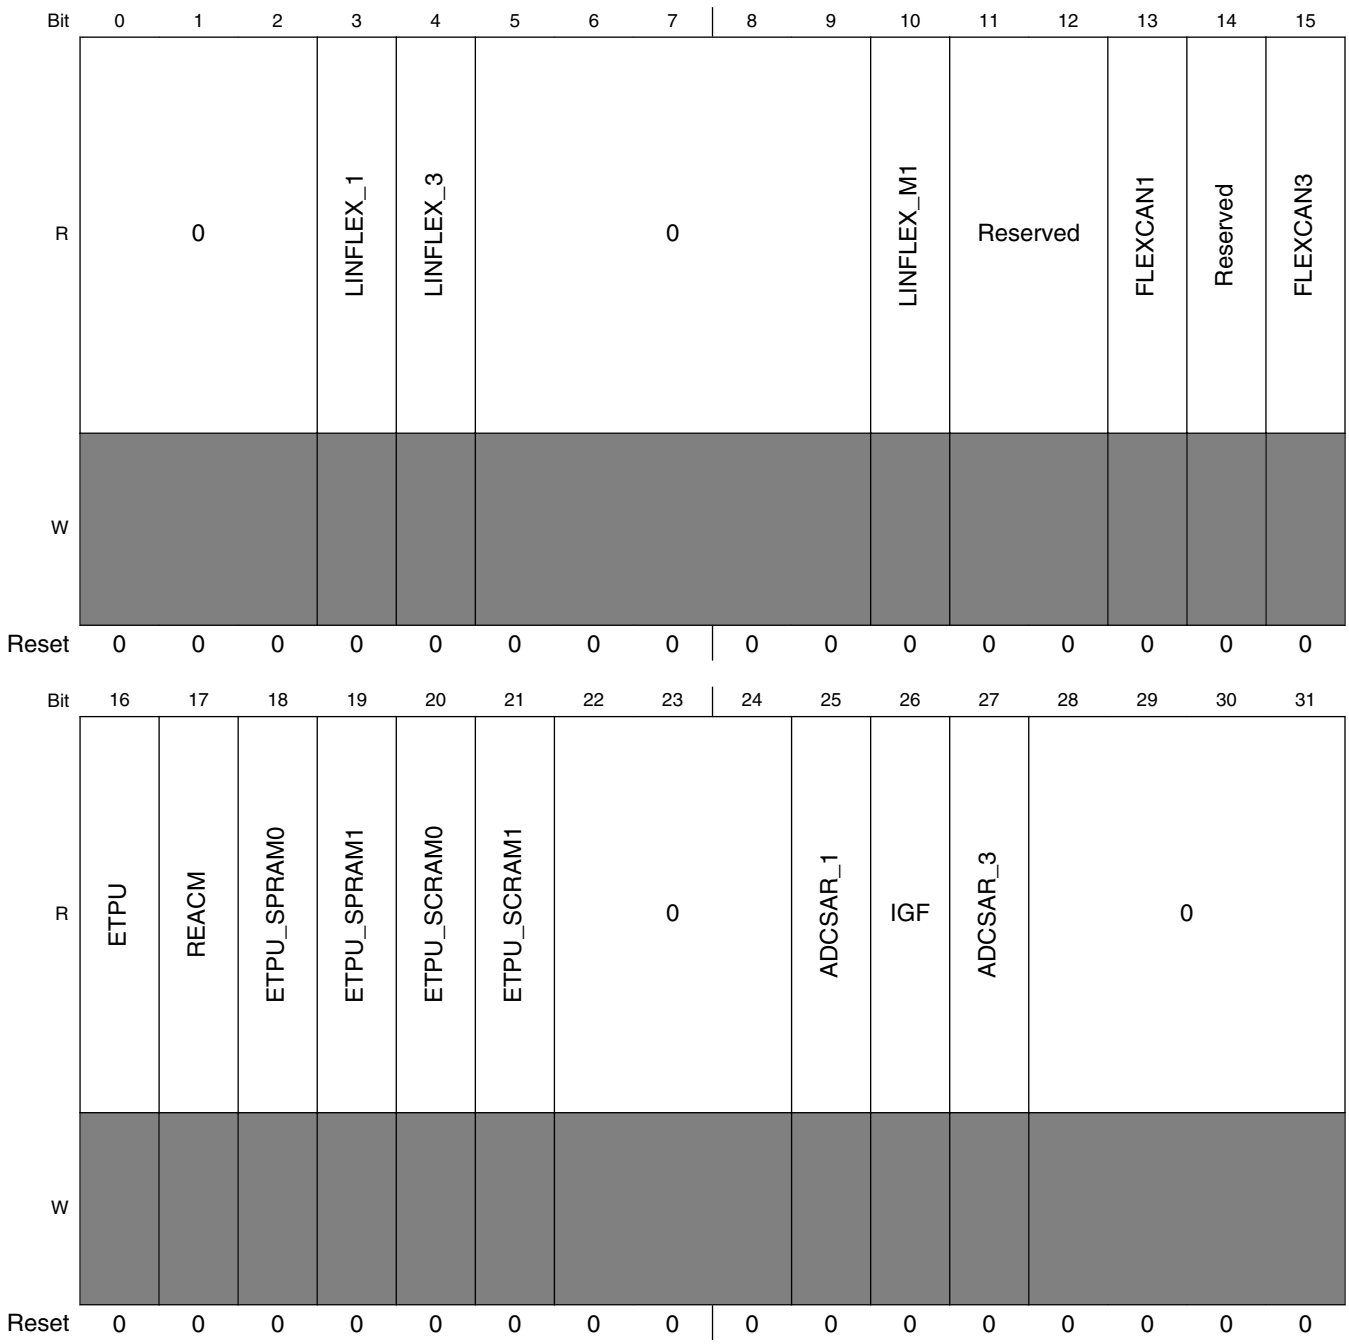
MC_ME_PS4 field descriptions

Field	Description
0–15 Reserved	This field is reserved.
16 S_DMA_CH_MUX3	(See the Description for the ME_PS0[S_PIT_RTI_1] register.)
17–31 Reserved	This field is reserved.

62.3.23 Peripheral Status 5 (MC_ME_PS5)

This register provides the status of the peripherals.

Address: 0h base + 74h offset = 74h



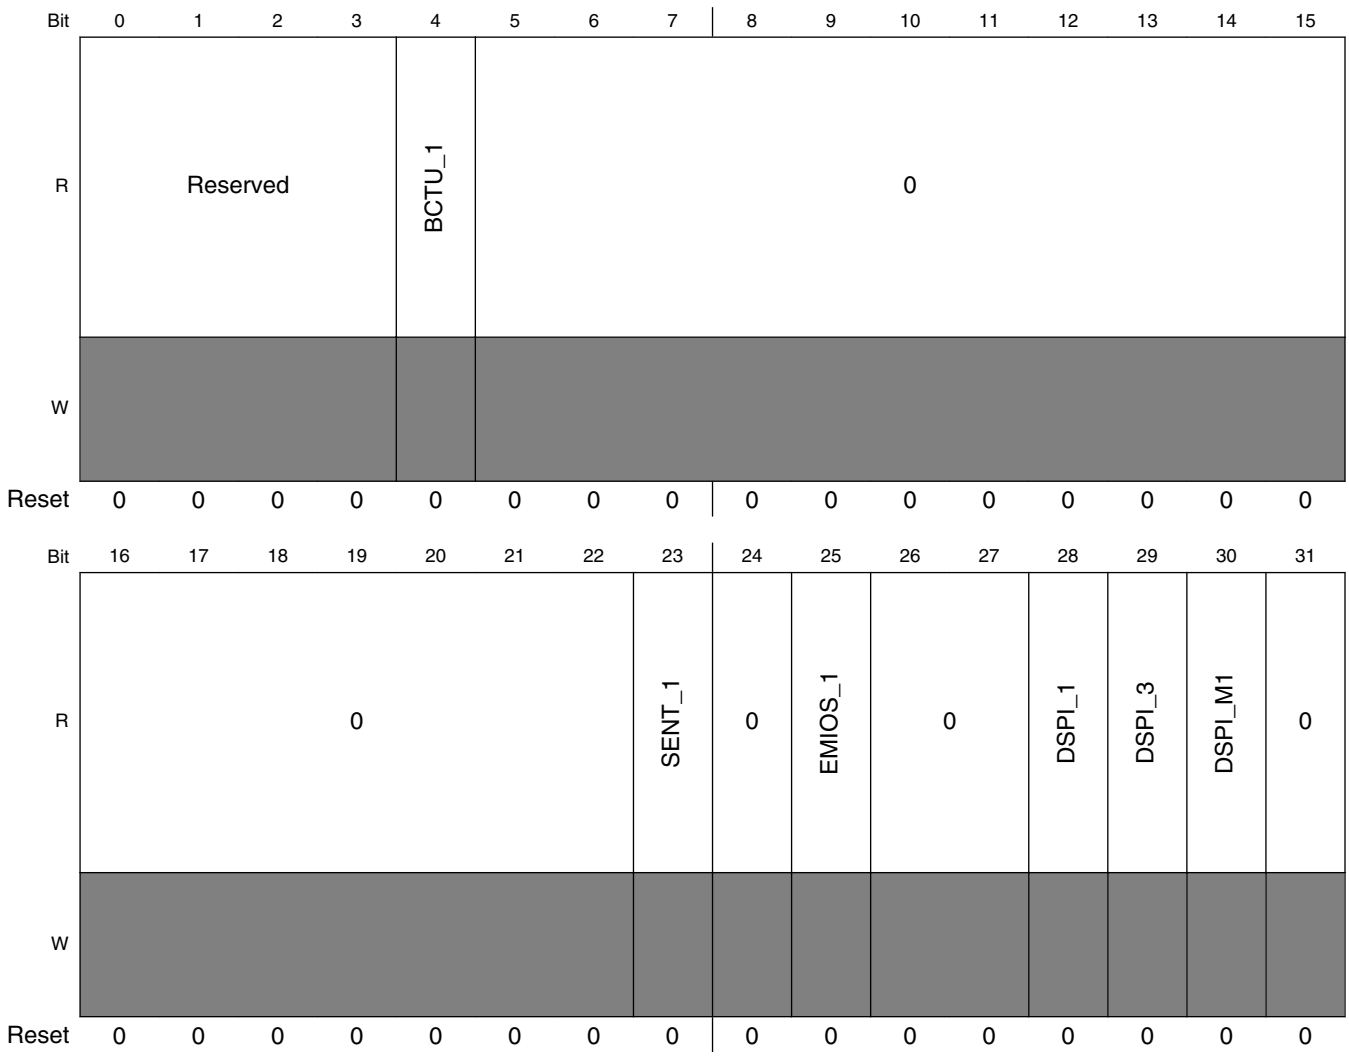
MC_ME_PS5 field descriptions

Field	Description
0–2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3 ADC_SD1	(See the Description for the ME_PS0[S_PIT_RTI_1] register.)
4–24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25 CRC_1	(See the Description for the ME_PS0[S_PIT_RTI_1] register.)
26–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

62.3.24 Peripheral Status 6 (MC_ME_PS6)

This register provides the status of the peripherals.

Address: 0h base + 78h offset = 78h



MC_ME_PS6 field descriptions

Field	Description
0–2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3 LINFLEX_1	(See the Description for the ME_PS0[S_PIT_RTI_1] register.)
4 LINFLEX_3	(See the Description for the ME_PS0[S_PIT_RTI_1] register.)
5–9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
10 LINFLEX_M1	(See the Description for the ME_PS0[S_PIT_RTI_1] register.)
11–12 Reserved	This field is reserved.
13 FLEXCAN1	(See the Description for the ME_PS0[S_PIT_RTI_1] register.)
14 Reserved	This field is reserved.
15 FLEXCAN3	(See the Description for the ME_PS0[S_PIT_RTI_1] register.)
16 ETPU	(See the Description for the ME_PS0[S_PIT_RTI_1] register.)
17 REACM	(See the Description for the ME_PS0[S_PIT_RTI_1] register.)
18 ETPU_SPRAM0	(See the Description for the ME_PS0[S_PIT_RTI_1] register.)
19 ETPU_SPRAM1	(See the Description for the ME_PS0[S_PIT_RTI_1] register.)
20 ETPU_SCRAM0	(See the Description for the ME_PS0[S_PIT_RTI_1] register.)
21 ETPU_SCRAM1	(See the Description for the ME_PS0[S_PIT_RTI_1] register.
22–24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25 ADCSAR_1	(See the Description for the ME_PS0[S_PIT_RTI_1] register.)
26 IGF	(See the Description for the ME_PS0[S_PIT_RTI_1] register.)
27 ADCSAR_3	(See the Description for the ME_PS0[S_PIT_RTI_1] register.)
28–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

62.3.25 Peripheral Status 7 (MC_ME_PS7)

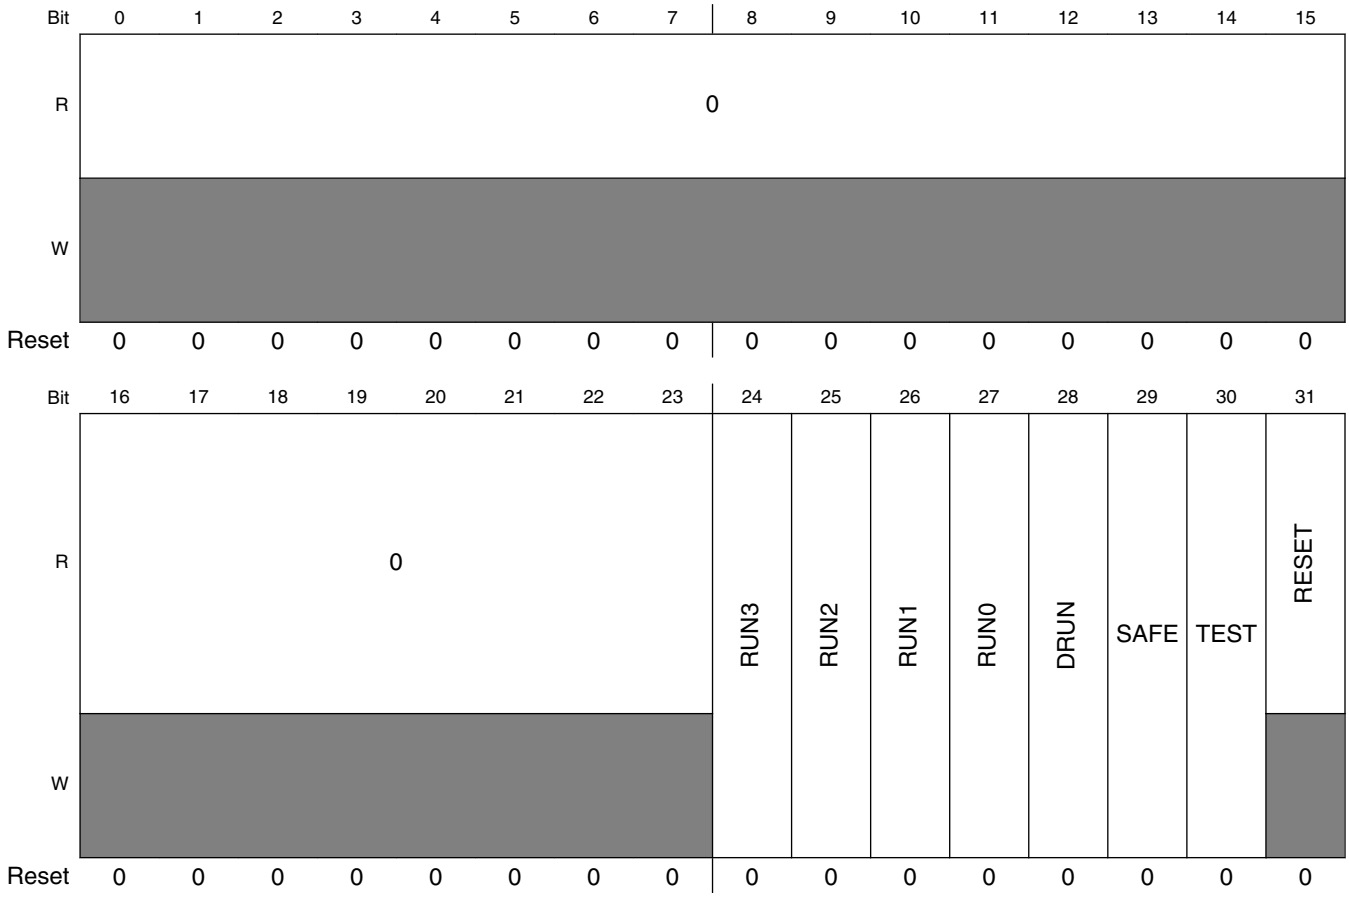
This register provides the status of the peripherals.

Address: 0h base + 7Ch offset = 7Ch

MC_ME_PS7 field descriptions

Field	Description
0–3 Reserved	This field is reserved.
4 BCTU_1	(See the Description for the ME_PS0[S_PIT_RTI_1] register.)
5–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23 SENT_1	(See the Description for the ME_PS0[S_PIT_RTI_1] register.)

Table continues on the next page...



MC_ME_PS7 field descriptions (continued)

Field	Description
24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25 EMIOS_1	(See the Description for the ME_PS0[S_PIT_RTI_1] register.)
26–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28 DSPI_1	(See the Description for the ME_PS0[S_PIT_RTI_1] register.)
29 DSPI_3	(See the Description for the ME_PS0[S_PIT_RTI_1] register.)
30 DSPI_M1	(See the Description for the ME_PS0[S_PIT_RTI_1] register.)
31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

62.3.26 Run Peripheral Configuration 0 (MC_ME_RUN_PC*n*)

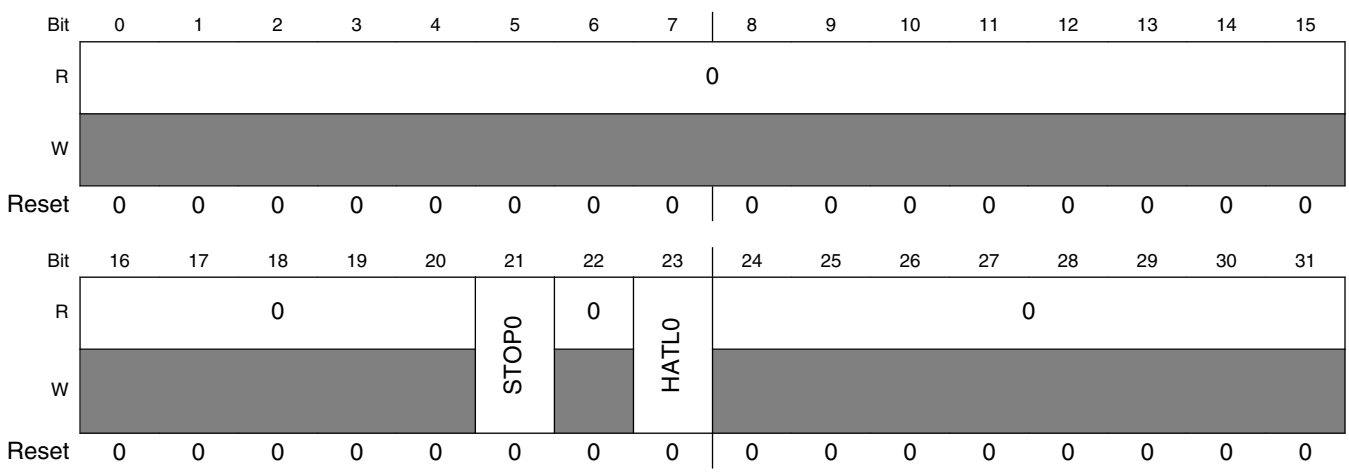
The RUN_PCn registers configure eight different types of peripheral behavior during run modes.

Address: 0h base + 80h offset + (4d × i), where i=0d to 7d

MC_ME_RUN_PC*n* field descriptions

Field	Description
0–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24 RUN3	Peripheral control during RUN3 0 Peripheral is frozen with clock gated 1 Peripheral is active
25 RUN2	Peripheral control during RUN2 0 Peripheral is frozen with clock gated 1 Peripheral is active
26 RUN1	Peripheral control during RUN1 0 Peripheral is frozen with clock gated

Table continues on the next page...



MC_ME_RUN_PC*n* field descriptions (continued)

Field	Description
	1 Peripheral is active
27 RUN0	Peripheral control during RUN0 0 Peripheral is frozen with clock gated 1 Peripheral is active
28 DRUN	Peripheral control during DRUN 0 Peripheral is frozen with clock gated 1 Peripheral is active
29 SAFE	Peripheral control during SAFE 0 Peripheral is frozen with clock gated 1 Peripheral is active
30 TEST	Peripheral control during TEST 0 Peripheral is frozen with clock gated 1 Peripheral is active
31 RESET	Peripheral control during RESET 0 Peripheral is frozen with clock gated 1 Peripheral is active

62.3.27 Low-Power Peripheral Configuration 0 (MC_ME_LP_PC*n*)

The LP_PCn registers configure eight different types of peripheral behavior during non-run modes.

Address: 0h base + A0h offset + (4d × i), where i=0d to 7d

MC_ME_LP_PC*n* field descriptions

Field	Description
0–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21 STOP0	Peripheral control during STOP0 0 Peripheral is frozen with clock gated 1 Peripheral is active
22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23 HATL0	Peripheral control during HALT0 0 Peripheral is frozen with clock gated 1 Peripheral is active
24–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

62.3.28 LFAST_0 Control (MC_ME_PCTL9)

The PCTLn registers select the configurations during run and non-run modes for each peripheral. The unoccupied locations contain a read-only byte value of 0x00.

Address: 0h base + C9h offset = C9h

Bit	0	1	2	3	4	5	6	7
Read	0	DBG_F	LP_CFG			RUN_CFG		
Write								
Reset	0	0	0	0	0	0	0	0

MC_ME_PCTL9 field descriptions

Field	Description
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 DBG_F	Peripheral control in debug mode - This bit controls the state of the peripheral in debug mode 0 Peripheral state depends on RUN_CFG/LP_CFG bits and the chip mode 1 Peripheral is frozen if not already frozen in chip modes. **NOTE:** This feature is useful to freeze the peripheral state while entering debug. For example, this may be used to prevent a reference timer from running while making a debug accesses.
2–4 LP_CFG	Peripheral configuration select for non-run modes - These bits associate a configuration as defined in the ME_LP_PC0 - 7 registers to the peripheral. 000 Selects ME_LP_PC0 configuration 001 Selects ME_LP_PC1 configuration 010 Selects ME_LP_PC2 configuration 011 Selects ME_LP_PC3 configuration

Table continues on the next page...

MC_ME_PCTL9 field descriptions (continued)

Field	Description
	100 Selects ME_LP_PC4 configuration
	101 Selects ME_LP_PC5 configuration
	110 Selects ME_LP_PC6 configuration
	111 Selects ME_LP_PC7 configuration
5–7 RUN_CFG	Peripheral configuration select for run modes - These bits associate a configuration as defined in the ME_RUN_PC0 - 7 registers to the peripheral. 000 Selects ME_RUN_PC0 configuration 001 Selects ME_RUN_PC1 configuration 010 Selects ME_RUN_PC2 configuration 011 Selects ME_RUN_PC3 configuration 100 Selects ME_RUN_PC4 configuration 101 Selects ME_RUN_PC5 configuration 110 Selects ME_RUN_PC6 configuration 111 Selects ME_RUN_PC7 configuration

62.3.29 SIPI_0 Control (MC_ME_PCTL11)

The PCTLn registers select the configurations during run and non-run modes for each peripheral. The unoccupied locations contain a read-only byte value of 0x00.

Address: 0h base + CBh offset = CBh

Bit	0	1	2	3	4	5	6	7
Read	0	DBG_F	LP_CFG			RUN_CFG		
Write								
Reset	0	0	0	0	0	0	0	0

MC_ME_PCTL11 field descriptions

Field	Description
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 DBG_F	(See the Description for the ME_PCTL9 register.)
2–4 LP_CFG	(See the Description for the ME_PCTL9 register.)
5–7 RUN_CFG	(See the Description for the ME_PCTL9 register.)

62.3.30 DECFILT_1 Control (MC_ME_PCTL28)

The PCTLn registers select the configurations during run and non-run modes for each peripheral. The unoccupied locations contain a read-only byte value of 0x00.

Address: 0h base + DCh offset = DCh

Bit	0	1	2	3	4	5	6	7
Read	0	DBG_F	LP_CFG			RUN_CFG		
Write								
Reset	0	0	0	0	0	0	0	0

MC_ME_PCTL28 field descriptions

Field	Description
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 DBG_F	(See the Description for the ME_PCTL9 register.)
2–4 LP_CFG	(See the Description for the ME_PCTL9 register.)
5–7 RUN_CFG	(See the Description for the ME_PCTL9 register.)

62.3.31 DECFILT_0 Control (MC_ME_PCTL29)

The PCTLn registers select the configurations during run and non-run modes for each peripheral. The unoccupied locations contain a read-only byte value of 0x00.

Address: 0h base + DDh offset = DDh

Bit	0	1	2	3	4	5	6	7
Read	0	DBG_F	LP_CFG			RUN_CFG		
Write								
Reset	0	0	0	0	0	0	0	0

MC_ME_PCTL29 field descriptions

Field	Description
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 DBG_F	(See the Description for the ME_PCTL9 register.)
2–4 LP_CFG	(See the Description for the ME_PCTL9 register.)
5–7 RUN_CFG	(See the Description for the ME_PCTL9 register.)

62.3.32 PIT_RTI_0 Control (MC_ME_PCTL30)

The PCTLn registers select the configurations during run and non-run modes for each peripheral. The unoccupied locations contain a read-only byte value of 0x00.

Address: 0h base + DEh offset = DEh

Bit	0	1	2	3	4	5	6	7
Read	0	DBG_F	LP_CFG			RUN_CFG		
Write								
Reset	0	0	0	0	0	0	0	0

MC_ME_PCTL30 field descriptions

Field	Description
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 DBG_F	(See the Description for the ME_PCTL9 register.)
2–4 LP_CFG	(See the Description for the ME_PCTL9 register.)
5–7 RUN_CFG	(See the Description for the ME_PCTL9 register.)

62.3.33 PIT_RTI_1 Control (MC_ME_PCTL31)

The PCTLn registers select the configurations during run and non-run modes for each peripheral. The unoccupied locations contain a read-only byte value of 0x00.

Address: 0h base + DFh offset = DFh

Bit	0	1	2	3	4	5	6	7
Read	0	DBG_F	LP_CFG			RUN_CFG		
Write								
Reset	0	0	0	0	0	0	0	0

MC_ME_PCTL31 field descriptions

Field	Description
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 DBG_F	(See the Description for the ME_PCTL9 register.)
2–4 LP_CFG	(See the Description for the ME_PCTL9 register.)
5–7 RUN_CFG	(See the Description for the ME_PCTL9 register.)

62.3.34 DMA_CH_MUX_0-2 Control (MC_ME_PCTL36)

The PCTLn registers select the configurations during run and non-run modes for each peripheral. The unoccupied locations contain a read-only byte value of 0x00.The PCTLn registers select the configurations during run and non-run modes for each peripheral. 14 TEST	Core control during TEST 0 CORE2 is frozen with clock gated 1 CORE2 is running
15 RESET	Core control during RESET - The core is always disabled during RESET.

62.3.79 CORE1 Address (MC_ME_CADDR0)

This register contains the boot address of CORE1 and a bit for controlling whether the core is to be reset on the next mode change that has the core configured to be running in the target mode.

These registers can be written only as words and cannot be written after a mode change request has been made until the mode transition has completed (i.e., while ME_GS[S_MTRANS] = ‘1’). A write access to any of these registers during this time will result in the ME_IS[ICONF_CC] flag being asserted.

ME_CADDR0 is pre-loaded with the value provided by the device configuration just before reset exit in order to ensure that CORE1 boots from the correct address after any chip reset if MC_CCTL0[DRUN] has a default value of '1’.

NOTE

The reset value of ME_CADDR0[ADDR] is determined by the chip configuration and boot mode.

Address: 0h base + 1E0h offset = 1E0h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Field	Description
0–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 RMC	Reset on Mode Change - The core will be reset on the next mode change that has the core configured to be running in the target mode. 0 CORE2 will not be reset on the next mode change 1 CORE2 will be reset on the next mode change that has the core configured to be running in the target mode

62.4 Functional Description

62.4.1 Mode Transition Request

The transition from one mode to another mode is normally handled by software by accessing the mode control register **ME_MCTL**. But the in case of special events, the mode transition can be automatically managed by hardware. In order to switch from one mode to another, the application should access the **ME_MCTL** register twice by writing

- the first time with the value of the key (0x5AF0) into the **KEY** bit field and the required target mode into the **TARGET_MODE** bit field,
- and the second time with the inverted value of the key (0xA50F) into the **KEY** bit field and the required target mode into the **TARGET_MODE** bit field.

Once a valid mode transition request is detected, the target mode configuration information is loaded from the corresponding **ME_<mode>_MC** register. The mode transition request may require a number of cycles depending on the programmed configuration, and software should check the **S_CURRENT_MODE** bit field and the

S_MTRANS bit of the global status register **ME_GS** to verify when the mode has been correctly entered and the transition process has completed. For a description of valid mode requests, please refer to Mode Transition Interrupts.

Any modification of the mode configuration register of the currently selected mode will not be taken into account immediately but on the next request to enter this mode. This means that transition requests such as ***RUN0…3*** → ***RUN0…3***, ***DRUN*** → ***DRUN***, ***SAFE*** → ***SAFE***, and ***TEST*** → ***TEST*** are considered valid mode transition requests. As soon as the mode request is accepted as valid, the **S_MTRANS** bit is set till the status in the **ME_GS** register matches the configuration programmed in the respective **ME_<mode>_MC** register.

Note

It is recommended that software polls the **S_MTRANS** bit in the **ME_GS** register after requesting a transition to ***HALT0*** or ***STOP0*** modes.

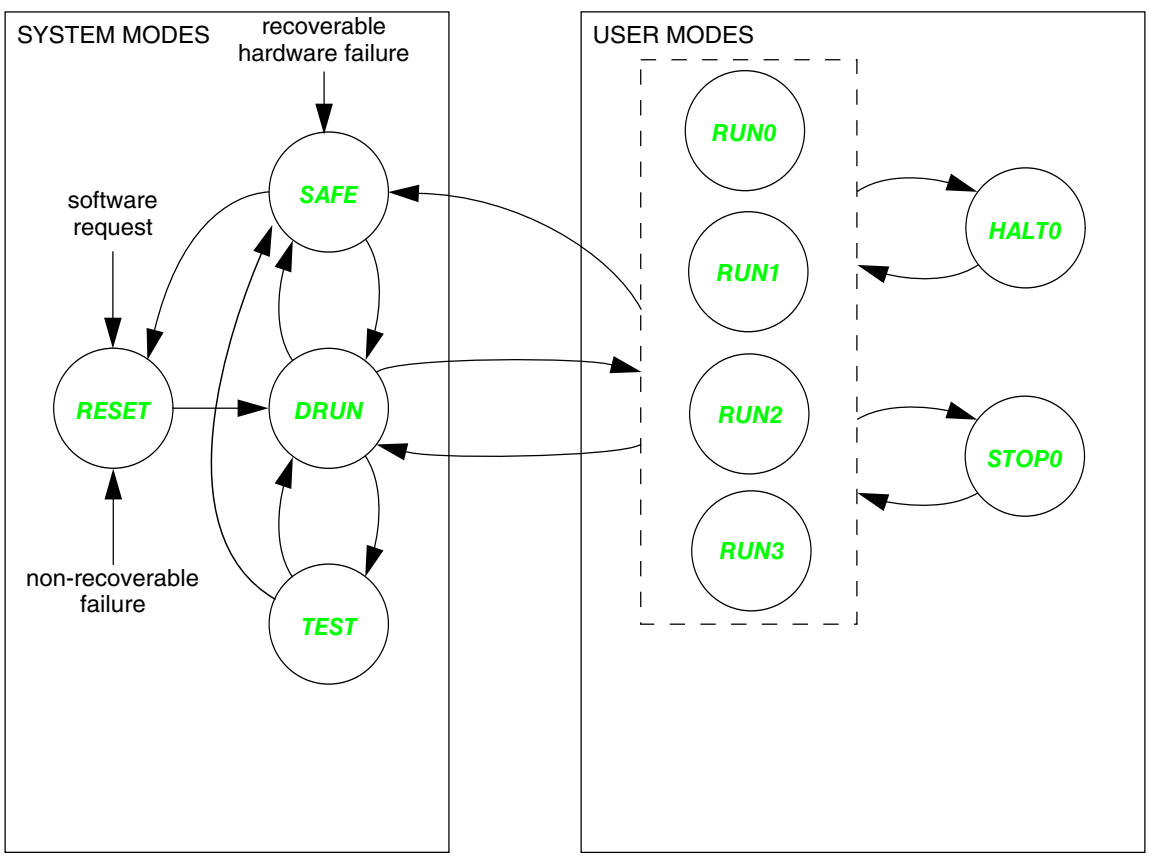

Figure 62-99. MC_ME Mode Diagram

All mode transitions shown in figure Figure 62-99 are initiated by software except for those from ***RESET*** and the low-power modes or to ***SAFE*** and ***RESET*** on a hardware failure. See Table 62-1 for a more detailed summary of mode entry and exit triggers.

62.4.2 Modes Details

62.4.2.1 *RESET* Mode

The chip enters this mode on the following events:

- from ***SAFE***, ***DRUN***, ***RUN0…3***, or ***TEST*** mode when the **TARGET_MODE** bit field of the **ME_MCTL** register is written with either "0000" for a 'functional' reset or "1111" for a 'destructive' reset
- from any mode due to a system reset by the MC_RGM because of some non-recoverable hardware failure in the system (see the MC_RGM chapter for details)

Transition to this mode is instantaneous, and the system remains in this mode until the reset sequence is finished. The mode configuration information for this mode is provided by the **ME_RESET_MC** register. This mode has a pre-defined configuration, and the 16 MHz internal RC oscillator is selected as the system clock.

62.4.2.2 *DRUN* Mode

The chip enters this mode on the following events:

- automatically from ***RESET*** mode after completion of the reset sequence
- from ***RUN0…3***, ***SAFE***, or ***TEST*** mode when the **TARGET_MODE** bit field of the **ME_MCTL** register is written with "0011"

As soon as any of the above events has occurred, a ***DRUN*** mode transition request is generated. The mode configuration information for this mode is provided by the **ME_DRUN_MC** register. In this mode, the flash, all clock sources, and the system clock configuration can be controlled by software as required. After system reset, the software execution starts with the default configuration selecting the 16 MHz internal RC oscillator as the system clock. The clock source configuration except system clock source 0 can be chosen by pre-loaded information in flash memory. This information is loaded into the **ME_DRUN_MC** register during ***PHASE3*** of the reset sequence.

This mode is intended to be used by software

- to initialize all registers as per the system needs

62.4.2.3 *SAFE* Mode

The chip enters this mode on the following events:

- from any mode except ***RESET*** when the **TARGET_MODE** bit field of the **ME_MCTL** register is written with "0010"
- from any mode except ***RESET*** due to a ***SAFE*** mode request generated by the MC_RGM because of some potentially recoverable hardware failure in the system (see the MC_RGM chapter for details)

Note

If a hardware ***SAFE*** mode request occurs during ***RESET***, depending on the timing of the ***SAFE*** mode request, ***SAFE*** mode may be entered immediately after the normal completion of the reset sequence or several system clock cycles after ***DRUN*** entry. The ***SAFE*** mode request does not have any influence on the execution of the reset sequence itself.

As soon as any of the above events has occurred, a ***SAFE*** mode transition request is generated. The mode configuration information for this mode is provided by the **ME_SAFE_MC** register. This mode has a pre-defined configuration, and the 16 MHz internal RC oscillator is selected as the system clock.

If the ***SAFE*** mode is requested by hardware, a ***SAFE*** mode interrupt is generated. See *SAFE* Mode Transition Interrupt for details.

If the ***SAFE*** mode is requested by software while some other mode transition process is ongoing, the new target mode becomes the ***SAFE*** mode regardless of other pending requests or new requests during the mode transition. No new mode request made during a transition to the ***SAFE*** mode will cause an invalid mode interrupt.

Note

If software requests to change to the ***SAFE*** mode and then requests to change back to the parent mode before the mode transition is completed, the chip's final mode after mode transition will be the ***SAFE*** mode, and an invalid mode transition interrupt will be generated.

As long as a ***SAFE*** event is active, the system remains in the ***SAFE*** mode, and any software mode request during this time is ignored and lost.

This mode is intended to be used by software

- to assess the severity of the cause of failure and then to either
  - re-initialize the chip via the ***DRUN*** mode, or
  - completely reset the chip via the ***RESET*** mode.

If the outputs of the system I/Os need to be forced to a high impedance state upon entering this mode, the **PDO** bit of the **ME_SAFE_MC** register should be set. The input levels remain unchanged.

62.4.2.4 *TEST* Mode

The chip enters this mode on the following events:

- from the ***DRUN*** mode when the **TARGET_MODE** bit field of the **ME_MCTL** register is written with "0001"

As soon as any of the above events has occurred, a ***TEST*** mode transition request is generated. The mode configuration information for this mode is provided by the **ME_TEST_MC** register. Except for the main voltage regulator, all resources of the system are configurable in this mode. The system clock to the whole system can be stopped by programming the **SYSCLK** bit field to "1111", and in this case, the only way to exit this mode is via a chip reset.

This mode is intended to be used by software

- to execute software test routines

62.4.2.5 *RUN0…3* Modes

The chip enters one of these modes on the following events:

- from the ***DRUN*** or another ***RUN0…3*** mode when the **TARGET_MODE** bit field of the **ME_MCTL** register is written with "0100…0111"
- from the ***HALT0*** mode due to an interrupt event
- from the ***STOP0*** mode due to an interrupt or wakeup event

As soon as any of the above events has occurred, a ***RUN0…3*** mode transition request is generated. The mode configuration information for these modes is provided by the **ME_RUN0…3_MC** registers. In these modes, the flash, all clock sources, and the system clock configuration can be controlled by software as required.

These modes are intended to be used by software

- to execute application routines

62.4.2.6 *HALT0* Mode

The chip enters this mode on the following events:

- from one of the ***RUN0…3*** modes when the **TARGET_MODE** bit field of the **ME_MCTL** register is written with "1000".

As soon as any of the above events has occurred, a ***HALT0*** mode transition request is generated. The mode configuration information for this mode is provided by **ME_HALT0_MC** register. This mode is quite configurable, and the **ME_HALT0_MC** register should be programmed according to the system needs. If there is a ***HALT0*** mode request while an interrupt request is active, the transition to ***HALT0*** is aborted with the resultant mode being the current mode, ***SAFE*** (on ***SAFE*** mode request), or ***DRUN*** (on reset), and an invalid mode interrupt is not generated.

This mode is intended as a first-level low-power mode with

- the core clocks frozen the additional core clocks frozen
- only a few peripherals running

and to be used by software

- to wait until it is required to do something and then to react quickly (i.e., within a few system clock cycles of an interrupt event)

The normal exit of the ***HALT0*** mode is from an interrupt event. Wakeup events will not cause ***HALT0*** mode exit.

Note

It is good practice for software to ensure that the **S_MTRANS** bit in the **ME_GS** register has been cleared on ***HALT0*** mode exit to ensure that the previous ***RUN0…3*** mode configuration has been fully restored before executing critical code.

62.4.2.7 *STOP0* Mode

The chip enters this mode on the following events:

- from one of the ***RUN0…3*** modes when the **TARGET_MODE** bit field of the **ME_MCTL** register is written with "1010".

As soon as any of the above events has occurred, a ***STOP0*** mode transition request is generated. The mode configuration information for this mode is provided by the **ME_STOP0_MC** register. This mode is fully configurable, and the **ME_STOP0_MC** register should be programmed according to the system needs. The following clock sources are switched off in this mode:

- the system PLL
- the secondary PLL

If there is a ***STOP0*** mode request while any interrupt or wakeup event is active, the transition to ***STOP0*** is aborted with the resultant mode being the current mode, ***SAFE*** (on ***SAFE*** mode request), or ***DRUN*** (on reset), and an invalid mode interrupt is not generated.

This can be used as an advanced low-power mode with the core clock frozen and almost all peripherals stopped.

This mode is intended as an advanced low-power mode with

- the core clock frozen
- the additional core clocks frozen
- almost all peripherals stopped

and to be used by software

- to wait until it is required to do something with no need to react quickly (e.g., allow for system clock source to be re-started)

The normal exit from the ***STOP0*** mode is by an interrupt or a wakeup event.

This mode can be used to stop all clock sources and thus preserve the chip status. When exiting the ***STOP0*** mode, the 16 MHz internal RC oscillator clock is selected as the system clock until the target clock is available.

Note

It is good practice for software to ensure that the **S_MTRANS** bit in the **ME_GS** register has been cleared on ***STOP0*** mode exit to ensure that the previous ***RUN0…3*** mode configuration has been fully restored before executing critical code.

The normal exit of the mode is from a wakeup event. Interrupt events will not cause mode exit.

62.4.3 Mode Transition Process

The process of mode transition follows the following steps in a pre-defined manner depending on the current chip mode and the requested target mode. In many cases of mode transition, not all steps need to be executed based on the mode control information, and some steps may not be applicable according to the mode definition itself.

Since the MC_ME ensures that all resources are in the proper state during the mode transition process, the following, for example, do not need to be checked by software.

- When the 4-40 MHz crystal oscillator is enabled in a mode configuration register, a mode transition to that mode will not complete until the End Of Count timeout occurs for the oscillator. Software does not need to interrogate the End Of Count timeout status bit.
- When a PLL is enabled in a mode configuration register, a mode transition to that mode will not complete until the PLL is locked. Software does not need to interrogate the PLL's lock status bit.

NOTE

After enabling the XOSC, an initiated mode transition is always completed, irrespective of whether there is a crystal on the board, whether the XTAL and EXTAL pins are open (floating) or whether the XTAL and EXTAL pins are shorted with a wire.

62.4.3.1 Target Mode Request

The target mode is requested by accessing the **ME_MCTL** register with the required keys. This mode transition request by software must be a valid request satisfying a set of pre-defined rules to initiate the process. If the request fails to satisfy these rules, it is ignored, and the **TARGET_MODE** bit field is not updated. An optional interrupt can be generated for invalid mode requests. Refer to Mode Transition Interrupts for details.

In the case of mode transitions occurring because of hardware events such as a reset, a ***SAFE*** mode request, or interrupt requests and wakeup events to exit from low-power modes, the **TARGET_MODE** bit field of the **ME_MCTL** register is automatically updated with the appropriate target mode. The mode change process start is indicated by the setting of the mode transition status bit **S_MTRANS** of the **ME_GS** register.

A ***RESET*** mode requested via the **ME_MCTL** register is passed to the MC_RGM, which generates a global system reset and initiates the reset sequence. The ***RESET*** mode request has the highest priority, and the MC_ME is kept in the ***RESET*** mode during the entire reset sequence.

The ***SAFE*** mode request has the next highest priority after reset. It can be generated either by software via the **ME_MCTL** register from all software running modes or by the MC_RGM after the detection of system hardware failures, which may occur in any mode.

62.4.3.2 Target Mode Configuration Loading

On completion of the Mode Transition Process step, the target mode configuration from the **ME_<target mode>_MC** register is loaded to start the resources (voltage sources, clock sources, flash, pads, etc.) control process.

An overview of resource control possibilities for each mode is shown in the following table. A '√' indicates that a given resource is configurable for a given mode.

Table 62-101. MC_ME Resource Control Overview

Resource	Mode						
	RESET	***TEST***	***SAFE***	***DRUN***	***RUN0...3***	***HALT0***	***STOP0***
IRC	on	√ on	on	on	on	√ on	√ on
XOSC	off	√ off	off	√ off	√ off	√ off	√ off
PLL0	off	√ off	off	√ off	√ off	√ off	off
PLL1	off	√ off	off	√ off	√ off	√ off	√ off
FLASH	normal	normal	normal	normal	normal	normal	normal
MVREG	on	on	on	on	on	√ on	√ on
PDO	off	√ off	√ on	off	off	off	√ off

62.4.3.3 Peripheral Clocks Disable

On completion of the Mode Transition Process step and the system clock frequency ramp-down of the System Clock Switching step, the MC_ME requests each peripheral to enter its stop mode when:

- the peripheral is configured to be disabled via the target mode, the peripheral configuration registers **ME_RUN_PC0…7** and **ME_LP_PC0…7**, and the peripheral control registers **ME_PCTL*n***

Note

The MC_ME automatically requests peripherals to enter their stop modes if the power domains in which they are residing are to be turned off due to a mode change. However, it is good practice for software to ensure that those peripherals that are to be powered down are configured in the MC_ME to be frozen.

Each peripheral acknowledges its stop mode request after closing its internal activity. The MC_ME then disables the corresponding clock(s) to this peripheral.

In the case of a ***SAFE*** mode transition request, the MC_ME does not wait for the peripherals to acknowledge the stop requests. The ***SAFE*** mode clock gating configuration is applied immediately regardless of the status of the peripherals' stop acknowledges.

Please refer to Peripheral Clock Gating for more details.

Each peripheral that may block or disrupt a communication bus to which it is connected ensures that these outputs are forced to a safe or recessive state when the chip enters the ***SAFE*** mode.

62.4.3.4 Processor Low-Power Mode Entry

If, on completion of the Peripheral Clocks Disable step, the mode transition is to the ***HALT0*** or ***STOP0*** mode, the MC_ME requests each processor to enter its stopped state. Each processor acknowledges its stop state request bit after completing all outstanding bus transactions.

If, on completion of the Peripheral Clocks Disable step, the mode transition is from a non-low-power mode to another non-low-power mode, the MC_ME requests each processor which is configured in the **ME_CCTL*n*** registers to be disabled to enter its stopped state. The processor acknowledges its stop state request bit after completing all outstanding bus transactions.

62.4.3.5 Processor Clocks Disable

If, on completion of the Processor Low-Power Mode Entry step, and all processors which are configured in the **ME_CCTL*n*** registers to be disabled are in their appropriate stopped state, the MC_ME disables the applicable processor clocks bits to achieve further power saving.

The clocks to processors which are configured to be running in both the current and target modes or disabled in both the current and target modes are unaffected while transitioning between non-low-power modes in that those bits of core_clk_en keep their previous value.

Note

Clocks to the whole chip including the processor and system memory can be disabled in ***TEST*** mode.

62.4.3.6 System Clock Disable

If, on completion of the Processor Clocks Disable step, all processor clocks have been disabled, the system clock used for non-processor system functions and memory is disabled.

62.4.3.7 Clock Sources Switch-On

On completion of the Processor Low-Power Mode Entry step, the MC_ME switches on all clock sources based on the **<clock source>ON** bits of the **ME_<current mode>_MC** and **ME_<target mode>_MC** registers. The following clock sources are switched on at this step:

- 16 MHz internal RC oscillator
- 4-40 MHz crystal oscillator

- PLL0
- PLL1

The clock sources that are required by the target mode are switched on. The duration required for the output clocks to be stable depends on the type of source, and all further steps of mode transition depending on one or more of these clocks waits for the stable status of the respective clocks. The availability status of these clocks is updated in the **S_<clock source>** bits of **ME_GS** register.

The clock sources which need to be switched off are unaffected during this process in order to not disturb the system clock which might require one of these clocks before switching to a different target clock.

62.4.3.8 Pad Outputs-On

On completion of the step, if the **PDO** bit of the **ME_<target mode>_MC** register is cleared, then

- all pad outputs are enabled to return to their previous state
- the I/O pads power sequence driver is switched on

62.4.3.9 Peripheral Clocks Enable

Based on the current and target chip modes, the peripheral configuration registers **ME_RUN_PC0…7**, **ME_LP_PC0…7**, and the peripheral control registers **ME_PCTLn,** the MC_ME enables the clocks for selected modules as required. This step is executed only after the process is completed, and if the value of the **PWRLVL** field of the **ME_<target mode>_MC** register is different from that of the **ME_<current mode>_MC** register's, the peripheral clock enable/disable isn't updated until after the system clock frequency ramp-down step of the System Clock Switching process is completed.

62.4.3.10 System and Processor Clocks Enable

The MC_ME enables the non-processor system clock and the clocks of all processors which are configured in the **ME_CCTL*n*** registers to be disabled in the current mode and to be running in the target mode.

The MC_ME initiates the resetting of all processors which are configured in the **ME_CCTL*n*** registers to be running in the target mode and which have their **RMC** bits in the **ME_CADDR*n*** registers set to '1'. The core_rst_b outputs remain asserted until the end of the mode transition as indicated by the **S_MTRANS** bit of the **MW_GS** register at which time they are deasserted.

If the value of the **PWRLVL** field of the **ME_<target mode>_MC** register is different from that of the **ME_<current mode>_MC** register's, the mode change handshake will not be initiated until after the system clock frequency ramp-down step of the System Clock Switching process is completed.

62.4.3.11 Processor Low-Power Mode Exit

On completion of the System and Processor Clocks Enable step, the MC_ME requests all processors which are configured in the **ME_CCTL*n*** registers to be disabled in the current mode and to be running in the target mode.

62.4.3.12 System Clock Switching

Based on the **SYSCLK** bit field of the **ME_<current mode>_MC** and **ME_<target mode>_MC** registers, if the target and current system clock configurations differ, the following method is implemented for clock switching.

- The target clock configuration for the 16 MHz internal RC oscillator takes effect only after the **S_IRC** bit of the **ME_GS** register is set by hardware (i.e., the 16 MHz internal RC oscillator has stabilized).
- The target clock configuration for the 4-40 MHz crystal oscillator takes effect only after the **S_XOSC** bit of the **ME_GS** register is set by hardware (i.e., the 4-40 MHz crystal oscillator has stabilized).
- The target clock configuration for the system PLL takes effect only after the **S_PLL0** bit of the **ME_GS** register is set by hardware (i.e., the system PLL has stabilized).
- If the clock is to be disabled, the **SYSCLK** bit field should be programmed with "1111". This is possible only in the ***TEST*** mode.

If the value of the **PWRLVL** field of the **ME_<target mode>_MC** register not equal to that of the **ME_<current mode>_MC** register's, a progressive clock switching is performed in the MC_CGM in order to reduce the impact of a sudden increase or drop in the power consumption of the device.

The current system clock configuration can be observed by reading the **S_SYSCLK** bit field of the **ME_GS** register, which is updated after every system clock switching. Until the target clock is available, the system uses the previous clock configuration.

System clock switching starts only after

- the Clock Sources Switch-On process has completed if the target system clock source is one of the following:
  - the 16 MHz internal RC oscillator
  - the 4-40 MHz crystal oscillator
- the Peripheral Clocks Disable process has completed in order not to change the system clock frequency before peripherals close their internal activitiesthe Peripheral Clocks Enable process has completed

An overview of system clock source selection possibilities for each mode is shown in the following table. A '√' indicates that a given clock source is selectable for a given mode.

Table 62-102. MC_ME System Clock Selection Overview

System Clock Source	Mode						
	RESET	***TEST***	***SAFE***	***DRUN***	***RUN0...3***	***HALT0***	***STOP0***
16 MHz int. RC osc.	√ (default)	√ (default)	√ (default)	√ (default)	√ (default)	√ (default)	√ (default)
4-40 MHz crystal osc.		√		√	√	√	√
system PLL		√		√	√	√	
system clock is disabled		√[1]					

1. disabling the system clock during ***TEST*** mode will require a reset in order to exit ***TEST*** mode

62.4.3.13 Pad Switch-Off

If the **PDO** bit of the **ME_<target mode>_MC** register is '1' then

- the outputs of the pads are forced to the high impedance state if the target mode is ***SAFE*** or ***TEST***

This step is executed only after the Peripheral Clocks Disable process has completed.

62.4.3.14 Clock Sources (with no Dependencies) Switch-Off

Based on the chip mode and the **<clock source>ON** bits of the **ME_<mode>_MC** registers, if a given clock source is to be switched off and no other clock source needs it to be on, the MC_ME requests the clock source to power down and updates its availability status bit **S_<clock source>** of the **ME_GS** register to '0'. The following clock sources are switched off at this step:

- the secondary PLL

For the clock sources related to the system clock, this step is executed only after the System Clock Switching process has completed.

62.4.3.15 Clock Sources (with Dependencies) Switch-Off

Based on the chip mode and the **<clock source>ON** bits of the **ME_<mode>_MC** registers, if a given clock source is to be switched off and all clock sources which need this clock source to be on have been switched off, the MC_ME requests the clock source to power down and updates its availability status bit **S_<clock source>** of the **ME_GS** register to '0'. The following clock sources are switched off at this step:

- the 4-40 MHz crystal oscillator
- the system PLL

This step is executed only after

- the System Clock Switching process has completed in order not to lose the current system clock during mode transition
- the Clock Sources (with no Dependencies) Switch-Off process has completed in order to, for example, prevent unwanted lock transitions

62.4.3.16 Current Mode Update

The current mode status bit field **S_CURRENT_MODE** of the **ME_GS** register is updated with the target mode bit field **TARGET_MODE** of the **ME_MCTL** register when :

- all the updated status bits in the **ME_GS** register match the configuration specified in the **ME_<target mode>_MC** register
- power sequences are done
- clock disable/enable process is finished
- processor low-power mode (stop) entry and exit processes are finished

Note

SAFE mode entry does not wait for the clock disable/enable process to finish. It only waits for the **ME_GS.S_RC** bit to be set. This is to ensure that the ***SAFE*** mode is entered as quickly as possible.

Software can monitor the mode transition status by reading the **S_MTRANS** bit of the **ME_GS** register. The mode transition latency can differ from one mode to another depending on the resources' availability before the new mode request and the target mode's requirements.

If a mode transition is taking longer to complete than is expected, the **ME_DMTS** register can indicate which process is still in progress.

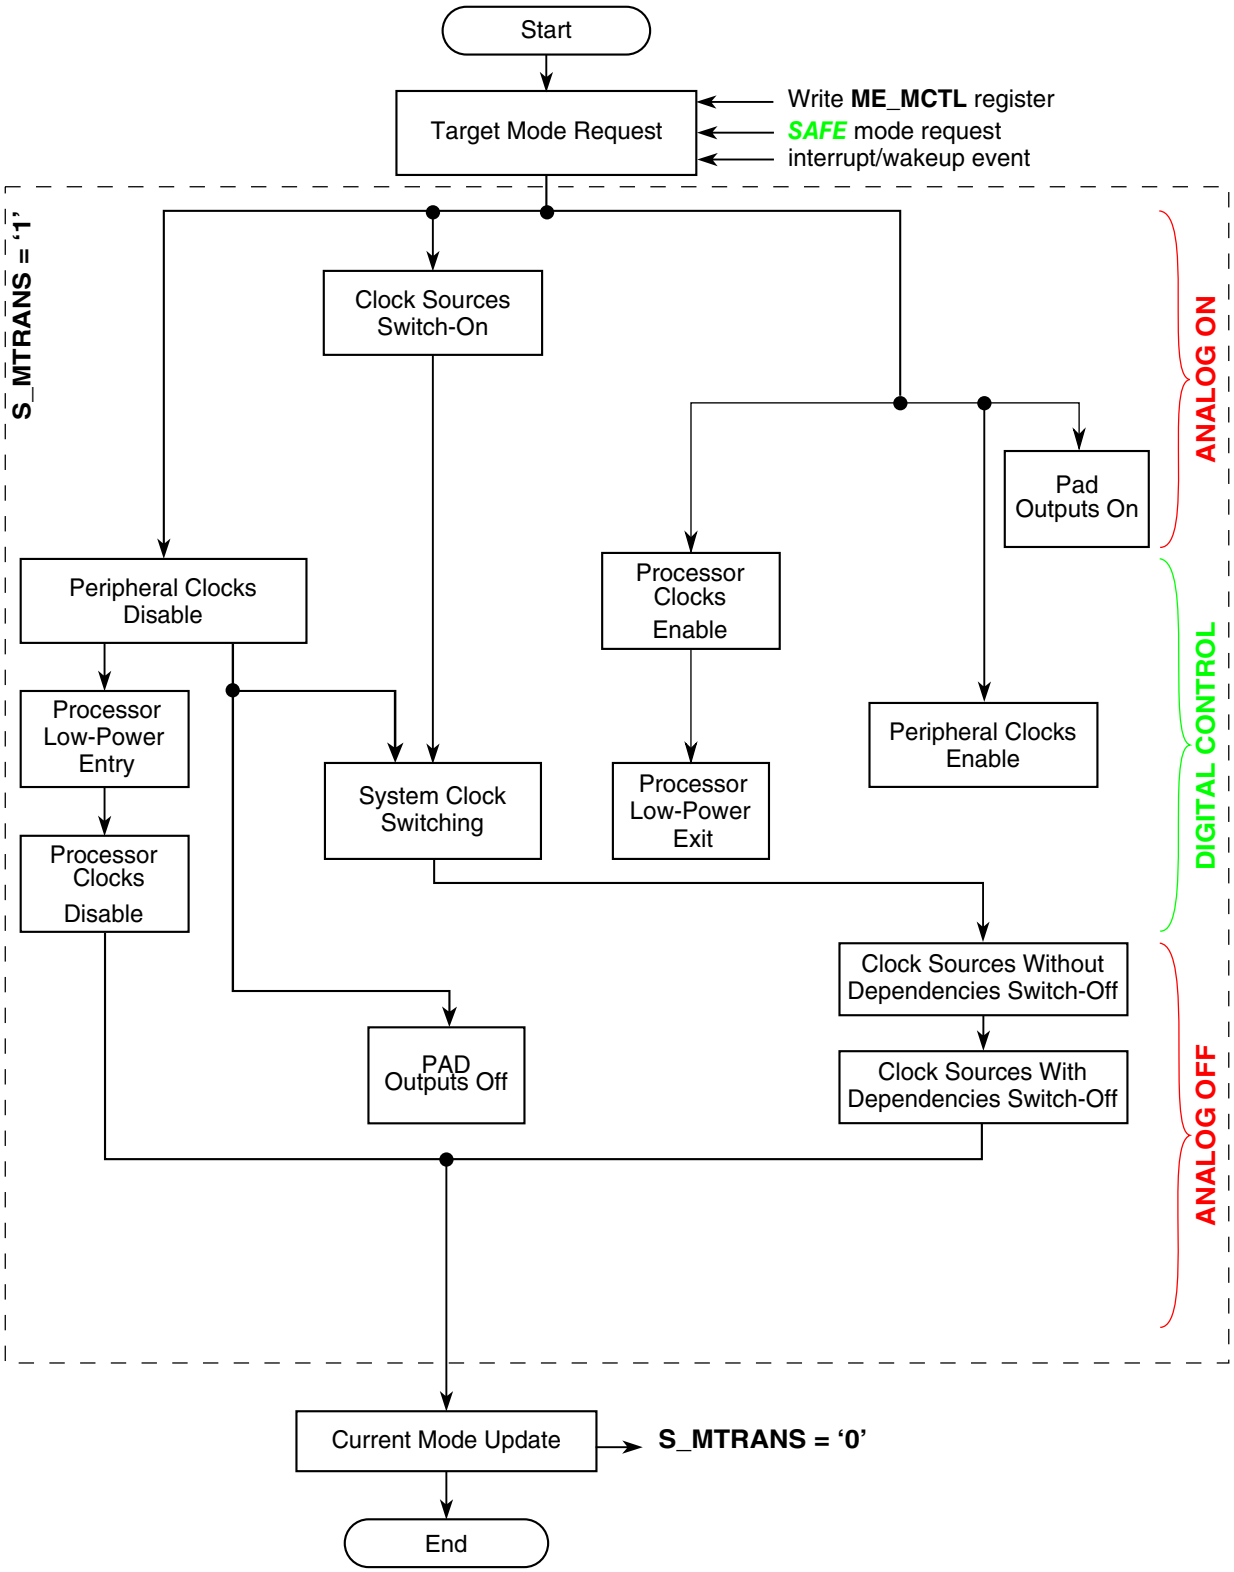

Figure 62-100. MC_ME Transition Diagram

62.4.4 Software Considerations for Preventing the Blocking of Mode Transitions

Mode transitions will not complete (i.e., mode transition is blocked) in certain conditions where

- resources are required in the target mode but are configured to be disabled in that target mode
- a low-power mode transition is attempted and there is a pending wakeup event
- a low-power mode transition is attempted and there is a pending interrupt

In these cases, **ME_STATUS[S_MTRANS]** never clears, **ME_IS[I_MTC]** never sets, and the invalid mode transition flags may not set.

While waiting for the mode transition to complete (e.g., polling **ME_GS[S_MTRANS]**), a timer can be used to detect if a mode transition takes too long. If the timer expires an error recovery function can be called.

To prevent mode transitions from being blocked, software must handle the following mode transition cases:

- **Enable required clock sources for the target mode's system clock selection.**

  Mode transitions can be blocked when a clock source to generate the system clock is not turned on in the target mode.

  Example for when XOSC is the reference clock for PLL0:

  > If the target mode is ***RUN1*** and **ME_RUN1_MC[SYSCLK]** is PLL0, then both **ME_RUN1_MC[XOSCON]** and **ME_RUN1_MC[PLL0ON]** must be set to '1'. If **ME_RUN1_MC[XOSCON]** is '0', the mode transition is blocked.

  Software must ensure that all required clock sources for generating the target mode's system clock are turned on for that target mode configuration.

- **Enable required clock sources for peripherals in the target mode.**

  Mode transitions can be blocked when an attempt is being made to stop a clock while one or more peripherals require this clock in the target mode.

  A given peripheral's clock is configured to be stopped in a target mode via peripheral configuration registers **ME_RUN_PC*x*** and **ME_LP_PC*x*** and the corresponding peripheral control register **ME_PCTL*x***. In addition, some peripherals may require local disabling before stopping their clocks via the MC_ME. Local disabling is accomplished by setting the peripheral's **MDIS** bit to '1'.

Modules requiring clocks being disabled before stopping them are:

- CAN modules

Example:

Assume a CAN module is using XOSC. A mode transition to ***RUN1*** is requested where **MC_RUN1_MC[XOSCON]** is '0'. The mode transition will not complete.

Software must disable the module whose clock source is to be turned off in the target mode.

- **Disable or service any pending interrupts when transitioning to low-power modes.**

  For transition into low power modes (***STOP0*** and ***HALT0***), mode transitions can be blocked by a peripheral's pending interrupt.

  Pending interrupts are detected by the MC_ME when the peripheral's interrupt flag is set, and the eripheral's interrupt enable is set.

  Note

  The **MSR[EE]** and **INTC_PSR*x*[PRI]** registers have no effect on the MC_ME detecting a pending interrupt.

  Software must either

  - disable interrupt enable flags in peripherals that may have their flag set, or,
  - detect and process the interrupt by either
    - polling the peripheral flag and servicing it in software, or,
    - taking the interrupt vector (requires **MSR[EE]** = 1 and **INTC_PSRx[PRI]** >0 for that peripheral.

- **Service any pending wakeup events when transitioning to low power modes.**

  For transition into low-power modes (***STOP0*** and ***HALT0***), mode transitions can be blocked by enabled wakeup events from the API or a wakeup pin transition.

  Example:

  The API is set to a very short value and enabled as a wakeup event. After the first of two writes to the **ME_MCTL** register to request a mode transition, the API expires. The mode transition will not complete because the wakeup event requires servicing.

Software must either

- ensure wakeup events cannot occur before low-power mode entry completion, or,
- detect and process the wakeup events during mode transition by either
  - polling the flags of enabled wakeup events in the **WISR** register and servicing it in software, or,
  - enabling wakeup events to cause an interrupt and execute the interrupt service routine (ISR).

Note

If the ISR also invokes a mode transition on it's own, then any prior writes to the **ME_MCTRL** register for the low-power mode transition will not be valid.

62.4.5 Protection of Mode Configuration Registers

While programming the mode configuration registers **ME_<mode>_MC**, the following rules must be respected. Otherwise, the write operation is ignored and an invalid mode configuration interrupt may be generated.

- If the 16 MHz internal RC oscillator is selected as the system clock, IRC must be on.
- If the 4-40 MHz crystal oscillator clock is selected as the system clock, XOSC must be on.
- If the system PLL clock is selected as the system clock, PLL0 must be on.
- If *CSRC_DEP[(12 × i) + j]* & csrc_dep_curr[(12 × i) + j] = '1' and **CSRC*j*ON** is '1', **CSRC*i*ON** must also be '1' (or in the case of *i* or *j* = 0, **RCON**).
- If PLL1 is on, XOSC must also be on.
- If PLL1 is on, PLL0 must also be on.

Note

Software must ensure that clock sources with dependencies other than those mentioned above are switched on as needed. There is no automatic protection mechanism to check this in the MC_ME.

- Configuration "00" for the **FLAON** bit field is reserved.
- System clock configurations marked as 'reserved' may not be selected.
- Configuration "1111" for the **SYSCLK** bit field is allowed only for the ***TEST*** mode, and only in this case may all system clock sources be turned off.

Note

If the system clock is stopped during ***TEST*** mode, the chip can exit only via a system reset.

62.4.6 Mode Transition Interrupts

The MC_ME provides interrupts for incorrectly configuring a mode, requesting an invalid mode transition, indicating a ***SAFE*** mode transition not due to a software request, and indicating when a mode transition has completed.

62.4.6.1 Invalid Mode Configuration Interrupt

Whenever a write operation is attempted to the **ME_<mode>_MC** registers violating the protection rules mentioned in Software Considerations for Preventing the Blocking of Mode Transitions, Mode transitions will not complete (i.e., mode transition is blocked) in certain conditions where the interrupt pending bit **I_ICONF** of the **ME_IS** register is set and an interrupt request is generated if the mask bit **M_ICONF** of the **ME_IM** register is '1'.

In addition, during a mode transition, if a clock source has been configured in the **ME_<target mode>_MC** register to be off and a peripheral requiring this clock source to be on has been enabled via the **ME_RUN_PC0…7/ME_LP_PC0…7** and **ME_PCTLn** registers, the interrupt pending bit **I_ICONF_CU** of the **ME_IS** register is set and an interrupt request is generated if the mask bit **M_ICONF_CU** of the **ME_IM** register is '1'.

If an attempt to write to one of the **ME_CCTLn** or **ME_CADDRn** registers is made after a mode change request has been made via the second write to the **ME_CTL** register and before the completion of that mode transition as indicated by the **S_MTRANS** bit in the **ME_GS** register deasserting, the interrupt pending bit **I_ICONF_CC** of the **ME_IS** register is set and an interrupt request is generated if the mask bit **M_ICONF_CC** of the **ME_IM** register is '1'.

62.4.6.2 Invalid Mode Transition Interrupt

The mode transition request is considered invalid under the following conditions:

- If the system is in the ***SAFE*** mode and the ***SAFE*** mode request from MC_RGM is active, and if the target mode requested is other than ***RESET*** or ***SAFE***, then this new mode request is considered to be invalid, and the **S_SEA** bit of the **ME_IMTS** register is set.
- If the **TARGET_MODE** bit field of the **ME_MCTL** register is written with a value different from the specified mode values (i.e., a non-existing mode), an invalid mode transition event is generated. When such a non existing mode is requested, the **S_NMA** bit of the **ME_IMTS** register is set. This condition is detected regardless of whether the proper key mechanism is followed while writing the **ME_MCTL** register. The following modes are defined as non-existing:
  - "1001"
  - "1011"
  - "1100"
  - "1101"
  - "1110"
- If some of the chip modes are disabled as programmed in the **ME_ME** register, their respective configurations are considered reserved, and any access to the **ME_MCTL** register with those values results in an invalid mode transition request. When such a disabled mode is requested, the **S_DMA** bit of the **ME_IMTS** register is set. This condition is detected regardless of whether the proper key mechanism is followed while writing the **ME_MCTL** register.
- If the target mode is not a valid mode with respect to the current mode, the mode request illegal status bit **S_MRI** of the **ME_IMTS** register is set. This condition is detected only when the proper key mechanism is followed while writing the **ME_MCTL** register. Otherwise, the write operation is ignored.

- If further new mode requests occur while a mode transition to a mode other than ***SAFE*** mode is in progress (the **S_MTRANS** bit of the **ME_GS** register is '1'), the mode transition illegal status bit **S_MTI** of the **ME_IMTS** register is set. This condition is detected only when the proper key mechanism is followed while writing the **ME_MCTL** register. Otherwise, the write operation is ignored.
- If a new mode request occurs while a mode transition to the ***SAFE*** mode is in progress (the **S_MTRANS** bit of the **ME_GS** register is '1'), the mode request ignored status bit **S_MRIG** of the **ME_IMTS** register is set. This condition is detected only when the proper key mechanism is followed while writing the **ME_MCTL** register. Otherwise, the write operation is ignored.

Note

As the causes of invalid mode transitions may overlap at the same time, the priority implemented for invalid mode transition status bits of the **ME_IMTS** register in the order from highest to lowest is **S_SEA**, **S_NMA**, **S_DMA**, **S_MRI**, **S_MRI**, and **S_MTI**.

As an exception, the mode transition request is not considered as invalid under the following conditions:

- A new request is allowed to enter the ***RESET*** or ***SAFE*** mode irrespective of the mode transition status.
- As the exit of ***HALT0*** and ***STOP0*** modes depends on the interrupts of the system which can occur at any instant, these requests to return to ***RUN0…3*** modes are always valid.
- In order to avoid any unwanted lockup of the chip modes, software can abort a mode transition by requesting the parent mode if, for example, the mode transition has not completed after a software determined 'reasonable' amount of time for whatever reason. The parent mode is the chip mode before a valid mode request was made.

CAUTION

Depending on the cause of an incomplete mode transition, aborting by requesting the parent mode might not succeed. In this case, software must request a change to either SAFE or RESET mode, because the cause of the lockup is most likely a hardware fault.

- Self-transition requests (e.g., ***RUN0*** → ***RUN0***) are not considered as invalid even when the mode transition process is active (i.e., **S_MTRANS** is '1'). During the low-power mode exit process, if the system is not able to enter the respective ***RUN0…3***

mode properly (i.e., all status bits of the **ME_GS** register match with configuration bits in the **ME_<mode>_MC** register), then software can only request the ***SAFE*** or ***RESET*** mode. It is not possible to request any other mode or to go back to the low-power mode again.

Whenever an invalid mode request is detected, the interrupt pending bit **I_IMODE** of the **ME_IS** register is set, and an interrupt request is generated if the mask bit **M_IMODE** of the **ME_IM** register is '1'.

62.4.6.3 *SAFE* Mode Transition Interrupt

Whenever the system enters the ***SAFE*** mode as a result of a ***SAFE*** mode request from the MC_RGM due to a hardware failure, the interrupt pending bit **I_SAFE** of the **ME_IS** register is set, and an interrupt is generated if the mask bit **M_SAFE** of **ME_IM** register is '1'.

The ***SAFE*** mode interrupt pending bit can be cleared only when the ***SAFE*** mode request is deasserted by the MC_RGM (see the MC_RGM chapter for details on how to clear a ***SAFE*** mode request). If the system is already in ***SAFE*** mode, any new ***SAFE*** mode request by the MC_RGM also sets the interrupt pending bit **I_SAFE**. However, the ***SAFE*** mode interrupt pending bit is not set when the ***SAFE*** mode is entered by a software request (i.e., programming of **ME_MCTL** register).

62.4.6.4 Mode Transition Complete interrupt

Whenever the system fully completes a mode transition (i.e., the **S_MTRANS** bit of **ME_GS** register transits from '1' to '0'), the interrupt pending bit **I_MTC** of the **ME_IS** register is set, and an interrupt request is generated if the mask bit **M_MTC** of the **ME_IM** register is '1'. The interrupt bit **I_MTC** is not set when entering low-power modes ***HALT0*** and ***STOP0*** in order to avoid the same event requesting the immediate exit of these low-power modes.

62.4.7 Peripheral Clock Gating

During all chip modes, each peripheral can be associated with a particular clock gating policy determined by two groups of peripheral configuration registers.

The run peripheral configuration registers **ME_RUN_PC0…7** are chosen only during the software running modes ***DRUN***, ***TEST***, ***SAFE***, and ***RUN0…3***. All configurations are programmable by software according to the needs of the application. Each configuration

register contains a mode bit which determines whether or not a peripheral clock is to be gated. Run configuration selection for each peripheral is done by the **RUN_CFG** bit field of the **ME_PCTL*n*** registers.

The low-power peripheral configuration registers **ME_LP_PC0…7** are chosen only during the low-power modes ***HALT0*** and ***STOP0***. All configurations are programmable by software according to the needs of the application. Each configuration register contains a mode bit which determines whether or not a peripheral clock is to be gated. Low-power configuration selection for each peripheral is done by the **LP_CFG** bit field of the **ME_PCTL*n*** registers.

Any modifications to the **ME_RUN_PC0…7**, **ME_LP_PC0…7**, and **ME_PCTL*n*** registers do not affect the clock gating behavior until a new mode transition request is generated.

Whenever the chip enters a debug session during any mode, the following occurs for each peripheral:

- The clock is gated if the **DBG_F** bit of the associated **ME_PCTL*n*** register is set. Otherwise, the peripheral clock gating status depends on the **RUN_CFG** and **LP_CFG** bits.

62.4.8 Initialization / Application Information

The following figure shows an example application flow for requesting a mode change and then waiting until the mode transition has completed.

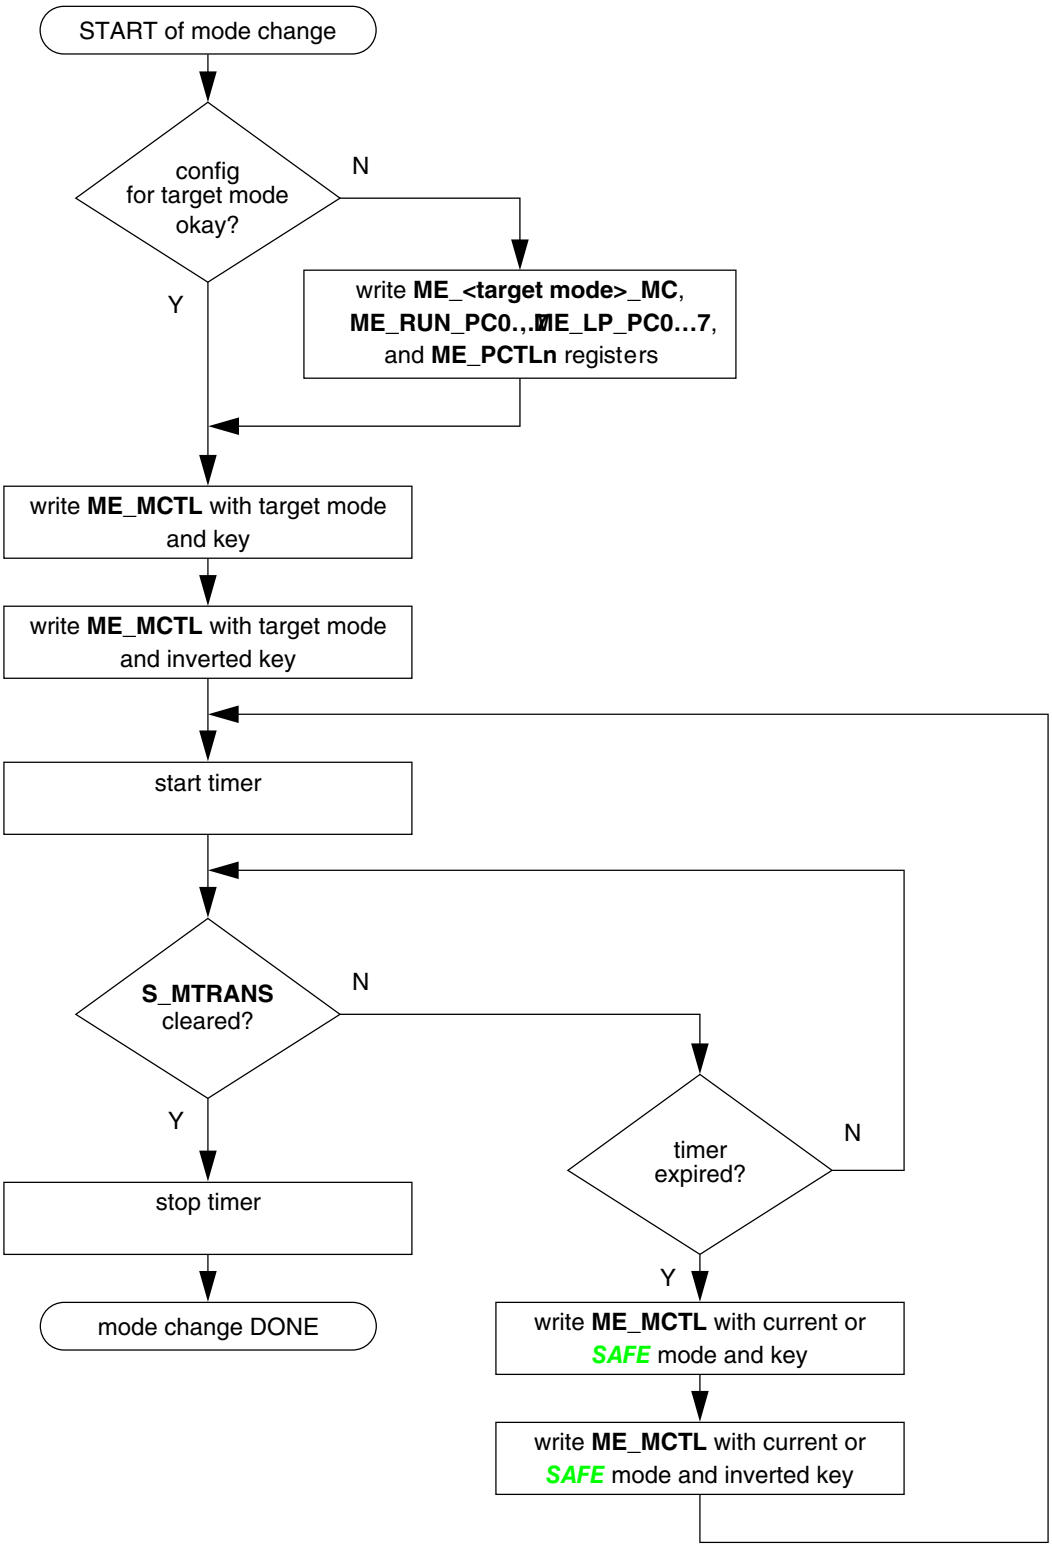

Figure 62-101. MC_ME Application Example Flow Diagram

Chapter 63
Calibration and Debug

63.1 Introduction

This chapter discusses the chip-specific information for the debug and calibration modules. All standards used have freely available specifications for tool developers.

The debug and calibration features for this device are provided in two separate dies: the Production die and the Buddy die, or Buddy Device (BD). The Production die is packaged alone in the Production Device (PD) package. The PD is also assembled into an Emulation and Debug Device (ED) package that consists of the Production die along with the Buddy die. The Buddy device supports additional debug capability.

The ED implements a high-speed serial Nexus trace auxiliary port. The Aurora interface allows the Nexus protocol information to be transmitted serially at high speed over four Aurora lanes. The Aurora protocol handles the encoding of the data and striping the information across the four Aurora lanes available on the device.

63.2 Core debug support

Internal debug support in the e200z425n cores allows for software and hardware debug by providing debug functions, such as instruction and data breakpoints and program trace modes. The cores have the capability of exiting reset halted in debug mode, such that no code runs. This allows debuggers to perform operations such as configuration of calibration remap or edit of overlay memory prior to user code execution.

For details, see Core Debug Support.

63.3 Run control and memory access

Run control is any operation required to control device operation. Run control includes starting and stopping the processor's execution of code, as well as accessing memory while the device is stopped to download code. The Debug and Calibration Interface (DCI) provides the central run control including cross-triggering of breakpoint conditions. This DCI provides support for the IEEE 1149.1 JTAG standard with the JTAG Controller (JTAGC) as well as the IEEE 1149.7 standard with the Compact JTAG (CJTAG) module. The JTAG interface supports both Boundary Scan and Debug modes. It is based on the IEEE 1149.1 and IEEE 1149.7 standards. The JTAG Controller (JTAGC) operates in the standard IEEE 1149.1 5-wire interface. The JTAGC can either be fed directly from the JTAG pins or the CJTAG module, which supports the IEEE 1149.7 standard.

The Sequence Processing Unit (SPU) provides cross-triggering of events from the device. The SPU can access some of the DCI run control features since it can control the $\overline{\text{EVTO}}$ pins and monitor the $\overline{\text{EVTI}}$ pins. Furthermore, the SPU can use system triggers to cause many different types of actions, including triggering a breakpoint cross-trigger (managed by the DCI).

The following table shows the JTAG operating frequencies.

Table 63-1. JTAG operating frequencies

PD configuration	PD system clock frequency [MHz]	Max JTAG frequency [MHz]	Notes
Unpowered, in reset state, or powered, out of reset, PLL not engaged	16	3.88	Assuming 64 MHz PD IRC with 30% tolerance
Powered, out of reset, PLL engaged	190	See datasheet	JTAG speed is limited by TDO delay (16 ns as per PES) and setup time with respect to TCK (5 ns)

63.3.1 Debug and Calibration Interface (DCI)

The Debug and Calibration Interface (DCI) module provides debug and calibration features. The DCI module includes the device JTAG Controller and the IEEE 1149.7 interface. The DCI provides the following features:

- Debug mode enable control for connected tools or software
- IEEE 1149.1 and 1149.7 controllers
- Debug break and cross-triggering control
- Synchronous restart control for all CPUs when exiting debug mode
- Tool hot plug capability
- Security access control
- Simultaneous operation for debug and calibration features

63.3.1.1 DCI signals

The DCI sends and receives the $\overline{\text{EVTI}}$[1:0] and $\overline{\text{EVTO}}$[1:0] signals to/from the cores and other modules. The tables below summarize the source and destination of $\overline{\text{EVTI}}$, $\overline{\text{EVTO}}$, and related signals for the PD and the BD. For example, for the PD, $\overline{\text{EVTI}}$[0] are outputs of the JTAGM and SPU and inputs to the cores and NXMC.

Table 63-3. PD DCI signals

Signal	Cores	NXMC	NAR	JTAGM	eTPU	SPU	DTS
$\overline{\text{EVTI}}$[0]	I	I	—	O	I	I/O	—
$\overline{\text{EVTI}}$[1]	—	—	—	O	—	I/O	—
$\overline{\text{EVTO}}$[0]	O	O	—	I[1, 1]	O	I/O	—
$\overline{\text{EVTO}}$[1]	—	—	—	I[1]	—	I/O	O
Core debug event	I	—	—	—	—	—	—
DCI cross triggering	O	—	—	—	O	—	—

1. The EVTO signal provided to the JTAGM is stretched by the DCI on the 16MHz IRC clock. Therefore, the incoming EVTO cannot be reliably detected by the JTAGM when the JTAGM clock is configured at less than 32MHz.

Table 63-4. BD DCI signals

Signal	RWA	NAR	NAL	JTAGM
$\overline{\text{EVTI}}$[0]	—	I	—	O

Table continues on the next page...

Table 63-4. BD DCI signals (continued)

Signal	RWA	NAR	NAL	JTAGM
EVTI[1]	—	—	—	O
EVTO[0]	—	—	—	I[1, 1]
EVTO[1]	—	—	—	I[1]

1. The EVTO signal provided to the JTAGM is stretched by the DCI on the 16MHz IRC clock. Therefore, the incoming EVTO cannot be reliably detected by the JTAGM when the JTAGM clock is configured at less than 32MHz.

The DCI sends the system debug signal, ipg_debug, to the modules below. For details regarding module functionality during system debug, refer to the individual module chapter.

63.3.1.2 DCI EVTx Pin Multiplexing Control Register (DCI_PINCR)

The DCI EVTx Pin Multiplexing Control Register (DCI_PINCR) is described below. The EVTI and EVTO functions share the same set of possible pins. If this register is written to enable both EVTI and EVTO on the same pin, the EVTI function is selected, although

this type of programming should be avoided. Programming the $\overline{\text{EVTI}}$ fields to select $\overline{\text{EVTI}}$[0] or $\overline{\text{EVTI}}$[1] inputs to come from more than one pin is considered a programming error and no pin is enabled.

63.3.1.3 JTAG Controller (JTAGC)

The JTAGC block provides the means to test chip functionality and connectivity while remaining transparent to system logic when not in test mode. Testing is performed via a boundary scan technique, as defined in the IEEE 1149.1-2001 standard. All data input to and output from the JTAGC block is communicated in serial format. All Nexus debug registers are accessed and configured via the JTAG Controller.

63.3.1.3.1 JTAGC ACCESS_AUX block instructions

The PD and BD ACCESS_AUX instructions are described in these tables.

Table 63-6. PD ACCESS_AUX 6-bit JTAG instructions

63.3.1.4 Compact JTAG (CJTAG)

The CJTAG module implements parts of the IEEE 1149.7 standard for test and debug capabilities.

63.3.2 JTAG Data Communication (JDC)

The JTAG Data Communication (JDC) module allows access to two registers by JTAG and software running on one of the CPUs in the device. These registers can be used to exchange data between an internal CPU and an external debug tool.

63.3.3 Sequence Processing Unit (SPU)

The Sequence Processing Unit (SPU) provides on-device logic analyzer trigger functions, such as performance monitoring, by using internal device signals as trigger sources. Performance monitor functions are available at both the system and CPU level. Complex trigger and system performance monitor functions are implemented in the SPU module. System-level performance monitor functions are integrated into the SPU complex trigger logic, thus allowing the counting and timing of any debug trigger combinations supported by the SPU.

Various clients generate watchpoints and other triggers when operating in Debug mode. The SPU collects these triggers and uses them as conditions for programmable sequences of states and resultant actions. The SPU provides the capability to create complex debug triggers. By configuring each of the events to trigger specific actions, it achieves complex logic-analyzer-like behavior, providing vital real-time visibility and the ability to debug system activities.

63.3.3.1 SPU Level1 Input Mux Configuration registers

The SPU Level1 Mux inputs for the L1SELn registers (where n = 0–7) are described in the following tables. The L1SEL0 register fields are described in the following table.

Table 63-8. L1SEL0 register field descriptions

63.4 Calibration interface

This device includes software enabled debugging and calibration mode. Apart from the JTAG sources, such as a JTAG-based tool, it is possible to generate JTAG sequences through software programming. To support a software debug session, the software can enable debug and calibration mode via an memory-mapped register in the JTAGM. Software based debug is not possible when a tool is connected. The presence of the tool is determined using the rising edge of the JCOMP pad to set an internal flag which, when set, disables the selection of JTAGM as a JTAG source.

Table 63-16. Reference links to related information

Related module	Reference
JTAG Master (JTAGM)	JTAG Master (JTAGM)
Development Tool Semaphore (DTS)	Development Tool Semaphore (DTS)
Flash memory controller	Flash memory controller

63.4.1 JTAG Master (JTAGM)

The JTAG Master (JTAGM) acts as JTAG master inside the device. The module has a parallel interface that can exchange data with another serial communication module or through software.

The data transferred to this module is transformed to produce TCK, TMS, TDI, and TRST outputs and to accept TDO inputs. The module allows these five signals to connect to the JTAGC as if the JTAG data were coming from an external tool. The JTAGM generates all required JTAG scan chains to allow software and high-speed serial communication access to all JTAG-mapped resources.

63.4.2 Development Trigger Semaphore (DTS)

The Development Trigger Semaphore (DTS) module enables software to signal an external tool by driving a persistent (affected only by reset or an external tool) signal on an external device pin. There are a variety of ways that this module can be used, including as a component of an external real-time data acquisition system.

Note

When used as a component of a triggered data-acquisition system, Nexus read/write access is via the JTAG interface of the Nexus debug port and is different than the data acquisition protocol defined in the IEEE-ISTO 5001-2003 or IEEE-ISTO 5001-2012 Nexus standards, which use the Nexus auxiliary port.

63.5 Flash calibration support

The flash memory controller supports calibration development by providing a remapping function to route flash accesses to overlay RAM. The calibration remap function supports the following overlay RAM targets:

- On-chip (PD) overlay RAM
- Extended off-chip (ED) overlay RAM
- Portion of the PD system RAM

63.6 Nexus Trace Aurora interface

The Aurora interface allows Nexus protocol information to be transmitted serially at high speed over multiple Aurora lanes to provide advanced trace information from the device. The Aurora protocol handles the encoding of the data and the striping of information across the lanes. The Aurora interface is only available on the Emulation and Debug Device. Trace information is transferred to the Buddy device for transmission via the Aurora interface. The PD only supports trace to the internal trace/calibration memory.

The Aurora information can be used to reconstruct events or operations that occurred inside the microcontroller. Nexus supports the transmission, through a single Aurora port, of information from multiple trace clients within the MCU. Each Nexus message is tagged with the source client identifier and the type of message. The actual trace information that is available depends on the Nexus client; generally, it can be individually enabled (both the type of message and the client). Table 63-17 shows a few examples of Nexus messages. All messages can be enabled to include a timestamp, with the exception of the messages from the eTPU.

Table 63-17. Nexus message types

Message Type	Description
Program trace	Nexus program trace messages transmit any discontinuities in the program flow, such as branches and interrupts. Multiple types of messages can be generated.
Ownership trace	Ownership trace provides information on process identification changes.
Watchpoint trace	Watchpoint messages are generated any time a watchpoint match occurs in the program or data flow, or as a result of SPU actions. These can be programmed for many types of events within the MCU.
Device identification	The device identification message allows information about the MCU to be transmitted upon startup to allow tools to identify the target system MCU type.
Debug status	Debug status messages provide additional information that may be needed to reconstruct software execution, such as whether the device has entered Debug or Low-power mode.
Data acquisition	Data acquisition messages are an optional feature that allows software control of information to be transmitted.
Error	Error messages are transmitted when an error condition occurs, such as internal buffer overflows.

The Nexus trace information can be output to internal memory, or the parallel information can be serialized for transmission over a serial interface through the Nexus Aurora interface.

The Nexus blocks do not have memory-mapped registers. The Nexus registers are accessed by the development tool via the JTAG port using a two step process. First, the specific block is selected by loading the corresponding ACCESS_AUX instruction as described in the JTAGC chapter. Next, after the block is selected, the Nexus registers are enabled by loading the enable instruction to the JTAGC Instruction Register (IR). The

enable instructions for the different Nexus clients are shown in the following table. After the enable instruction is received, the development tool has access to the Nexus registers of the selected client.

Table 63-18. Nexus client JTAG enable instructions

Module	Enable instruction	Opcode
Production Die		
Cores	CORE_ENABLE	0x7C (10 bits)
NXMC	NEXUS_ENABLE	0x0 (4 bits)
NAR		
SPU		
eTPU		
Buddy Die		
RWA	CORE_ENABLE	0x7C (10 bits)
NAR	NEXUS_ENABLE	0x0 (4 bits)
NAL		

All of the internal JTAG modules are accessed through a single JTAG connection to the device. In the case of the ED, all JTAG communication is performed through the JTAG interface located in the BD. In the production package configuration, access is performed through the JTAG interface located in the PD.

With the hierarchical JTAG configuration, the BD JTAGC is considered the master JTAG TAP controller. The PD JTAGC TAP controller is selected via an AUX_ACCESS instruction. Other TAP controllers residing on the BD are also selected via AUX_ACCESS instructions (NAR, RWA, BD_DCI). Once control is transferred from the BD JTAGC to the PD JTAGC via the AUX_ACCESS instruction, all other PD TAP controllers are then selected via AUX_ACCESS instructions executed by the PD JTAGC. This is also referenced as TAP-sharing and is shown in the following figure.

NOTE

On the Emulation device, when the PAUSE-DR/UPDATE-DR state is executed to pass control of the JTAG TAP controller, control is always passed to the top level JTAG TAP controller, in other words, the DCI of the BD. For this reason, it is recommended that all JTAG operations, except when the BD clients need to be accessed, that all PD JTAG access be preceded with ACCESS_PD_JTAGC command. If the device is not an ED, the access is ignored.

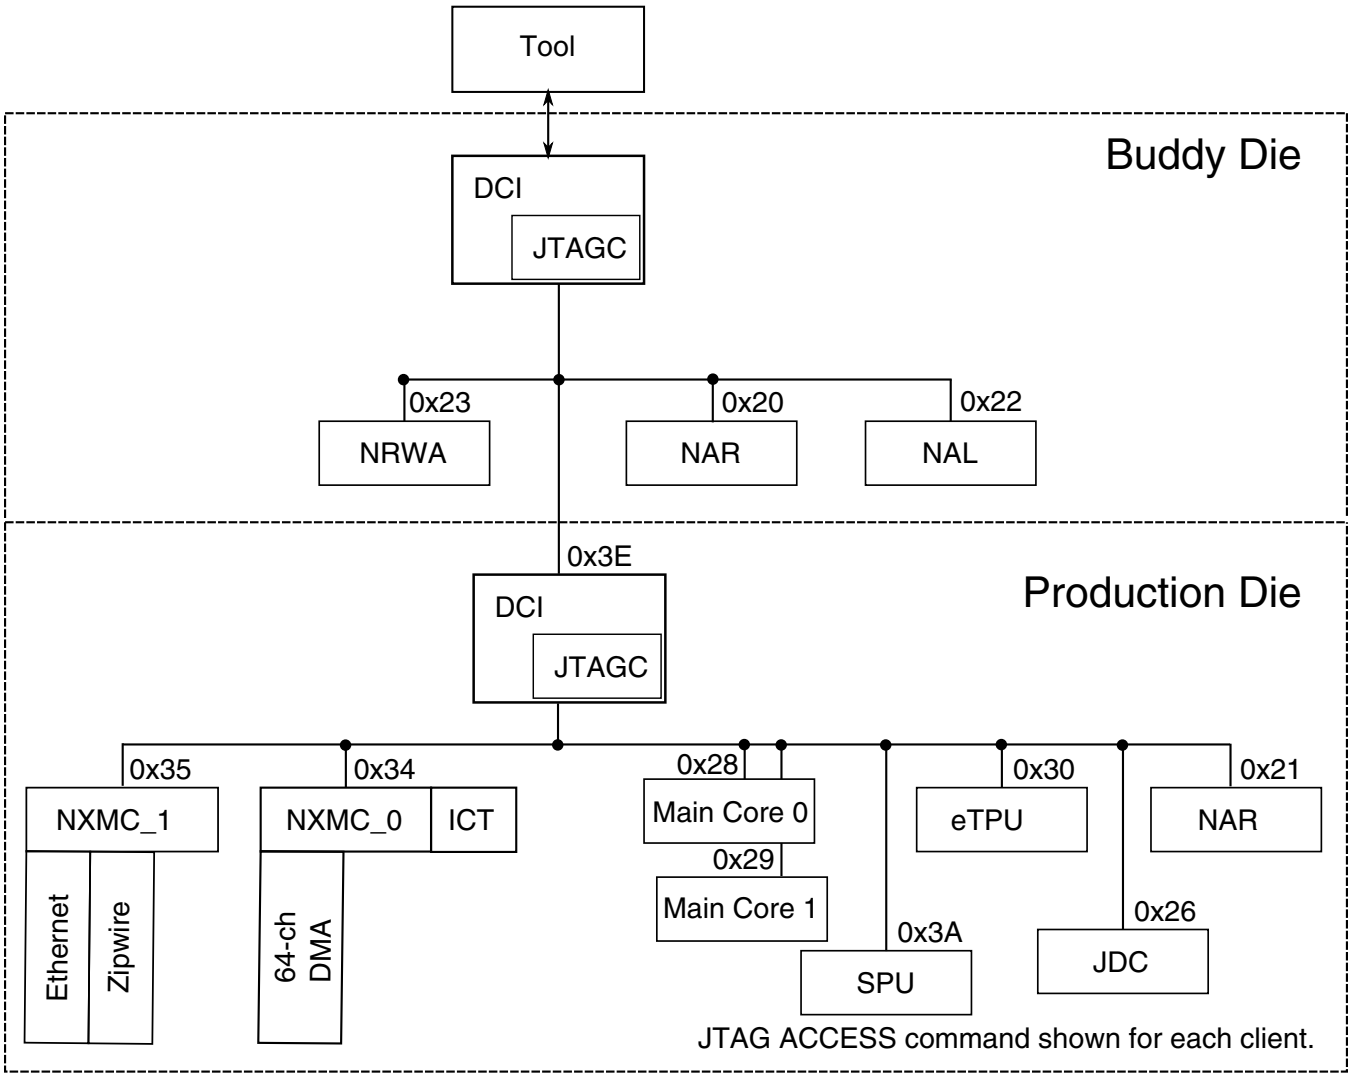

Figure 63-1. JTAG hierarchal view

Table 63-19. Reference links to related information

Related module	Reference
Production Device Nexus Aurora Router (NAR)	Production Device Nexus Aurora Router (NAR)

63.6.1 Nexus Aurora overview

The IEEE-ISTO 5001-2011 standard adds a new type of auxiliary trace port that supports a higher bandwidth. This new interface type uses the Aurora protocol to reformat the parallel Nexus messages into one or more output serial lanes of data, where a lane is defined as a 2-pin Low Voltage Differential Signals (LVDS) interface. The protocol handles striping the data onto the multiple lanes. Each lane uses an 8b/10b encoded LVDS driver. The encoding allows the receiver to recover clocking information.

The Aurora physical interface is based on the XAUI (10 Gigabit Attachment Unit Interface) standard used in communication protocols, which covers the jitter, differential skew, inter-lane skew, and bit error rate requirements.

The Aurora protocol covers lane initialization and channel bonding for both simplex and duplex implementations. The current implementation uses a simplex output-only connection from the MCU to the external tool.

The Aurora interface connects Nexus parallel trace output to an Aurora Protocol Engine (APE), the Aurora Lane Control (ALC), and the Nexus Aurora Physical interface (NAP). Figure 63-2 shows the Aurora interface block diagram, where the number of lanes, n, is 4.

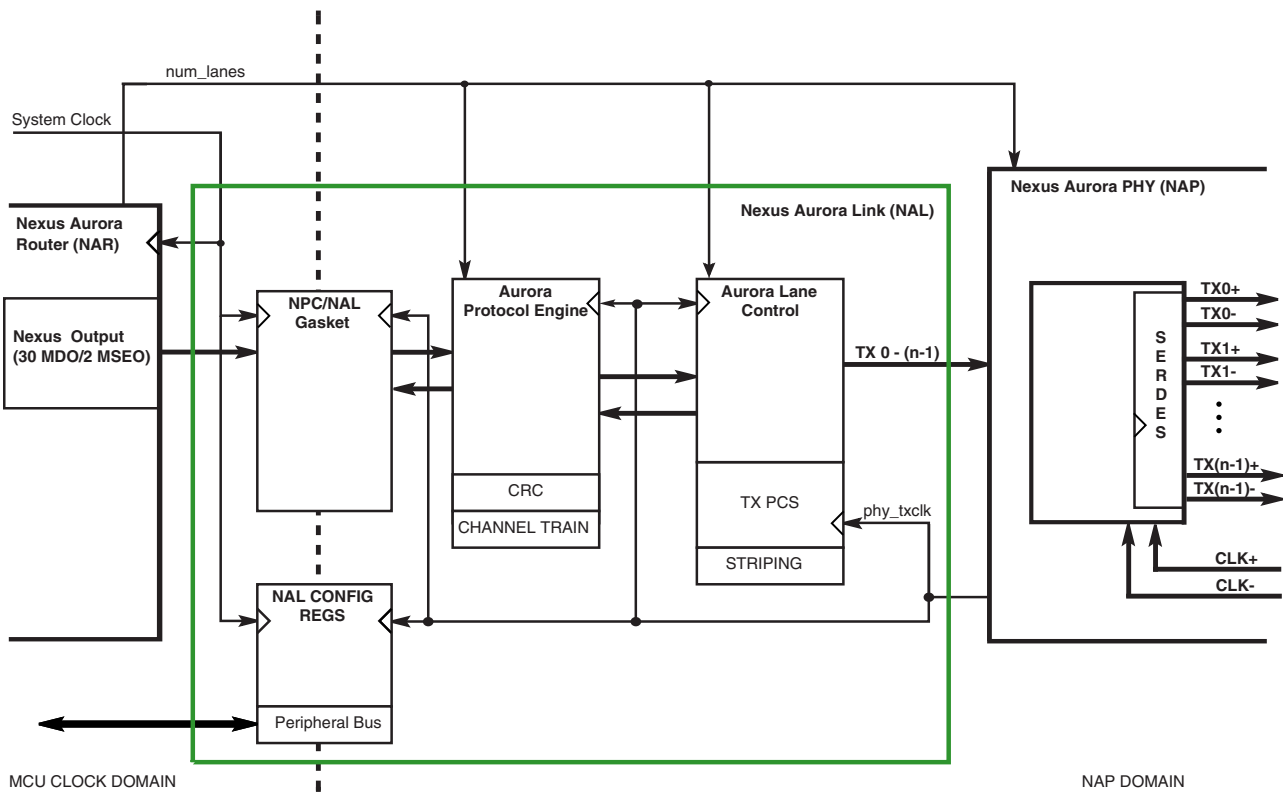

Figure 63-2. Aurora interface block diagram

63.6.2 Nexus Aurora Router (NAR)

The Nexus Aurora Router (NAR) manages the Nexus trace information from each of the Nexus clients. The NAR takes the parallel trace information from each of the connected clients, buffers it to avoid overruns, and routes it to either the internal overlay RAM or the Buddy Device, where it is stored in on-chip SRAM or transmitted out of the device through the Aurora interface.

16 KB of trace SRAM is available on the PD (located in the flash module), and 1 MB of trace SRAM is available in the ED. (Some of this SRAM may be used for calibration overlay content as well as trace content.) Similarly, a smaller NAR output queue is located on the PD (2 KB), and a much larger NAR output queue is located in the ED (8 KB). The physical Aurora pins are only available on the ED. Figure 63-3 shows the NAR block diagram.

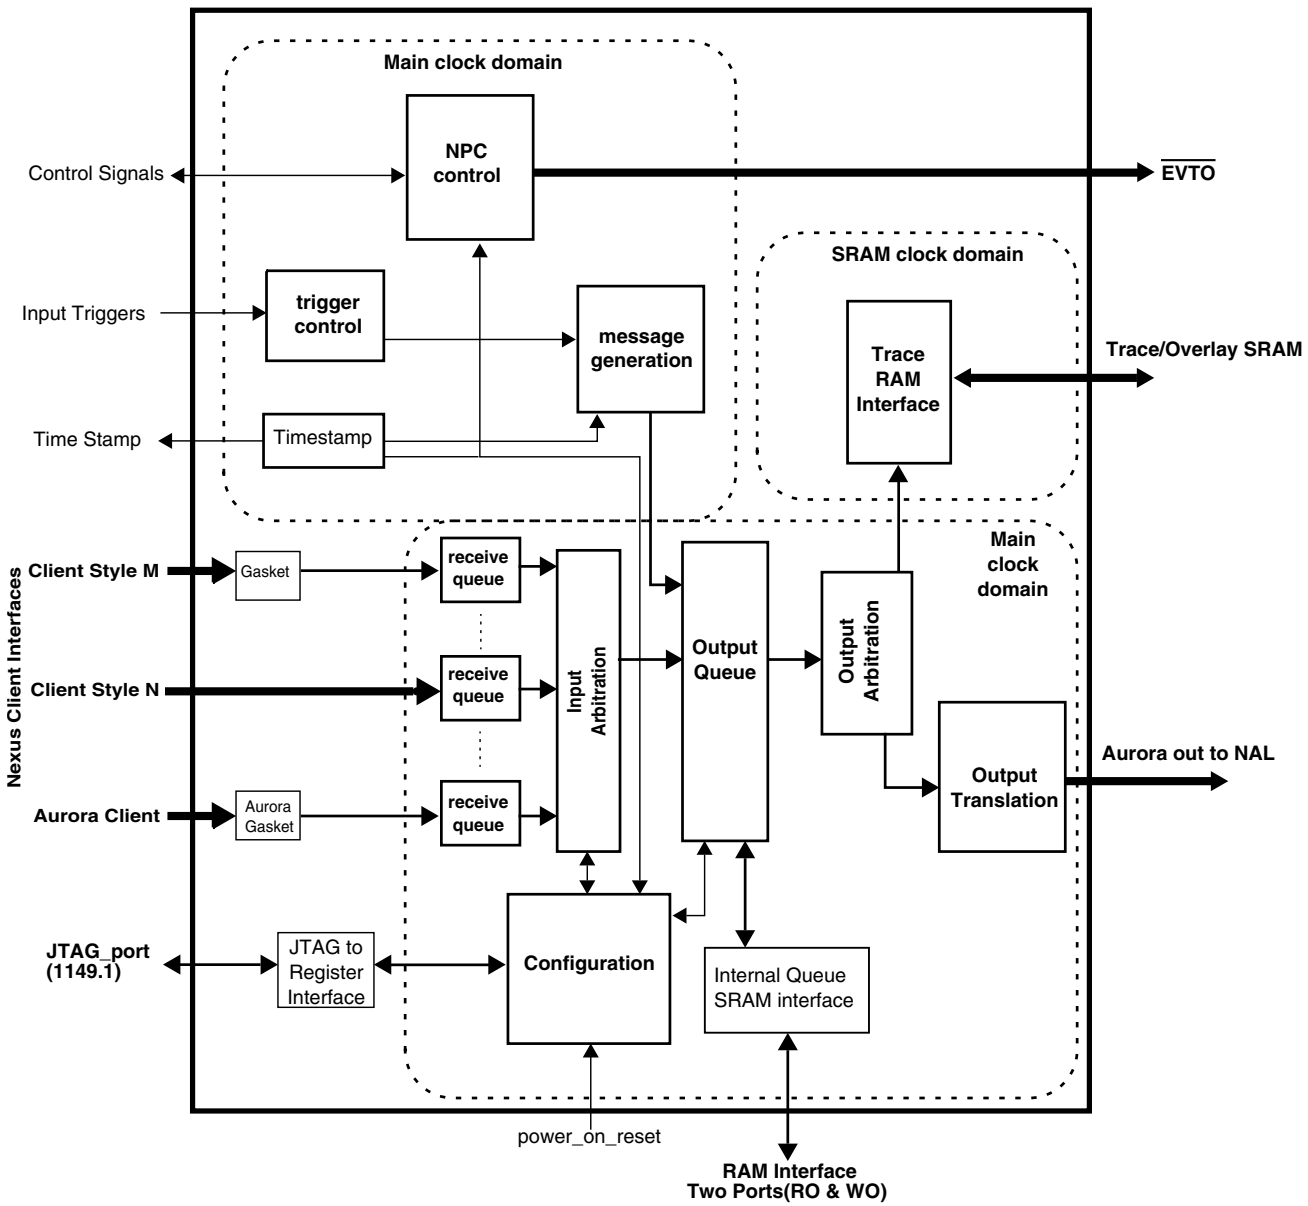

Figure 63-3. NAR block diagram

63.6.2.1 NAR clients

The PD NAR module has seven clients, with client index 1–7. Clients 8–16 are not connected. The client connections and the corresponding NAR client index are shown in the following table. The NAR client index is used in the NAR_STCR, NAR_CSSR, and NAR_CDR registers. The source trace ID is used in the NAR_SFR.

Table 63-20. PD NAR clients

Client index	Client	Nexus source trace ID (SRC)	Beats per client (Bn)
—	NAR	0b1111 (0xF)	—
1	—	—	—
2	Core 0	0b0000 (0x0)	1
3	Core 1	0b0001 (0x1)	1
4	NXMC Client 1 Concentrator	0b1101 (0xD)	1
5	NXMC Client 0 Concentrator	0b1100 (0xC)	1
6	eTPUA	0b0100 (0x4)	1
	eTPUB	0b0101 (0x5)	1
	eTPU_CDC_AB	0b0110 (0x6)	1
7	—	—	—
8	—	—	—
9	—	—	—
10	—	—	—
11	—	—	—
12	—	—	—
13	—	—	—
14	—	—	—
15	—	—	—
16	—	—	—

The BD NAR module has one client and the client connections and the corresponding NAR client index are shown in the following table.

Table 63-21. BD NAR clients

Client index	Client	Nexus source trace ID (SRC)	Beats per client (Bn)
1	PD NAR	0b1110 (0xE)	2

The NAR is limited writing trace information to the overlay RAM. The PD NAR only has access to the 16 KB internal overlay RAM. Therefore, the PD NAR trace memory bus base address registers (NAR_TBALO and NAR_TBAHI) must specify a base address in the range 0x0D000000–0x0D003FFF. The BD NAR also has access to 1 MB

of extended overlay RAM. Therefore, the BD NAR trace memory bus base address registers (NAR_TBALO and NAR_TBAHI) must specify a base address in the range 0x0C00_0000 to 0x0C0F_FFFF.

The NUM_LANES field of the NAR_NAPCR is described in the following table.

Table 63-22. NAR_NAPCR field descriptions

Field	Description	
19–16 NUM_LANE	TX Lane Configuration. Number of enabled TX lanes.	
	0000	Disable NAP and NAL

	0111	Reserved
	1000	Reserved
	1001–1111	Reserved

63.6.3 Nexus Aurora Link (NAL)

The Nexus Aurora Link (NAL) is only included in the Emulation and Debug Device. The Nexus Aurora Link (NAL) consists of all the logic on the MCU needed to implement the connection up to the physical-layer serializer and transmitter (no receiver). It includes Aurora control and data multiplexing, data-encoding and striping, and the Physical Coding Sublayer (PCS) portion of the protocol.

Debug data in the Nexus format from multiple clients is packetized into a 32-bit format by the clients and then collected by the NAR. The NAL encodes the message data (8b/10b), stripes it across the lanes, and inserts Aurora control characters (such as start of message, end of message, idle, clock compensation characters, and so on) around the payload. The NAL PCS drives the Nexus Aurora Physical (NAP) interface.

63.6.4 Nexus Aurora PHY (NAP)

The Nexus Aurora PHY (NAP) is only included in the Emulation and Debug Device. The NAP, in conjunction with the Nexus Aurora Link (NAL), supports one-way simplex high-speed serial communication with an external debugger. The NAP receives 8b/10b encoded data from the ALC block in the NAL and transmits this data onto a given PHY

lane's LVDS pads. The NAL performs lane striping with settings in the NAL and NAR specifying lane configuration. Each NAP lane consists of a Data Symbol Character Accumulator that registers the 10-bit character for that lane from the ALC on the rising edge of the NAL clock. A serializer takes the 10-bit character and serializes it into the individual transmit data bits at the PHY clock rate to be transmitted via the LVDS output drivers to the external debugger receive channel.

Note

The NAL performs static link training for an attached debugger's PHY. The NAP is not directly aware of the link training operation, since it merely transmits the data presented to it by the NAL.

On the receive data side of the external debugger, it is the responsibility of the external debugger to perform elastic buffering, symbol detection, symbol locking (called "lane alignment" in Aurora terminology), 10b/8b decoding, decode and disparity error tracking, and CRC checking in the received data stream.

Figure 63-4 shows a block diagram of the Nexus Aurora Physical (NAP) interface and the LVDS output drivers, where the number of lanes, n, is 4.

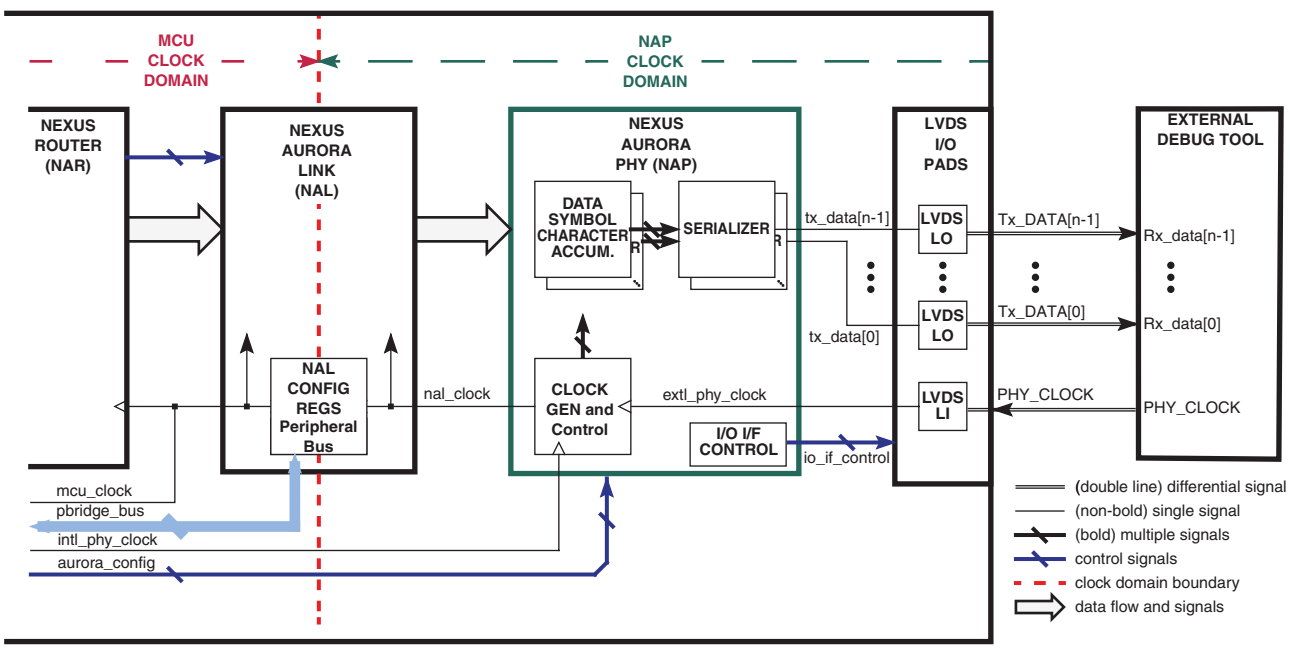

Figure 63-4. NAP block diagram

63.7 Nexus clients

Nexus supports the transmission, through a single Aurora port, of information from multiple trace clients within the device.

Table 63-23. Reference links to related information

Enhanced Time Processing Unit (eTPU)	Enhanced Time Processing Unit (eTPU)
e200z4 Nexus Support	Nexus Module
Nexus Crossbar Multi-Master Client (NXMC)	Nexus Crossbar Multi-Master Client (NXMC)

63.7.1 Enhanced Time Processing Unit (eTPU)

eTPU is an intelligent, semi-autonomous co-processor designed for timing control. Operating in parallel with the Host CPU, the eTPU processes instructions and real-time input events, performs output waveform generation, and accesses shared data without Host intervention. Consequently, for each timer event, the Host CPU setup and service times are minimized or eliminated.

The Nexus ETPU Development Interface (NDEDI) provides real-time development capabilities for the eTPU2 system in compliance with the IEEE-ISTO 5001-2002 standard. The NDEDI interfaces to the eTPU via dedicated trace busses. The main development features supported are:

- Breakpoint/watchpoint configuration
- Debug mode register access
- Enter debug mode at reset negation or during normal execution
- Single stepping of instructions
- Branch trace
- Data trace
- Ownership trace
- Watchpoint trace

Combined, these features make the interface compliant with Class 3 of the IEEE-ISTO 5001-2002 standard.

63.7.2 e200z4 Nexus 3

The e200z425n3 Nexus 3 modules provide real-time development capabilities for e200z4d processors in compliance with the IEEE-ISTO 5001 standard. This module provides development support capabilities without requiring the use of address and data pins for internal visibility.

The development features supported are Program Trace, Data Trace, Watchpoint Messaging, Ownership Trace, Data Acquisition Messaging, and Read/Write Access via the JTAG interface. The Nexus 3 module also supports two Class 4 features: Watchpoint Triggering and Processor Overrun Control.

63.7.3 Nexus Crossbar Multi-master Client (NXMC)

The Nexus Crossbar Multi-master Client (NXMC) module provides real-time trace capabilities in compliance with the IEEE-ISTO Nexus 5001-2011 standard. This module provides development support capabilities for SoCs without requiring address and data pins for internal visibility. A portion of the pin interface is also compliant with the IEEE 1149.1 JTAG standard.

63.7.3.1 NXMC block connections

To provide Nexus data trace messaging from bus masters on the master ports of the crossbar (XBAR) that do not inherently have a trace client, a Nexus Crossbar Multi-Master Client (NXMC) monitors traffic into the master port of the XBAR. Two NXMCs are implemented: one for the fast masters and one for the slow masters. Trace messages transmitted over the Nexus interface (or stored in trace memory) include which NXMC generated the message as well as an identifier for the pre-concentrator source of the message. In addition to XBAR bus master trace capability, the NXMC also allows for in-circuit trace capability that can be used to trace the Sequence Processing Unit (SPU) counter values. The two external hardware watchpoint triggers of each NXMC are used to generate timestamps (four total—two from each NXMC) for events from the SPU.

The following figure shows a block diagram illustrating the NXMC integration.

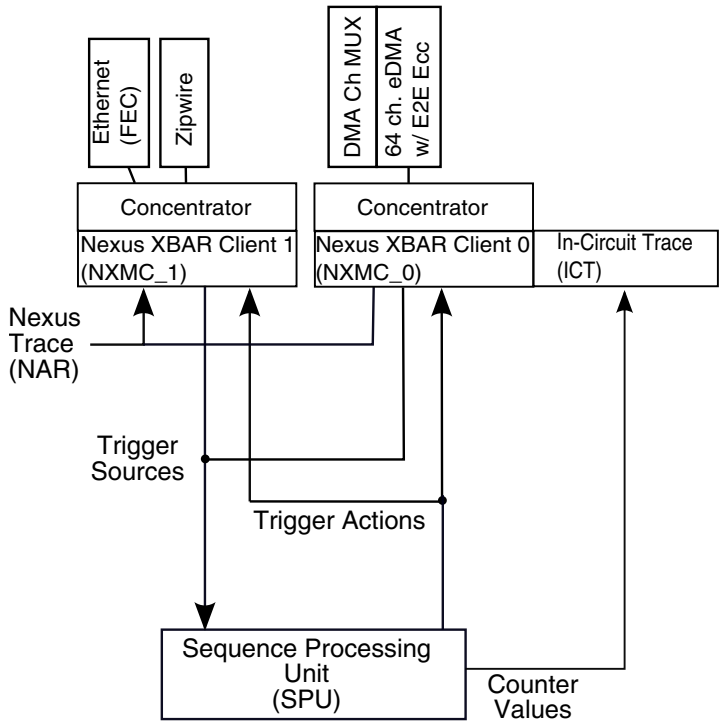

Figure 63-5. NXMC integration block diagram

The values of the trace master ID or in-circuit client ID, along with the Nexus message source identifier for the different clients are shown in the following table.

Table 63-24. NXMC source and master client IDs

Client		Nexus trace source ID (SRC)	Trace master ID or In-circuit trace client ID (MASTER)
In-Circuit Trace	SPU	0b1011	0b0000
XBAR Client 0 Concentrator	eDMA Controller	0b1100	0b0011
(fast masters)	Reserved		All other values
XBAR Client 1 Concentrator	Ethernet	0b1101	0b0100
(slow masters)	Zipwire		0b1000
	Reserved		All other values

Chapter 64
Core Debug Support

64.1 Overview

Internal debug support in the core allows for software and hardware debug by providing debug functions, such as instruction and data breakpoints and program trace modes. For software based debugging, debug facilities consisting of a set of software accessible debug registers and interrupt mechanisms are provided. These facilities are also available to a hardware based debugger which communicates using a modified IEEE 1149.1 Test Access Port (TAP) controller and pin interface. When hardware debug is enabled, the debug facilities controlled by hardware are protected from software modification.

Software debug facilities are defined as part of *PowerISA 2.06*. supports a subset of these defined facilities. In addition to the facilities defined in *PowerISA 2.06*, provides additional flexibility and functionality in the form of additional instruction breakpoints, linked instruction and data breakpoints, and extended range and value masking. These features are also available to a hardware-based debugger.

When not being used for debugging purposes, a portion of the debug facilities may be configured to provide a stack limit checking mechanism.

64.1.1 Software Debug Facilities

provides debug facilities to enable hardware and software debug functions, such as instruction and data breakpoints and program single stepping. The debug facilities consist of a set of debug control registers (DBCR0–2,4–8, EDBRAC0), a set of address compare registers (IAC1–8, DAC1–4), a set of 64-bit data value compare registers (DVC1, DVC2), a Debug Status Register (DBSR) for enabling and recording various kinds of debug events, a Debug Data Effective Address Register (DDEAR), and a special Debug interrupt type built into the interrupt mechanism.

The debug facilities also provide a mechanism for software-controlled processor reset, and debug mode entry. In addition, the Performance Monitor may be configured to utilize the debug interrupt type. Also, the Memory Protection Unit (MPU) may be configured to generate debug events using region descriptors which are not utilized for performing a protection function.

Software debug facilities are enabled by setting the internal debug mode bit in Debug Control register 0 ($DBCR0_{IDM}$). When internal debug mode is enabled, debug events can occur, and can be enabled to record exceptions in the Debug Status register (DBSR). If enabled by MSR_{DE}, these recorded exceptions cause Debug interrupts to occur. When $DBCR0_{IDM}$ is cleared (and $EDBCR0_{EDM}$ is cleared as well), no debug events occur, and no status flags are set in DBSR unless already set. In addition, when $DBCR0_{IDM}$ is cleared (or is overridden by $EDBCR0_{EDM}$ being set and EDBRAC0 indicating no resource is "owned" by software) no Debug interrupts will occur, regardless of the contents of DBSR. A software Debug interrupt handler may access all system resources and perform necessary functions appropriate for system debug.

64.1.1.1 *PowerISA 2.06* Compatibility

The core implements a subset of the *PowerISA 2.06* internal debug features. The following restrictions on functionality are present:

- Instruction address compares do not support compare on physical (real) addresses.
- Data address compares do not support compare on physical (real) addresses.

64.1.2 Additional Debug Facilities

In addition to the debug functionality defined in *PowerISA 2.06*, provides capability to link instruction and data breakpoints, provides additional instruction and data breakpoints, extended range and value masking, multiple watchpoint outputs, provides capability for the Performance Monitor to generate debug events, and allows for sharing of debug resources between software and a hardware debugger. (See Sharing Debug Resources by Software/Hardware.) A data trace port is also provided.

64.1.2.1 Data Trace Port

The data trace port interface is provided to assist in implementing extended debug watchpoint/breakpoint/trace capture capability with logic external to the core. This port provides information corresponding to each read or write access completed without error

by the CPU. In order to report data accesses, the Nexus 3 DTC register DI control bit must be set to trace data accesses, not instruction accesses (i.e. the normal setting. See the "Data Trace Control Register (DTC)" section in the Nexus 3 Module chapter. The data trace port will report aligned accesses, and most misaligned accesses as one access, unless the two portions of a misaligned access are non-contiguous, such as when the second portion of the misaligned access is to address 0. Also, for accesses generated by a LSP load/store instruction using circular addressing mode which crosses a buffer boundary, the two portions of the misaligned access will be reported separately, since otherwise it is not possible to correctly correlate the data with the initial access address.

64.1.3 Hardware Debug Facilities

The core contains facilities that allow for external test and debugging. A modified IEEE 1149.1 control interface is used to communicate with the core resources. This interface is implemented through a standard 1149.1 TAP (test access port) controller.

By using public instructions, the external debugger can freeze or halt the core, read and write internal state and debug facilities, single-step instructions, and resume normal execution.

Hardware Debug is enabled by setting the External Debug Mode enable bit in External Debug Control register 0 ($EDBCR0_{EDM}$), which is also aliased to $DBCR0_{EDM}$. Setting $EDBCR0_{EDM}$ overrides the Internal Debug Mode enable bit $DBCR0_{IDM}$ unless resources are provided back to software via the settings in EDBRAC0. When the Hardware Debug facility is enabled, software is blocked from modifying the "hardware-owned" debug facilities. In addition, since resources are "owned" by the hardware debugger, inconsistent values may be present if software attempts to read "hardware-owned" debug-related resources.

When hardware debug is enabled by setting $EDBCR0_{EDM}$=1, the control registers and resources described in Debug registers are reserved for use by the external debugger. The same events described in Software Debug Events and Exceptions are also used for external debugging, but exceptions are not generated to running software. Hardware-owned debug events enabled in the respective DBCR0–8 registers are recorded in the EDBSR0 register (not the DBSR) regardless of MSR_{DE}, and no debug interrupts are generated unless a) the resource is granted back to software via EDBRAC0 settings, and b) debug mode entry is not masked by the corresponding event bit in EDBSRMSK0. Instead, the CPU will enter debug mode when an enabled event causes a EDBSR0 bit to become set. $EDBCR0_{EDM}$, EDBSR0, EDBSRMSK0, EDDEAR, and EDBRAC0 may only be written through the OnCE port.

Access to most debug resources (registers) requires that the CPU clock (**m_clk**) be running in order to perform write accesses from the external hardware debugger.

64.1.4 Sharing Debug Resources by Software/Hardware

Debug resources may be shared by a hardware debugger and software debug based on the settings of debug control register EDBRAC0. When $EDBCR0_{EDM}$ is set, EDBRAC0 settings determine which debug resources are allocated to software and which resources remain under exclusive hardware control. Software-owned resources which set DBSR bits when $DBCR0_{IDM}$=1 will cause a debug interrupt to occur when enabled with MSR_{DE}. Hardware-owned resources which set EDBSR0 bits when $EDBCR0_{EDM}$=1 will cause an entry into debug mode if the event is not masked in EDBSRMSK0. EDBRAC0 is read-only by software. When resource sharing is enabled, ($EDBCR0_{EDM}$=1 and $EDBRAC0_{IDM}$=1), only software-owned resources may be modified by software. Hardware always has full access to all registers and all register fields through the OnCE register access mechanism, and it is up to the debug firmware to properly implement modifications to these registers with read-modify-write operations to implement any control sharing with software. Hardware-owned resources will set status bits in the EDBSR0 register instead of in DBSR, and will report the effective address of data breakpoints in EDDEAR instead of DDEAR. Settings in EDBRAC0 should be considered by the debug firmware in order to preserve software settings of control and status registers as appropriate when hardware modifications to the debug registers are performed.

64.1.4.1 Simultaneous Hardware and Software Debug Event Handing

Since it is possible that a "hardware-owned" resource can produce a debug event in conjunction with a software-owned resource producing a different debug event simultaneously, a priority ordering mechanism is implemented which guarantees that the hardware event is handled as soon as possible, while preserving the recognition of the software event. The CPU will give highest priority to the software event initially in order to reach a recoverable boundary, and then will give highest priority to the hardware event in order to enter debug mode as near the point of event occurrence as possible. This is implemented by allowing software exception handing to begin internal to the CPU and to reach the point where the current program counter and MSR values have been saved into DSRR0/1, and the new PC pointing to the debug interrupt handler, along with the new MSR updates. At this point, hardware priority takes over, and the CPU enters debug mode.

The following figure shows the debug resources.

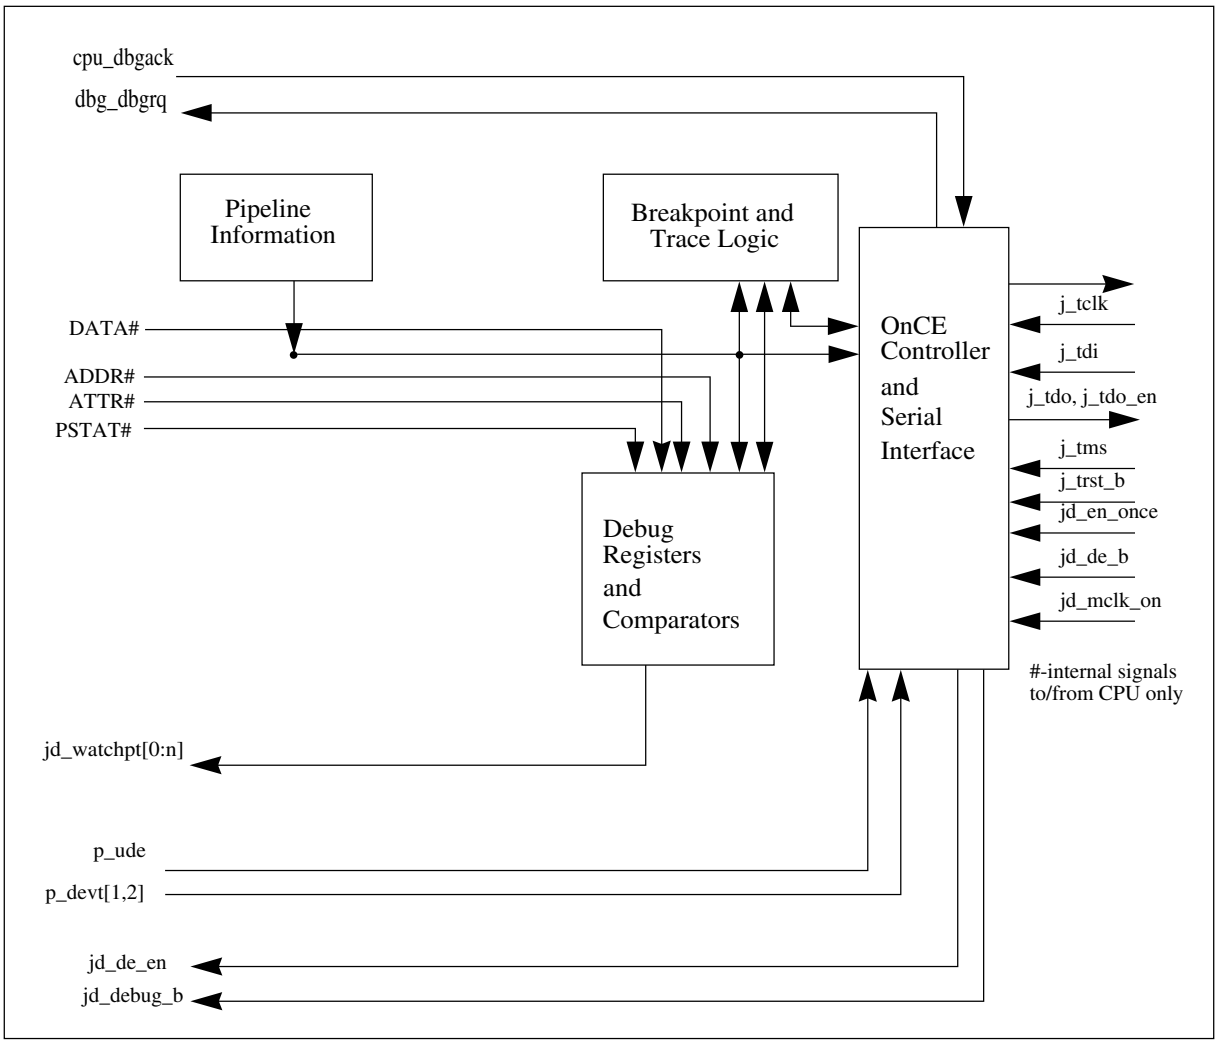

Figure 64-1. Debug Resources

64.2 Software Debug Events and Exceptions

Software debug events and exceptions are available when internal debug mode is enabled ($DBCR0_{IDM}$=1) and not overridden by external debug mode ($EDBCR0_{EDM}$ must either be cleared or corresponding resources must be allocated to software debug by the settings in EDBRAC0). When enabled, debug events cause debug exceptions to be recorded in the Debug Status Register. Specific event types are enabled by the Debug Control Registers (DBCR0–8). The Unconditional Debug Event (UDE) is an exception to this rule; it is always enabled. Once a Debug Status Register (DBSR) bit is set by a debug resource which is "owned" by software (other than MRR, DAC_OFST, or VLES), if Debug interrupts are enabled by MSR_{DE}, a Debug interrupt will be generated. The debug interrupt handler is responsible for ensuring that multiple repeated debug interrupts do not occur by clearing the DBSR as appropriate.

Certain debug events are not allowed to occur when MSR_{DE}=0 and $DBCR0_{IDM}$=1. In such situations, no debug exception occurs and thus no DBSR bit is set. Other debug events may cause debug exceptions and set DBSR bits regardless of the state of MSR_{DE}. A Debug interrupt will be delayed until MSR_{DE} is later set to '1'.

When a Debug Status Register bit is set while MSR_{DE}=0, an Imprecise Debug Event flag ($DBSR_{IDE}$) will also be set to indicate that an exception bit in the Debug Status Register was set while Debug interrupts were disabled. Debug interrupt handler software can use this bit to determine whether the address recorded in Debug Save/Restore Register 0 is an address associated with the instruction causing the debug exception, or the address of the instruction which enabled a delayed Debug interrupt by setting the MSR_{DE} bit. A **mtmsr** or **mtdbcr0** which causes both MSR_{DE} and $DBCR0_{IDM}$ to become set, enabling precise debug mode, may cause an Imprecise (Delayed) Debug exception to be generated due to an earlier recorded event in the Debug Status register.

There are eight types of debug events defined by *PowerISA 2.06*:

1. Instruction Address Compare debug events
2. Data Address Compare debug events
3. Trap debug events
4. Branch Taken debug events
5. Instruction Complete debug events
6. Interrupt/Critical Interrupt Taken debug events
7. Return/Critical Return debug events
8. Unconditional debug events

In addition, defines additional debug events:

- The External debug events DEVT1 and DEVT2 which are described in External debug event.
- The Performance Monitor Interrupt event PMI which is described in Performance Monitor Interrupt debug event.

The debug configuration supports most of these event types. Unsupported *PowerISA 2.06* defined functionality is as follows:

- Instruction Address Compare and Data Address Compare *Real address* mode is not supported

A brief description of each of the event types follows.

64.2.1 Instruction Address Compare Event

Instruction Address Compare debug events occur when enabled and execution is attempted of an instruction at an address that meets the criteria specified in the DBCR0, DBCR1, DBCR5, DBCR6, and IAC1–8 Registers. Instruction Address compares may specify user/supervisor mode, along with an effective address, masked effective address, or range of effective addresses for comparison. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. IAC events will not occur when an instruction would not have normally begun execution due to a higher priority exception at an instruction boundary.

IAC compares perform a 31-bit compare for VLE instruction storage accesses. Each halfword fetched by the instruction fetch unit will be marked with a set of bits indicating whether an Instruction Address Compare occurred on that halfword. Debug exceptions will occur if enabled and a 16-bit instruction, or the first halfword of a 32-bit instruction, is tagged with an IAC hit.

64.2.2 Data Address Compare Event

Data Address Compare debug events occur when enabled and execution of a load or store class instruction results in a data access that meets the criteria specified in the DBCR0, DBCR2, DBCR4, DBCR7–8, DAC1–4, DVC1, and DVC2 Registers. Data address compares may specify user/supervisor mode, along with an effective address, masked effective address, or range of effective addresses for comparison. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. Four address compare values (DAC1–4) are provided.

The effective address of the load or store operation is recorded in the DDEAR register when a data address compare event is recorded in DBSR if the previous values of the $DBSR_{DAC\{R,W\}}$ bits are zero. Once a DDEAR update is performed, these bits must be cleared by software prior to another DDEAR hardware update occurring. A subsequent DAC event will not update the DDEAR register if either of the $DBSR_{DAC\{R,W\}}$ bits are set.

Note

In contrast to the *PowerISA 2.06* definition, Data Address Compare events on do not prevent the load or store class instruction from completing. If a load or store class instruction

completes successfully without a Data Storage interrupt, Data Address Compare exceptions are reported at the completion of the instruction. If the exception results in a precise Debug interrupt, the address value saved in DSRR0 is the address of the instruction following the load or store class instruction. For DVC DAC events, the exception can be imprecisely reported even further past the load or store class instruction generating the event (without necessarily affecting $DBSR_{IDE}$) and the saved address value can point to a subsequent instruction past the next instruction. This occurrence is indicated in the $DBSR_{DAC_OFST}$ field.

If a load or store class instruction does not complete successfully due to a Data Storage exception or a machine check condition for the load or store, and a Data Address Compare debug exception also occurs, the result is an imprecise Debug interrupt, the address value saved in DSRR0 is the address of the load or store class instruction, and the $DBSR_{IDE}$ bit will be set. In addition to occurring when $DBCR0_{IDM}$=1, this circumstance can also occur when $EDBCR0_{EDM}$=1 and the event is hardware-owned, in which case $EDBSR0_{IDE}$ will be set.

Note

DAC events will not be recorded if a load multiple word or store multiple word instruction is interrupted prior to completion by a critical input or external input interrupt.

Note

DAC events are not signaled on the second portion of a misaligned load or store that is broken up into two separate accesses.

Note

DAC events are not signaled on the **mpure** or **mpuwe** MPU instructions.

Note

DAC[1,2] events are not signaled if DVC[1,2]M is non-zero and a DSI exception occurs on the load or store, since the load or store access is not performed. For a **lmw** or **stmw** transfer

however, if a DVC successfully occurs on a transfer and a later transfer encounters a DSI exception, the DAC event will be reported, since a successful data value compare took place.

Note

Due to internal pipeline status, for a reported DAC event on a **lmw** or **stmw** transfer, the value stored in the DDEAR/EDDEAR will be the effective address of the first transfer of the sequence, and not necessarily the precise transfer that caused the DAC event.

64.2.2.1 Data Address Compare Event Status Updates

Data Address Compare debug events with Data Value compares can be reported ambiguously in several circumstances involving issuing a sequence of load or store class instructions. Due to the CPU pipeline and the delay in performing the data value compare following completion of the access, if the first load or store class instruction generates a DVC DAC, a second and possibly third load or store class instruction may also generate a DAC or DVC DAC event, or may generate a DSI exception with or without a simultaneous DAC event.

Also, since non-load/store instructions may be dual-issued in combination with a load/store instruction, the actual number of additional instructions that are completed following a recognized DVC DAC on a load/store instruction may vary from 0 to 5. This value will be reported in the $DBSR_{DAC_OFST}$ field when the DVC DAC status is recorded.

Table 64-1 outlines the settings of the DBSR, DSRR0 saved value, and potential updating of the ESR register for various exception cases on sequences of load/store class instructions. Not all exception combinations are covered in the table, such as IAC, ISI, or Alignment exceptions on subsequent instructions. In general these exceptions will cause further instruction issue to be halted, execution of the excepting instruction to be aborted, and reporting of these exceptions will be masked. The saved DSRR0 value will point to this excepting instruction, and the exception(s) may be regenerated after returning from the debug interrupt handler and attempting to re-execute the instruction pointed to by DSRR0. In addition, in the examples in Table 64-1, the DAC_OFST and DSRR0 values assume no dual issue occurs. If dual-issue occurs with the first, second, or third column, then the DAC_OFST and DSRR0 values will point beyond the values shown.

Table 64-1. DAC events and Resultant Updates

1st load/store class instruction	2nd instruction (load/store class unless otherwise specified)	3rd instruction (load/store class unless otherwise specified)	Result
DSI, no DAC	—	—	Take DSI exception, no DBSR update. Update ESR.
DSI, with DACx	—	—	Take Debug exception, DBSR update setting DACx and IDE, DAC_OFST not set. DSRR0 points to 1st load/store class instruction. No ESR update.
DACx	—	—	Take Debug exception, DBSR update setting DACx, DAC_OFST not set. DSRR0 points to 2nd load/store class instruction. No ESR update.
DVC DACx	No exceptions, any instruction	No exceptions, Non-ldst instruction	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b001. DSRR0 points to 3rd instruction. No ESR update.
DVC DACx	No exceptions	No exceptions, Ldst instruction	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b010. DSRR0 points to instruction after 3rd instruction. No ESR update.
DVC DACx	DSI, no DAC	—	Take Debug exception, DBSR update setting DACx, DAC_OFST not set. DSRR0 points to 2nd load/store class instruction. No ESR update. **Note:** in this case the 2nd ld/st exception is masked. This behavior is implementation dependent and may differ on other CPUs.
DVC DACx	DSI, with DACy	—	Take Debug exception, DBSR update setting DACx. DAC_OFST not set. DSRR0 points to 2nd load/store class instruction. No ESR update. **Note:** in this case the 2nd ld/st exception is masked. This behavior is implementation dependent and may differ on other CPUs.
DVC DACx	DACy	—	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b001. DSRR0 points to 3rd instruction. **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.
DVC DACx	DVC DACy,Normal Ldst	Non-Ldst instruction	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b001. DSRR0 points to the 3rd instruction. **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.
DVC DACx	DVC DACy,Normal Ldst	Ldst instruction,no exception	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b010. DSRR0 points to instruction after the 3rd load/store class instruction. **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.
DVC DACx	DVC DACy,Normal Ldst	DSI Error, with or without DAC	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b001. No ESR update. DSRR0 points to 3rd instruction. **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case. **Note:** in this case the 3rd ld/st exception is masked. This behavior is implementation dependent and may differ on other CPUs.

Table continues on the next page...

Table 64-1. DAC events and Resultant Updates (continued)

1st load/store class instruction	2nd instruction (load/store class unless otherwise specified)	3rd instruction (load/store class unless otherwise specified)	Result
DVC DACx	DVC DACy,Normal Ldst	DACy, or DVC DAC_y Normal Ldst or multiple word Ldst	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b010. DSRR0 points to instruction after the 3rd load/store class instruction. **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.
DVC DACx	DVC DACy,Ldst multiple (lmw, stmw)	Any instruction including ld/st	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b001. DSRR0 points to the 3rd instruction. **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.
DVC DACx	Any instruction(no exception)	DSI, with or without DAC,Normal Ldst or multiple word Ldst	Take Debug exception, DBSR update setting DACx. DAC_OFST set to 3'b001. DSRR0 points to the 3rd instruction. No ESR update. **Note:** in this case the 3rd ld/st exception is masked. This behavior is implementation dependent and may differ on other CPUs.
DVC DACx	Any instruction(no exception)	DACy, or DVC DAC_y Normal Ldst or multiple word Ldst	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b010. DSRR0 points to instruction after the 3rd class instruction. **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.

Table 64-2 through Table 64-5 show some example updates for specific code sequences of dual issuing of load/store class instructions with non-load/store class instructions and the results of DAC and DVC events on selected ones of the load/store instructions.

Table 64-2. DAC events and Resultant Updates, Dual-issue case 1

Instruction Sequence: The following pairs dual-issue: (1) load/store (2) alu (3) load/store (4) alu (5) load/store (6) alu	Event(s)	Result
	Instruction (1): DSI, no DAC	Take DSI exception, no DBSR update, Update ESR.
	Instruction (1): DSI, with DACx	Take Debug exception, DBSR update setting DACx and IDE, DAC_OFST set to 3'b000. DSRR0 points to instruction (1). No ESR update.
	Instruction (1): DACx	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b000. DSRR0 points to instruction (2). No ESR update.
	Instruction (1): DVC DACx No other exceptions	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b100. DSRR0 points to instruction (6). No ESR update. No debug event updates for instruction (6)
	Instruction (1): DVC DACx Instruction (3): DSI, with or without DAC	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b001. DSRR0 points to instruction (3). No ESR update. No debug event updates for instructions (3)–(6). **Note:** in this case the 2nd ld/st exception is masked. This behavior is implementation dependent and may differ on other CPUs.
	Instruction (1): DVC DACx Instruction (3): DACy	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b010. DSRR0 points to instruction (4). No debug event updates for instructions (4)–(6). **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.
	Instruction (1): DVC DACx Instruction (3): DVC DACy	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b100. DSRR0 points to instruction (6). No ESR update. No debug event updates for instruction (6). **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.

Instruction Sequence: The following pairs dual-issue: (1) load/store (2) alu (3) alu (4) alu (5) load/store (6) alu	Event(s)	Result
	Instruction (1): DSI, no DAC	Take DSI exception, no DBSR update, Update ESR.
	Instruction (1): DSI, with DACx	Take Debug exception, DBSR update setting DACx and IDE, DAC_OFST set to 3'b000. DSRR0 points to instruction (1). No ESR update.
	Instruction (1): DACx	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b000. DSRR0 points to instruction (2). No ESR update.
	Instruction (1): DVC DACx No other exceptions	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b100. DSRR0 points to instruction (6). No ESR update. No debug event updates for instruction (6).
	Instruction (1): DVC DACx Instruction (5): DSI, with or without DAC	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b011. DSRR0 points to instruction (5). No ESR update. No debug event updates for instructions (5)–(6). **Note:** in this case the 2nd ld/st exception is masked. This behavior is implementation dependent and may differ on other CPUs.
	Instruction (1): DVC DACx Instruction (5): DACy	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b100. DSRR0 points to instruction (6). No debug event updates for instruction (6). **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.
	Instruction (1): DVC DACx Instruction (5): DVC DACy	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b100. DSRR0 points to instruction (6). No ESR update. No debug event updates for instruction (6) **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.

Table 64-5. DAC events and Resultant Updates, Dual-issue case 4

Instruction Sequence: The following pairs dual-issue: (1) load/store (2) alu (3) load/store (4) alu (5) alu (6) alu	Event(s)	Result
	Instruction (1): DSI, no DAC	Take DSI exception, no DBSR update, Update ESR.
	Instruction (1): DSI, with DACx	Take Debug exception, DBSR update setting DACx and IDE, DAC_OFST set to 3'b000. DSRR0 points to instruction (1). No ESR update.
	Instruction (1): DACx	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b000. DSRR0 points to instruction (2). No ESR update.
	Instruction (1): DVC DACx No other exceptions	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b011. DSRR0 points to instruction (5). No ESR update. No debug event updates for instructions (5)–(6)
	Instruction (1): DVC DACx Instruction (3): DSI, with or without DAC	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b001. DSRR0 points to instruction (3). No ESR update. No debug event updates for instructions (3)–(6). **Note:** in this case the 2nd ld/st exception is masked. This behavior is implementation dependent and may differ on other CPUs.
	Instruction (1): DVC DACx Instruction (3): DACy	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b010. DSRR0 points to instruction (4). No debug event updates for instructions (4)–(6). **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.
	Instruction (1): DVC DACx Instruction (3): DVC DACy	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b011. DSRR0 points to instruction (5). No ESR update. No debug event updates for instructions (5)–(6). **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.

64.2.3 Linked Instruction Address Compare and Data Address Compare Events

Data Address Compare 1, 2, 3, and 4 debug events may be 'linked' with an Instruction Address Compare event by setting the DAC[1–4]LNK control bits in DBCR2 and DBCR8 to further refine when a Data Address Compare debug event is generated. DAC1

may be linked with IAC1, DAC2 (when not used as a mask or range bounds register) may be linked with IAC3. DAC3 may be linked with IAC5, DAC4 (when not used as a mask or range bounds register) may be linked with IAC7. When linked, a DAC debug event occurs when the same instruction that generates the DAC 'hit' also generates a corresponding linked IAC 'hit'. When linked, the IAC event is not recorded in the Debug Status register, regardless of whether a corresponding linked DAC event occurs, or whether the IAC event enable is set.

When enabled and execution of a load or store class instruction results in a data access with an address that meets the criteria specified in the DBCRx, DACx, and DVCx Registers, and the instruction also meets the criteria for generating an Instruction Address Compare event, a Linked Data Address Compare debug event occurs. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. The normal DAC1 status bit in the DBSR is used for recording these events. The IAC status bit is not set if the corresponding Instruction Address Compare register is linked.

Linking is enabled using control bits in DBCR2 and DBCR8. Note that linking is only available in EDM or IDM. Attempts to use linking otherwise are ignored.

Note

Linked DAC events will not be recorded if a load multiple word or store multiple word type instruction is interrupted prior to completion by a critical input or external input interrupt.

64.2.4 Trap Debug Event

A Trap debug event (TRAP) occurs if Trap debug events are enabled ($DBCR0_{TRAP}$=1), a Trap instruction (**tw**) is executed, and the conditions specified by the instruction for the trap are met. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. When a Trap debug event occurs, the $DBSR_{TRAP}$ bit is set to 1 to record the debug exception.

64.2.5 Branch Taken Debug Event

A Branch Taken debug event (BRT) occurs if Branch Taken debug events are enabled ($DBCR0_{BRT}$=1) and execution is attempted of a branch instruction that will be taken (either an unconditional branch, or a conditional branch whose branch condition is true), and MSR_{DE}=1. Branch Taken debug events are not recognized if MSR_{DE}=0 at the time of execution of the branch instruction and thus $DBSR_{IDE}$ can not be set by a Branch Taken

debug event. When a Branch Taken debug event is recognized, the $DBSR_{BRT}$ bit is set to 1 to record the debug exception, and the address of the branch instruction will be recorded in DSRR0.

64.2.6 Instruction Complete Debug Event

An Instruction Complete debug event (ICMP) occurs if Instruction Complete debug events are enabled ($DBCR0_{ICMP}$=1), execution of any instruction is completed, and MSR_{DE}=1. If execution of an instruction is suppressed due to the instruction causing some other exception that is enabled to generate an interrupt, then the attempted execution of that instruction does not cause an Instruction Complete debug event. The ***se_sc*** instruction does not fall into the category of an instruction whose execution is suppressed, since the instruction actually executes and then generates a System Call interrupt. In this case, the Instruction Complete debug exception will also be set. When an Instruction Complete debug event is recognized, $DBSR_{ICMP}$ is set to 1 to record the debug exception and the address of the next instruction to be executed will be recorded in DSRR0.

Instruction Complete debug events are not recognized if MSR_{DE}=0 at the time of execution of the instruction, thus $DBSR_{IDE}$ is not generally set by an ICMP debug event.

One circumstance may cause the $DBSR_{ICMP}$ and $DBSR_{IDE}$ bits to be set. This occurs when a EFPU Round exception occurs. Since the instruction is by definition completed (SRR0 points to the following instruction), this interrupt takes higher priority than the Debug interrupt so as not to be lost, and $DBSR_{IDE}$ is set to indicate the imprecise recognition of a Debug interrupt. In this case, the Debug interrupt will be taken with SRR0 pointing to the instruction following the instruction that generated the EFPU Round exception, and DSRR0 will point to the Round exception handler. In addition to occurring when $DBCR0_{IDM}$=1, this circumstance can also occur when $EDBCR0_{EDM}$=1 and the event is hardware-owned, in which case $EDBSR0_{IDE}$ will be set.

Note

Instruction complete debug events are not generated by the execution of an instruction that sets MSR_{DE} to '1' while $DBCR0_{ICMP}$=1, nor by the execution of an instruction that sets $DBCR0_{ICMP}$ to '1' while MSR_{DE}=1.

64.2.7 Interrupt Taken Debug Event

An Interrupt Taken debug event (IRPT) occurs if Interrupt Taken debug events are enabled ($DBCR0_{IRPT}$=1) and a base-class interrupt occurs. Only base-class interrupts (an interrupt using SRR0/1) cause an Interrupt Taken debug event. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. When an Interrupt Taken debug event occurs, the $DBSR_{IRPT}$ bit is set to 1 to record the debug exception. The value saved in DSRR0 will be the address of the non-critical interrupt handler.

64.2.8 Critical Interrupt Taken Debug Event

A Critical Interrupt Taken debug event (CIRPT) occurs if Critical Interrupt Taken debug events are enabled ($DBCR0_{CIRPT}$=1) and a critical interrupt occurs. Only critical class interrupts (an interrupt using CSRR0/1) cause a Critical Interrupt Taken debug event. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. When a Critical Interrupt Taken debug event occurs, the $DBSR_{CIRPT}$ bit is set to 1 to record the debug exception. The value saved in DSRR0 will be the address of the critical interrupt handler.

64.2.9 Return Debug Event

A Return debug event (RET) occurs if Return debug events are enabled ($DBCR0_{RET}$=1) and an attempt is made to execute an **se_rfi** instruction. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. When a Return debug event occurs, the $DBSR_{RET}$ bit is set to 1 to record the debug exception.

If MSR_{DE}=0 at the time of the execution of the **se_rfi** (i.e. before the MSR is updated by the **se_rfi**), then $DBSR_{IDE}$ is also set to 1 to record the imprecise debug event.

If MSR_{DE}=1 at the time of the execution of the **se_rfi**, a Debug interrupt will occur provided there exists no higher priority exception that is enabled to cause an interrupt. Debug Save/Restore Register 0 will be set to the address of the **se_rfi** instruction.

64.2.10 Critical Return Debug Event

A Critical Return debug event (CRET) occurs if Critical Return debug events are enabled ($DBCR0_{CRET}$=1) and an attempt is made to execute an **se_rfci** instruction. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. When a Critical Return debug event occurs, the $DBSR_{CRET}$ bit is set to 1 to record the debug exception.

If MSR_{DE}=0 at the time of the execution of the **se_rfci** (i.e. before the MSR is updated by the **se_rfci**), then $DBSR_{IDE}$ is also set to 1 to record the imprecise debug event.

If MSR_{DE}=1 at the time of the execution of the **se_rfci**, a Debug interrupt will occur provided there exists no higher priority exception that is enabled to cause an interrupt. Debug Save/Restore Register 0 will be set to the address of the **se_rfci** instruction.

64.2.11 External debug event

An External debug event (DEVT1, DEVT2) occurs if External debug events are enabled ($DBCR0_{DEVT1}$=1 or $DBCR0_{DEVT2}$=1), and the respective **p_devt1** or **p_devt2** input signal transitions to the asserted state while the CPU is not in the Stopped state. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. When an External debug event occurs, $DBSR_{DEVT\{1,2\}}$ is set to '1' to record the debug exception. This debug event is an asynchronous event, but is only sampled when the CPU **m_clk** is active.

64.2.12 Unconditional debug event

An Unconditional debug event (UDE) occurs when the Unconditional Debug Event (**p_ude**) input transitions to the asserted state. The Unconditional debug event is the only debug event that does not have a corresponding enable bit for the event in DBCR0. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. When an Unconditional debug event occurs, the $DBSR_{UDE}$ bit is set to '1' to record the debug exception. This debug event is an asynchronous event.

64.2.13 Performance Monitor Interrupt debug event

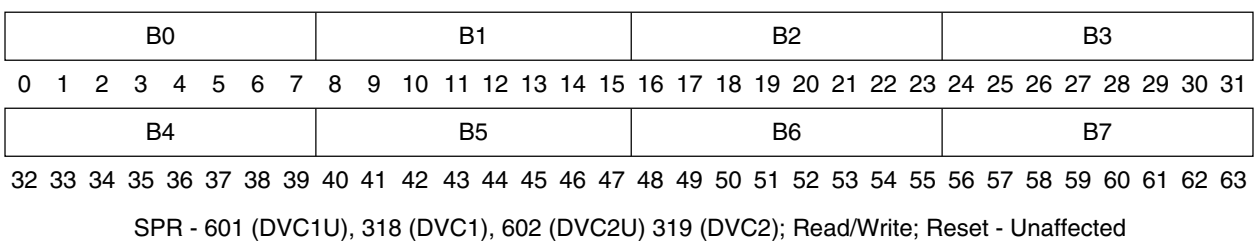
A Performance Monitor Interrupt debug event (PMI) occurs if Performance Monitor Interrupt debug events are enabled ($PMGC0_{UDI}$=1), and a performance monitor interrupt event occurs. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. When a Performance Monitor Interrupt debug event occurs, $DBSR_{PMI}$ is set to '1' to record the debug exception. This debug event is an asynchronous event.

64.3 Debug registers

This section describes debug-related registers that are software accessible. These registers are intended for use by special debug tools and debug software, not by general application code.

Access to these registers (other than DBSR) by software is conditioned by the External Debug mode control bit ($EDBCR0_{EDM}$) and the settings of debug control register EDBRAC0, which can be set by the hardware debug port. If $EDBCR0_{EDM}$ is set and if the bit in EDBRAC0 corresponding to the resource is cleared, software is prevented from modifying debug register values other than in DBSR, since the resource is not "owned" by software. Software always has ownership of DBSR. Execution of a **mtspr** instruction targeting a debug register or register field not "owned" by software will not cause modifications to occur, and no exception will be signaled. In addition, since the external debugger hardware may be manipulating debug register values, the state of these registers or register fields not "owned" by software is not guaranteed to be consistent if accessed (read) by software with a **mfspr** instruction, other than the $DBCR0_{EDM}$ bit itself and the EDBRAC0 register. Hardware always has full access to all registers and all register fields through the OnCE register access mechanism, and it is up to the debug firmware to properly implement modifications to these registers with read-modify-write operations to implement any control sharing with software. Settings in EDBRAC0 should be considered by the debug firmware in order to preserve software settings of control registers as appropriate when hardware modifications to the debug registers is performed.

64.3.1 Debug Address and Value Registers



Instruction Address Compare registers IAC1–8 are used to hold instruction addresses for address comparison purposes. In addition, IAC2 and IAC4 may hold mask information for IAC1 and IAC3 respectively and IAC6 and IAC8 may hold mask information for IAC5 and IAC7 respectively, when *Address Bit Match* compare modes are selected. Note that when performing instruction address compares, the low order bit of the instruction address and the corresponding IAC register is ignored for VLE instructions.

Data Address Compare registers DAC1–4 are used to hold data access addresses for address comparison purposes. In addition, DAC2 and DAC4 may hold mask information for DAC1 and DAC3 respectively when *Address Bit Match* compare modes are selected.

Data Value Compare registers DVC1 and DVC2 are used to hold data values for data comparison purposes. DVC1 and DVC2 are 64-bit registers. Data value comparisons are used to qualify Data Address compare 1 and 2 debug events. Data value comparisons are

not available for Data address compare 3–4 events. DVC1 is associated with DAC1, and DVC2 is associated with DAC2. The most significant byte of the DVC1(2) register (labeled B0 in the following figure) corresponds to the byte data value transferred to/from memory byte offset 0, 8, …, and the least significant byte of the register (labeled B7 in the following figure) corresponds to byte offset 7, F, … . When enabled for performing data value comparisons, each enabled byte in DVC1(2) is compared with the memory value transferred on the corresponding active byte lane of the data memory interface to determine if a match occurs. Inactive byte lanes do not participate in the comparison, they are implicitly masked. The Byte Strobe Assertion for Transfers table in the Core Complex Overview chapter shows active byte lanes for data transfers. Software must also program the DVC1(2) register byte positions based on the alignment of the access. Misaligned accesses are not fully supported, since the data address and data value comparisons are only performed on the initial access in the case of a misaligned access; thus, accesses that cross a 64-bit boundary cannot be fully matched. For address and size combinations that involve two transfers, only the initial transfer is used for data address and value matching.

DVC1 and DVC2 may be read or written using **mtspr** and **mfspr** instructions. The DVC1U and DVC2U SPR numbers (601,602) are used for accessing the upper 32-bit portion of the DVC register. The DVC1 and DVC2 SPR numbers (318,319) are used for accessing the lower 32-bit portion of the DVC register.

SPR - 601 (DVC1U), 318 (DVC1), 602 (DVC2U) 319 (DVC2); Read/Write; Reset - Unaffected

Figure 64-2. DVC1, DVC2 registers

64.3.2 Debug Control and Status registers

Debug Control Registers (DBCR0–8 and EDBRAC0) are used to enable debug events, reset the processor, and set the debug mode of the processor. The Debug Status register (DBSR) records debug exceptions while Internal Debug mode is enabled. The Debug Data Effective Address register (DDEAR) records the effective address of a Data Address Compare event while Internal Debug mode is enabled.

requires that a context synchronizing instruction follow a **mtspr** DBCR0–8 or DBSR to ensure that any alterations enabling/disabling debug events are effective. The context synchronizing instruction may or may not be affected by the alteration. Typically, an **se_isync** instruction is used to create a synchronization boundary beyond which it can be guaranteed that the newly written control values are in effect.

For watchpoint generation, configuration settings contained in DBCR1–8 are used, even though the corresponding event(s) may be disabled (via DBCR0) from setting DBSR flags.

64.3.2.1 Debug Control Register 0 (DBCR0)

Debug Control Register 0 is used to enable debug modes and controls which debug events are allowed to set DBSR or EDBSR0 flags. adds some implementation specific bits to this register, as seen in the following figure.

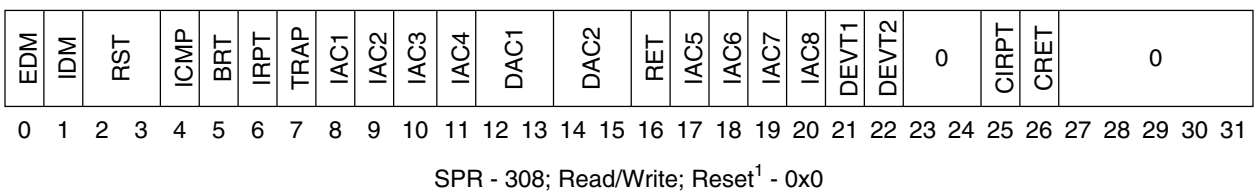


Figure 64-3. Debug Control Register 0 (DBCR0) register

Note

[1] $DBCR0_{EDM}$ is affected by **j_trst_b** or **m_por** assertion, and remains reset while in the Test_Logic_Reset state, but is not affected by **p_reset_b**. All other bits are reset by processor reset **p_reset_b** if $DBCR0_{EDM}$=0, as well as unconditionally by **m_por**. If $DBCR0_{EDM}$=1, EDBRAC0 masks off hardware-owned resources (other than RST) from reset by **p_reset_b**, and only software-owned resources indicated by EDBRAC0 and the $DBCR0_{RST}$ field will be reset by **p_reset_b**. The $DBCR0_{RST}$ field will always be reset by **p_reset_b** regardless of the value of $DBCR0_{EDM}$.

The following provides bit definitions for Debug Control Register 0.

Table 64-6. DBCR0 field descriptions

Bit	Name	Description
0	EDM	External Debug mode. This bit is read-only by software. When external debug mode is enabled, hardware-owned resources in debug registers are not affected by processor reset p_reset_b. This allows the debugger to set up hardware debug events that remain active across a processor reset.
		0 External debug mode disabled. Internal debug events not mapped into external debug events. 1 External debug mode enabled. Hardware-owned debug events will not cause the CPU to vector to interrupt code. Software is not permitted to write to debug registers {DBCR0–8, IAC1–8, DAC1–4, DVC1–2[U]} unless permitted by settings in EDBRAC0. Hardware-owned events will set status bits in EDBSR0. Programming Notes: It is recommended that debug status bits in the Debug Status Registers be cleared before disabling external debug mode to avoid any internal imprecise debug interrupts. Software may use this bit to determine if external debug has control over the debug registers. The hardware debugger must set the EDM bit to '1' before other bits in this register (and other debug registers) may be altered. On the initial setting of this bit to '1', all other bits are unchanged. This bit is only writable through the OnCE port.
1	IDM	Internal Debug mode 0 Debug exceptions are disabled. Debug events do not affect DBSR. 1 Debug exceptions are enabled. Enabled debug events owned by software will update the DBSR. If MSR_{DE}=1, the occurrence of a debug event, or the recording of an earlier debug event in the Debug Status Register when MSR_{DE} was cleared, will cause a Debug interrupt.
2:3	RST	Reset Control 00 No function 01 **p_dbrstc[1]** pin asserted by Debug Reset Control. Allows external device to initiate processor or system reset 10 **p_dbrstc[0]** pin asserted by Debug Reset Control. Allows external device to initiate processor or system reset. 11 Reserved
4	ICMP	Instruction Complete Debug Event Enable 0 ICMP debug events are disabled 1 ICMP debug events are enabled
5	BRT	Branch Taken Debug Event Enable 0 BRT debug events are disabled 1 BRT debug events are enabled
6	IRPT	Interrupt Taken Debug Event Enable 0 IRPT debug events are disabled 1 IRPT debug events are enabled
7	TRAP	Trap Taken Debug Event Enable 0 TRAP debug events are disabled 1 TRAP debug events are enabled

64.3.2.2 Debug Control Register 1 (DBCR1)

Debug Control Register 1 is used to configure Instruction Address Compare operation. The DBCR1 register is shown in the following figure.

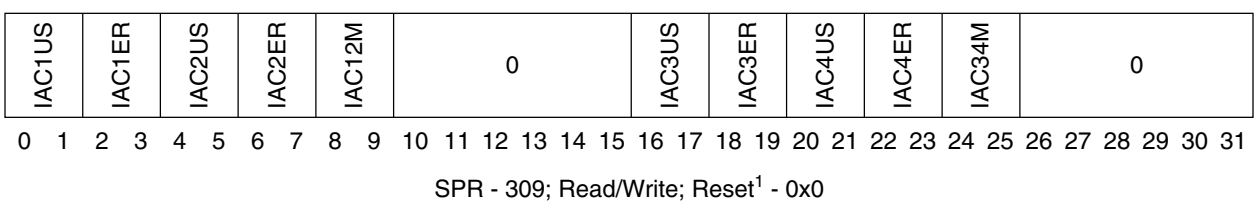

Figure 64-4. DBCR1 Register

Note

[1] Reset by processor reset **p_reset_b** if $EDBCR0_{EDM}$=0, as well as unconditionally by **m_por**. If $EDBCR0_{EDM}$=1, EDBRAC0 masks off hardware-owned resources from reset by **p_reset_b** and only software-owned resources indicated by EDBRAC0 will be reset by **p_reset_b**.

The following table provides bit definitions for Debug Control Register 1.

Table 64-7. DBCR1 field descriptions

Bit	Name	Description
0:1	IAC1US	Instruction Address Compare 1 User/Supervisor Mode 00 IAC1 debug events not affected by MSR_{PR} 01 Reserved 10 IAC1 debug events can only occur if MSR_{PR}=0 (Supervisor mode) 11 IAC1 debug events can only occur if MSR_{PR}=1. (User mode)
2:3	IAC1ER	Instruction Address Compare 1 Effective/Real Mode 00 IAC1 debug events are based on effective address 01 Unimplemented (Book E real address compare), no match can occur 10 IAC1 debug events are based on effective address and can only occur if MSR_{IS}=0 11 IAC1 debug events are based on effective address and can only occur if MSR_{IS}=1
4:5	IAC2US	Instruction Address Compare 2 User/Supervisor Mode 00 IAC2 debug events not affected by MSR_{PR} 01 Reserved 10 IAC2 debug events can only occur if MSR_{PR}=0 (Supervisor mode) 11 IAC2 debug events can only occur if MSR_{PR}=1. (User mode)
6:7	IAC2ER	Instruction Address Compare 2 Effective/Real Mode 00 IAC2 debug events are based on effective address 01 Unimplemented (Book E real address compare), no match can occur 10 IAC2 debug events are based on effective address and can only occur if MSR_{IS}=0 11 IAC2 debug events are based on effective address and can only occur if MSR_{IS}=1
8:9	IAC12M	Instruction Address Compare 1/2 Mode 00 Exact address compare. IAC1 debug events can only occur if the address of the instruction fetch is equal to the value specified in IAC1. IAC2 debug events can only occur if the address of the instruction fetch is equal to the value specified in IAC2. 01 Address bit match. IAC1 debug events can occur only if the address of the instruction fetch, ANDed with the contents of IAC2 are equal to the contents of IAC1, also ANDed with the contents of IAC2. IAC2 debug events do not occur. IAC1US and IAC1ER settings are used. 10 Inclusive address range compare. IAC1 debug events can occur only if the address of the instruction fetch is greater than or equal to the value specified in IAC1 and less than the value specified in IAC2. IAC2 debug events do not occur. IAC1US and IAC1ER settings are used. 11 Exclusive address range compare. IAC1 debug events can occur only if the address of the instruction fetch is less than the value specified in IAC1 or is greater than or equal to the value specified in IAC2. IAC2 debug events do not occur. IAC1US and IAC1ER settings are used.
10:15	—	Reserved
16:17	IAC3US	Instruction Address Compare 3 User/Supervisor Mode 00 IAC3 debug events not affected by MSR_{PR} 01 Reserved 10 IAC3 debug events can only occur if MSR_{PR}=0 (Supervisor mode) 11 IAC3 debug events can only occur if MSR_{PR}=1 (User mode)

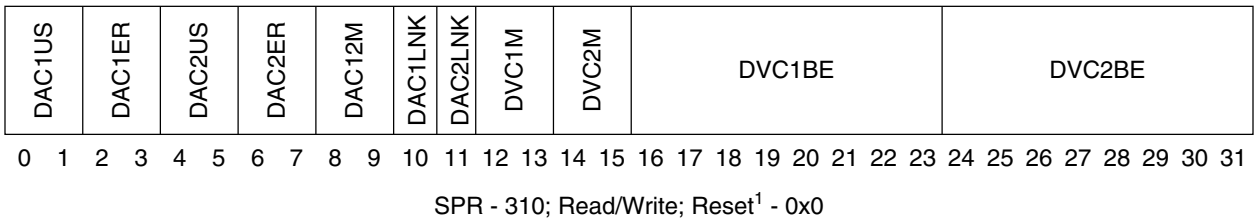

Table continues on the next page...

Table 64-7. DBCR1 field descriptions (continued)

Bit	Name	Description
18:19	IAC3ER	Instruction Address Compare 3 Effective/Real Mode 00 IAC3 debug events are based on effective address 01 Unimplemented (Book E real address compare), no match can occur 10 IAC3 debug events are based on effective address and can only occur if MSR_{IS}=0 11 IAC3 debug events are based on effective address and can only occur if MSR_{IS}=1
20:21	IAC4US	Instruction Address Compare 4 User/Supervisor Mode 00 IAC4 debug events not affected by MSR_{PR} 01 Reserved 10 IAC4 debug events can only occur if MSR_{PR}=0 (Supervisor mode). 11 IAC4 debug events can only occur if MSR_{PR}=1. (User mode)

24:25	IAC34M	Instruction Address Compare 3/4 Mode 00 Exact address compare. IAC3 debug events can only occur if the address of the instruction fetch is equal to the value specified in IAC3. IAC4 debug events can only occur if the address of the instruction fetch is equal to the value specified in IAC4. 01 Address bit match. IAC3 debug events can occur only if the address of the instruction fetch, ANDed with the contents of IAC4 are equal to the contents of IAC3, also ANDed with the contents of IAC4. IAC4 debug events do not occur. IAC3US and IAC3ER settings are used. 10 Inclusive address range compare. IAC3 debug events can occur only if the address of the instruction fetch is greater than or equal to the value specified in IAC3 and less than the value specified in IAC4. IAC4 debug events do not occur. IAC3US and IAC3ER settings are used. 11 Exclusive address range compare. IAC3 debug events can occur only if the address of the instruction fetch is less than the value specified in IAC3 or is greater than or equal to the value specified in IAC4. IAC4 debug events do not occur. IAC3US and IAC3ER settings are used.
26:31	—	Reserved

64.3.2.3 Debug Control Register 2 (DBCR2)

Debug Control Register 2 is used to configure Data Address Compare and Data Value Compare operation.The DBCR2 register is shown in the following figure.

SPR - 310; Read/Write; Reset[1] - 0x0

Figure 64-5. DBCR2 Register

Note

[1] Reset by processor reset **p_reset_b** if $EDBCR0_{EDM}$=0, as well as unconditionally by **m_por**. If $EDBCR0_{EDM}$=1, EDBRAC0 masks off hardware-owned resources from reset by **p_reset_b** and only software-owned resources indicated by EDBRAC0 will be reset by **p_reset_b**.

The following table provides bit definitions for Debug Control Register 2.

Table 64-8. DBCR2 Bit Definitions

Bit	Name	Description
0:1	DAC1US	Data Address Compare 1 User/Supervisor Mode 00 DAC1 debug events not affected by MSR_{PR} 01 Reserved 10 DAC1 debug events can only occur if MSR_{PR}=0 (Supervisor mode) 11 DAC1 debug events can only occur if MSR_{PR}=1 (User mode)
2:3	DAC1ER	Data Address Compare 1 Effective/Real Mode 00 DAC1 debug events are based on effective address 01 Unimplemented (Book E real address compare), no match can occur 10 DAC1 debug events are based on effective address and can only occur if MSR_{DS}=0 11 DAC1 debug events are based on effective address and can only occur if MSR_{DS}=1
4:5	DAC2US	Data Address Compare 2 User/Supervisor Mode 00 DAC2 debug events not affected by MSR_{PR} 01 Reserved 10 DAC2 debug events can only occur if MSR_{PR}=0 (Supervisor mode) 11 DAC2 debug events can only occur if MSR_{PR}=1. (User mode)
6:7	DAC2ER	Data Address Compare 2 Effective/Real Mode 00 DAC2 debug events are based on effective address 01 Unimplemented (Book E real address compare), no match can occur 10 DAC2 debug events are based on effective address and can only occur if MSR_{DS}=0 11 DAC2 debug events are based on effective address and can only occur if MSR_{DS}=1

Table continues on the next page...

Table 64-8. DBCR2 Bit Definitions (continued)

Bit	Name	Description
8:9	DAC12M	Data Address Compare 1/2 Mode 00 Exact address compare. DAC1 debug events can only occur if the address of the data access is equal to the value specified in DAC1. DAC2 debug events can only occur if the address of the data access is equal to the value specified in DAC2. 01 Address bit match. DAC1 debug events can occur only if the address of the data access ANDed with the contents of DAC2, are equal to the contents of DAC1 also ANDed with the contents of DAC2. DAC2 debug events do not occur. DAC1US and DAC1ER settings are used. 10 Inclusive address range compare. DAC1 debug events can occur only if the address of the data access is greater than or equal to the value specified in DAC1 and less than the value specified in DAC2. DAC2 debug events do not occur. DAC1US and DAC1ER settings are used. 11 Exclusive address range compare. DAC1 debug events can occur only if the address of the data access is less than the value specified in DAC1 or is greater than or equal to the value specified in DAC2. DAC2 debug events do not occur. DAC1US and DAC1ER settings are used.
10	DAC1LNK	Data Address Compare 1 Linked. When linked to IAC1, DAC1 debug events are conditioned based on whether the instruction also generated an IAC1 debug event. Note that linking is only available in EDM or IDM. 0 No effect 1 DAC1 debug events are linked to IAC1 debug events. IAC1 debug events do not affect DBSR When linked to IAC1, DAC1 debug events are conditioned based on whether the instruction also generated an IAC1 debug event. Note that linking is only available in EDM or IDM.
11	DAC2LNK	Data Address Compare 2 Linked. When linked to IAC3, DAC2 debug events are conditioned based on whether the instruction also generated an IAC3 debug event. DAC2 can only be linked if DAC12M specifies Exact Address Compare since DAC2 debug events are not generated in the other compare modes. Note that linking is only available in EDM or IDM. 0 No effect 1 DAC 2 debug events are linked to IAC3 debug events. IAC3 debug events do not affect DBSR

Table continues on the next page...

Table 64-8. DBCR2 Bit Definitions (continued)

Bit	Name	Description
12:13	DVC1M	Data Value Compare 1 Mode When $DBCR4_{DVC1C}$=0: 00 DAC1 debug events not affected by data value compares. 01 DAC1 debug events can only occur when all bytes specified in the DVC1BE field match the corresponding data byte values for active byte lanes of the memory access. 10 DAC1 debug events can only occur when any byte specified in the DVC1BE field matches the corresponding data byte value for active byte lanes of the memory access. 11 DAC1 debug events can only occur when all bytes specified in the DVC1BE field within at least one of the halfwords of the data value of the memory access matches the corresponding DVC1 value. **NOTE:** Inactive byte lanes of the memory access are automatically masked. When $DBCR4_{DVC1C}$=1: 00 Reserved 01 DAC1 debug events can only occur when any byte specified in the DVC1BE field does not match the corresponding data byte value for active byte lanes of the memory access. If all active bytes match, then no event will be generated. 10 DAC1 debug events can only occur when all bytes specified in the DVC1BE field do not match the corresponding data byte values for active byte lanes of the memory access. If any active byte match occurs, no event will be generated. 11 Reserved **NOTE:** Note: Inactive byte lanes of the memory access are automatically masked.
14:15	DVC2M	Data Value Compare 2 Mode When $DBCR4_{DVC2C}$=0: 00 DAC2 debug events not affected by data value compares. 01 DAC2 debug events can only occur when all bytes specified in the DVC2BE field match the corresponding data byte values for active byte lanes of the memory access. 10 DAC2 debug events can only occur when any byte specified in the DVC2BE field matches the corresponding data byte value for active byte lanes of the memory access. 11 DAC2 debug events can only occur when all bytes specified in the DVC2BE field within at least one of the halfwords of the data value of the memory access matches the corresponding DVC2 value. **NOTE:** Inactive byte lanes of the memory access are automatically masked. When $DBCR4_{DVC2C}$=1: 00 Reserved 01 DAC2 debug events can only occur when any byte specified in the DVC2BE field does not match the corresponding data byte value for active byte lanes of the memory access. If all active bytes match, then no event will be generated. 10 DAC2 debug events can only occur when all bytes specified in the DVC2BE field do not match the corresponding data byte values for active byte lanes of the memory access. If any active byte match occurs, no event will be generated. 11 Reserved **NOTE:** Inactive byte lanes of the memory access are automatically masked.

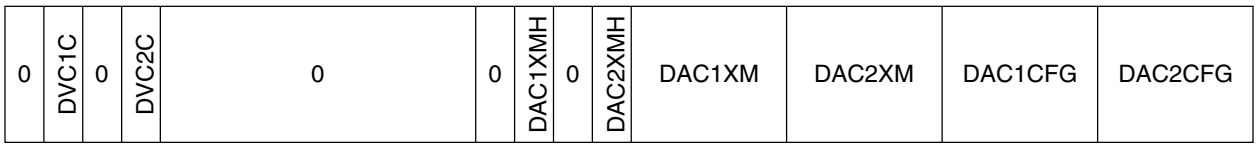

Table continues on the next page...

Table 64-8. DBCR2 Bit Definitions (continued)

Bit	Name	Description
16:23	DVC1BE	Data Value Compare 1 Byte Enables Specifies which bytes in the aligned doubleword value associated with the memory access are compared to the corresponding bytes in DVC1. Inactive byte lanes of a memory access smaller than 64 bits are automatically masked by hardware. If all bits in the DVC1BE field are clear, then a match will occur regardless of the data. Misaligned accesses that cross a doubleword boundary are not fully supported. 1xxxxxxx Byte lane 0 is enabled for comparison with the value in bits 0:7 of DVC1. x1xxxxxx Byte lane 1 is enabled for comparison with the value in bits 8:15 of DVC1. xx1xxxxx Byte lane 2 is enabled for comparison with the value in bits 16:23 of DVC1. xxx1xxxx Byte lane 3 is enabled for comparison with the value in bits 24:31 of DVC1. xxxx1xxx Byte lane 4 is enabled for comparison with the value in bits 32:39 of DVC1. xxxxx1xx Byte lane 5 is enabled for comparison with the value in bits 40:47 of DVC1. xxxxxx1x Byte lane 6 is enabled for comparison with the value in bits 48:55 of DVC1. xxxxxxx1 Byte lane 7 is enabled for comparison with the value in bits 56:63 of DVC1.
24:31	DVC2BE	Data Value Compare2 Byte Enables Specifies which bytes in the aligned doubleword value associated with the memory access are compared to the corresponding bytes in DVC2. Inactive byte lanes of a memory access smaller than 64 bits are automatically masked by hardware. If all bits in the DVC1BE field are clear, then a match will occur regardless of the data. Misaligned accesses that cross a doubleword boundary are not fully supported. 1xxxxxxx Byte lane 0 is enabled for comparison with the value in bits 0:7 of DVC2. x1xxxxxx Byte lane 1 is enabled for comparison with the value in bits 8:15 of DVC2. xx1xxxxx Byte lane 2 is enabled for comparison with the value in bits 16:23 of DVC2. xxx1xxxx Byte lane 3 is enabled for comparison with the value in bits 24:31 of DVC2. xxxx1xxx Byte lane 4 is enabled for comparison with the value in bits 32:39 of DVC2. xxxxx1xx Byte lane 5 is enabled for comparison with the value in bits 40:47 of DVC2. xxxxxx1x Byte lane 6 is enabled for comparison with the value in bits 48:55 of DVC2. xxxxxxx1 Byte lane 7 is enabled for comparison with the value in bits 56:63 of DVC2.

64.3.2.4 Debug Control Register 4 (DBCR4)

Debug Control Register 4 is used to extend data address and value compare matching functionality. DBCR4 is shown in the following figure.

SPR - 563; Read/Write; Reset[1] - 0x0

Figure 64-6. DBCR4 Register

Note

[1] DBCR4 is reset by processor reset **p_reset_b** if $EDBCR0_{EDM}$=0, as well as unconditionally by **m_por**. If $EDBCR0_{EDM}$=1, EDBRAC0 masks off hardware-owned resources from reset by **p_reset_b** and only software-owned resources indicated by EDBRAC0 will be reset by **p_reset_b**.

The following table provides bit definitions for Debug Control Register 4.

Table 64-9. DBCR4 field description

Bit	Name	Description
0	—	Reserved
1	DVC1C	Data Value Compare 1 Control. DVC1C controls whether DVC1 data value comparisons utilize the normal compare operation, or an alternate “inverted compare” operation. In inverted polarity mode, data value compares perform a not-equal comparison. See details in the DBCR2 register definition. 0 Normal DVC1 operation. Inverted polarity DVC1 operation
2	—	Reserved
3	DVC2C	Data Value Compare 2 Control. DVC2C controls whether DVC2 data value comparisons utilize the normal compare operation, or an alternate “inverted compare” operation. In inverted polarity mode, data value compares perform a not-equal comparison. See details in the DBCR2 register definition 0 Normal DVC2 operation. 1 Inverted polarity DVC2 operation
4:12	—	Reserved
13	DAC1XMH	Data Address Compare 1 Extended Mask Control High. DAC1XMH extends the range of the DAC1XM field. 0 - DAC1XM masks 0–15 low-order address bits 1 - DAC1XM masks 16–31 low-order address bits
14	—	Reserved
15	DAC2XMH	Data Address Compare 2 Extended Mask Control High. . DAC2XMH extends the range of the DAC2XM field. 0 DAC2XM masks 0–15 low-order address bits 1 DAC2XM masks 16–31 low-order address bits

Table continues on the next page...

Table 64-9. DBCR4 field description (continued)

Bit	Name	Description
16:19	DAC1XM	Data Address Compare 1 Extended Mask Control. DAC1XM allows for binary power of 2 address range compares for DAC1 without requiring the use of DAC2. Value of DAC1XMH || DAC1XM: 00000 No additional masking when DBCR2[DAC12M] = 00 00001 - 11111 Exact Match Bit Mask. One to 31 low-order bits are masked in DAC1 when comparing the storage address with the value in DAC1 for exact address compare (DBCR2[DAC12M] = 00). Address ranges of 2 bytes to 2GB are supported.
20:23	DAC2XM	Data Address Compare 2 Extended Mask Control Value of DAC2XMH || DAC2XM: 00000 No additional masking when DBCR2[DAC12M] = 00 00001 - 11111 Exact Match Bit Mask. One to 31 low-order bits are masked in DAC2 when comparing the storage address with the value in DAC2 for exact address compare (DBCR2[DAC12M] = 00). Address ranges of 2 bytes to 2GB are supported. DAC2XM allows for binary power of 2 address range compares for DAC2.
24:27	DAC1CFG	Data Address Compare 1 Configuration 0000 DAC1 debug watchpoints are enabled for load-type or store-type data storage accesses when $DBCR0_{DAC1}$=00 0001 DAC1 debug watchpoints are enabled only for store-type data storage accesses when $DBCR0_{DAC1}$=00 0010 DAC1 debug watchpoints are enabled only for load-type data storage accesses when $DBCR0_{DAC1}$=00 0011 Reserved 01xx Reserved 1000 DAC1 address comparisons are used for stack limit checking. DAC1 address comparisons are qualified with use of GPR R1 in <EA> calculation for most load or store instructions. No debug events occur for DAC1. When a qualified DAC1 match occurs, a machine check exception is generated for supervisor-mode accesses or a DSI is generated for user-mode accesses, and a DAC1 watchpoint is generated. $DBCR0_{DAC1}$ and $DBCR2_{DVC1M}$ settings are ignored. 1001 – 1111 Reserved DAC1CFG controls whether DAC1 data address comparisons utilize the normal PowerISA operation for generating both debug events and watchpoints, a watchpoint-only function, or a stack limit checking function (with watchpoint). **NOTE:** unlike the DAC3–4CFG fields, debug event enabling for DAC1 is controlled by the DAC1 field in DBCR0. The DAC1CFG encodings 0000–0010 are used to control watchpoint generation when $DBCR0_{DAC1}$=0; when $DBCR0_{DAC1}$!=00, DAC1 watchpoints will fire whenever a DAC1 debug event occurs.

Table continues on the next page...

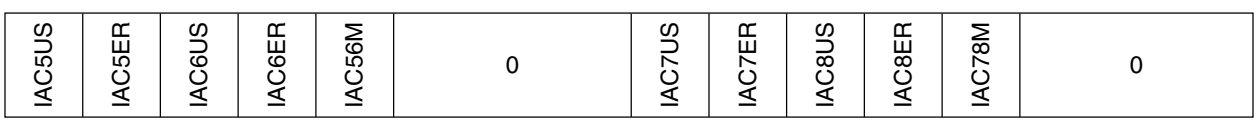

Table 64-9. DBCR4 field description (continued)

Bit	Name	Description
28:31	DAC2CFG	Data Address Compare 2 Configuration 0000 DAC2 debug watchpoints are enabled for load-type or store-type data storage accesses when $DBCR0_{DAC2}$=00 0001 DAC2 debug watchpoints are enabled only for store-type data storage accesses when $DBCR0_{DAC2}$=00 0010 DAC2 debug watchpoints are enabled only for load-type data storage accesses when $DBCR0_{DAC2}$=00 0011 Reserved 01xx Reserved 1xxx Reserved DAC2CFG controls whether DAC2 data address comparisons utilize the normal compare operation for generating both debug events and watchpoints, or a watchpoint-only function. **NOTE:** Unlike the DAC3–4CFG fields, debug event enabling for DAC2 is controlled by the DAC2 field in DBCR0. The DAC2CFG encodings 0000–0010 are used to control watchpoint generation when $DBCR0_{DAC2}$=00. When $DBCR0_{DAC2}$!=00, DAC2 watchpoints will fire whenever a DAC2 debug event occurs.

64.3.2.5 Debug Control Register 5 (DBCR5)

Debug Control Register 5 is used to configure Instruction Address Compare operation for IAC5–8. The DBCR5 register is shown in the following figure.

.

SPR - 564; Read/Write; Reset[1] - 0x0

Figure 64-7. DBCR5 Register

Note

[1] Reset by processor reset **p_reset_b** if $EDBCR0_{EDM}$=0, as well as unconditionally by **m_por**. If $EDBCR0_{EDM}$=1, EDBRAC0 masks off hardware-owned resources from reset by **p_reset_b** and only software-owned resources indicated by EDBRAC0 will be reset by **p_reset_b**.

The following table provides bit definitions for Debug Control Register 5.

Table 64-10. DBCR5 field descriptions

Bit(s)	Name	Description
0:1	IAC5US	Instruction Address Compare 5 User/Supervisor Mode 00 IAC5 debug events not affected by MSR_{PR} 01 Reserved 10 IAC5 debug events can only occur if MSR_{PR}=0 (Supervisor mode) 11 IAC5 debug events can only occur if MSR_{PR}=1. (User mode)
2:3	IAC5ER	Instruction Address Compare 5 Effective/Real Mode 00 IAC5 debug events are based on effective address 01 Unimplemented (Book E real address compare), no match can occur 10 IAC5 debug events are based on effective address and can only occur if MSR_{IS}=0 11 IAC5 debug events are based on effective address and can only occur if MSR_{IS}=1
4:5	IAC6US	Instruction Address Compare 6 User/Supervisor Mode 00 IAC6 debug events not affected by MSR_{PR} 01 Reserved 10 IAC6 debug events can only occur if MSR_{PR}=0 (Supervisor mode) 11 IAC6 debug events can only occur if MSR_{PR}=1. (User mode)
6:7	IAC6ER	Instruction Address Compare 6 Effective/Real Mode 00 IAC6 debug events are based on effective address 01 Unimplemented (Book E real address compare), no match can occur 10 IAC6 debug events are based on effective address and can only occur if MSR_{IS}=0 11 IAC6 debug events are based on effective address and can only occur if MSR_{IS}=1
8:9	IAC56M	Instruction Address Compare 5/6 Mode 00 Exact address compare. IAC5 debug events can only occur if the address of the instruction fetch is equal to the value specified in IAC5. IAC6 debug events can only occur if the address of the instruction fetch is equal to the value specified in IAC6. 01 Address bit match. IAC5 debug events can occur only if the address of the instruction fetch, ANDed with the contents of IAC6 are equal to the contents of IAC5, also ANDed with the contents of IAC6. IAC6 debug events do not occur. IAC5US and IAC5ER settings are used. 10 Inclusive address range compare. IAC5 debug events can occur only if the address of the instruction fetch is greater than or equal to the value specified in IAC5 and less than the value specified in IAC6. IAC6 debug events do not occur. IAC5US and IAC5ER settings are used. 11 Exclusive address range compare. IAC5 debug events can occur only if the address of the instruction fetch is less than the value specified in IAC5 or is greater than or equal to the value specified in IAC6. IAC6 debug events do not occur. IAC5US and IAC5ER settings are used.
10:15	—	Reserved

24:25	IAC78M	Instruction Address Compare 7/8 Mode 00 Exact address compare. IAC7 debug events can only occur if the address of the instruction fetch is equal to the value specified in IAC7. IAC8 debug events can only occur if the address of the instruction fetch is equal to the value specified in IAC8. 01 Address bit match. IAC7 debug events can occur only if the address of the instruction fetch, ANDed with the contents of IAC8 are equal to the contents of IAC7, also ANDed with the contents of IAC8. IAC8 debug events do not occur. IAC7US and IAC7ER settings are used. 10 Inclusive address range compare. IAC7 debug events can occur only if the address of the instruction fetch is greater than or equal to the value specified in IAC7 and less than the value specified in IAC8. IAC8 debug events do not occur. IAC7US and IAC7ER settings are used. 11 Exclusive address range compare. IAC7 debug events can occur only if the address of the instruction fetch is less than the value specified in IAC7 or is greater than or equal to the value specified in IAC8. IAC8 debug events do not occur. IAC7US and IAC7ER settings are used.
26:31	—	Reserved

64.3.2.6 Debug Control Register 6 (DBCR6)

Debug Control Register 6 is used to extend instruction address compare matching functionality. DBCR6 is shown in the following figure.

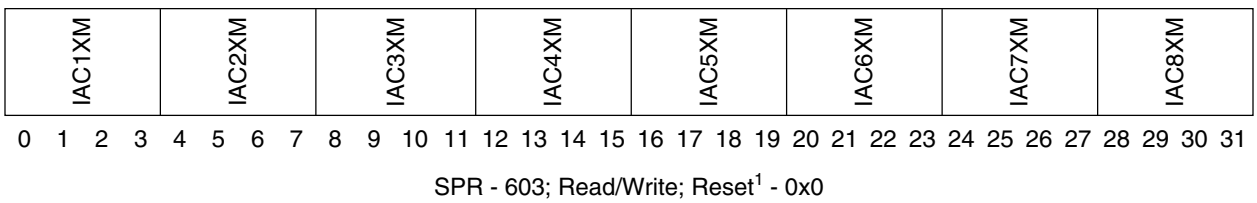

Figure 64-8. DBCR6 Register

Note

[1] DBCR6 is reset by processor reset **p_reset_b** if $EDBCR0_{EDM}$=0, as well as unconditionally by **m_por**. If $EDBCR0_{EDM}$=1, EDBRAC0 masks off hardware-owned resources from reset by **p_reset_b** and only software-owned resources indicated by EDBRAC0 will be reset by **p_reset_b**.

The following table provides bit definitions for Debug Control Register 6.

Table 64-11. DBCR6 field descriptions

Bit	Name	Description
0:3	IAC1XM	Instruction Address Compare 1 Extended Mask Control. IAC1XM allows for binary power of 2 address range compares for IAC1 without requiring the use of IAC2. 0000 No additional masking when DBCR1[IAC12M]=00 0001 - 1100 Exact Match Bit Mask. Number of low order bits masked in IAC1 when comparing the storage address with the value in IAC1 for exact address compare (DBCR1[IAC12M]=00). Ranges up to 4 KB are supported. 1101 - 1111 Reserved
4:7	IAC2XM	Instruction Address Compare 2 Extended Mask Control. IAC2XM allows for binary power of 2 address range compares for IAC2 without requiring the use of IAC1. 0000 No additional masking when DBCR1[IAC12M]=00 0001 - 1100 Exact Match Bit Mask. Number of low order bits masked in IAC2 when comparing the storage address with the value in IAC2 for exact address compare (DBCR1[IAC12M]=00). Ranges up to 4 KB are supported. 1101 - 1111 Reserved
8:11	IAC3XM	Instruction Address Compare 3 Extended Mask Control. IAC3XM allows for binary power of 2 address range compares for IAC1 without requiring the use of IAC2. 0000 No additional masking when DBCR1[IAC34M]=00 0001 - 1100 Exact Match Bit Mask. Number of low order bits masked in IAC3 when comparing the storage address with the value in IAC3 for exact address compare (DBCR1[IAC34M]=00). Ranges up to 4 KB are supported. 1101 - 1111 Reserved

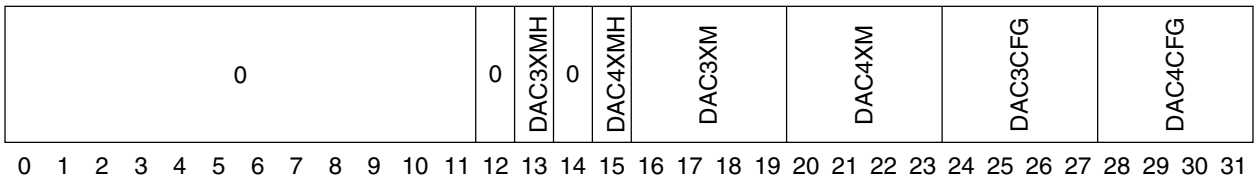

Table continues on the next page...

Table 64-11. DBCR6 field descriptions (continued)

Bit	Name	Description
12:15	IAC4XM	Instruction Address Compare 4 Extended Mask Controll. IAC4XM allows for binary power of 2 address range compares for IAC4 without requiring the use of IAC3. 0000 No additional masking when DBCR1[IAC34M]=00 0001 - 1100 Exact Match Bit Mask. Number of low order bits masked in IAC4 when comparing the storage address with the value in IAC4 for exact address compare (DBCR1[IAC34M]=00). Ranges up to 4 KB are supported. 1101 - 1111 Reserved
16:19	IAC5XM	Instruction Address Compare 5 Extended Mask Control. IAC5XM allows for binary power of 2 address range compares for IAC5 without requiring the use of IAC6. 0000 No additional masking when DBCR5[IAC56M]=00 0001 - 1100 Exact Match Bit Mask. Number of low order bits masked in IAC5 when comparing the storage address with the value in IAC5 for exact address compare (DBCR5[IAC56M]=00). Ranges up to 4 KB are supported. 1101 - 1111 Reserved
20:23	IAC6XM	Instruction Address Compare 6 Extended Mask Control. IAC6XM allows for binary power of 2 address range compares for IAC6 without requiring the use of IAC5. 0000 No additional masking when DBCR5[IAC56M]=00 0001 - 1100 Exact Match Bit Mask. Number of low order bits masked in IAC6 when comparing the storage address with the value in IAC6 for exact address compare (DBCR5[IAC56M]=00). Ranges up to 4 KB are supported. 1101 - 1111 Reserved
24:27	IAC7XM	Instruction Address Compare 7 Extended Mask Control. IAC7XM allows for binary power of 2 address range compares for IAC7 without requiring the use of IAC8. 0000 No additional masking when DBCR5[IAC78M]=00 0001 - 1100 Exact Match Bit Mask. Number of low order bits masked in IAC7 when comparing the storage address with the value in IAC7 for exact address compare (DBCR5[IAC78M]=00). Ranges up to 4 KB are supported. 1101 - 1111 Reserved
28:31	IAC8XM	Instruction Address Compare 8 Extended Mask Control. IAC8XM allows for binary power of 2 address range compares for IAC8 without requiring the use of IAC7. 0000 No additional masking when DBCR5[IAC78M]=00 0001 - 1100 Exact Match Bit Mask. Number of low order bits masked in IAC8 when comparing the storage address with the value in IAC8 for exact address compare (DBCR5[IAC78M]=00). Ranges up to 4 KB are supported. 1101 - 1111 Reserved

64.3.2.7 Debug Control Register 7 (DBCR7)

Debug Control Register 7 is used to enable and configure Data Address Compare 3 and 4 functionality. DBCR7 is shown in the following figure.

SPR - 596; Read/Write; Reset[1] - 0x0

Figure 64-9. DBCR7 Register

Note

[1] DBCR7 is reset by processor reset **p_reset_b** if $EDBCR0_{EDM}$=0, as well as unconditionally by **m_por**. If $EDBCR0_{EDM}$=1, EDBRAC0 masks off hardware-owned resources from reset by **p_reset_b** and only software-owned resources indicated by EDBRAC0 will be reset by **p_reset_b**.

The following table provides bit definitions for Debug Control Register 7.

Table 64-12. DBCR7 Field Descriptions

Bit	Name	Description
0:12	—	Reserved
13	DAC3XMH	Data Address Compare 3 Extended Mask Control High .DAC3XMH extends the range of the DAC3XM field
		0 DAC3XM masks 0–15 low-order address bits 1 DAC3XM masks 16–31 low-order address bits
14	—	Reserved
15	DAC4XMH	Data Address Compare 4 Extended Mask Control High. . DAC4XMH extends the range of the DAC4XM field.
		0 DAC4XM masks 0–15 low-order address bits 1 DAC4XM masks 16–31 low-order address bits
16:19	DAC3XM	Data Address Compare 3 Extended Mask Control. DAC3XM allows for binary power of 2 address range compares for DAC3 without requiring the use of DAC4.
		Value of DAC3XMH || DAC3XM: 00000 No additional masking when DBCR8[DAC34M] = 00 00001 - 11111 Exact Match Bit Mask. One to 31 low-order bits are masked in DAC3 when comparing the storage address with the value in DAC3 for exact address compare (DBCR8[DAC34M] = 00). Address ranges of 2 bytes to 2GB are supported.

Table continues on the next page...

Table 64-12. DBCR7 Field Descriptions (continued)

Bit	Name	Description
20:23	DAC4XM	Data Address Compare 4 Extended Mask Control. DAC4XM allows for binary power of 2 address range compares for DAC4 without requiring the use of DAC3.
		Value of DAC4XMH || DAC4XM: 00000 No additional masking when DBCR8[DAC34M] = 00 00001 - 11111 Exact Match Bit Mask. One to 31 low-order bits are masked in DAC4 when comparing the storage address with the value in DAC4 for exact address compare (DBCR8[DAC34M] = 00). Address ranges of 2 bytes to 2GB are supported.
24:27	DAC3CFG	Data Address Compare 3 Configuration. DAC3CFG controls whether DAC3 data address comparisons utilize the normal compare operation for generating both debug events and watchpoints, a watchpoint-only function, or a stack limit checking function (with watchpoint).
		0000 DAC3 debug watchpoints are enabled for load-type or store-type data storage accesses 0001 DAC3 debug watchpoints are enabled only for store-type data storage accesses 0010 DAC3 debug watchpoints are enabled only for load-type data storage accesses 0011 Reserved 0100Reserved 0101 DAC3 debug events and watchpoints are enabled only for store-type data storage accesses 0110 DAC3 debug events and watchpoints are enabled only for load-type data storage accesses 0111 DAC3 debug events and watchpoints are enabled for load-type or store-type data storage accesses 1000 DAC3 address comparisons are used for stack limit checking. DAC3 address comparisons are qualified with use of GPR R1 in <EA> calculation for most load or store instructions. No debug events occur for DAC3. When a qualified match occurs, a machine check exception is generated for supervisor-mode accesses or a DSI is generated for user-mode accesses, and a DAC3 watchpoints is generated. 1001 - 1111 Reserved

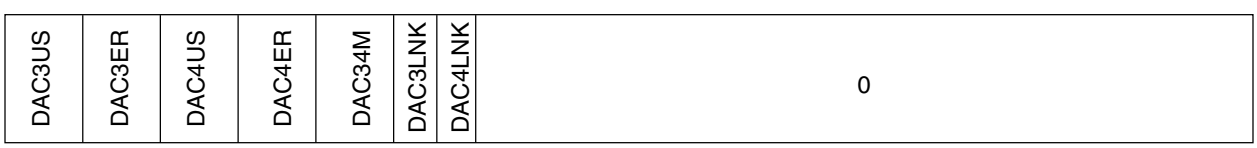

Table continues on the next page...

Table 64-12. DBCR7 Field Descriptions (continued)

Bit	Name	Description
28:31	DAC4CFG	Data Address Compare 4 Configuration. DAC4CFG controls whether DAC4 data address comparisons utilize the normal compare operation for generating both debug events and watchpoints, or a watchpoint-only function.
		0000 DAC4 debug watchpoints are enabled for load-type or store-type data storage accesses
		0001 DAC4 debug watchpoints are enabled only for store-type data storage accesses
		0010 DAC4 debug watchpoints are enabled only for load-type data storage accesses
		0011 Reserved
		0100 Reserved
		0101 DAC4 debug events and watchpoints are enabled only for store-type data storage accesses
		0110 DAC4 debug events and watchpoints are enabled only for load-type data storage accesses
		0111 DAC4 debug events and watchpoints are enabled for load-type or store-type data storage accesses
		1xxx Reserved

64.3.2.8 Debug Control Register 8 (DBCR8)

Debug Control Register 8 is used to configure Data Address Compare 3 and 4 operation. The DBCR8 register is shown in the following figure.

SPR - 597; Read/Write; Reset[1] - 0x0

Figure 64-10. DBCR8 Register

Note

[1] Reset by processor reset **p_reset_b** if $EDBCR0_{EDM}$=0, as well as unconditionally by **m_por**. If $EDBCR0_{EDM}$=1, EDBRAC0 masks off hardware-owned resources from reset by **p_reset_b** and only software-owned resources indicated by EDBRAC0 will be reset by **p_reset_b**.

The following table provides bit definitions for Debug Control Register 8.

Table 64-13. DBCR8 Bit Definitions

Bit(s)	Name	Description
0:1	DAC3US	Data Address Compare 3 User/Supervisor Mode 00 - DAC3 debug events not affected by MSR_{PR} 01 - Reserved 10 - DAC3 debug events can only occur if MSR_{PR}=0 (Supervisor mode) 11 - DAC3 debug events can only occur if MSR_{PR}=1. (User mode)
2:3	DAC3ER	Data Address Compare 3 Effective/Real Mode 00 - DAC3 debug events are based on effective address 01 - Unimplemented (Book E real address compare), no match can occur 10 - DAC3 debug events are based on effective address and can only occur if MSR_{DS}=0 11 - DAC3 debug events are based on effective address and can only occur if MSR_{DS}=1
4:5	DAC4US	Data Address Compare 4 User/Supervisor Mode. 00 - DAC4 debug events not affected by MSR_{PR} 01 - Reserved 10 - DAC4 debug events can only occur if MSR_{PR}=0 (Supervisor mode) 11 - DAC4 debug events can only occur if MSR_{PR}=1. (User mode)
6:7	DAC4ER	Data Address Compare 4 Effective/Real Mode 00 - DAC4 debug events are based on effective address 01 - Unimplemented (Book E real address compare), no match can occur 10 - DAC4 debug events are based on effective address and can only occur if MSR_{DS}=0 11 - DAC4 debug events are based on effective address and can only occur if MSR_{DS}=1
8:9	DAC34M	Data Address Compare 3/4 Mode 00 - Exact address compare. DAC3 debug events can only occur if the address of the data access is equal to the value specified in DAC3. DAC4 debug events can only occur if the address of the data access is equal to the value specified in DAC4. 01 - Address bit match. DAC3 debug events can occur only if the address of the data access ANDed with the contents of DAC4, are equal to the contents of DAC3 also ANDed with the contents of DAC4. DAC4 debug events do not occur. DAC3US and DAC3ER settings are used. 10 - Inclusive address range compare. DAC3 debug events can occur only if the address of the data access is greater than or equal to the value specified in DAC3 and less than the value specified in DAC4. DAC4 debug events do not occur. DAC3US and DAC3ER settings are used. 11 - Exclusive address range compare. DAC3 debug events can occur only if the address of the data access is less than the value specified in DAC3 or is greater than or equal to the value specified in DAC4. DAC4 debug events do not occur. DAC3US and DAC3ER settings are used.

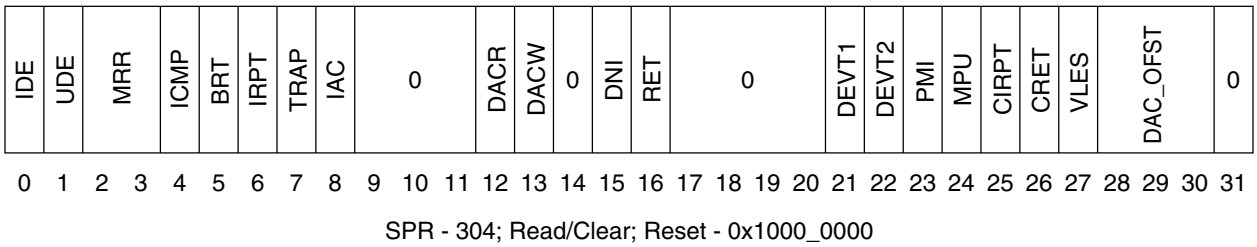

Table continues on the next page...

Table 64-13. DBCR8 Bit Definitions (continued)

Bit(s)	Name	Description
10	DAC3LNK	Data Address Compare 3 Linked 0 - No effect 1 - DAC3 debug events are linked to IAC5 debug events. IAC5 debug events do not affect DBSR When linked to IAC5, DAC3 debug events are conditioned based on whether the instruction also generated an IAC5 debug event. Note that linking is only available in EDM or IDM.
11	DAC4LNK	Data Address Compare 4 Linked 0 - No effect 1 - DAC4 debug events are linked to IAC7 debug events. IAC7 debug events do not affect DBSR When linked to IAC7, DAC4 debug events are conditioned based on whether the instruction also generated an IAC7 debug event. Note that linking is only available in EDM or IDM.
12:31	—	Reserved

64.3.2.9 Debug Status Register (DBSR)

The Debug Status Register (DBSR) contains status on debug events and the most recent processor reset. The Debug Status Register is set via hardware, and read and cleared via software. Bits in the Debug Status Register can be cleared using **mtspr***DBSR,RS*. Clearing is done by writing to the Debug Status Register with a 1 in any bit position that is to be cleared and 0 in all other bit positions. The write data to the Debug Status Register is not direct data, but a mask. A '1' causes the bit to be cleared, and a '0' has no effect. Debug Status bits are set by Debug events only while Internal Debug Mode is enabled ($DBCR0_{IDM}$=1). When debug interrupts are enabled (MSR_{DE}=1 $DBCR0_{IDM}$=1 and $EDBCR0_{EDM}$=0, or MSR_{DE}=1, $DBCR0_{IDM}$=1, $EDBCR0_{EDM}$=1 and software is allocated resource(s) via EDBRAC0), a set bit in DBSR other than MRR, DAC_OFST, or VLES will cause a debug interrupt to be generated. The debug interrupt handler is responsible for clearing DBSR bits prior to returning to normal execution. When resource sharing is enabled, ($EDBCR0_{EDM}$=1 and $EDBRAC0_{IDM}$=1), only software-owned resources may be modified by software, and status bits associated with hardware-owned resources will not be set by hardware in DBSR. The DBSR register is shown in the following figure.

SPR - 304; Read/Clear; Reset - 0x1000_0000

Figure 64-11. DBSR Register

The following table provides bit definitions for the Debug Status Register.

Table 64-14. DBSR Bit Definitions

Bit(s)	Name	Description
0	IDE	Imprecise Debug Event Set to 1 if MSR_{DE}=0 and $DBCR0_{IDM}$=1 and a debug event causes its respective Debug Status Register bit to be set to 1. It may also be set to '1' if an imprecise debug event occurs due to a DAC event on a load or store which is terminated with error, or if an ICMP event occurs in conjunction with a EFPU FP round exception.
1	UDE	Unconditional Debug Event Set to 1 if an Unconditional debug event occurred.
2:3	MRR	Most Recent Reset. 00 - No reset occurred since these bits were last cleared by software 01 - A hard reset occurred since these bits were last cleared by software 10 - Reserved 11 - Reserved
4	ICMP	Instruction Complete Debug Event Set to 1 if an Instruction Complete debug event occurred.
5	BRT	Branch Taken Debug Event Set to 1 if an Branch Taken debug event occurred.
6	IRPT	Interrupt Taken Debug Event Set to 1 if an Interrupt Taken debug event occurred.
7	TRAP	Trap Taken Debug Event Set to 1 if a Trap Taken debug event occurred.
8	IAC	Instruction Address Compare Debug Event Set to 1 if an IAC debug event occurred.
9:11	—	Reserved
12	DACR	Data Address Compare Read Debug Event Set to 1 if a read-type DAC debug event occurred
13	DACW	Data Address Compare Write Debug Event Set to 1 if a write-type DAC debug event occurred
14	—	Reserved
15	DNI	DNI Debug Event Set to 1 if a DNI debug event occurred

Table continues on the next page...

Table 64-14. DBSR Bit Definitions (continued)

Bit(s)	Name	Description
16	RET	Return Debug Event Set to 1 if a Return debug event occurred
17:20	—	Reserved
21	DEVT1	External Debug Event 1 Debug Event Set to 1 if a DEVT1 debug event occurred
22	DEVT2	External Debug Event 2 Debug Event Set to 1 if a DEVT2 debug event occurred
23	PMI	Performance Monitor Interrupt Debug Event Set to 1 if a Performance Monitor Interrupt event occurred with $PMGC0_{UDI}$=1
24	MPU	Memory Protection Unit Debug Event Set to 1 if a MPU debug event occurred. For MPU debug events, the IAC, DACR, or DACW status bit will also be set, depending on the type of access which matched a region descriptor enabled to generate debug events, in order to further define the type of MPU debug event. Note that software MPU debug events on data accesses normally occur after the data access is performed and the instruction completes, thus act like a normal DAC debug event. The instruction may not complete if a DSI occurs. In this case, IDE will be set to indicate this occurrence.
25	CIRPT	Critical Interrupt Taken Debug Event Set to 1 if a Critical Interrupt Taken debug event occurred.
26	CRET	Critical Return Debug Event Set to 1 if a Critical Return debug event occurred
27	VLES	VLE Status Set to 1 if an ICMP, BRT, TRAP, RET, CRET, IAC, or DAC debug event occurred on a PowerISA VLE Instruction. Undefined for IRPT, CIRPT, DEVT[1,2], and UDE events
28:30	DAC_OFST	Data Address Compare Offset Indicates offset-1 of saved DSRR0 value from the address of the load or store instruction which took a DAC Debug exception, unless a simultaneous DSI error occurs, in which case this field is set to 3'b000 and $DBSR_{IDE}$ is set to 1. Normally set to 3'b000 by a non-DVC DAC. A DVC DAC may set this field to any value.
31	—	Reserved

64.3.2.10 Debug Data Effective Address Register (DDEAR)

The Debug Data Effective Address Register (DDEAR) contains address information for data address compare debug events (DAC or MPU DAC). DDEAR is update by hardware with the effective address of the load or store operation when a data address compare event is recorded in DBSR if the previous values of the $DBSR_{DAC\{R,W\}}$ bits are zero. Once a DDEAR update is performed, these bits must be cleared by software prior to

another DDEAR hardware update occurring. A subsequent DAC or MPU DAC event will not update the DDEAR register if either of the $DBSR_{DAC\{R,W\}}$ bits are set, in order to capture the first event address.

The DDEAR register is shown in the following table.

Data Effective Address																															
0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

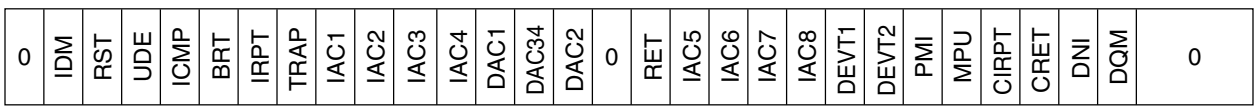
SPR - 600; Read/Write; Reset - unaffected

Figure 64-12. DDEAR Register

64.3.3 External Debug Resource Allocation Control Register (EDBRAC0)

The External Debug Resource Allocation Control Register (EDBRAC0) controls resource allocation when $EDBCR0_{EDM}$ is set to '1'. EDBRAC0 provides a mechanism for the hardware debugger to share certain debug resources with software. Individual resources are allocated based on the settings of EDBRAC0 when $EDBCR0_{EDM}$=1. EDBRAC0 settings are ignored when $EDBCR0_{EDM}$=0.

Hardware-owned resources which generate debug events update EDBSR0 instead of DBSR and cause entry into debug mode if the event is not masked in EDBSRMSK0, while software-owned resources which generate debug events if $DBCR0_{IDM}$=1 update DBSR, causing debug interrupts to occur if MSR_{DE}=1. EDBRAC0 is controlled via the OnCE port hardware, and is read-only to software.



The DBSR status register is always owned by software. Debug status bits in DBSR are set by software-owned debug events only while Internal Debug Mode is enabled. When debug interrupts are enabled (MSR_{DE}=1 $DBCR0_{IDM}$=1 and $EDBCR0_{EDM}$=0, or MSR_{DE}=1, $DBCR0_{IDM}$=1 and $EDBCR0_{EDM}$=1 and software is allocated resource(s) via EDBRAC0), a set bit in DBSR by an event which is software-owned (other than MRR, DAC_OFST, or VLES) will cause a debug interrupt to be generated.

Debug status bits in EDBSR0 are set by hardware-owned debug events only while External Debug Mode is enabled ($EDBCR0_{EDM}$=1). When $EDBCR0_{EDM}$=1, a set bit in EDBSR0 by an event which is hardware-owned (other than IDE, DAC_OFST, or VLES) will cause entry into debug mode unless entry is masked via EDBSRMSK0.

If $EDBCR0_{EDM}$=1, DBSR status bits corresponding to hardware-owned debug events are masked from being set by hardware.

Software-owned resources may be modified by software, but only the corresponding control bits in DBCR0–8 or MPU0CSR0 are affected by execution of a **mtspr**, thus only a portion of these registers may be affected, depending on the allocation settings in EDBRAC0. The debug interrupt handler is still responsible for clearing DBSR bits for software-owned resources prior to returning to normal execution. Hardware always has full access to all registers and register fields through the OnCE register access mechanism, and it is up to the debug firmware to properly implement modifications to these registers with read-modify-write operations to implement any control sharing with software. Settings in EDBRAC0 should be considered by the debug firmware in order to preserve software settings of control and status registers as appropriate when hardware modifications to the debug registers is performed.

The EDBRAC0 register is shown in the following figure.

SPR - 638; Read-only by Software; Reset - Unaffected by **p_reset_b,** reset to 0x00000180 by **m_por** or while in the test-logic-reset OnCE controller state

Figure 64-13. EDBRAC0 Register

Table 64-14 provides bit definitions for the Debug External Resource Control Register. Note that EDBRAC0 controls are disabled when EDBCR0EDM=0.

Table 64-15. EDBRAC0 Bit Definitions

Bit(s)	Name	Description
0	—	Reserved
1	IDM	Internal Debug Mode control 0 - Internal Debug mode may not be enabled by software. $DBCR0_{IDM}$ is owned exclusively by hardware. **mtspr** DBCR0–8 and other debug registers is always ignored. No resource sharing occurs, regardless of the settings of other fields in EDBRAC0. Hardware exclusively owns all resources. 1 - Internal Debug mode may be enabled by software. $DBCR0_{IDM}$ is owned by software. $DBCR0_{IDM}$ is software readable/writable. When $EDBRAC0_{IDM}$=1, software writes to hardware-owned bits in DBCR0–8 via **mtspr** are ignored.
2	RST	Reset Field Control 0 - $DBCR0_{RST}$ owned exclusively by hardware debug. No **mtspr** access by software to $DBCR0_{RST}$ field. 1 - $DBCR0_{RST}$ accessible by software debug. $DBCR0_{RST}$ is software readable/writable.
3	UDE	Unconditional Debug Event 0 - Event owned by hardware debug. 1 - Event owned by software debug.

Table continues on the next page...

Table 64-15. EDBRAC0 Bit Definitions (continued)

Bit(s)	Name	Description
4	ICMP	Instruction Complete Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{ICMP}$ field. 1 - Event owned by software debug. $DBCR0_{ICMP}$ is software readable/writable.
5	BRT	Branch Taken Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{BRT}$ field. 1 - Event owned by software debug. $DBCR0_{BRT}$ is software readable/writable.
6	IRPT	Interrupt Taken Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{IRPT}$ field. 1 - Event owned by software debug. $DBCR0_{IRPT}$ is software readable/writable.
7	TRAP	Trap Taken Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{TRAP}$ field. 1 - Event owned by software debug. $DBCR0_{TRA}$P is software readable/writable.
8	IAC1	Instruction Address Compare 1 Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to IAC1 control and status fields. 1 - Event owned by software debug. IAC1 control fields are software readable/writable.
9	IAC2	Instruction Address Compare 2 Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to IAC2 control and status fields. 1 - Event owned by software debug. IAC2 control fields are software readable/writable.
10	IAC3	Instruction Address Compare 3 Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to IAC3 control and status fields. 1 - Event owned by software debug. IAC3 control fields are software readable/writable.
11	IAC4	Instruction Address Compare 4 Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to IAC4 control and status fields. 1 - Event owned by software debug. IAC4 control fields are software readable/writable.
12	DAC1	Data Address Compare 1 Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to DAC1 control and status fields. 1 - Event owned by software debug. DAC1 control fields are software readable/ writable.
13	DAC34	Data Address Compare 3 and 4 Debug Events 0 - Events owned by hardware debug. No **mtspr** access by software to DAC3 and DAC4 control and status fields. 1 - Event owned by software debug. DAC3 and DAC4 control fields are software readable/writable.

Table continues on the next page...

Table 64-15. EDBRAC0 Bit Definitions (continued)

Bit(s)	Name	Description
14	DAC2	Data Address Compare 2 Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to DAC2 control and status fields. 1 - Event owned by software debug. DAC2 control fields are software readable/ writable.
15	—	Reserved
16	RET	Return Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{RET}$ field. 1 - Event owned by software debug. $DBCR0_{RET}$ is software readable/writable.
17	IAC5	Instruction Address Compare 5 Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to IAC5 control and status fields. 1 - Event owned by software debug. IAC5 control fields are software readable/writable.
18	IAC6	Instruction Address Compare 6 Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to IAC6 control and status fields. 1 - Event owned by software debug. IAC6 control fields are software readable/writable.
19	IAC7	Instruction Address Compare 7 Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to IAC7 control and status fields. 1 - Event owned by software debug. IAC7 control fields are software readable/writable.
20	IAC8	Instruction Address Compare 8 Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to IAC8 control and status fields. 1 - Event owned by software debug. IAC8 control are software readable/writable.
21	DEVT1	External Debug Event Input 1 Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{DEVT1}$ field. 1 - Event owned by software debug. $DBCR0_{DEVT1}$ is software readable/writable.
22	DEVT2	External Debug Event Input 2 Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{DEVT2}$ field. 1 - Event owned by software debug. $DBCR0_{DEVT2}$ is software readable/writable.
23	PMI	Performance Monitor Interrupt Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to the PMRs. Performance monitor interrupts set $EDBSR0_{PMI}$ regardless of the setting of $PMGC0_{UDI}$ 1 - Event owned by software debug. PMRs are software readable/writable. **Note:** this bit is reset to '1'.

Table continues on the next page...

Table 64-15. EDBRAC0 Bit Definitions (continued)

Bit(s)	Name	Description
24	MPU	Memory Protection Unit Debug Event 0 - Event owned by hardware debug. No **mpuwe** access by software to region descriptors which have the DEBUG control bit set to '1' or to the $MPU0CSR0_{DRDEN,DWDEN,IDEN}$ control bits, unless the CPU is in a debug session (**jd_debug_b** is asserted). MPU debug events set $EDBSR0_{MPU}$, and if not masked by $EDBSRMSK0_{MPU}$, one of $EDBSR0_{IAC}$, $EDBSR0_{DACR}$, or $EDBSR0_{DACW}$. MPU flash invalidates do not affect DEBUG=1 entries unless the CPU is in a debug session (**jd_debug_b** is asserted). 1 - Event owned by software debug. All region descriptors and the $MPU0CSR0_{DRDEN,DWDEN,IDEN}$ control bits are software readable/writable. **Note:** this bit is reset to '1'.
25	CIRPT	Critical Interrupt Taken Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{CIRPT}$ field. 1 - Event owned by software debug. $DBCR0_{CIRPT}$ is software readable/writable.
26	CRET	Critical Return Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{CRET}$ field. 1 - Event owned by software debug. $DBCR0_{CRET}$ is software readable/writable.
27	DNI	DNI Instruction Debug Control 0 - DNI resource owned by hardware debug. Execution of an **e_dni** or **se_dni** instruction results in entry into debug mode. 1 - DNI resource owned by software debug. Execution of an **e_dni** or **se_dni** instruction results in either a debug interrupt ($DBCR0_{IDM}$=1 and MSR_{DE}=1) or a nop ($DBCR0_{IDM}$=0 or MSR_{DE}=0). **Note:** DNI events are not blocked during a debug session
28	DQM	Data Acquisition Messaging Registers 0 - $DEVENT_{DQTAG}$ and DDAM register are exclusively owned by hardware debug. No **mtspr** access by software to $DEVENTD_{QTAG}$ field or DDAM register. Attempted access by software is ignored. 1 - $DEVENT_{DQTAG}$ and DDAM register are owned by software. Software has read/write access to $DEVENT_{DQTAG}$ field and DDAM register.
29:31	—	Reserved

Table 64-16 shows which resources are controlled by EDBRAC0 settings.

1. Note: IDM not required to be set to enable software access.

EDBRAC0 also controls which bits or fields in DBCR0–8, MPU0CSR0, and the PMRs are reset by assertion of **p_reset_b** when $EDBCR0_{EDM}$=1. Only software-owned bits or fields as shown in Table 64-16 are affected in this case, except that $DBCR0_{RST}$ and $DBSR_{MRR}$ are updated by assertion of **p_reset_b** regardless of the value of $EDBCR0_{EDM}$ or EDBRAC0.

64.3.4 Debug Event Select Register (DEVENT)

The Debug Event Select Register allows instrumented software to internally generate signals when a **mtspr** instruction is executed and this register is accessed. The values written to this register determine which of the **p_devnt_out[0:7]** processor output signals are asserted upon access. Writing a '1' to any of these bit positions will cause a one clock pulse to be generated on the corresponding output. For **p_devnt_out[0:3]**, a corresponding **jd_watchpt[x]** output is asserted as well to indicate a watchpoint has occurred. These signals may be used for internal core debug resources as well as for SoC level cross-triggering. See the SoC User's Manual for more information on SoC use cases.

The $DEVENT_{DEVNT}$ register field value is undefined on a read; it may or may not remain set to the last value written. Since it is unconditionally shared by hardware debug and software, software should not rely on any value remaining.

The upper 8 bits of the DEVENT register also provide the DQTAG used to identify channels within Data Acquisition Messages. See the "Data Acquisition ID Tag Field" section in the Nexus 3 Module chapter for more detail on the DQTAG.

The DEVENT register is shown in the following figure.

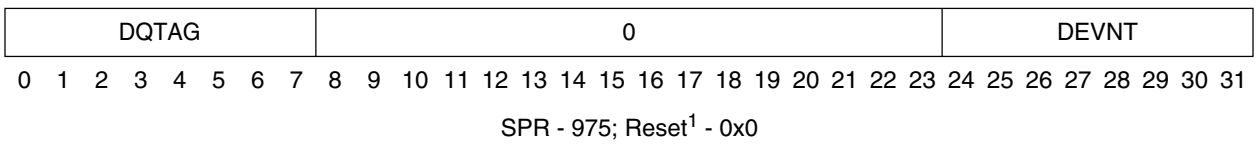

Figure 64-14. DEVENT Register

Note

[1] Reset by processor reset **p_reset_b** if $EDBCR0_{EDM}$=0, as well as unconditionally by **m_por**. If $EDBCR0_{EDM}$=1, EDBRAC0 masks off hardware-owned resources from reset by **p_reset_b** and only software-owned resources indicated by EDBRAC0 will be reset by **p_reset_b**. Note that DEVNT field is shared by hardware and software but is always reset by **p_reset_b**.

The following table provides bit definitions for the Debug Event Register.

Table 64-17. DEVENT Bit Definitions

Bit(s)	Name	Description
0:7	DQTAG	Data Acquisition Message IDTAG channel identifier (supplied to Nexus 3)
8:23	—	Reserved, should be cleared.

Table continues on the next page...

Table 64-17. DEVENT Bit Definitions (continued)

Bit(s)	Name	Description	
24:31	DEVNT	Debug Event Signals	
			00000000 - No signal is asserted
			xxxxxxx1 - **p_devnt_out[0]** and **jd_watchpt[12]** are asserted for one clock
			xxxxxx1x - **p_devnt_out[1]** and **jd_watchpt[13]** are asserted for one clock
			xxxxx1xx - **p_devnt_out[2]** and **jd_watchpt[20]** are asserted for one clock
			xxxx1xxx - **p_devnt_out[3]** and **jd_watchpt[21]** are asserted for one clock
			xxx1xxxx - **p_devnt_out[4]** is asserted for one clock
			xx1xxxxx - **p_devnt_out[5]** is asserted for one clock
			x1xxxxxx - **p_devnt_out[6]** is asserted for one clock
			1xxxxxxx - **p_devnt_out[7]** is asserted for one clock

64.3.5 Debug Data Acquisition Message Register (DDAM)

The Debug Data Acquisition Message Register allows instrumented software to generate real-time Data Acquisition Messages (as defined by Nexus 3) via a **mtspr** instruction to this register. See the "Data Acquisition Messaging" section in the Nexus 3 Module chapter for details.

The DDAM register is shown in the following figure.

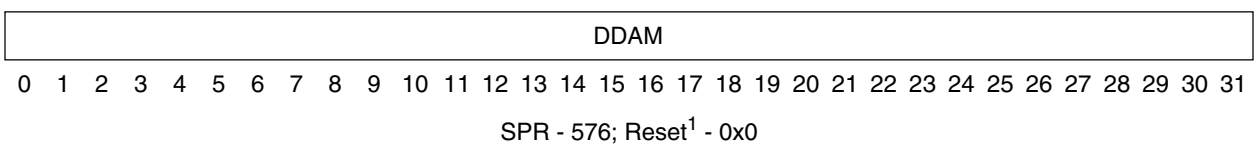

Figure 64-15. DDAM Register

Note

[1] Reset by processor reset **p_reset_b** if $EDBCR0_{EDM}$=0, as well as unconditionally by **m_por**. If $EDBCR0_{EDM}$=1, EDBRAC0 masks off hardware-owned resources from reset by **p_reset_b** and only software-owned resources indicated by EDBRAC0 will be reset by **p_reset_b**.

The following table provides bit definitions for the Debug Data Acquisition Message Register.

Table 64-18. DDAM Bit Definitions

Bit(s)	Name	Description
0:31	DDAM	Value to be transmitted in a Data Acquisition Message (DQM) (supplied to Nexus 3 with strobe)

64.4 Using Debug Resources for Stack Limit Checking

The DAC1,2 and DAC3,4 resources can be used for stack overflow/underflow detection when not being used as a hardware or software debug resource. Stack limit checking is available regardless of EDM or IDM mode, and when resources used for stack limit checking are owned by software, will utilize a DSI or machine check exception. Software-owned stack limit checking does not require IDM to be set. Hardware owned stack limit checking requires EDM to be set.

When stack limit checking is enabled, and DAC resources used for stack limit checking are owned by software, DAC events are not generated for resources configured to perform stack limit checking, and no DBSR DAC status flag will be set due to a detected stack limit violation. Instead, depending on the processor mode, a data storage interrupt or a machine check exception is signaled. When stack limit checking is enabled, and DAC resources used for stack limit checking are owned by hardware, DAC events will be generated for resources configured to perform stack limit checking, and the EDBSR0 DAC status flag will be set due to a detected stack limit violation, causing entry into debug halted mode in the same way as a DAC exception normally does. The only difference is that qualification of the access address is performed as discussed in the next paragraph.

Stack limit checking is implemented in the same way as range compares using DAC1,2 or 3,4, or extended masking using DAC1 or DAC3, but qualify a load or store access address with the use of GPR R1 as the base or index register used to compute an effective address when a load or store instruction is executed. No stack limit checking is performed for other instructions which may calculate an EA using GPR R1 such as cache, MMU/ MPU management instructions, or instructions which indicate GPR R1 is used to hold a decoration value (for decorated load/store type instructions) or a modify specifier (for LSP load/store instructions w/modify). When DAC resources configured to perform stack limit checking are not owned by hardware, if a stack limit violation occurs when performing the load or store, the access is aborted, and an error report machine check is generated, with MCSRR0 pointing to the address of the load or store access which generated the stack overflow/underflow. If DAC resources configured to perform stack

limit checking are owned by hardware, then a normal DAC event is generated (but qualified with use of GPR R1), and debug mode entry will occur in the same manner as for a non-stack limit DAC event.

Enabling of this functionality is described in more detail in Table 64-9. Note that IDM is not required to be set for software-owned stack limit checking.

In contrast to the normal case of DAC address matching resulting in a debug event, the stack limit check address compare logic operates differently for stack limit checking. When using resources for stack limit checking, a DACn hit to a resource enabled for performing stack limit checking on a stack access indicates a stack limit violation.

When stack limit checking is enabled by the setting of the $DBCR4_{DAC1CFG}$ field to '1000' or the $DBCR8_{DAC3CFG}$ field to '1000' (or both), and the corresponding DACn resources are owned by software, DACn events are not generated and the DBSR DAC status flag will not be set due to a detected stack limit hit. Instead, if stack limit checking is enabled for supervisor mode stack accesses in DAC1 or DAC3, and a compare hit occurs for a supervisor mode stack access (A load or store using GPR R1 in the <EA> calculation), a machine check exception is signaled. If stack limit checking is enabled for user mode accesses, a DSI exception is signaled when a stack limit checking enabled DAC1 or DAC3 compare hit occurs for a user mode access. A watchpoint for DAC1 or DAC3 will be generated when the stack limit violation is detected, even though the instruction does not complete. Stack limit checking for supervisor mode stack accesses is considered enabled when either the $DBCR4_{DAC1CFG}$ field is set to '1000' with $DBCR2_{DAC1US}$ set to '00' or '10', or the $DBCR7_{DAC3CFG}$ field is set to '1000' with $DBCR8_{DAC3US}$ set to '00' or '10', or both. Stack limit checking for user mode stack accesses is considered enabled when either the $DBCR4_{DAC1CFG}$ field is set to '1000' with $DBCR2_{DAC1US}$ set to '00' or '01', or the $DBCR7_{DAC3CFG}$ field is set to '1000' with $DBCR8_{DAC3US}$ set to '00' or '01', or both. Note that unlike regular debug DAC events, both halves of a misaligned access are checked for limit violations.

When stack limit checking is enabled for a stack access, and DACn resources are owned by hardware, the EDBSR0 DAC status flag will be set due to a detected stack limit violation, to cause entry into debug halted mode or to generate a watchpoint, or both, in the same way as a DAC event normally does, i.e. after the access has completed. The only difference is that qualification of the access address is performed as discussed in the next paragraph. If the access is aborted due to a DSI or other exception such as machine check condition, the $EDBSR0_{IDE}$ status bit will also be set to indicate that the data access instruction was not completed.

Stack limit checking is implemented in the same way as address compares using DACn, but qualify a load or store access address with the use of GPR R1 as the base or index register used to compute an effective address when a load or store instruction is executed. No stack limit checking is performed for other instructions which may calculate an EA

using GPR R1 such as cache, MMU/MPU management instructions, or instructions which indicate GPR R1 is used to hold a decoration value (for decorated load/store type instructions) or a modify specifier (for LSP load/store instructions w/modify). When DACn resources are not owned by hardware, if a stack limit violation occurs (a hit to a stack limit enabled DAC is detected) when performing the load or store, the access request is aborted and the access is not performed. Instead, for supervisor mode accesses, an error report machine check exception is generated, with MCSRR0 pointing to the address of the load or store instruction which generated the stack overflow/underflow, and for user mode accesses, a DSI exception is generated, with SRR0 pointing to the address of the load or store instruction which generated the stack overflow/underflow. If all stack limit check enabled DACn resources are owned by hardware, then a DAC event is generated (but qualified with use of GPR R1), and debug mode entry will occur in the same manner as for a non-stack limit DAC event. In this case, the instruction and access will normally have completed, in the same manner as a normal DAC event.

Independent limit checks for supervisor and user accesses may be implemented by allocating independent DACn resources to each, or a single limit may be applied using a single DACn resource. Typically, a DAC1,2 pair operating in exclusive address range mode is utilized for stack limit checking for a single shared limit. For separate limits, DAC3,4 may also be utilized. If more than one DACn resource is utilized, a DAC hit on any resource utilized for stack limit checking will cause the corresponding stack limit exception action to occur. If both a hardware-owned and a software-owned resource generate a stack limit exception for a given load or store, the software resource will have priority, since it is detected prior to completion of the access, and the access is aborted, thus the hardware event will not occur.

Enabling of this functionality is described in more detail in the description of the DACnCFG fields in Table 64-9 and Table 64-12 in Debug Control and Status registers. Note that for DAC1 and DAC2, access type (read, write) control is part of DBCR0.

64.5 External Debug Support

External debug support is supplied through the OnCE controller serial interface which allows access to internal CPU registers and other system state while the CPU is halted in debug mode. All debug resources including DBCR0–8, DBSR, IAC1–8, DAC1–4, and DVC1–2 are accessible through the serial OnCE interface in external debug mode. Setting the $EDBCR0_{EDM}$/$DBCR0_{EDM}$ bit to '1' through the OnCE interface enables external debug mode, and unless otherwise permitted by the settings in EDBRAC0, disables software updates to the debug control registers. When $EDBCR0_{EDM}$ is set, debug events enabled to set respective status bits will also cause the CPU to enter Debug Mode if the event is not masked in EDBSRMSK0, as opposed to generating Debug Interrupts,

unless the specific events are allocated to software via the settings in EDBRAC0. In Debug Mode, the CPU is halted at a recoverable boundary, and an external Debug Control Module may control CPU operation through the On-Chip Emulation logic (OnCE).

Note that the descriptions of events in the subsections of Software Debug Events and Exceptions refer to setting DBSR status bits, however, when resources are owned by hardware, the events for those resources set the respective status bits in EDBSR0 instead of DBSR.

Note

On the initial setting of $EDBCR0_{EDM}$ to '1', other bits in DBCR0 will remain unchanged. After $EDBCR0_{EDM}$ has been set, all debug register resources may be subsequently controlled through the OnCE interface. The CPU should be placed into debug mode via the OCR_{DR} control bit prior to writing EDM to '1'. This gives the debugger the opportunity to cleanly write to the DBCRx registers and the DBSR to clear out any residual state / control information which could cause unintended operation.

Note

It is intended for the CPU to remain in external debug mode ($EDBCR0_{EDM}$=1) in order to single step or perform other debug mode entry/ reentry via the OCR_{DR}, by performing go+noexit commands, or by assertion of the **jd_de_b** signal.

Note

$EDBCR0_{EDM}$ operation will be blocked if OnCE operation is disabled (**jd_en_once** negated) regardless of whether it is set or cleared. This means that if $EDBCR0_{EDM}$ was previously set, and then **jd_en_once** is negated (this should not occur), entry into debug mode will be blocked, and all *hardware* debug events are blocked. Watchpoints are not blocked.

Due to clock domain design, the CPU clock (**m_clk**) must be active in order to perform writes to debug registers other than the OnCE Command register (OCMD), the OnCE Control register (OCR), External Debug Control Register 0 (EDBCR0), External Debug Status register 0 (EDBSR0), External Debug Status Register Mask 0 (EDBSRMSK0), or the $EDBCR0_{EDM}$ bit. Register read data is synchronized back to the **j_tclk** clock domain. The OnCE Control register provides the capability of signaling the system level clock controller that the CPU clock should be activated if not already active.

Updates to the DBCRx, DBSR, and most other debug registers via the OnCE interface should be performed with the CPU in debug mode to guarantee proper operation. Due to the various points in the CPU pipeline where control is sampled and event handshaking is performed, it is possible that modifications to these registers while the CPU is running may result in early or late entry into debug mode, and may have incorrect status posted in the DBSR register.

If resource sharing is enabled via EDBRAC0, updates to the EDBRAC0, DBCRx, and DBSR registers must be performed with the CPU in debug mode, since simultaneous updates of register portions could otherwise be attempted, and such updates are not guaranteed to properly occur. The results of such an attempt are undefined.

64.5.1 External Debug Registers

The external debug registers are used for controlling several debug aspects of the core and reporting status while in External Debug Mode.

64.5.1.1 External Debug Control Register 0 (EDBCR0)

EDBCR0 is a control register accessible to an external debugger through the OnCE/Jtag port. An external development tool can write to this register in order to enable external debug mode or to enable Debugger Notify Halt instructions (**e_dnh**, **se_dnh**), as well as to control aspects of Debugger Notify Interrupt instructions (**e_dni**, **se_dni**).

EDBCR0 is not accessible by software, However, the state of $EDBCR0_{EDM}$ is reflected as a read-only bit in $DBCR0_{EDM}$ to software. There is only one physical EDM bit implemented; it is reflected in both the DBCR0 and EDBCR0 registers, and may be written and read using either register by the hardware debugger. For future compatibility, EDBCR0 updates are preferred.

EDBCR0 is shown in the following figure.

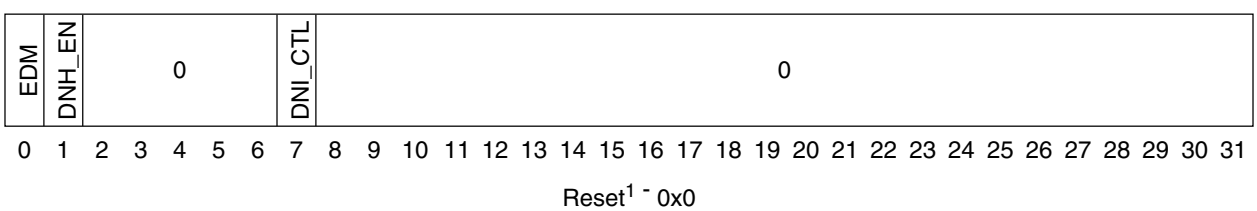

Figure 64-16. EDBCR0 Register

Note

[1] EDBCRO is affected (reset) by **j_trst_b** or **m_por** assertion, and remains reset while in the Test_Logic_Reset state, but is not affected by **p_reset_b.**

The following table provides bit definitions for External Debug Control Register 0.

Table 64-19. EDBCR0 Bit Definitions

Bit(s)	Name	Description
0	EDM	External Debug Mode. This bit is also reflected in DBCR0 0 - External debug mode disabled. Internal debug events not mapped into external debug events. 1 - External debug mode enabled. Hardware-owned events will not cause the CPU to vector to interrupt code. Software is not permitted to write to debug registers {DBCRx, IAC1-8, DAC1-4, DVC1-2[U]} unless permitted by settings in EDBRAC0. When external debug mode is enabled, hardware-owned resources in debug registers are not affected by processor reset **p_reset_b**. This allows the debugger to set up hardware debug events which remain active across a processor reset.
1	DNH_EN	**dnh** Instruction Enable 0 - execution of **e_dnh** and **se_dnh** instructions cause illegal instruction exceptions to occur. 1 - execution of **e_dnh** and **se_dnh** instructions cause entry into debug mode and a debug halt occurs, regardless of the value of EDM.
2:6	---	Reserved
7	DNI_CTL	**dni** Instruction Control 0 - When the **dni** resource is owned by hardware, the MSR_{DE} bit is cared, and when MSRDE=0, execution of **e_dni** and **se_dni** instructions are nop'ed and no entry into debug mode occurs. 1 - When the **dni** resource is owned by hardware, the MSR_{DE} bit is don't-cared, and execution of **e_dni** and **se_dni** instructions cause entry into debug mode and a debug halt occurs, regardless of the value of MSR_{DE}. Note that this control bit is only used when the dni resource is owned by hardware via control in $EDBRAC0_{DNI}$, and thus also only when EDM=1
8:31	---	Reserved

64.5.1.2 External Debug Status Register 0 (EDBSR0)

The External Debug Status Register 0 (EDBSR0) contains status on debug events owned by hardware. The External Debug Status Register 0 is set via hardware, and read and cleared via OnCE access by the debugger. Clearing is done by writing to the External Debug Status Register via the OnCE port, with a '1' in any bit position that is to be

cleared and '0' in all other bit positions. The write data to EDBSR0 is not direct data, but a mask. A '1' causes the bit to be cleared, and a '0' has no effect. The EDBSR0 register is shown in the following figure.

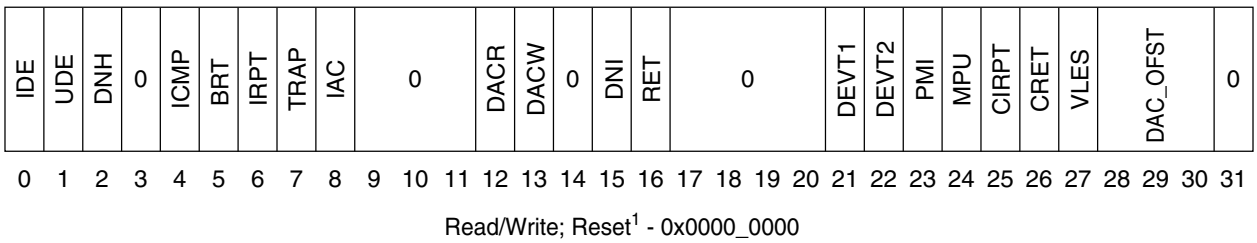

Figure 64-17. EDBSR0 Register

Note

[1] Reset by **j_trst_b** or **m_por** assertion, and remains reset while in the Test_Logic_Reset state or while $EDBCRO_{EDM}$=O.

The following table provides bit definitions for External Debug Status Register 0.

Table 64-20. EDBSR0 Bit Definitions

Bit(s)	Name	Description
0	IDE	Imprecise Debug Event Set to 1 if $EDBCR0_{EDM}$=1 and an imprecise debug event occurs for a hardware-owned DAC event due to a load or store which is terminated with error, or if a hardware-owned ICMP event occurs in conjunction with a EFPU round exception. This bit will not be set for imprecise debug events which are masked via settings in EDBSRMSK0.
1	UDE	Unconditional Debug Event Set to 1 if a hardware-owned Unconditional debug event occurred.
2	DNH	Debugger Notify Halt Event Set to 1 if a debugger notify halt instruction was executed and caused a debug halt.
3	—	Reserved
4	ICMP	Instruction Complete Debug Event Set to 1 if a hardware-owned Instruction Complete debug event occurred.
5	BRT	Branch Taken Debug Event Set to 1 if a hardware-owned Branch Taken debug event occurred.
6	IRPT	Interrupt Taken Debug Event Set to 1 if a hardware-owned Interrupt Taken debug event occurred.
7	TRAP	Trap Taken Debug Event Set to 1 if a hardware-owned Trap Taken debug event occurred.
8	IAC	Instruction Address Compare 1 Debug Event Set to 1 if a hardware-owned IAC debug event occurred.
9:11	—	Reserved

Table continues on the next page...

Table 64-20. EDBSR0 Bit Definitions (continued)

Bit(s)	Name	Description
12	DACR	Data Address Compare Read Debug Event Set to 1 if a hardware-owned read-type DAC debug event occurred
13	DACW	Data Address Compare Write Debug Event Set to 1 if a hardware-owned write-type DAC1 debug event occurred
14	—	Reserved
15	DNI	DNI Debug Event Set to 1 if a hardware-owned DNI debug event occurred
16	RET	Return Debug Event Set to 1 if a hardware-owned Return debug event occurred
17:20	—	Reserved
21	DEVT1	External Debug Event 1 Debug Event Set to 1 if a hardware-owned DEVT1 debug event occurred
22	DEVT2	External Debug Event 2 Debug Event Set to 1 if a hardware-owned DEVT2 debug event occurred
23	PMI	Performance Monitor Interrupt Debug Event Set to 1 if a Performance Monitor Interrupt event occurred with $EDBRAC0_{PMI}$=0 regardless of the setting of $PMGC0_{UDI}$
24	MPU	Memory Protection Unit Debug Event Set to 1 if a hardware-owned MPU debug event occurred. For MPU debug events, if $EDBSRMSK0_{MPU}$ is cleared, the IAC, DACR, or DACW status bit will also be set, depending on the type of access which matched a region descriptor enabled to generate debug events, in order to further define the type of MPU debug event. If $EDBSRMSK0_{MPU}$ is set at the time a MPU debug event occurs, the IAC, DACR, and DACW status bits will not be set by MPU debug events, in order to properly mask the MPU debug event. Note that hardware MPU debug events on data accesses normally occur after the data access is performed and the instruction completes, thus act like a normal DAC debug event. The instruction may not complete if a DSI occurs. In this case, IDE will be set to indicate this occurrence.
25	CIRPT	Critical Interrupt Taken Debug Event Set to 1 if a hardware-owned Critical Interrupt Taken debug event occurred.
26	CRET	Critical Return Debug Event Set to 1 if a hardware-owned Critical Return debug event occurred
27	VLES	VLE Status Set to 1 if a hardware-owned ICMP, BRT, TRAP, RET, CRET, IAC, or DAC debug event occurred on a PowerISA VLE Instruction. Also set for execution of an e_dnh or se_dnh instruction when enabled by $EDBCR0_{DNH_EN}$. Undefined for IRPT, CIRPT, DEVT[1,2], and UDE events
28:30	DAC_OFST	Data Address Compare Offset Indicates offset-1 of saved DSRR0 value from the address of the load or store instruction which took a hardware-owned DAC Debug exception, unless a simultaneous DSI error occurs, in which case this field is set to 3'b000 and $EDBSR0_{IDE}$ is set to 1. Normally set to 3'b000 by a non-DVC DAC. A DVC DAC may set this field to any value.

Table continues on the next page...

Table 64-20. EDBSR0 Bit Definitions (continued)

Bit(s)	Name	Description
31	—	Reserved

64.5.1.3 External Debug Status Register Mask 0 (EDBSRMSK0)

The External Debug Status Register Mask 0 (EDBSRMSK0) is used to mask debug events set in EDBSR0 from causing entry into debug halted mode. A '1' stored in any mask bit prevents debug mode entry caused by the corresponding bit being set in EDBSR0. The mask has no effect on DBSR actions or on the setting of EDBSR0 status bits by hardware-owned events, except that the IDE bit will not be set by imprecise hardware-owned debug events which are masked. EDBSRMSK0 may be used to allow debug events owned by hardware to be configured for watchpoint generation purposes without causing debug mode entry when the watchpoint occurs. EDBSRMSK0 is read and written via OnCE access by the debugger. No software access is provided. The EDBSRMSK0 register is shown in the following figure.

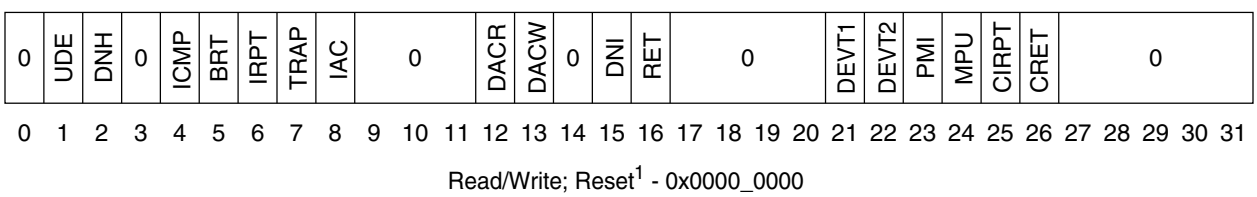

Figure 64-18. EDBSRMSK0 Register

Note

[1] Reset by **j_trst_b** or **m_por** assertion, and remains reset while in the Test_Logic_Reset state or while $EDBCRO_{EDM}$=O.

The following table provides bit definitions for External Debug Status Register Mask 0.

Table 64-21. EDBSRMSK0 Bit Definitions

Bit(s)	Name	Description
0	—	Reserved
1	UDE	Unconditional Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{UDE}$
2	DNH	Debugger Notify Halt Event Set to 1 to mask debug mode entry by $EDBSR0_{DNH}$
3	—	Reserved

Table continues on the next page...

Table 64-21. EDBSRMSK0 Bit Definitions (continued)

Bit(s)	Name	Description
4	ICMP	Instruction Complete Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{ICMP}$
5	BRT	Branch Taken Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{BRT}$
6	IRPT	Interrupt Taken Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{IRPT}$
7	TRAP	Trap Taken Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{TRAP}$
8	IAC	Instruction Address Compare Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{IAC}$
9:11	—	Reserved
12	DACR	Data Address Compare 1 Read Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{DACR}$
13	DACW	Data Address Compare 1 Write Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{DACW}$
14	—	Reserved
15	DNI	DNI Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{DNI}$
16	RET	Return Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{RET}$
17:20	—	Reserved
21	DEVT1	External Debug Event 1 Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{DEVT1}$
22	DEVT2	External Debug Event 2 Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{DEVT2}$
23	PMI	Performance Monitor Interrupt Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{PMI}$
24	MPU	Memory Protection Unit Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{MPU}$
25	CIRPT	Critical Interrupt Taken Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{CIRPT}$
26	CRET	Critical Return Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{CRET}$
22:31	—	Reserved

64.5.1.4 External Debug Data Effective Address Register (EDDEAR)

The External Debug Data Effective Address Register (EDDEAR) contains address information for hardware-owned data address compare debug events, including MPU DAC events. EDDEAR is update by hardware with the effective address of the load or store operation when an unmasked data address compare event is recorded in EDBSR0 if the previous values of $EDBSR0_{DAC\{R,W\}}$ bits which are unmasked in EDBSRMSK0 are zero. Once an EDDEAR update is performed, these unmasked bits must be cleared by the hardware debugger prior to another EDDEAR hardware update occurring. A subsequent hardware-owned unmasked DAC event will not update the EDDEAR register if either of the $EDBSR0_{DAC\{R,W\}}$ bits are set and are not masked by EDBSRMSK0, in order to capture the first unmasked event address. EDDEAR is read and written via OnCE access by the debugger. No software access is provided.

The EDDEAR register is shown in the following figure.

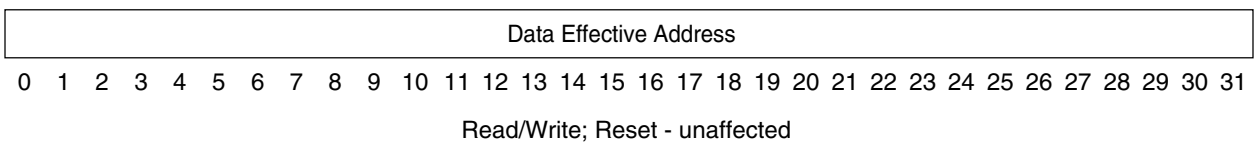

Figure 64-19. EDDEAR Register

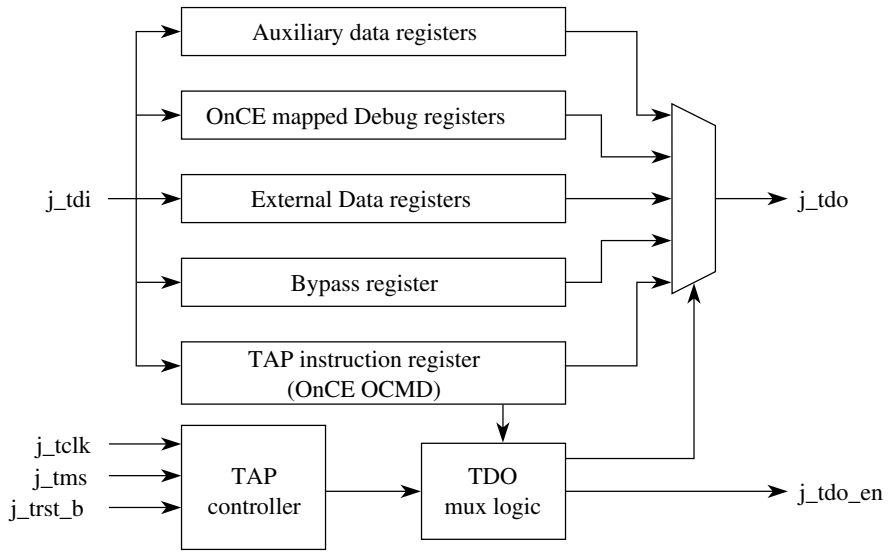
64.5.2 OnCE Introduction

The on-chip emulation circuitry (OnCE™/Nexus Class 1 interface) provides a means of interacting with the core and integrated system so that a user may examine registers, memory, or on-chip peripherals facilitating hardware/software development. OnCE operation is controlled via an industry standard IEEE 1149.1 TAP controller. By using public instructions, the external hardware debugger can freeze or halt the CPU, read and write internal state, and resume normal execution. The core does not contain IEEE 1149.1 standard boundary cells on its interface, as it is a building block for further integration. It does not support the JTAG related boundary scan instruction functionality, although JTAG public instructions may be decoded and signaled to external logic.

The OnCE logic provides for Nexus Class 1 static debug capability (utilizing the same set of resources available to software while in internal debug mode).

In order to enable full OnCE operation, the **jd_enable_once** input signal must be asserted. In some system integrations, this is automatic, since the input will be tied asserted. Other integrations may require the execution of the Enable OnCE command via the TAP and appropriate entry of serial data. Exact requirements will be documented by the integrated product specification. The **jd_enable_once** input signal should not change state during a debug session, or undefined activity may occur.

The following figures show the TAP controller state model and the TAP registers implemented by the OnCE logic.



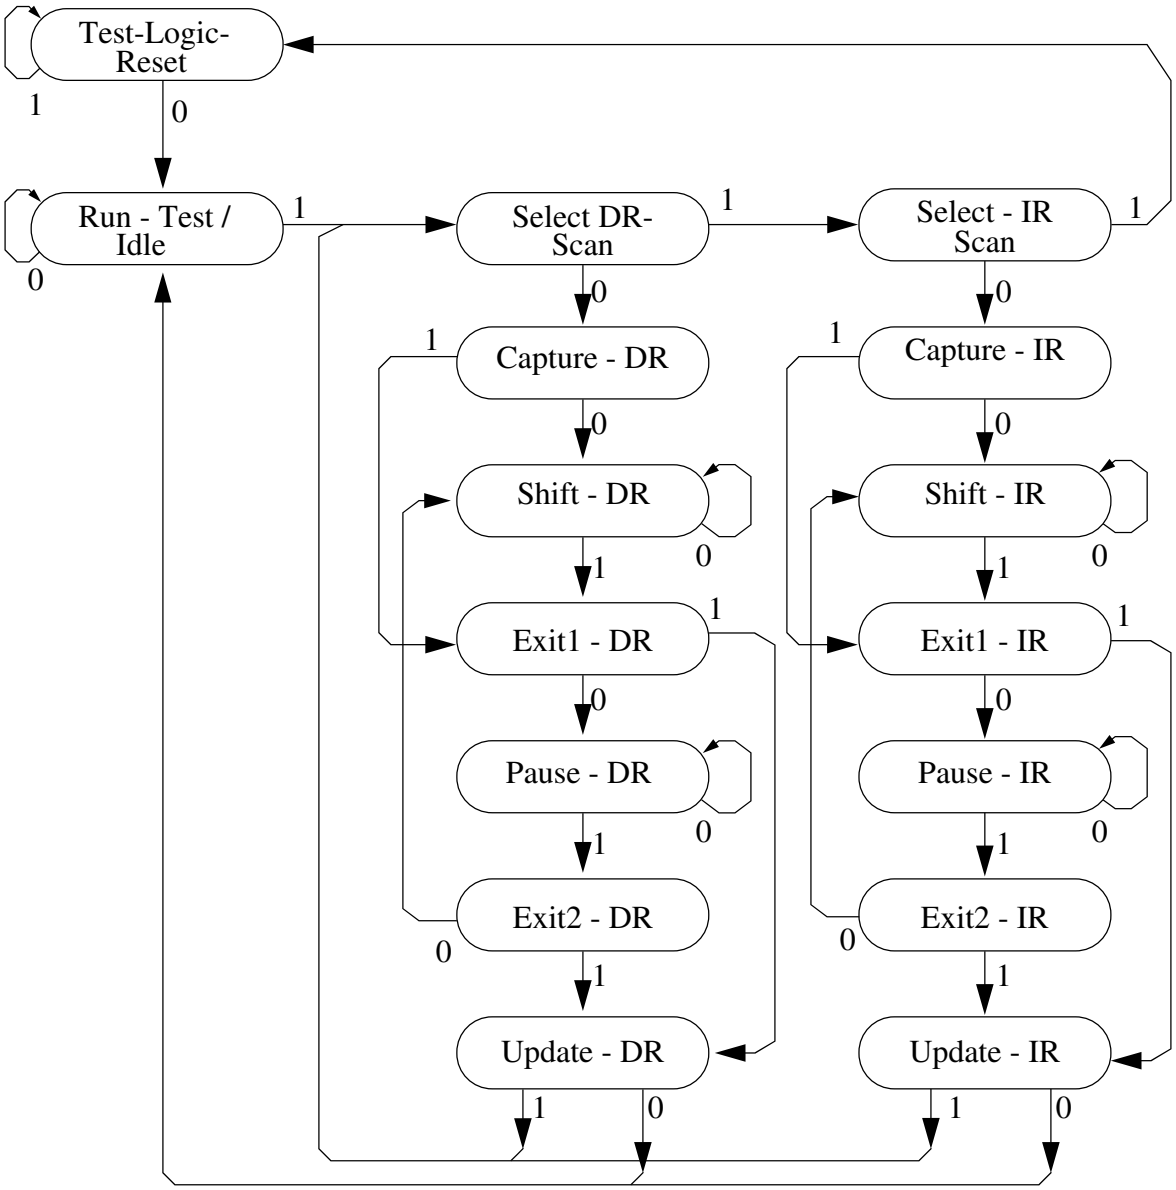


Figure 64-20. OnCE TAP Controller and Registers

The OnCE controller is implemented as a 16-state FSM, with a one-to-one correspondence to the states defined for the JTAG TAP controller.

Access to processor registers and the contents of memory locations are performed by enabling external debug mode (setting $EDBCR0_{EDM}$ to '1'), placing the processor into debug mode, followed by scanning instructions and data into and out of the CPU Scan Chain (CPUSCR); execution of scanned instructions by the CPU is used as the method to access required data. Memory locations may be read by scanning a load instruction into the CPU core which will reference the desired memory location, executing the load instruction, and then scanning out the result of the load. Other resources are accessed in a similar manner.

The initial entry by the CPU into the debug state (or mode) from normal, Waiting, Stopped, or Halted states (all indicated via the OnCE Status Register (OSR), OnCE Status Register) by assertion of one or more debug requests, begins a *debug session*. The **jd_debug_b** output signal indicates that a debug session is in progress, and the OSR will

indicate the CPU is in the debug state. Instructions may the be single-stepped by scanning new values into the CPUSCR, and performing a OnCE go+noexit command (See OnCE Command Register (OCMD)). The CPU will then temporarily exit the debug state (but not the debug session) to execute the instruction, and will then return to the debug state (again indicated via the OnCE Status Register (OSR)). The debug session remains in force until the final OnCE go+exit command is executed, at which time the CPU will return to the previous state it was in (unless a new debug request is pending). A scan into the CPUSCR is required prior to executing each go+exit or go+noexit OnCE command.

64.5.3 JTAG/OnCE Pins

The JTAG/OnCE pin interface is used to transfer OnCE instructions and data to the OnCE control block. Depending on the particular resource being accessed, the CPU may need to be placed in the Debug mode. For resources outside of the CPU block and contained in the OnCE block, the processor is not disturbed, and may continue execution. If a processor resource is required, an internal debug request (**dbg_dbgrq**) may be asserted to the CPU by the OnCE controller, and causes the CPU to finish the current instruction being executed, save the instruction pipeline information, enter Debug Mode, and wait for further commands. Asserting **dbg_dbgrq** will cause the chip to temporarily exit the Waiting, Stopped or Halted power management states.

The following table details the primary JTAG/OnCE interface signals.

Table 64-22. JTAG/OnCE Primary Interface Signals

Signal name	Type	Description
j_trst_b	I	JTAG test reset
j_tclk	I	JTAG test clock
j_tms	I	JTAG test mode select
j_tdi	I	JTAG test data input
j_tdo	O	Test data out to master controller or pad
j_tdo_en[1]	O	Enables TDO output buffer

1. j_tdo_en is asserted when the TAP controller is in the shift_DR or shift_IR state.

A full description of JTAG pins is provided in the JTAG Support Signals section of the Core Complex Overview.

64.5.4 OnCE Internal Interface Signals

The following paragraphs describe the OnCE interface signals to other internal blocks associated with the OnCE controller.

64.5.4.1 CPU Debug Request (dbg_dbgrq)

The **dbg_dbgrq** signal is asserted by the OnCE control logic to request the CPU to enter the debug state. It may be asserted for a number of different conditions, and causes the CPU to finish the current instruction being executed, save the instruction pipeline information, enter the debug mode, and wait for further commands.

64.5.4.2 CPU Debug Acknowledge (cpu_dbgack)

The **cpu_dbgack** signal is asserted by the CPU upon entering the debug state. This signal is used as part of the handshake mechanism between the OnCE control logic and the rest of the CPU. The CPU core may enter debug mode either through a software or hardware event.

64.5.4.3 CPU Address, Attributes

The CPU address and attribute information are used by the Nexus3 unit with information for real-time address trace information.

64.5.4.4 CPU Data

The CPU data buses are used to supply the Nexus3 debug unit with information for real-time data trace capability.

64.5.5 OnCE Interface Signals

The following paragraphs describe additional OnCE interface signals to other external blocks such as a Nexus controller and external blocks which may need information pertaining to debug operation.

64.5.5.1 OnCE Enable (jd_en_once)

The OnCE enable signal **jd_en_once** is used to enable the OnCE controller to allow certain instructions and operations to be executed. Assertion of this signal will enable the full OnCE command set, as well as operation of control signals and OnCE Control register functions. When this signal is disabled, only the Bypass, ID and Enable_OnCE

commands are executed by the OnCE unit, and all other commands default to a "Bypass" command. The OnCE Status register (OSR) is not visible when OnCE operation is disabled. In addition, OnCE Control register (OCR) functions are disabled, as is the operation of the **jd_de_b** input. Secure systems may choose to leave the **jd_en_once** signal negated until a security check has been performed. Other systems should tie this signal asserted to enable full OnCE operation. The **j_en_once_regsel** output signal is provided to assist external logic performing security checks.

The **jd_en_once** input must only change state during the Test-Logic-Reset, Run-Test/ Idle, or Update_DR TAP states. A new value will take affect after one additional **j_tclk** cycle of synchronization. In addition, **jd_enable_once** input signal must not change state during a debug session, or undefined activity may occur.

64.5.5.2 OnCE Debug Request/Event (jd_de_b, jd_de_en)

If implemented at the SoC level, a system level bidirectional open drain debug event pin **DE_b** (not part of the interface) provides a fast means of entering the Debug Mode of operation from an external command controller (when input) as well as a fast means of acknowledging the entering of the Debug Mode of operation to an external command controller (when output). The assertion of this pin by a command controller causes the CPU core to finish the current instruction being executed, save the instruction pipeline information, enter Debug Mode, and wait for commands to be entered. If **DE_b** was used to enter the Debug Mode then **DE_b** must be negated after the OnCE controller responds with an acknowledge and before sending the first OnCE command. The assertion of this pin by the CPU Core acknowledges that it has entered the Debug Mode and is waiting for commands to be entered.

To support operation of this system pin, the OnCE logic supplies the **jd_de_en** output and samples the **jd_de_b** input when OnCE is enabled (**jd_en_once** asserted). Assertion of **jd_de_b** will cause the OnCE logic to place the CPU into Debug Mode. Once Debug Mode has been entered, the **jd_de_en** output will be asserted for three **j_tclk** periods to signal an acknowledge. **jd_de_en** can be used to enable the open-drain pulldown of the system level **DE_b** pin.

For systems which do not implement a system level bidirectional open drain debug event pin **DE_b**, the **jd_de_en** and **jd_de_b** signals may still be used to handshake debug entry.

64.5.5.3 OnCE Debug Output (jd_debug_b)

The OnCE Debug output **jd_debug_b** is used to indicate to on-chip resources that a debug session is in progress. Peripherals and other units may use this signal to modify normal operation for the duration of a debug session, which may involve the CPU executing a sequence of instructions solely for the purpose of visibility/system control which are not part of the normal instruction stream the CPU would have executed had it not been placed in debug mode. This signal is asserted the first time the CPU enters the debug state, and remains asserted until the CPU is released by a write to the OnCE Command Register with the GO and EX bits set, and a register specified as either "No Register Selected" or the CPUSCR. This signal will remain asserted even though the CPU may enter and exit the debug state for each instruction executed under control of the OnCE controller. See OnCE Command Register (OCMD) for more information on the function of the GO and EX bits. This signal is not normally used by the CPU.

64.5.5.4 CPU Clock On Input (jd_mclk_on)

The CPU Clock On input **jd_mclk_on** is used to indicate that the CPU's **m_clk** input is active. This input signal is expected to be driven by system logic external to the core, is synchronized to the **j_tclk** (scan clock) clock domain, and is presented as a status flag on the **j_tdo** output during the Shift_IR state. External firmware may use this signal to ensure proper scan sequences will occur to access debug resources in the **m_clk** clock domain.

64.5.5.5 Watchpoint Events (jd_watchpt[0:31])

The **jd_watchpt[0:31]** signals may be asserted by the OnCE control logic to signal that a watchpoint condition has occurred. Watchpoints do not directly cause the CPU to be affected. They are provided to allow external visibility only or for triggering purposes. Watchpoint events are conditioned by the settings in the DBCRxx registers, as well as by the DEVENT register, the DTC/DTSA/DTEA registers, the Performance Monitor control register settings, and generation of MPU debug events. Refer to Table 64-28 for details of the signal assignments. Note that assertion of most watchpoint outputs is conditioned on being in EDM or IDM. The Performance monitor, DEVENT, and DTC watchpoints are not conditioned however, and may assert regardless of the state of EDM or IDM. In addition, DAC1 or DAC3 watchpoints may be generated for stack limit violation occurrences when those resources are configured to perform stack limit checking, regardless of the state of EDM or IDM.

64.5.5.6 Update DR w/go+exit (j_ocmd_go_exit)

This signal indicates the TAP controller is in the Update_DR state and that the go and exit bits in the OnCE Command register are high, and RS indicates "no register selected". This signal will assert regardless of whether the CPU is currently in debug mode. It may be monitored by external logic to cause a synchronous exit from debug mode of other modules (but not other CPUs) in the system. A debugger can place all of the CPU tap controllers in parallel, scan in a go+exit command with "no register selected", and sequence through the Update_DR state to cause any CPU currently in debug mode to exit. CPUs which are not it debug mode will ignore the command.

64.5.6 OnCE Controller and serial interface

The OnCE Controller contains the OnCE command register, the OnCE decoder, and the status/control register. The following figure is a block diagram of the OnCE controller. In operation, the OnCE Command register acts as the IR for the TAP controller, and all other OnCE resources are treated as data registers (DR) by the TAP controller. The Command register is loaded by serially shifting in or parallel loading commands during the TAP controller Shift-IR state, and is loaded during the Update-IR state. The Command register selects a resource to be accessed as a data register (DR) during the TAP controller Capture-DR, Shift-DR and Update-DR states.

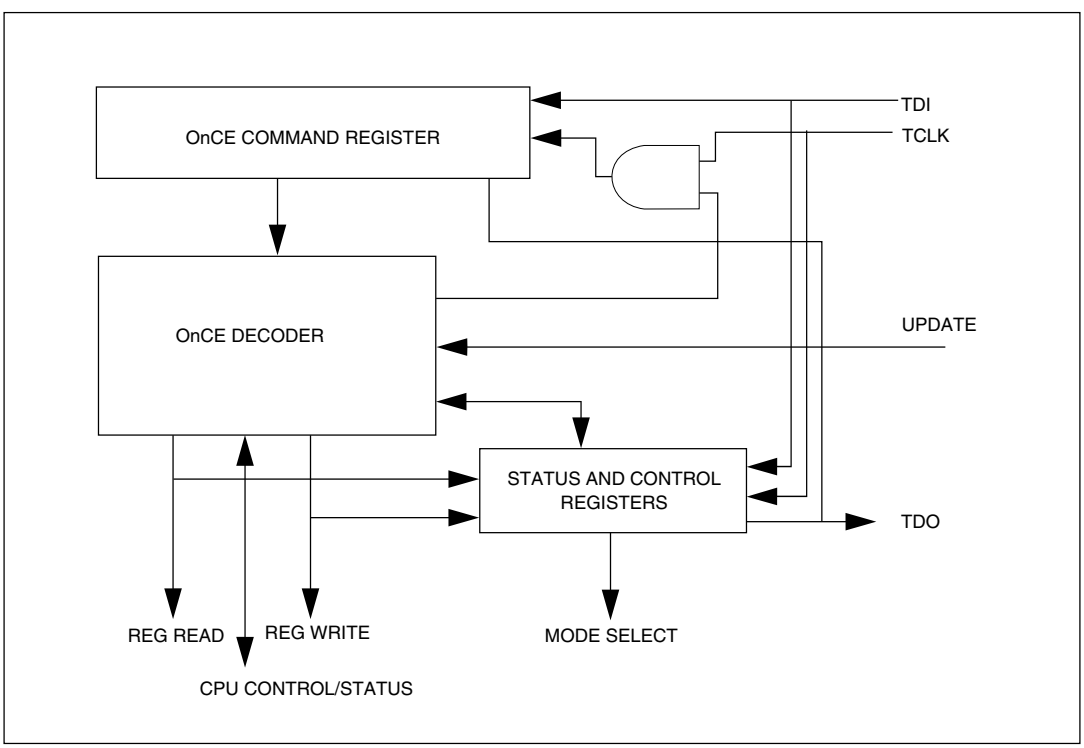

Figure 64-21. OnCE Controller and Serial Interface

64.5.6.1 OnCE Status Register

Status information regarding the state of the CPU is latched into the OnCE Status register when the OnCE controller state machine enters the Capture-IR state. When OnCE operation is enabled, this information is provided on the **j_tdo** output in serial fashion when the Shift_IR state is entered following a Capture-IR. Information is shifted out least significant bit first.

MCLK	ERR	0	RESET	HALT	STOP	DEBUG	WAIT	0	1
0	1	2	3	4	5	6	7	8	9

Figure 64-22. OnCE Status Register

The following table provides bit definitions for the Once Status Register.

Table 64-23. OnCE Status Register Bit Definitions

Bit(s)	Name	Description
0	MCLK	MCLK **m_clk** Status Bit 0 - Inactive state 1 - Active state This status bit reflects the logic level on the **jd_mclk_on** input signal after capture by **j_tclk**.
1	ERR	ERROR This bit is used to indicate that an error condition occurred during attempted execution of the last single-stepped instruction (GO+NoExit with CPUSCR or No Register Selected in OCMD), and that the instruction may not have been properly executed. This could occur if an Interrupt (all classes including External, Critical, machine check, Storage, Alignment, Program, etc.) occurred while attempting to perform the instruction single step. In this case, the CPUSCR will contain information related to the first instruction of the Interrupt handler, and no portion of the handler will have been executed.
3	RESET	RESET Mode This bit reflects the inverted logic level on the CPU **p_reset_b** input after capture by **j_tclk**.
4	HALT	HALT Mode This bit reflects the logic level on the CPU **p_halted** output after capture by **j_tclk**.
5	STOP	STOP Mode This bit reflects the logic level on the CPU **p_stopped** output after capture by **j_tclk**.
6	DEBUG	Debug Mode This bit is asserted once the CPU is in debug mode. It is negated once the CPU exits debug mode (even during a debug session)
7	WAIT	Waiting Mode This bit reflects the logic level on the CPU **p_waiting** output after capture by **j_tclk**.

Table continues on the next page...

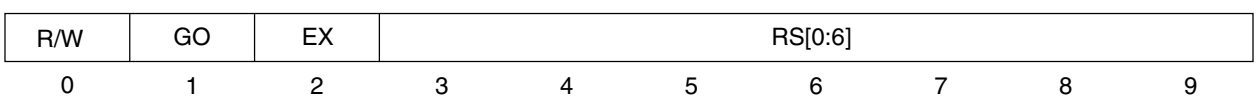

Table 64-23. OnCE Status Register Bit Definitions (continued)

Bit(s)	Name	Description
8	0	Reserved, set to 0 for 1149.1 compliance
9	1	Reserved, set to 1 for 1149.1 compliance

64.5.6.2 OnCE Command Register (OCMD)

The OnCE Command Register (OCMD) is a 10-bit shift register that receives its serial data from the TDI pin and serves as the instruction register (IR). It holds the 10-bit commands to be used as input for the OnCE Decoder. The Command Register is shown in Figure 64-23. The OCMD is updated when the TAP controller enters the Update-IR state. It contains fields for controlling access to a resource, as well as controlling single-step operation and exit from OnCE mode.

Although the OCMD is updated during the Update-IR TAP controller state, the corresponding resource is accessed in the DR scan sequence of the TAP controller, and as such, the Update-DR state must be transitioned through in order for an access to occur. In addition, the Update-DR state must also be transitioned through in order for the single-step and/or exit functionality to be performed, even though the command appears to have no data resource requirement associated with it.

Reset - 10'b1000000010 on assertion of **j_trst_b** or **m_por** , or while in the Test_Logic_Reset state

Figure 64-23. OnCE Command Register

Table 64-24 provides bit definitions for the Once Command Register.

Table 64-24. OnCE Command Register Bit Definitions

Bit(s)	Name	Description
0	R/W	Read/Write Command Bit The R/W bit specifies the direction of data transfer. The table below describes the options defined by the R/W bit. **Note:** The R/W bit generally ignored for read-only or write-only registers, although the PC FIFO pointer is only guaranteed to be update when R/W=1. In addition, it is ignored for all bypass operations. When performing writes, most registers are sampled in the Capture-DR state into a 32-bit shift register, and subsequently shifted out on **j_tdo** during the first 32 clocks of Shift-DR. 0 - Write the data associated with the command into the register specified by RS[0:6] 1 - Read the data contained in the register specified by RS[0:6]
1	GO	Go Go Command Bit If the GO bit is set, and the CPU is currently in debug mode, the CPU will execute the instruction which resides in the IR register in the CPUSCR. To execute the instruction, the processor leaves the debug mode, executes the instruction, and if the EX bit is cleared, returns to the debug mode immediately after executing the instruction. The processor goes on to normal operation if the EX bit is set, and no other debug request source is asserted. The GO command is executed only if the operation is a read/write to CPUSCR or a read/write to "No Register Selected". Otherwise the GO bit is ignored.The processor will leave the debug mode after the TAP controller Update-DR state is entered. On a GO+NoExit operation, returning to debug mode is treated as a debug event, thus exceptions such as machine checks and interrupts may take priority and prevent execution of the intended instruction. Debug firmware should mask these exceptions as appropriate. The OSR_{ERR} bit indicates such an occurrence. If the CPU is not currently in debug mode, then the GO command will be ignored. Note that asynchronous interrupts are blocked on a GO+Exit operation until the first instruction to be executed begins execution. See Exiting Debug Mode and Interrupt Blocking. 0 - Inactive (no action taken) 1 - Execute instruction in IR
2	EX	Exit Command Bit 0 - Remain in debug mode 1 - Leave debug mode If the EX bit is set, the processor will leave the debug mode and resume normal operation until another debug request is generated. The Exit command is executed only if the Go command is issued, and the operation is a read/write to CPUSCR or a read/write to "No Register Selected". Otherwise the EX bit is ignored. The processor will leave the debug mode after the TAP controller Update-DR state is entered. Note that if the DR bit in the OnCE control register is set or remains set, or if a bit in EDBSR0 is set and $EDBCR0_{EDM}$=1 (external debug mode is enabled), or if another debug request source is asserted, then the processor may return to the debug mode *without* execution of an instruction, even though the EX bit was set. Note that asynchronous interrupts are blocked on a GO+Exit operation until the first instruction to be executed begins execution. See Exiting Debug Mode and Interrupt Blocking.

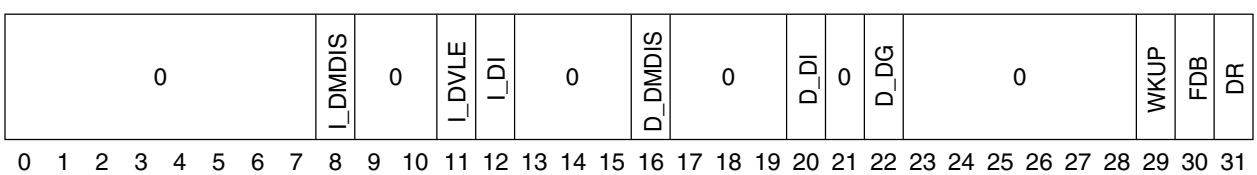
111 1110	Enable_OnCE[1]
111 1111	Bypass

1. Causes assertion of the j_en_once_regsel output.

The Once Decoder receives as input the 10-bit command from the OCMD, and status signals from the processor, and generates all the strobes required for reading and writing the selected OnCE registers.

Single stepping of instructions is performed by placing the CPU in debug mode, scanning in appropriate information into the CPUSCR, and setting the Go bit (with the EX bit cleared) with the RS field indicating either the CPUSCR or No Register Selected. After executing a single instruction, the CPU will re-enter debug mode and await further commands. During single-stepping, exception conditions may occur if not properly masked by debug firmware (interrupts, machine checks, bus error conditions, etc.) and



may prevent the desired instruction from being successfully executed. The OSR_{ERR} bit is set to indicate this condition. In these cases, values in the CPUSCR will correspond to the first instruction of the exception handler.

Additionally, the $EDBCR0_{EDM}$ bit is forced to '1' internally while single-stepping to prevent Debug events from generating Debug interrupts. Also, during a debug session, the DBSR register is frozen from updates due to debug events other than execution of a DNI-type instruction, regardless of EDBCR0EDM. DBSR may still be modified during a debug session via a single-stepped **mtspr** instruction, or via OnCE access.

If the CPU is not currently in debug mode, go+exit and go+noexit commands are ignored, although for a go+exit command with "No Register Selected", the j_ocmd_go_exit output will be asserted.

64.5.6.3 OnCE Control Register (OCR)

The OnCE Control Register is a 32-bit register used to force the core into debug mode and to enable / disable sections of the OnCE control logic. It also provides control over the MPU during a debug session (see MPU Operation During Debug). The control bits are read/write. These bits are only effective while OnCE is enabled (**jd_en_once** asserted). The OCR is shown in the following figure.

Reset - 0xo000_0000 on **m_por, j_trst_b,** or entering Test_logic_Reset state

Figure 64-24. OnCE Control Register

The following table provides bit definitions for the OnCE Control Register.

Table 64-26. OnCE Control Register Bit Definitions

Bit(s)	Name	Description
0:7	—	Reserved

Table continues on the next page...

Table 64-26. OnCE Control Register Bit Definitions (continued)

Bit(s)	Name	Description
8	I_DMDIS	Instruction Side Debug MPU Disable Control Bit (I_DMDIS) 0 - MPU not disabled for debug sessions 1 - MPU disabled for debug sessions This bit may be used to control whether the MPU is enabled normally, or whether the MPU is disabled during a debug session for Instruction Accesses. When enabled, the MPU functions normally. When disabled, for Instruction Accesses, the I bit is taken from the OCR bit I_DI. The SX and UX access permission control bits are set to'1' to allow full access. When disabled, no MPU exceptions are generated for Instruction accesses. External access errors can still occur. MPU entries with DEBUG=1 are not affected by this control bit.
9:10	—	Reserved
11	I_DVLE	Instruction Side Debug 'VLE' Attribute Bit (I_DVLE) This bit is used to provide the 'VLE' attribute bit to be used during a debug session. Note: this bit is ignored, since VLE is always enabled.
12	I_DI	Instruction Side Debug 'I' Attribute Bit (I_DI) This bit is used to provide the 'I' attribute bit to be used for Instruction accesses for Instruction accesses during a debug session.
13:15	—	Reserved
16	D_DMDIS	Data Side Debug MPU Disable Control Bit (D_DMDIS) 0 - MPU not disabled for debug sessions 1 - MPU disabled for debug sessions This bit may be used to control whether the MPU is enabled normally, or whether the MPU is disabled during a debug session for Data Accesses. When enabled, the MPU functions normally. When disabled, for Data Accesses, the MPU I and G bits are taken from the OCR bits D_DI and D_DG. The SR, SW, UR, and UW access permission control bits are set to'1' to allow full access. When disabled, no MPU exceptions are generated for Data accesses. External access errors can still occur. MPU entries with DEBUG=1 are not affected by this control bit.
17:19	—	Reserved
20	D_DI	Data Side Debug 'I' Attribute Bit (D_DI) This bit is used to provide the 'I' attribute bit to be used for Data accesses during a debug session.
21	—	Reserved
22	D_DG	Data Side Debug 'G' Attribute Bit (D_DG) This bit is used to provide the 'G' attribute bit to be used for Data accesses during a debug session.
23:28	—	Reserved
29	WKUP	Wakeup Request Bit (WKUP) This control bit may be used to force the **p_wakeup** output signal to be asserted. This control function may be used by debug firmware to request that the chip-level clock controller restore the **m_clk** input to normal operation regardless of whether the CPU is in a low power state to ensure that debug resources may be properly accessed by external hardware through scan sequences.

Table continues on the next page...

Table 64-26. OnCE Control Register Bit Definitions (continued)

Bit(s)	Name	Description
30	FDB	Force Breakpoint Debug Mode Bit (FDB) This control bit is used to determine whether the processor is operating in breakpoint debug enable mode or not. The processor may be placed in breakpoint debug enable mode by setting this bit. In breakpoint debug enable mode, execution of the '**bkpt**' pseudo- instruction will cause the processor to enter debug mode, as if the **jd_de_b** input had been asserted. This bit is qualified with $EDBCR0_{EDM}$, which must be set for FDB to take effect. Note that this bit has no effect on **e_dnh** or **se_dnh** instruction operation.
31	DR	CPU Debug Request Control Bit This control bit is used to unconditionally request the CPU to enter the Debug Mode. The CPU will indicate that Debug Mode has been entered via the data scanned out in the shift-IR state. 0 - No Debug Mode request 1 - Unconditional Debug Mode request When the DR bit is set the processor will enter Debug mode at the next instruction boundary.

64.5.7 Access to Debug Resources

Resources contained in the OnCE Module which do not require the processor core to be halted for access may be accessed while the core is running, and will not interfere with processor execution. Accesses to other resources such as the CPUSCR require the core to be placed in debug mode to avoid synchronization hazards. Debug firmware may ensure that it is safe to access these resources by determining the state of the core prior to access. Note that a scan operation to update the CPUSCR is required prior to exiting debug mode if debug mode has been entered.

Some cases of write accesses other than accesses to the OnCE Command and Control registers, or the EDM bit of DBCR0 require **m_clk** to be running for proper operation. The OnCE control register provides a means of signaling this need to a system level clock control module via the OCR_{WKUP} control bit.

In addition, since the CPU may cause multiple bits of certain registers to change state, reads of certain registers while the CPU is running (DBSR, etc.) may not have consistent bit settings unless read twice with the same value indicated. In order to guarantee that the contents are consistent, the CPU should be placed into debug mode, or multiple reads should be performed until consistent values have been obtained on consecutive reads.

The following table provides a list of access requirements for OnCE registers.

Table 64-27. OnCE Register Access Requirements

Register name	Access requirements					Notes
	Requires jd_en_once to be asserted	Requires EDBCR0 $_{EDM}$ = 1 for write access	Requires m_clk active for Write Access	Requires CPU to be halted for Read Access	Requires CPU to be halted for Write Access	
Enable_OnCE	N	N	N	N	—	
Bypass	N	N	N	N	N	
CPUSCR	Y	Y	Y	Y	Y	
DAC1–4	Y	Y	Y	N	*[1, 1]	
DBCR0	Y	Y	Y	N	*[1]	*EDBCR0$_{EDM}$ access only requires **jd_en_once** asserted
DBCR1–8	Y	Y	Y	N	*[1]	
DEVENT	Y	Y	Y	N	*[1]	
EDBRAC0 (DBERC0)	Y	N	Y	N	*[1]	
DBSR	Y	Y	Y	N[2, 2]	*[1]	
EDBCR0	Y	N	N	N	N	
EDBSR0	Y	N	Y	N	N	
EDBSRMSK0	Y	N	N	N	N	
IAC1–8	Y	Y	Y	N	*[1]	
JTAG ID	N	N	—	N	—	Read-only
MPU0CSR0	Y	N	Y	N	N	
OCR	Y	N	N	N	N	
OSR	Y	N	—	N	—	Read-only, accessed by scanning out IR while **jd_en_once** is asserted
Cache Debug Access Control (CDACNTL)	Y	N	Y	N	N	CPU gives lowest priority to a Cache access request when it is not debug halted
Cache Debug Access Data (CDADATA)	Y	N	Y	N	N	CPU gives lowest priority to a Cache access request when it is not debug halted
Nexus3-Access	Y	N	N	N	N	
PMR-Access	Y	N	N	N	N	
PMR Registers	Y	Y	Y	N	N	
External GPRs	Y	N	N	N	N	
LSRL Select	Y	N	?	?	?	System Test logic implementation determines LSRL functionality

1. Writes to these registers while the CPU is running may have unpredictable results due to the pipelined nature of operation, and the fact that updates are not synchronized to a particular clock, instruction, or bus cycle boundary, therefore it is strongly recommended to ensure the processor is first placed into debug mode before updates to these registers are performed.
2. Reads of these registers while the CPU is running may not give data that is self-consistent due to synchronization across clock domains.

64.5.8 Methods of Entering Debug Mode

The OnCE Status Register indicates that the CPU has entered the debug mode via the DEBUG status bit. The following sections describe how Debug Mode is entered assuming the OnCE circuitry has been enabled. OnCE operation is enabled by the assertion of the **jd_en_once** input See OnCE Enable (jd_en_once).

64.5.8.1 External Debug Request During RESET

Holding the **jd_de_b** signal asserted during the assertion of **p_reset_b,** and continuing to hold it asserted following the negation of **p_reset_b** causes the core to enter Debug Mode. After receiving an acknowledge via the OnCE Status Register DEBUG bit, the external command controller should negate the **jd_de_b** signal before sending the first command. Note that in this case the core does not execute an instruction before entering Debug Mode, although the first instruction to be executed will be fetched prior to entering Debug Mode in order to properly initialize the CPUSCR.

64.5.8.2 Debug Request During RESET

Asserting a debug request by setting the DR bit in the OCR during the assertion of **p_reset_b** and then negating **p_reset_b** causes the chip to enter debug mode. In this case the CPU will fetch the first instruction of the reset exception handler in order to properly initialize the CPUSCR, but does not execute an instruction before entering debug mode.

64.5.8.3 Debug Request During Normal Activity

Asserting a debug request by setting the DR bit in the OCR during normal chip activity causes the chip to finish the execution of the current instruction and then enter the debug mode. Note that in this case the chip completes the execution of the current instruction and stops after the newly fetched instruction enters the CPU instruction register. This process is the same for any newly fetched instruction including instructions fetched by the interrupt processing, or those that will be aborted by the interrupt processing.

64.5.8.4 Debug Request During Waiting, Halted or Stopped State

Asserting a debug request by setting the DR bit in the OCR when the chip is in the Waiting state (**p_waiting** asserted), Halted state (**p_halted** asserted) or Stopped state (**p_stopped** asserted) causes the CPU to exit the state and enter the debug mode once the CPU clock **m_clk** has been restored. Note that in this case, the CPU will negate the **p_waiting, p_halted** and **p_stopped** outputs. Once the debug session has ended, the CPU will return to the state it was in prior to entering debug mode.

To signal the chip-level clock generator to re-enable **m_clk**, the **p_wakeup** output will be asserted whenever the debug block is asserting a debug request to the CPU due to OCR_{DR} being set, or **jd_de_b** assertion, and will remain set from then until the debug session ends (**jd_debug_b** goes from asserted to negated). In addition, the status of the **jd_mclk_on** input (after synchronization to the **j_tclk** clock domain) may be sampled along with other status bits from the **j_tdo** outputs during the Shift_IR TAP controller state. This status may be used if necessary by external debug firmware to ensure proper scan sequences occur to registers in the **m_clk** clock domain.

64.5.8.5 Software Request During Normal Activity

Upon executing a '**bkpt**' pseudo-instruction (defined to be an all 0's instruction opcode) when the OCR register's (FDB) bit is set (debug mode enable control bit is true), and $EDBCR0_{EDM}$=1, the CPU enters the debug mode after the instruction following the '**bkpt**' pseudo-instruction has entered the instruction register.

64.5.8.6 Debug Notify Halt Instructions

The **e_dnh** and **se_dnh** instructions allow software to transition the core from a running state to a debug halted state if enabled by $EDBCR0_{DNH_EN}$, and provide the external debugger with bits reserved in the instruction itself to pass additional information. Entry into debug mode is ***not*** conditioned on $EDBCR0_{EDM}$, allowing for debug of software debug handlers as well as other software. When the CPU enters a debug halted state due to a **e_dnh** or **se_dnh** instruction, the instruction will be stored in the CPUSCR[IR] portion, and the CPUSCR[PC] value will point to the instruction. The external debugger should update the CPUSCR prior to exiting the debug halted state to point past the **e_dnh** or **se_dnh** instruction.

64.5.9 CPU Status and Control Scan Chain Register (CPUSCR)

A number of on-chip registers store the CPU pipeline status and are configured in a single scan chain for access by the OnCE controller. The CPUSCR register contains these processor resources, which are used to restore the pipeline and resume normal chip activity upon return from the debug mode, as well as a mechanism for the emulator software to access processor and memory contents. The following figure shows the block diagram of the pipeline information registers contained in the CPUSCR. Once debug mode has been entered, it is required to scan in and update this register prior to exiting debug mode.

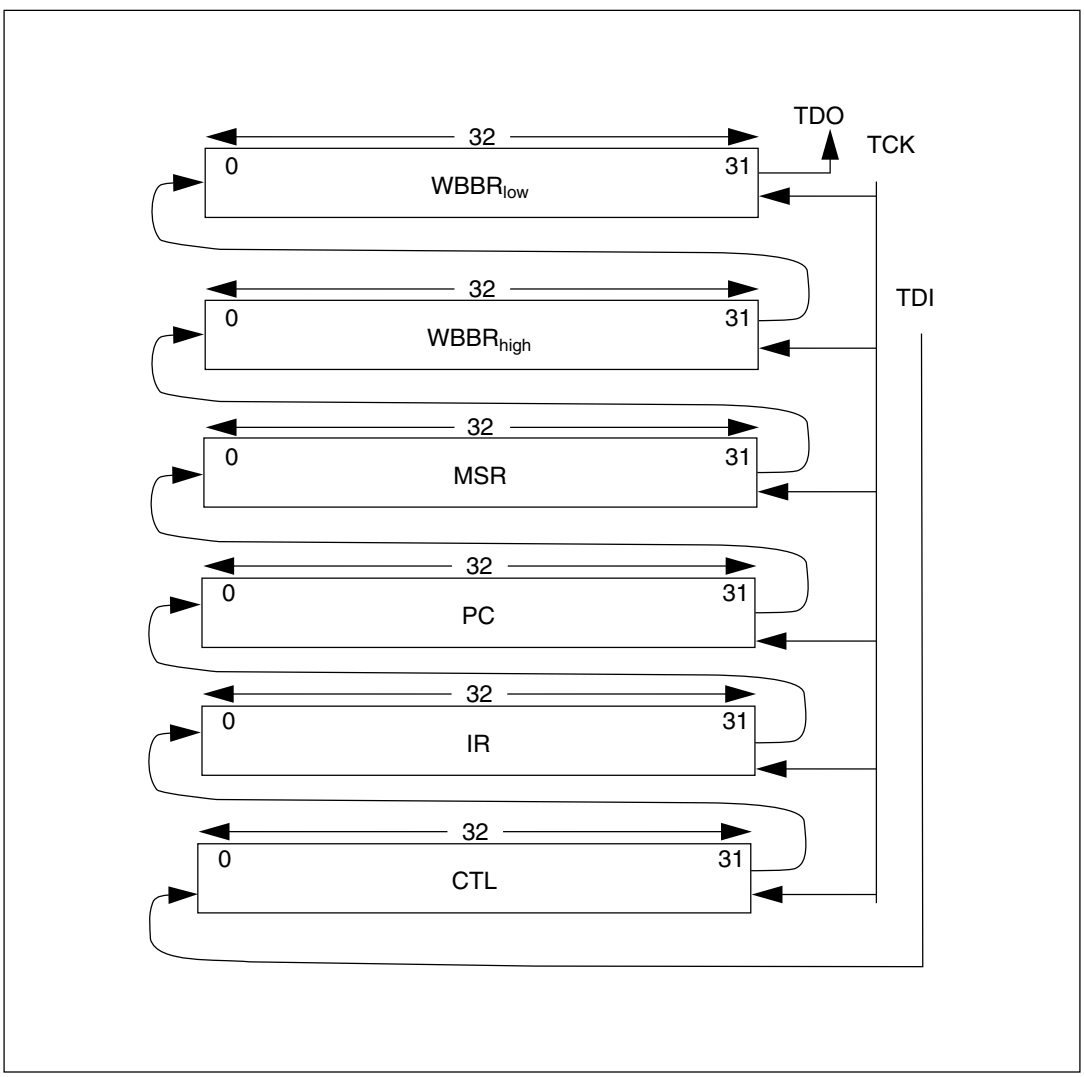


Figure 64-25. CPU Scan Chain Register (CPUSCR)

64.5.9.1 Instruction Register (IR)

The Instruction Register (IR) provides a mechanism for controlling the debug session by serving as a means for forcing in selected instructions, and then causing them to be executed in a controlled manner by the debug control block. The opcode of the next instruction to be executed when entering debug mode is contained in this register when the scan-out of this chain begins. This value should be saved for later restoration if continuation of the normal instruction stream is desired.

On scan-in, in preparation for exiting debug mode, this register is filled with an instruction opcode selected by debug control software. By selecting appropriate instructions and controlling the execution of those instructions, the results of execution may be used to examine or change memory locations and processor registers. The debug control module external to the processor core will control execution by providing a single-step capability. Once the debug session is complete and normal processing is to be resumed, this register may be loaded with the value originally scanned out.

64.5.9.2 Control State Register (CTL)

The Control State Register (CTL) is a 32-bit register that stores the value of certain internal CPU state variables before the debug mode is entered. This register is affected by the operations performed during the debug session and should normally be restored by the external command controller when returning to normal mode. In addition to saved internal state variables, two of the bits are used by emulation firmware to control the debug process. In certain circumstances, emulation firmware must modify the content of this register as well as the PC and IR values in the CPUSCR before exiting debug mode. These cases are described below.

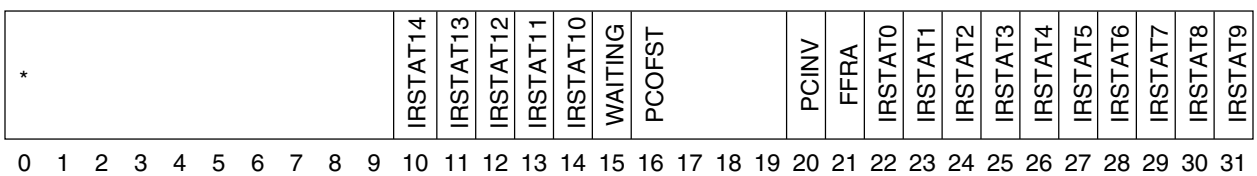

Figure 64-26. Control State Register (CTL)

WAITING — WAITING State Status

This bit indicates whether the CPU was in the waiting state prior to entering debug mode. If set, the CPU was in the waiting state. Upon exiting a debug session, the value of this bit in the restored CPUSCR will determine whether the CPU re-enters the waiting state on a go+exit.

0- CPU was not in the waiting state when debug mode was entered

1- CPU was in the waiting state when debug mode was entered

PCOFST — PC Offset Field

Table continues on the next page...

This field indicates whether the value in the PC portion of the CPUSCR must be adjusted prior to exiting debug mode. Due to the pipelined nature of the CPU, the PC value must be backed-up by emulation software in certain circumstances. The PCOFST field specifies the value to be subtracted from the original value of the PC. This adjusted PC value should be restored into the PC portion of the CPUSCR just prior to exiting debug mode with a go+exit. In the event the PCOFST is non-zero, the IR should be loaded with a nop instruction instead of the original IR value, other wise the original value of IR should be restored. (But see PCINV which overrides this field)

0000 - No correction required.

0001 - Subtract 0x04 from PC.

0010 - Subtract 0x08 from PC.

0011 - Subtract 0x0C from PC.

0100 - Subtract 0x10 from PC.

0101 - Subtract 0x14 from PC.

all other encodings are reserved

* — Internal State Bits

These control bits represent internal processor state and should be restored to their original value after a debug session is completed, i.e when a OnCE command is issued with the GO and EX bits set and not ignored. When performing instruction execution during a debug session. See OnCE Debug Output (jd_debug_b), which is not part of the normal program execution flow, these bits should be set to a 0.

PCINV — PC and IR Invalid Status Bit

This status bit indicates that the values in the IR and PC portions of the CPUSCR are invalid. Exiting debug mode with the saved values in the PC and IR will have unpredictable results. Debug firmware should initialize the PC and IR values in the CPUSCR with desired values prior to exiting debug mode if this bit was set when debug mode was initially entered.

0= No error condition exists.

1= Error condition exists. PC and IR are corrupted.

FFRA— Feed Forward RA Operand Bit

This control bit causes the content of the $WBBR_{lo}$ to be used as the RA operand value (RS for logical, mtspr, mtdcr, cntlzw, and shift operations, RX for VLE se_ instructions, RT for e_{logical_op}2i type instructions, RB for evaddiw, evsubifw, and the value to use as the PC for calculating the LR update value for branch with link type instructions) of the first instruction to be executed following an update of the CPUSCR. For most LSP instructions using rA||rB as a 64-bit source operand, $WBBR_{hi, lo}$ is used to supply the 64-bit source value.

This allows the debug firmware to update processor registers — initialize the $WBBR_{lo}$ with the desired value, set the FFRA bit, and execute a ori Rx,Rx,0 instruction to the desired register.

Note: not all instructions support using the FFRA control. FFRA is mainly intended for use with the ori instruction to allow the debugger to write to a GPR. Support for other instructions is implementation-dependent.

0= No action.

1= Content of $WBBR_{lo}$ or $WBBR_{hi,lo}$ used as operand value

IRStat0 — IR Status Bit 0

This control bit indicates a TEA status for the IR.

0= No TEA occurred on the fetch of this instruction.

1= TEA occurred on the fetch of this instruction.

IRStat1 — IR Status Bit 1

This control bit is reserved.

IRStat2 — IR Status Bit 2

Table continues on the next page...

This control bit indicates an Instruction Address Compare 1 event status for the IR.

0= No Instruction Address Compare event 1 occurred on the fetch of this instruction.

1= An Instruction Address Compare event 1 occurred on the fetch of this instruction.

IRStat3 — IR Status Bit 3

This control bit indicates an Instruction Address Compare 2 event status for the IR.

0= No Instruction Address Compare 2 event occurred on the fetch of this instruction.

1= An Instruction Address Compare 2 event occurred on the fetch of this instruction.

IRStat4 — IR Status Bit 4

This control bit indicates an Instruction Address Compare 3 event status for the IR.

0= No Instruction Address Compare event 3 occurred on the fetch of this instruction.

1= An Instruction Address Compare event 3 occurred on the fetch of this instruction.

IRStat5 — IR Status Bit 5

This control bit indicates an Instruction Address Compare 4 event status for the IR.

0= No Instruction Address Compare 4 event occurred on the fetch of this instruction.

1= An Instruction Address Compare 4 event occurred on the fetch of this instruction.

IRStat6 — IR Status Bit 6

This control bit indicates a Parity Error status for the IR.

0= No Parity Error occurred on the fetch of this instruction.

1= Parity Error occurred on the fetch of this instruction from the I-Cache or the IMEM.

IRStat7 — IR Status Bit 7

This control bit indicates a Precise External Termination Error status for the IR.

0= No Precise External Termination Error occurred on the fetch of this instruction.

1= A Precise External Termination Error occurred on the fetch of this instruction.

IRStat8 — IR Status Bit 8

This control bit indicates the PowerISA VLE status for the IR.

0= IR contains a BookE instruction. (unused encoding)

1= IR contains a PowerISA VLE instruction, aligned in the Most Significant Portion of IR if 16-bit.

- this bit should not be modified by the debugger, otherwise the resulting operation is boundedly undefined. It should always indicate VLE (=1).

IRStat9 — IR Status Bit 9

This control bit is reserved.

IRStat10 — IR Status Bit 10

This control bit indicates an Instruction Address Compare 5 event status for the IR.

0= No Instruction Address Compare 5 event occurred on the fetch of this instruction.

1= An Instruction Address Compare 5 event occurred on the fetch of this instruction.

IRStat11 — IR Status Bit 11

This control bit indicates an Instruction Address Compare 6 event status for the IR.

0= No Instruction Address Compare 6 event occurred on the fetch of this instruction.

1= An Instruction Address Compare 6 event occurred on the fetch of this instruction.

IRStat12 — IR Status Bit 12

This control bit indicates an Instruction Address Compare 7 event status for the IR.

Table continues on the next page...

0= No Instruction Address Compare 7 event occurred on the fetch of this instruction.

1= An Instruction Address Compare 7 event occurred on the fetch of this instruction.

IRStat13 — IR Status Bit 13

This control bit indicates an Instruction Address Compare 8 event status for the IR.

0= No Instruction Address Compare 8 event occurred on the fetch of this instruction.

1= An Instruction Address Compare 8 event occurred on the fetch of this instruction.

IRStat14 — IR Status Bit 14

This control bit indicates an MPU Instruction Address Compare event status for the IR.

0= No MPU Instruction Address Compare event occurred on the fetch of this instruction.

1= An MPU Instruction Address Compare event occurred on the fetch of this instruction.

Emulation firmware should modify the content of the CTL, PC, and IR values in the CPUSCR during execution of debug related instructions as well as just prior to exiting debug with a go+exit command. During the debug session, the CTL register should be written with the FFRA bit set as appropriate, and all other bit set to '0', and the IR set to the value of the desired instruction to be executed. IRStat8 will be used to determine the type of instruction present in the IR.

Just prior to exiting debug mode with a go+exit, the PCINV status bit which was originally present when debug mode was first entered should be tested, and if set, the PC and IR initialized for performing whatever recovery sequence is appropriate for a faulted exception vector fetch. If the PCINV bit is cleared, then the PCOFST bits should be examined to determine whether the PC value must be adjusted. Due to the pipelined nature of the CPU, the PC value must be backed-up by emulation software in certain circumstances. The PCOFST field specifies the value to be subtracted from the original value of the PC. This adjusted PC value should be restored in to the PC portion of the CPUSCR just prior to exiting debug mode with a go+exit. In the event the PCOFST is non-zero, the IR should be loaded with a nop instruction (such as **ori r0,r0,0**) instead of the original IR value, otherwise the original value of IR should be restored. Note that when a correction is made to the PC value, it will generally point to the last completed instruction, although that instruction will not be re-executed. The nop instruction is executed instead, and instruction fetch and execution will resume at location PC+4. IRStat8 will be used to determine the type of instruction present in the IR, thus should be cleared in this case. Note that debug events which may occur on the nop (ICMP) will be generated if enabled.

For the CTL register, the internal state bits should be restored to their original value. The IRStatus bits should be set to '0's if the PC was adjusted. If no PC adjustment was performed, emulation firmware should determine whether other IRStat flags should be set to '0' to avoid re-entry into debug mode for an instruction breakpoint request. Upon exiting debug mode with go+exit, if one of these bits is set, debug mode will be re-entered prior to any further instruction execution.

64.5.9.3 Program Counter Register (PC)

The PC is a 32-bit register that stores the value of the program counter which was present when the chip entered the debug mode. It is affected by the operations performed during the debug mode and must be restored by the external command controller when the CPU returns to normal mode. PC normally points to the instruction contained in the IR portion of CPUSCR. If debug firmware wishes to redirect program flow to an arbitrary location, the PC and IR should be initialized to correspond to the first instruction to be executed upon resumption of normal processing. Alternatively, the IR may be set to a nop and the PC set to point to the location prior to the location at which it is desired to redirect flow to. On exiting debug mode, the nop will be executed, and instruction fetch and execution will resume at PC+4.

64.5.9.4 Write-Back Bus Register ($WBBR_{low}$, $WBBR_{high}$)

WBBR is used as a means of passing operand information between the CPU and the external command controller. Whenever the external command controller needs to read the contents of a register or memory location, it will force the chip to execute an instruction that brings that information to WBBR. $WBBR_{low}$ holds the 32-bit result of most instructions including load data returned for a load or load with update instruction. For LSP instructions which generate 64-bit results, $WBBR_{low}$ holds the low-order 32 bits of the result. $WBBR_{high}$ holds the updated effective address calculated by a load with update instruction. For LSP instructions which generate 64-bit results, $WBBR_{high}$ holds the high-order 32 bits of the result. It is undefined for other instructions.

As an example, to read the 32 bits of processor register **r1**, an **ori r1,r1,0** instruction is executed, and the result value of the instruction will be latched into $WBBR_{low}$. The contents of $WBBR_{low}$ can then be delivered serially to the external command controller. To update a processor resource, this register is initialized with a data value to be written, and an **ori** instruction is executed which uses this value as a substitute data value. The Control State register FFRA bit forces the value of the $WBBR_{low}$ to be substituted for the normal RS source value of the **ori** instruction, thus allowing updates to processor registers to be performed. (Refer to Control State Register (CTL) for more detail on the CTL_{FFRA} bit.)

$WBBR_{low}$ and $WBBR_{high}$ are generally undefined on instructions which do not writeback a result, and due to control issues are not defined on **lmw** or branch instructions as well.

64.5.9.5 Machine State Register (MSR)

The MSR is a 32-bit register used to read/write the Machine State Register. Whenever the external command controller needs to save or modify the contents of the Machine State Register, this register is used.This register is affected by the operations performed during the debug mode and must be restored by the external command controller when returning to normal mode.

64.5.9.6 Exiting Debug Mode and Interrupt Blocking

When exiting debug mode with a Go+Exit, "asynchronous" interrupts are blocked until the first instruction to be executed begins execution. This includes External and Critical input, NMI, and machine check interrupts. Asynchronous debug interrupts are not blocked however, and the CPU will re-enter debug mode without executing an instruction following Go+Exit, although it may fetch an instruction and discard it. Exceptions due to an illegal instruction or error flags set within the CPUSCR CTL register are not blocked, since they apply to the instruction in the CPUSCR IR.

64.5.10 Reserved Registers (Reserved)

The Reserved Registers are used to control various test control logic. These registers are not intended for customer use. To preclude device and/or system damage, these registers should not be accessed.

64.6 Watchpoint Support

supports the generation and signalling of watchpoints when operating in internal debug mode ($DBCR0_{IDM}$=1) or in external debug mode ($EDBCR0_{EDM}$=1). Watchpoints are indicated with a dedicated set of interface signals. The **jd_watchpt[0:31]** output signals are used to indicate that a watchpoint has occurred. Certain watchpoints however (DEVENT-based, DTC-based, and Performance Monitor watchpoints) are not qualified with $EDBCR0_{EDM}$ or $DBCR0_{IDM}$.

Each debug address compare function (IAC1–8, DAC1–4), as well as other event types are capable of triggering a watchpoint output. The DBCRx control fields are used to configure watchpoints, regardless of whether events are enabled in DBCR0. Watchpoints may occur whenever an associated event would have been posted in the Debug Status Register if enabled. No explicit enable bits are provided for watchpoints; they are always enabled by definition, although the data address compare watchpoints may be controlled

for read and write accesses via configuration fields in DBCR4, 7, and 9. During a debug session, debug events (other than PMI, DEVT1 and DEVT2) with a corresponding DBSR bit are blocked from asserting a watchpoint. The Performance Monitor, DEVNT-based and DTC-based watchpoints are not blocked during a debug session. If not desired, for address-based events the base address values for these events may be programmed to an unused system address. MSR_{DE} has no effect on watchpoint generation.

External logic may monitor the assertion of these signals for debugging or triggering purposes. Watchpoints are signaled in the clock cycle following the occurrence of the actual event. The Nexus3 module also monitors assertion of a portion of these output signals (**jd_watchpt[0:31]**) for various development control purposes. (See the "Watchpoint Trace Messaging" section in the Nexus 3 Module chapter.)

Note that these signals are **m_clk** domain signals, not **j_tclk** domain signals.

The following table shows the **jd_watchpt[0:31]** output signal assignments to various debug events.

Table 64-28. Watchpoint Output Signal Assignments

Signal Name	Type	Description
jd_watchpt[0]	IAC1	Instruction Address Compare 1 watchpoint
		Asserted whenever an IAC1 compare occurs regardless of being enabled to set DBSR status
jd_watchpt[1]	IAC2	Instruction Address Compare 2 watchpoint
		Asserted whenever an IAC2 compare occurs regardless of being enabled to set DBSR status
jd_watchpt[2]	IAC3	Instruction Address Compare 3 watchpoint
		Asserted whenever an IAC3 compare occurs regardless of being enabled to set DBSR status
jd_watchpt[3]	IAC4	Instruction Address Compare 4 watchpoint
		Asserted whenever an IAC4 compare occurs regardless of being enabled to set DBSR status
jd_watchpt[4]	DAC1	Data Address Compare 1 watchpoint
		Asserted whenever a DAC1 compare occurs regardless of being enabled to set DBSR status, based on $DBCR4_{DAC1CFG}$ settings
jd_watchpt[5]	DAC2	Data Address Compare 2 watchpoint
		Asserted whenever a DAC2 compare occurs regardless of being enabled to set DBSR status, based on $DBCR4_{DAC2CFG}$ settings
jd_watchpt[6]	DAC3	Data Address Compare 3 watchpoint
		Asserted whenever a DAC3 compare occurs regardless of being enabled to set DBSR status, based on $DBCR7_{DAC3CFG}$ settings
jd_watchpt[7]	DAC4	Data Address Compare 4 watchpoint
		Asserted whenever a DAC4 compare occurs regardless of being enabled to set DBSR status, based on $DBCR7_{DAC4CFG}$ settings

Table continues on the next page...

Table 64-28. Watchpoint Output Signal Assignments (continued)

Signal Name	Type	Description
jd_watchpt[8]	IAC5	Instruction Address Compare 5 watchpoint
		Asserted whenever an IAC5 compare occurs regardless of being enabled to set DBSR status
jd_watchpt[9]	IAC6	Instruction Address Compare 6 watchpoint
		Asserted whenever an IAC6 compare occurs regardless of being enabled to set DBSR status
jd_watchpt[10]	DEVT1	Debug Event Input 1 watchpoint
		Asserted whenever a DEVT1 debug event occurs regardless of being enabled to set DBSR status
jd_watchpt[11]	DEVT2	Debug Event Input 2 watchpoint
		Asserted whenever a DEVT2 debug event occurs regardless of being enabled to set DBSR status
jd_watchpt[12]	DEVNT0	Debug Event Output 0 watchpoint
		Asserted whenever a '1' is written to the bit of the DEVNT field of the DEVENT debug register corresponding to jd_watchpt[12]
jd_watchpt[13]	DEVNT1	Debug Event Output 1 watchpoint
		Asserted whenever a '1' is written to the bit of the DEVNT field of the DEVENT debug register corresponding to jd_watchpt[13]
jd_watchpt[14]	IAC7	Instruction Address Compare 7 watchpoint
		Asserted whenever an IAC7 compare occurs regardless of being enabled to set DBSR status
jd_watchpt[15]	IAC8	Instruction Address Compare 8 watchpoint
		Asserted whenever an IAC8 compare occurs regardless of being enabled to set DBSR status
jd_watchpt[16]	IRPT	Interrupt watchpoint
		Asserted whenever an IRPT debug event occurs regardless of being enabled to set DBSR status
jd_watchpt[17]	RET	Return watchpoint
		Asserted whenever a RET debug event occurs regardless of being enabled to set DBSR status
jd_watchpt[18]	CIRPT	Critical Interrupt watchpoint
		Asserted whenever a CIRPT debug event occurs regardless of being enabled to set DBSR status
jd_watchpt[19]	CRET	Critical Return watchpoint
		Asserted whenever a CRET debug event occurs regardless of being enabled to set DBSR status
jd_watchpt[20]	DEVNT2	Debug Event Output 2 watchpoint
		Asserted whenever a '1' is written to the bit of the DEVNT field of the DEVENT debug register corresponding to jd_watchpt[20]
jd_watchpt[21]	DEVNT3	Debug Event Output 3 watchpoint
		Asserted whenever a '1' is written to the bit of the DEVNT field of the DEVENT debug register corresponding to jd_watchpt[21]

Table continues on the next page...

Table 64-28. Watchpoint Output Signal Assignments (continued)

Signal Name	Type	Description
jd_watchpt[22]	PMEVENT	Performance Monitor Event input watchpoint
		Asserted whenever **p_pm_event** transitions from a '0' to a '1' while **m_clk** is running
jd_watchpt[23]	PMC0	Performance Monitor Counter 0 watchpoint
		Asserted whenever PMC0 triggers an event based on $PMLCa0_{PMP}$
jd_watchpt[24]	PMC1	Performance Monitor Counter 1 watchpoint
		Asserted whenever PMC1 triggers an event based on $PMLCa1_{PMP}$
jd_watchpt[25]	PMC2	Performance Monitor Counter 2 watchpoint
		Asserted whenever PMC2 triggers an event based on $PMLCa2_{PMP}$
jd_watchpt[26]	PMC3	Performance Monitor Counter 3 watchpoint
		Asserted whenever PMC3 triggers an event based on $PMLCa3_{PMP}$
jd_watchpt[27]	MPU	Memory Protection Unit watchpoint
		Asserted whenever a the MPU generates a debug event based on region descriptor matches with DEBUG control enabled.
jd_watchpt[28]	TRAP	TRAP watchpoint
		Asserted whenever an TRAP debug event occurs regardless of being enabled to set DBSR status
jd_watchpt[29]	DTC1	Data Trace Control Range 1 watchpoint
		Asserted whenever an access meets the conditions for DTC Range 1
jd_watchpt[30]	DTC2	Data Trace Control Range 2 watchpoint
		Asserted whenever an access meets the conditions for DTC Range 2
jd_watchpt[31]	DTC3	Data Trace Control Range 3 watchpoint
		Asserted whenever an access meets the conditions for DTC Range 3

64.7 MPU Operation During Debug

A debug session begins when the CPU initially enters debug mode, and ends when a OnCE command with GO+EXIT is executed, releasing the CPU for normal operation. If desired during a debug session, the debug firmware may substitute default values obtained from the OnCE Control Register for Access Attribute (I, G) bits. Refer to the bit definitions in the OCR (OnCE Control Register (OCR) for more detail.

Normal operation of the MPU may be modified during a 'debug session' via the OnCE Control Register (OCR). A debug session begins when the CPU initially enters debug mode, and ends when a OnCE command with GO+EXIT is executed, releasing the CPU for normal operation. If desired during a debug session, the debug firmware may disable

the MPU protection mechanism and may substitute default values for the Access Protection (UX, UR, UW, SX, SR, SW) bits, and values obtained from the OnCE Control Register for Memory Attributes (I, G) bits normally provided by a matching MPU entry.

When disabled during a debug session, no MPU-related storage interrupt conditions will occur. If the debugger desires to use the normal protection mechanism, the MPU may be left enabled in the OnCE OCR, and normal protections provided by the MPU (including the possibility of a storage interrupt) will remain in effect.

The OCR control bits are used when debug mode is entered. Refer to the bit definitions in the OCR (OnCE Control Register (OCR) for more detail. When the MPU is disabled for instruction accesses (OCR_{I_DMDIS}) or for data accesses (OCR_{D_DMDIS}), substituted access attribute bits will control operation on respective accesses initiated during debug.

64.8 Cache Array Access During Debug

The cache arrays may be read and written during debug mode via the CDACNTL and CDADATA debug registers.

64.9 Basic Steps for Enabling, Using, and Exiting External Debug Mode

The following steps show one possible scenario for a debugger wishing to use the external debug facilities. *This simplified flow is intended to illustrate basic operations, but does not cover all potential methods in depth.*

Enabling External Debug Mode and initializing Debug registers

- The debugger should ensure that the **jd_en_once** control signal is asserted in order to enable OnCE operation
- Select the OCR and write a value to it in which OCR_{DR}, OCR_{WKUP}, are set to '1'. The tap controller must step through the proper states as outlined earlier. This step will place the CPU in a debug state in which it is halted and awaiting single-step commands or a release to normal mode
- Scan out the value of the OSR to determine that the CPU clock is running and the CPU has entered the Debug state. This can be done in conjunction with a Read of the CPUSCR. The OSR is shifted out during the Shift_IR state. The CPUSCR will be shifted out during the Shift_DR state. The debugger should save the scanned-out value of CPUSCR for later restoration.

- Select the DBCR0 register and update it with the $EDBCR0_{EDM}$ bit set
- Clear the DBSR status bits
- Write appropriate values to the DBCR0–8, IAC, and DAC registers. Note that the initial write to DBCR0 will only affect the EDM bit, so the remaining portion of the register must now be initialized, keeping the EDM bit set

At this point the system is ready to commence debug operations. Depending on the desired operation, different steps must occur.

- Optionally, ensure that the values entered into the MSR portion of the CPUSCR during the following steps cause interrupt to be disabled (clearing MSR_{EE} and MSR_{CE}). This will ensure that external interrupt sources do not cause single-step errors.

To single-step the CPU:

- debugger scans in either a new or a previously saved value of the CPUSCR (with appropriate modification of the PC and IR as described in Control State Register (CTL)), with a Go+Noexit OnCE Command value.
- The debugger scans out the OSR with "no-register selected", Go cleared, and determines that the PCU has re-entered the Debug state and that no ERR condition occurred

To return the CPU to normal operation (without disabling external debug mode)

- The OCR_{DR} control bit should be cleared, leaving the OCR_{WKUP} bit set
- The debugger restores the CPUSCR with a previously saved value of the CPUSCR (with appropriate modification of the PC and IR as described in Control State Register (CTL)), with a Go+Exit OnCE Command value.
- The OCR_{WKUP} bit may then be cleared

To exit External Debug Mode

- The debugger should place the CPU in the debug state via the OCR_{DR} with OCR_{WKUP} asserted, scanning out and saving the CPUSCR
- The debugger should write the DBCR0–8 registers as needed, likely clearing every enable except the $EDBCR0_{EDM}$ bit
- The debugger should write the DBSR to a cleared state

- The debugger should re-write the DBCR0 with all bits including EDM cleared
- The debugger should clear the OCR_{DR} bit
- The debugger restores the CPUSCR with the previously saved value of the CPUSCR (with appropriate modification of the PC and IR as described in Control State Register (CTL)), with a Go+Exit OnCE Command value.
- The OCR_{WKUP} bit may then be cleared

Note

These steps are meant by way of examples, and are not meant to be an exact template for debugger operation.

Chapter 65
Debug and Calibration Interface (DCI)

65.1 Introduction

The Debug and Calibration Interface (DCI) module provides debug and calibration features for the MCU. It includes a standard IEEE 1149.1/1149.7 compatible JTAG interface which is used to connect with an external JTAG tool using a low frequency clock interface.

It also features a software based debug mode which can be controlled by the MCU without using an external tool. Additionally, the DCI provides features for debug control using break-points and synchronous restart of the cores. This chapter describes the DCI features for the Production device (PD) only.

65.1.1 Features

The DCI features are the following:

- Debug mode enable control for connected tool or software
- IEEE 1149.1 and IEEE 1149.7 controllers
- Debug break and cross-triggering control
- Synchronous restart control for CPU(s) when exiting debug mode
- Tool hot plug capability
- Security access control
- Debug reset control

65.1.2 Overview

The DCI can take the following different inputs for its JTAG signals:

- P.JTAG—JTAG signals coming from the Production device JTAG pads. This is the standard 5-pin JTAG interface and is the default operating mode.
- M.JTAG—JTAG signals generated by JTAGM module using software debug mode.
    - In software debug mode, there is no tool, and debug software running on the MCU generates the JTAG packets and writes them to JTAGM using special debug registers in the JTAGM module.

By default the DCI operates in standard 5-pin JTAG mode (IEEE 1149.1). It can be configured in 3-pin reduced pin JTAG mode (IEEE 1149.7) after starting from standard 5-pin JTAG mode.

When reduced pin JTAG mode (IEEE 1149.7) is configured TMSC pin is configured in bidirectional mode during operation.

The DCI also provides a centralized break control for system IPs and cores, which can be controlled by an external tool as well as the internal debug peripherals such as timers/ SPU, etc. The DCI also provides the Event Out ($\overline{\text{EVTO}}$) signals to the debug tool in case of the occurrence of any internal debug event.

This figure shows the DCI block diagram.

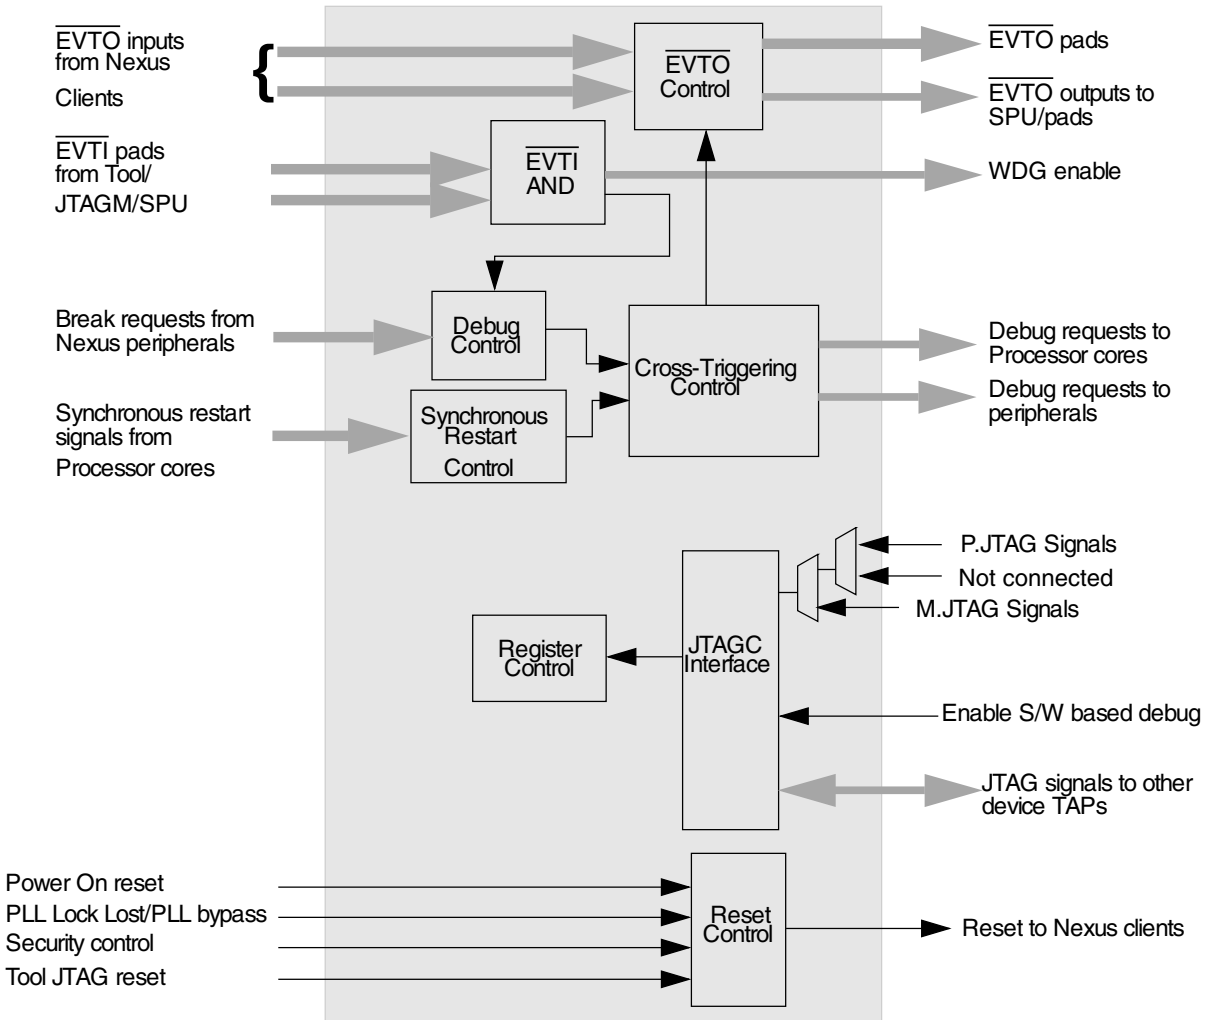

Figure 65-1. DCI block diagram

This figure shows the DCI configuration for the standard production package.

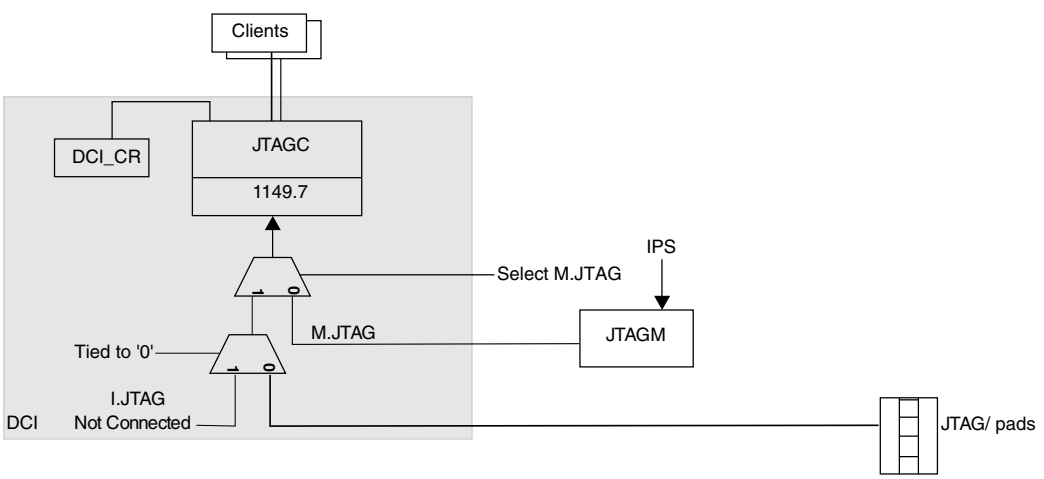

Figure 65-2. DCI in a standard configuration

65.1.3 Operating modes

Selection between various JTAG sources is done using a JTAGM register bit, JTAGM_MCR[DTM]. The JTAGM bit, JTAGM_MCR[DTM], is programmable via memory-mapped registers. JTAGM is selected as a JTAG source when JTAGM_MCR[DTM] is set.

This table shows a summary of the configuration options.

Table 65-1. DCI JTAG source selection

JTAGM_MCR[DTM]	DCI Source	JCOMP
0	P.JTAG (Standard JTAG)	Asserted
1	M.JTAG (Software)	Negated

The reset signal to the DCI block consists of the following:

- Power-on reset, Low/High voltage detection on IO/Core supplies
- JCOMP reset

The DCI puts the JTAGC TAP in reset when either power-on/low-voltage-detect reset is asserted or JCOMP is negated.

The M.JTAG provides an alternate interface to the debug logic.

When no debug tool is connected, device power-on reset puts the DCI in standard 5-pin JTAG mode. This configures the TDO pin in output mode with the reset value (1'b0). There is no change in port values if no debug tool is connected.

This table contains the operating mode descriptions.

Table 65-2. DCI operating modes

Mode	Description
DCI_JTAG	JTAG mode. This is the default state after power-on reset. In this mode the DCI is in JTAG mode (controlled with P.JTAG) and is controlled by an external JTAG tool.
DCI_SW_DBG	Software Debug State. This state is achieved when no tool is present and software sets the JTAGM_MCR[DTM] bit. The DCI is then controlled using M.JTAG signals.

65.1.3.1 Software enabled debug and calibration mode

Apart from the JTAG sources, such as a JTAG-based tool, it is possible to generate JTAG sequences through software programming.

To support a software debug session via a CAN or SPI link, the software can enable debug and calibration mode via an memory-mapped register. It is done first by setting a control bit in the JTAGM (JTAGM_MCR[DTM]). For more details, refer to the JTAGM documentation. When enabled, the DCI is configured to receive M.JTAG signals which are driven by JTAGM registers accessible through software. Software can control all DCI features like any other JTAG source.

After a system reset, the JTAGM_MCR[DTM] bit is reset and the JCOMP pad is pulled-low, thus keeping the DCI in the reset state. Therefore, software is required to first change to a non-secured mode. Then it can program the JTAGM_MCR[DTM] bit, to select M.JTAG as the source inside the DCI, and then set the JTAGM_MCR[jtagm_JCOMP] bit present in the JTAGM, which takes all debug modules out of reset.

When MCR[jtagm_JCOMP] is programmed to 0, the JTAGC block reset is asserted, thus putting the debug and calibration logic in reset state. This bit is used during software based debug to initialize the debug and calibration logic.

Software based debug is not possible when a tool is connected. The presence of the tool is determined using the rising edge of the JCOMP pad to set an internal flag which, when set, disables the selection of JTAGM as a JTAG source.

NOTE

It is recommended to utilize either hardware based debug (JTAG) or software based debug. If only one of the debug method is used, all three connection methods (connect and reset target, connect and break application, connect and keep application running) are supported.

65.1.3.2 Nexus reset control

The JCOMP input that is used as the primary reset signal for the DCI is also used by the DCI to generate a single-bit reset signal for other Nexus blocks. It is used to reset all debug functions without affecting any system level functions. The DCI provides the reset signal for all Nexus blocks. This reset is controlled using the following signals:

- Power-on reset/Low voltage detect

- JCOMP
- SoC Debug_Enable signal
- System PLL is out of lock state and not bypassed

Asserting power-on reset, negating JCOMP, or negating the Debug_Enable signal, results in asynchronous entry into reset state. Following negation of power-on reset, the Nexus reset signal remains asserted until the system clock achieves lock or in bypass mode, as indicated by the system clock lock status signal, and Debug_Enable is asserted and JCOMP is asserted. Any subsequent loss of PLL lock does not generate a Nexus reset. This reset signal is unaffected by other sources of reset.

The following table shows how the Nexus reset is asserted/negated based on various signals.

Table 65-3. Nexus Reset Truth Table

POR	JCOMP	Debug_Enable	PLL lock	Nexus reset
Assert	X	X	X	Assert
X	Negate	X	X	Assert
X	X	Disable	X	Assert
X	X	X	Unlocked	Assert
Negate	Assert	Enable	Locked	Negate

65.1.3.3 System watchdog control

The DCI is also used to enable or disable the Software Watchdog Timer (SWT). The DCI provides a single bit SWT enable signal which is used to control all SWTs in the MCU. For this, the $\overline{\text{EVTI}}$[0] pin is used. If the $\overline{\text{EVTI}}$[0] pin remains high when the tool asserts JCOMP, then the SWT is enabled. But if the tool drives the $\overline{\text{EVTI}}$[0] pin low before asserting JCOMP pin, then the SWT is disabled. By default the SWT is enabled and a tool has an option to enable/disable the SWT using the $\overline{\text{EVTI}}$[0] pin.

65.1.3.4 Break control

The DCI provides central break control among the CPUs and non-CPU debug modules such as timers, DMA, Watchdog and other peripherals.

There are various different input sources that provide debug requests:

- $\overline{\text{EVTI}}$[1:0] signals from EVTI pads

- $\overline{\text{EVTI}}$[1:0] signals from JTAGM
- $\overline{\text{EVTI}}$[1:0] signals from the Sequence Processing Unit (SPU)

The DCI generates following debug request signals:

- Debug Request signal to be used for all non-CPU peripherals
- External Debug Request to be used to request external debug event to processor cores
- OnCE Debug Request to be used to request OnCE debug event to processor cores
- All break control requests are issued simultaneously to CPUs and peripherals, then synchronized to each clock domain

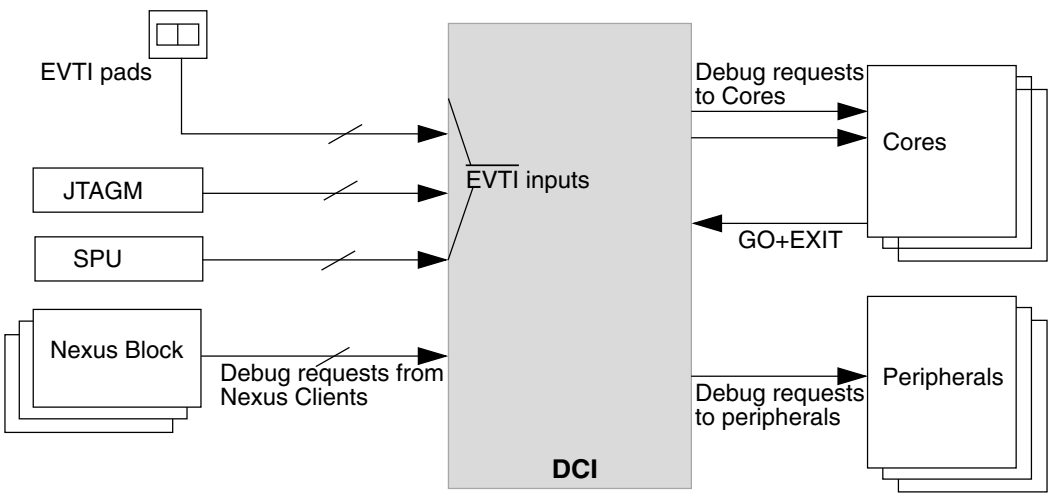

Figure 65-3. DCI debug control mechanism

The various sources of $\overline{\text{EVTI}}$[1:0] inputs are synchronized and logically ANDed in the DCI to generate two debug requests $\overline{\text{DCI_EVTI}}$[1:0] for the processor cores and non-CPU peripherals. Of these two inputs, $\overline{\text{EVTI}}$[0] is used to generate debug requests for non-CPU peripherals and for processor cores through the external debug request signal. The other input, $\overline{\text{EVTI}}$[1], is also used to generate debug requests for non-CPU peripherals and it generates debug requests to processor cores through the OnCE debug request signal.

The external debug request to processor core is asserted as a single cycle pulse and is synchronized on the respective core clock. The OnCE debug request is negated when the acknowledge signal from the Cores is asserted. The CPU(s) remain in the debug state until GO+EX command is executed for that CPU. Exiting a CPU out of debug state by executing GO+EX command does not take other CPUs out of debug state. The peripheral

debug request is negated when the processor core(s) execute GO+EXIT command. The $\overline{\text{EVTI}}$[1:0] signals coming from the pads are enabled for debug control using DCI_CR[5:4] bits.

In order to selectively enable/disable debug requests to system peripherals, the respective debug enable bit inside the peripheral should be used.

This figure shows the timing sequence.

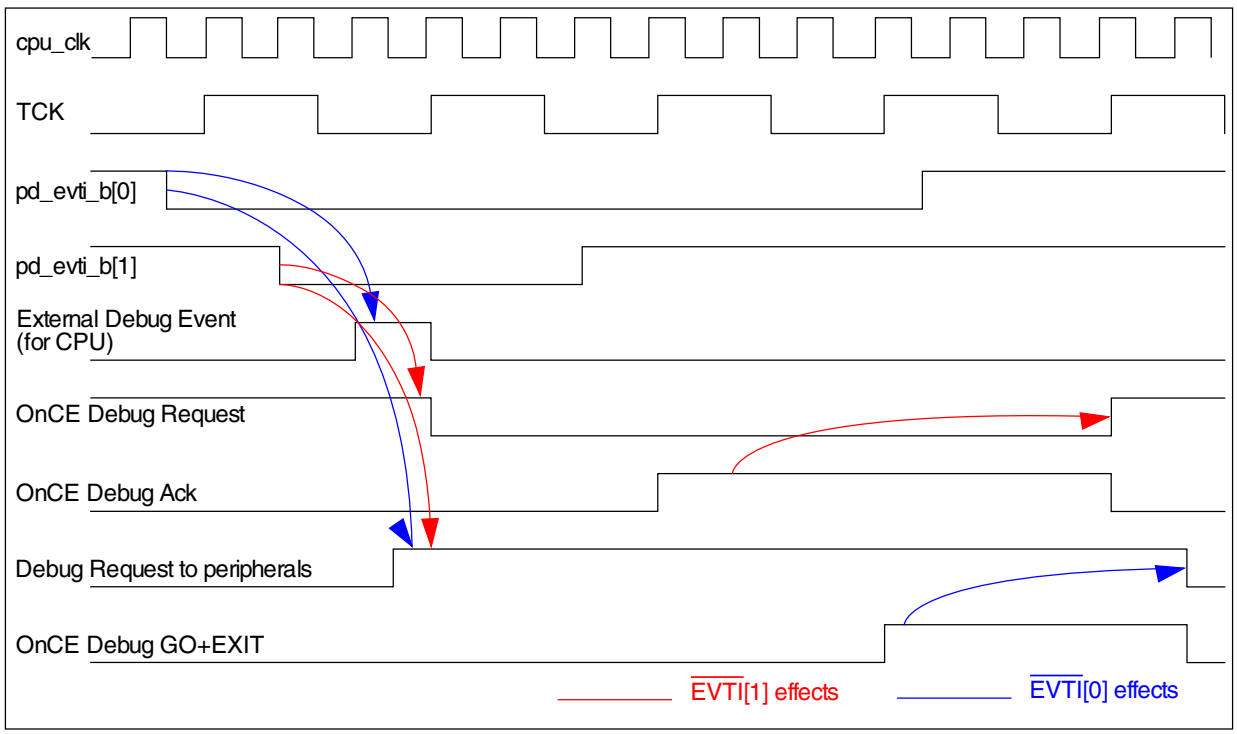

Figure 65-4. DCI debug signal generation

65.1.3.5 Cross-triggering control

Many of the blocks in the device, including the Nexus trace blocks and more sophisticated peripherals, have debug features that allow them to request device-wide breaks to enter debug mode. Many blocks can be programmed to halt operation upon debug mode entry or ignore it and continue normal operation. All debug mode entry requests are input to the DCI, ORed together and the result is used to produce the debug requests to the CPUs and non-CPU peripherals.

The cross-triggering feature is implemented through selectively enabling debug control bits in the respective modules. Processor cores (enabled using DBCR0[DEVT1] bit) and non-core peripherals can be programmed to halt operation through their respective control bits. Cross-triggering provides a selective feature to put modules in debug mode upon receiving halt request signals from Nexus modules.

65.1.3.6 Synchronous restart control

The DCI implements a synchronous restart control feature to synchronously restart all debug peripherals (CPU and non-CPU peripherals which are put in debug state). This is accomplished with the following steps:

1. The tool sequentially scans into CPUSCR for each processor core to restore the proper processor state.
2. The tool scans into the Production device tap controller the AUX_PARALLEL instruction, which then selects all processor core tap controllers in parallel.
3. To synchronously exit any combination of processor cores from debug mode, the tool simultaneously scans into all processor core tap instruction registers (OCMD) the 10-bit sequence 0x180 (i.e. set GO and EX, clear RS[0:6]).
4. If a processor core is out of debug mode, it sets a flag OnCE GO+EXIT.
5. When the OR of the processor core OnCE GO+EXIT signals is asserted, then all other selected non-processor cores and peripherals in debug would also be synchronously exited from debug mode. It is done by negating peripheral debug request signal.

65.1.3.7 EVTO management

The EVTO management block diagram is presented in the following figure.

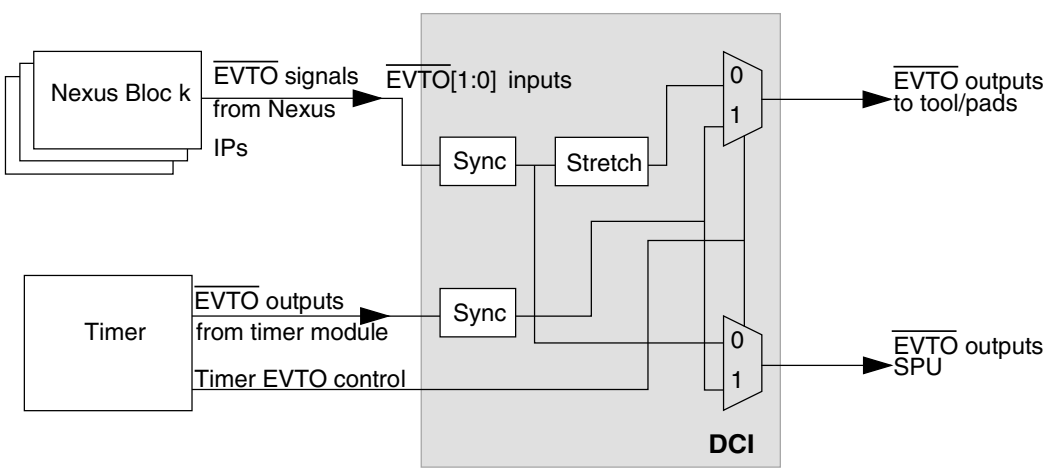

Figure 65-5. DCI EVTO management

The DCI module controls sharing of the EVTO outputs between all Nexus Clients including the cores that produce $\overline{\text{EVTO}}$[1:0] signals. The DCI uses a high frequency clock to sample EVTO signals coming from all modules which might generate EVTO outputs at their own clock frequency. After receiving a single clock period of asserted $\overline{\text{EVTO}}$[1:0] signals from any Nexus client, the DCI immediately asserts $\overline{\text{EVTO}}$[1:0] outputs and stretches it for a minimum of one output clock period for the output to the tool(Figure 65-6). The DCI also generates EVTO outputs in other device clock domains so that other Nexus clients can receive EVTO inputs without the need of any synchronization. EVTO function is active as long as the DCI is not in reset.

The DCI also allows the timer to take control of the EVTO outputs by controlling a timer register. If these fields are programmed to HALT/TIM/TOM/ATOM EVTO value, the timer EVTO outputs are directly available on the ports bypassing the stretch logic.

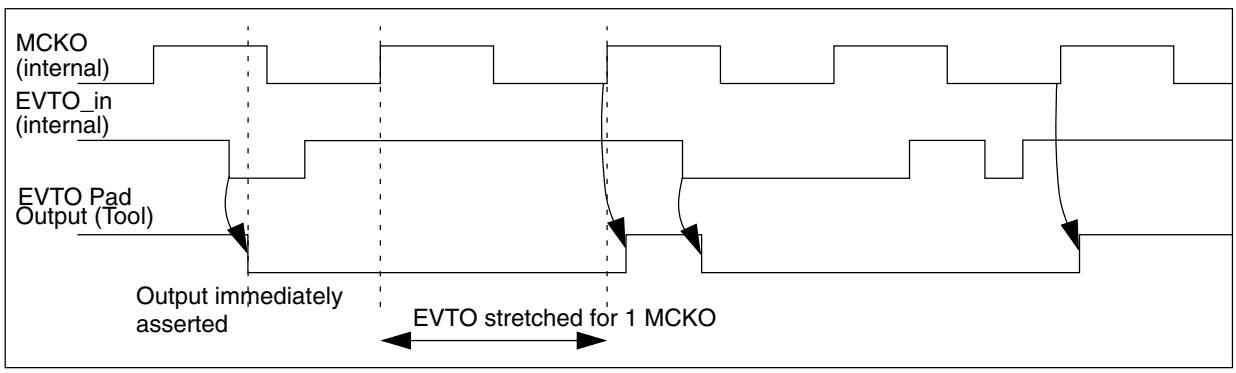

Figure 65-6. DCI EVTO timing diagram

65.1.3.8 Reset control

The DCI includes control bits to allow a connected tool to force a reset of the connected device. The description is as follows:

- Force functional reset—This reset is generated by programming the DCI_CR[FPD_FUNC] bit. When set, it forces functional reset. This bit has to be reset by the tool to negate the reset signal.
- Force POR or destructive reset—This reset is generated by programming DCI_CR[FPD_DEST] bit. When set it forces destructive reset. This bit has to be reset by the tool to negate the reset signal.

These reset signals are directly connected to the respective DCI_CR bits. The DCI does not reset the DCI_CR bits after generation of the respective reset signals. The tool must specifically reset the appropriate DCI_CR bits to remove the reset signals. These reset control bits can be set/reset through JTAG programming, and only reset through JCOMP assertion or Power-on-reset.

65.2 External signal description

The JTAGC module used inside DCI module defines the interface with external signals. It consists of five signals (TMS/TDI/TDO/TCK/JCOMP) that connect to off chip development tools and allow access to test support functions. For more details for JTAG signals, refer to JTAGC documentation.

65.3 Register description

The PD DCI module contains two registers, DCI_CR and DCI_PINCR, which are present inside the JTAGC module. These registers are only controlled using the JTAGC TAP and no memory-mapped registers are present.

65.3.1 DCI control register (DCI_CR)

The DCI_CR is a 32-bit data register. This register is programmed using JTAG shift with the corresponding enable instruction described in the JTAGC chapter. The following table shows the format of the DCI_CR.

	31	30	29	28	27	26	25	24
R W	Reserved							
Reset	1	1	1	1	1	1	1	1

	23	22	21	20	19	18	17	16
R W	Reserved							
Reset	1	1	1	1	1	1	1	1

	15	14	13	12	11	10	9	8
R W	Reserved					Reserved	FPD_FUNC	FPD_DEST
Reset	1	1	1	1	1	0	0	0

	7	6	5	4	3	2	1	0
R W	Reserved	Reserved	EVTI1_PAD_EN	EVTI0_PAD_EN	EVTO1_PAD_EN	EVTO0_PAD_EN	Reserved	Reserved
Reset	0	0	0	0	0	0	0	0

The DCI_CR is described in this table.

Table 65-4. DCI_CR field descriptions

Field	Description	
9 FPD_FUNC	Force functional reset	
	0	Do not force functional reset
	1	Force functional reset
8 FPD_DEST	Force destructive reset	
	0	Do not force destructive reset
	1	Force destructive reset
5 EVTI1_PAD_EN	$\overline{\text{EVTI}}$[1] feature enable	
	0	$\overline{\text{EVTI}}$[1] disabled (default)
	1	$\overline{\text{EVTI}}$[1] enabled
4 EVTI0_PAD_EN[1, 1]	$\overline{\text{EVTI}}$[0] feature enable	
	0	$\overline{\text{EVTI}}$[0] disabled (default)
	1	$\overline{\text{EVTI}}$[0] enabled
3 EVTO1_PAD_EN	Output enable for $\overline{\text{EVTO}}$[1] pad	
	0	$\overline{\text{EVTO}}$[1] pad output not enabled (default)
	1	$\overline{\text{EVTO}}$[1] pad output enabled

Table continues on the next page...

Table 65-4. DCI_CR field descriptions (continued)

Field	Description	
2 EVTO0_PAD_EN	Output enable for $\overline{\text{EVTO}}$[0] pad	
	0	$\overline{\text{EVTO}}$[0] pad output not enabled (default)
	1	$\overline{\text{EVTO}}$[0] pad output enabled

1. In an ED that has both PD and BD, EVTI1_PAD_EN and EVTI0_PAD_EN must be programmed in both BD and PD instances of the DCI in order to allow events generated on the BD to pass through the BD DCI and reach the PD DCI.

65.3.2 DCI EVTx pin multiplexing control register (DCI_PINCR)

The DCI_PINCR is a 32-bit data register. This register is programmed using JTAG shift with the corresponding enable instruction described in the JTAGC chapter. For a description of the DCI_PINCR functionality, see the Calibration and Debug configuration chapter which describes how the modules are configured.

Chapter 66
JTAG Controller (JTAGC)

66.1 Introduction

The JTAGC block provides the means to test chip functionality and connectivity while remaining transparent to system logic when not in test mode. Testing is performed via a boundary scan technique, as defined in the IEEE 1149.1-2001 standard. All data input to and output from the JTAGC block is communicated in serial format.

66.1.1 Block diagram

The following is a simplified block diagram of the JTAG Controller (JTAGC) block. Refer to the chip-specific configuration information as well as Register description for more information about the JTAGC registers.

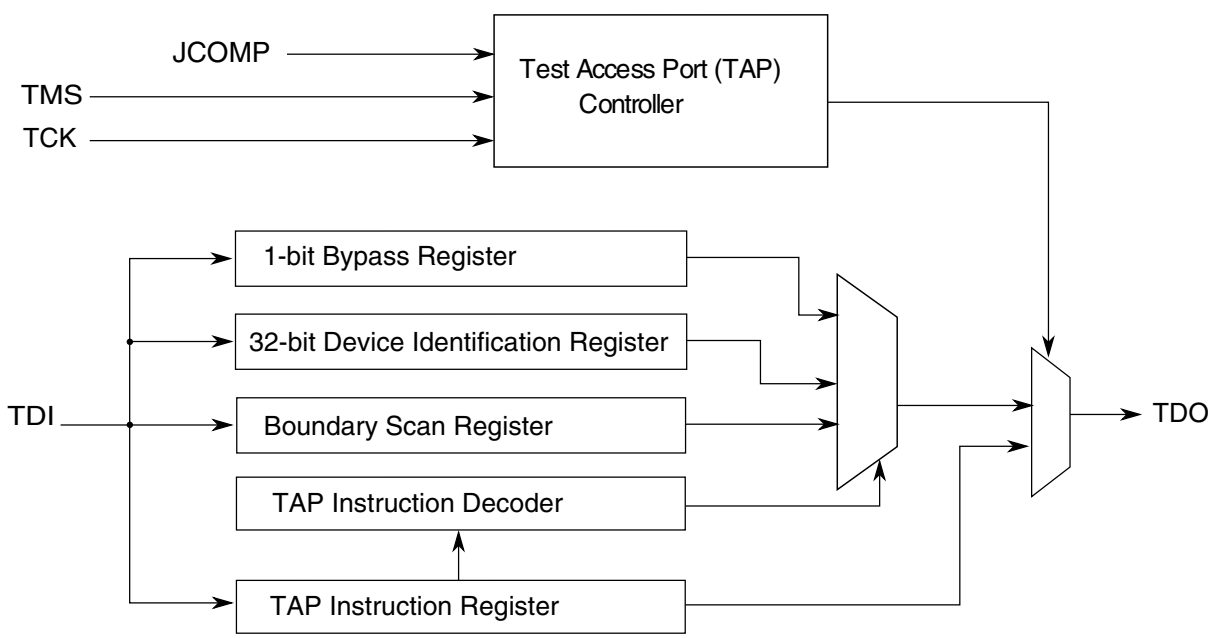

Figure 66-1. JTAG (IEEE 1149.1) block diagram

66.1.2 Features

The JTAGC block is compliant with the IEEE 1149.1-2001 standard, and supports the following features:

- IEEE 1149.1-2001 Test Access Port (TAP) interface
  - 4 pins (TDI, TMS, TCK, and TDO)
- JCOMP input that provides reset control
- Instruction register that supports several IEEE 1149.1-2001 defined instructions as well as several public and private device-specific instructions. Refer to Table 66-4 for a list of supported instructions.
- Sharing of the TAP with other TAP controllers via ACCESS_AUX_x instructions
- JTAG_PASSWORD register
- Bypass register, boundary scan register, data registers, and device identification register.
- TAP controller state machine that controls the operation of the data registers, instruction register and associated circuitry.

66.1.3 Modes of operation

The JTAGC block uses JCOMP and a power-on reset indication as its primary reset signals. Several IEEE 1149.1-2001 defined test modes are supported, as well as a bypass mode.

66.1.3.1 Reset

The JTAGC block is placed in reset when either power-on reset is asserted, JCOMP is negated, or the TMS input is held high for enough consecutive rising edges of TCK to sequence the TAP controller state machine into the Test-Logic-Reset state. Holding TMS high for five consecutive rising edges of TCK guarantees entry into the Test-Logic-Reset state regardless of the current TAP controller state. Asserting power-on reset or setting JCOMP to a value other than the value required to enable the JTAGC block results in asynchronous entry into the reset state. While in reset, the following actions occur:

- The TAP controller is forced into the Test-Logic-Reset state, thereby disabling the test logic and allowing normal operation of the on-chip system logic to continue unhindered
- The instruction register is loaded with the IDCODE instruction

66.1.3.2 IEEE 1149.1-2001 defined test modes

The JTAGC block supports several IEEE 1149.1-2001 defined test modes. A test mode is selected by loading the appropriate instruction into the instruction register while the JTAGC is enabled. Supported test instructions include EXTEST, HIGHZ, CLAMP, SAMPLE and SAMPLE/PRELOAD. Each instruction defines the set of data register(s) that may operate and interact with the on-chip system logic while the instruction is current. Only one test data register path is enabled to shift data between TDI and TDO for each instruction.

The boundary scan register is enabled for serial access between TDI and TDO when the EXTEST, SAMPLE or SAMPLE/PRELOAD instructions are active. The single-bit bypass register shift stage is enabled for serial access between TDI and TDO when the BYPASS, HIGHZ, CLAMP or reserved instructions are active. The functionality of each test mode is explained in more detail in JTAGC block instructions.

66.1.3.3 Bypass mode

When no test operation is required, the BYPASS instruction can be loaded to place the JTAGC block into bypass mode. While in bypass mode, the single-bit bypass shift register is used to provide a minimum-length serial path to shift data between TDI and TDO.

66.2 External signal description

The JTAGC consists of a set of signals that connect to off chip development tools and allow access to test support functions. The JTAGC signals are outlined in the following table and described in the following sections.

Table 66-1. JTAG signal properties

Name	I/O	Function	Reset State	Pull
TCK	Input	Test Clock	—	Down

Table continues on the next page...

Table 66-1. JTAG signal properties (continued)

Name	I/O	Function	Reset State	Pull
TDI	Input	Test Data In	—	Up
TDO	Output	Test Data Out	High Z[1, 1]	—
TMS	Input	Test Mode Select	—	Up
JCOMP	Input	JTAG Compliancy	—	Down

1. TDO output buffer enable is negated when the JTAGC is not in the Shift-IR or Shift-DR states. A weak pull may be implemented at the TDO pad for use when JTAGC is inactive.

66.2.1 TCK—Test clock input

Test Clock Input (TCK) is an input pin used to synchronize the test logic and control register access through the TAP.

66.2.2 TDI—Test data input

Test Data Input (TDI) is an input pin that receives serial test instructions and data. TDI is sampled on the rising edge of TCK.

66.2.3 TDO—Test data output

Test Data Output (TDO) is an output pin that transmits serial output for test instructions and data. TDO is three-stateable and is actively driven only in the Shift-IR and Shift-DR states of the TAP controller state machine, which is described in TAP controller state machine.

66.2.4 TMS—Test mode select

Test Mode Select (TMS) is an input pin used to sequence the IEEE 1149.1-2001 test control state machine. TMS is sampled on the rising edge of TCK.

66.2.5 JCOMP—JTAG compliancy

The JCOMP signal provides IEEE 1149.1-2001 compatibility and provides the ability to share the TAP. The JTAGC TAP controller is enabled when JCOMP is set to the JTAGC enable encoding, otherwise the JTAGC TAP controller remains in reset.

66.3 Register description

This section provides a detailed description of the JTAGC block registers accessible through the TAP interface, including data registers and the instruction register. Individual bit-level descriptions and reset states of each register are included. These registers are not memory-mapped and can only be accessed through the TAP.

66.3.1 Instruction register

The JTAGC block uses a 6-bit instruction register as shown in the following figure. The instruction register allows instructions to be loaded into the block to select the test to be performed or the test data register to be accessed or both. Instructions are shifted in through TDI while the TAP controller is in the Shift-IR state, and latched on the falling edge of TCK in the Update-IR state. The latched instruction value can only be changed in the Update-IR and Test-Logic-Reset TAP controller states. Synchronous entry into the Test-Logic-Reset state results in the IDCODE instruction being loaded on the falling edge of TCK. Asynchronous entry into the Test-Logic-Reset state results in asynchronous loading of the IDCODE instruction. During the Capture-IR TAP controller state, the instruction shift register is loaded with the value 000001b, making this value the register's read value when the TAP controller is sequenced into the Shift-IR state.

	5	4	3	2	1	0
R	0	0	0	0	0	1
W	Instruction Code					
Reset:	0	0	0	0	0	1

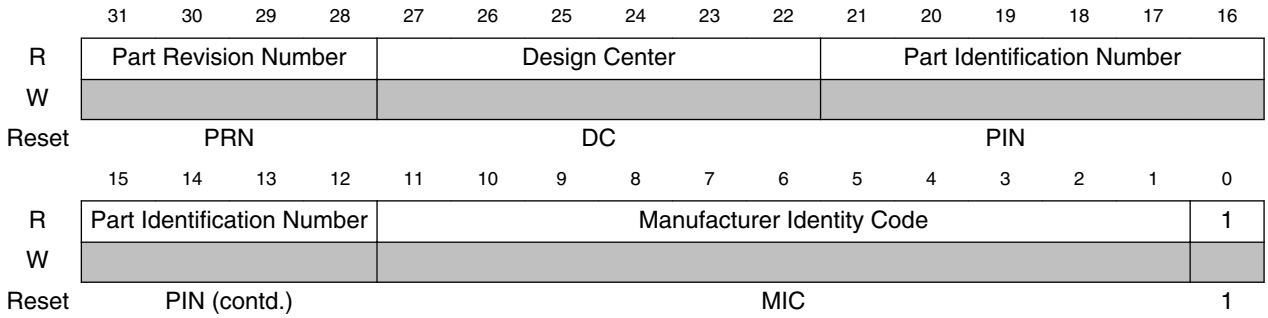

Figure 66-2. Instruction register

66.3.2 Bypass register

The bypass register is a single-bit shift register path selected for serial data transfer between TDI and TDO when the BYPASS, CLAMP, HIGHZ or reserve instructions are active. After entry into the Capture-DR state, the single-bit shift register is set to a logic 0. Therefore, the first bit shifted out after selecting the bypass register is always a logic 0.

66.3.3 Device identification register

The device identification (JTAG ID) register, shown in the following figure, allows the revision number, part number, manufacturer, and design center responsible for the design of the part to be determined through the TAP. The device identification register is selected for serial data transfer between TDI and TDO when the IDCODE instruction is active. Entry into the Capture-DR state while the device identification register is selected loads the IDCODE into the shift register to be shifted out on TDO in the Shift-DR state. No action occurs in the Update-DR state.

The following table describes the device identification register functions.

Table 66-2. Device identification register field descriptions

Field	Description
PRN	Part Revision Number. Contains the revision number of the part. Value is 0x1.
DC	Design Center. Indicates the design center. Value is 0x20.
PIN	Part Identification Number. Contains the part number of the device. 0x346.
MIC	Manufacturer Identity Code. Contains the reduced Joint Electron Device Engineering Council (JEDEC) ID. Value is 0x00E.
IDCODE ID	IDCODE Register ID. Identifies this register as the device identification register and not the bypass register. Always set to 1.

66.3.4 JTAG_PASSWORD register

The JTAG_PASSWORD register is a 256-bit shift register path from TDI to TDO selected when the ENABLE_JTAG_PASSWORD instruction is active. The default reset value of the JTAG_PASSWORD register is 256'b0. The JTAG_PASSWORD register transfers its value to a parallel hold register on the rising edge of TCK when the TAP controller state machine is in the Update-DR state. Once the ENABLE_JTAG_PASSWORD instruction is executed, the register value remains valid until a JTAG reset occurs. The operation of this register is described in the security documentation.

	255	...	2	1	0
R	JTAG_PASSWORD				
W					
Reset:	*[1]	*	*	*	*

1. The reset value of JTAG_PASSWORD is 256 'b0.

The following table describes the JTAG_PASSWORD register functions.

Table 66-3. JTAG_PASSWORD register field descriptions

Field	Description
JTAG_PASSWORD	JTAG Password. The JTAG_PASSWORD bits are used to provide the JTAG password for security.

66.3.5 Boundary scan register

The boundary scan register is connected between TDI and TDO when the EXTEST, SAMPLE or SAMPLE/PRELOAD instructions are active. It is used to capture input pin data, force fixed values on output pins, and select a logic value and direction for bidirectional pins. Each bit of the boundary scan register represents a separate boundary scan register cell, as described in the IEEE 1149.1-2001 standard and discussed in Boundary scan. The size of the boundary scan register and bit ordering is device-dependent and can be found in the device BSDL file.

66.4 Functional description

This section explains the JTAGC functional description.

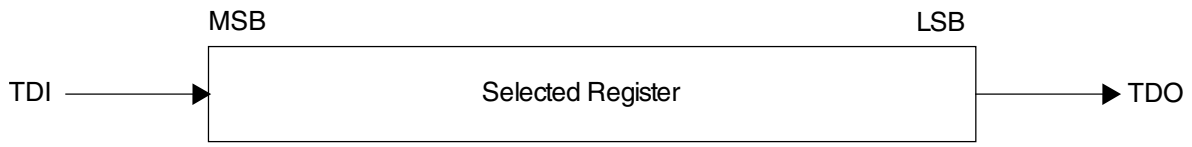
66.4.1 JTAGC reset configuration

While in reset, the TAP controller is forced into the Test-Logic-Reset state, thus disabling the test logic and allowing normal operation of the on-chip system logic. In addition, the instruction register is loaded with the IDCODE instruction.

66.4.2 IEEE 1149.1-2001 (JTAG) Test Access Port

The JTAGC block uses the IEEE 1149.1-2001 TAP for accessing registers. This port can be shared with other TAP controllers on the MCU. Ownership of the port is determined by the value of the currently loaded instruction. For more detail on TAP sharing via JTAGC instructions refer to ACCESS_AUX_x instructions.

Data is shifted between TDI and TDO though the selected register starting with the least significant bit, as illustrated in the following figure. This applies for the instruction register, test data registers, and the bypass register.



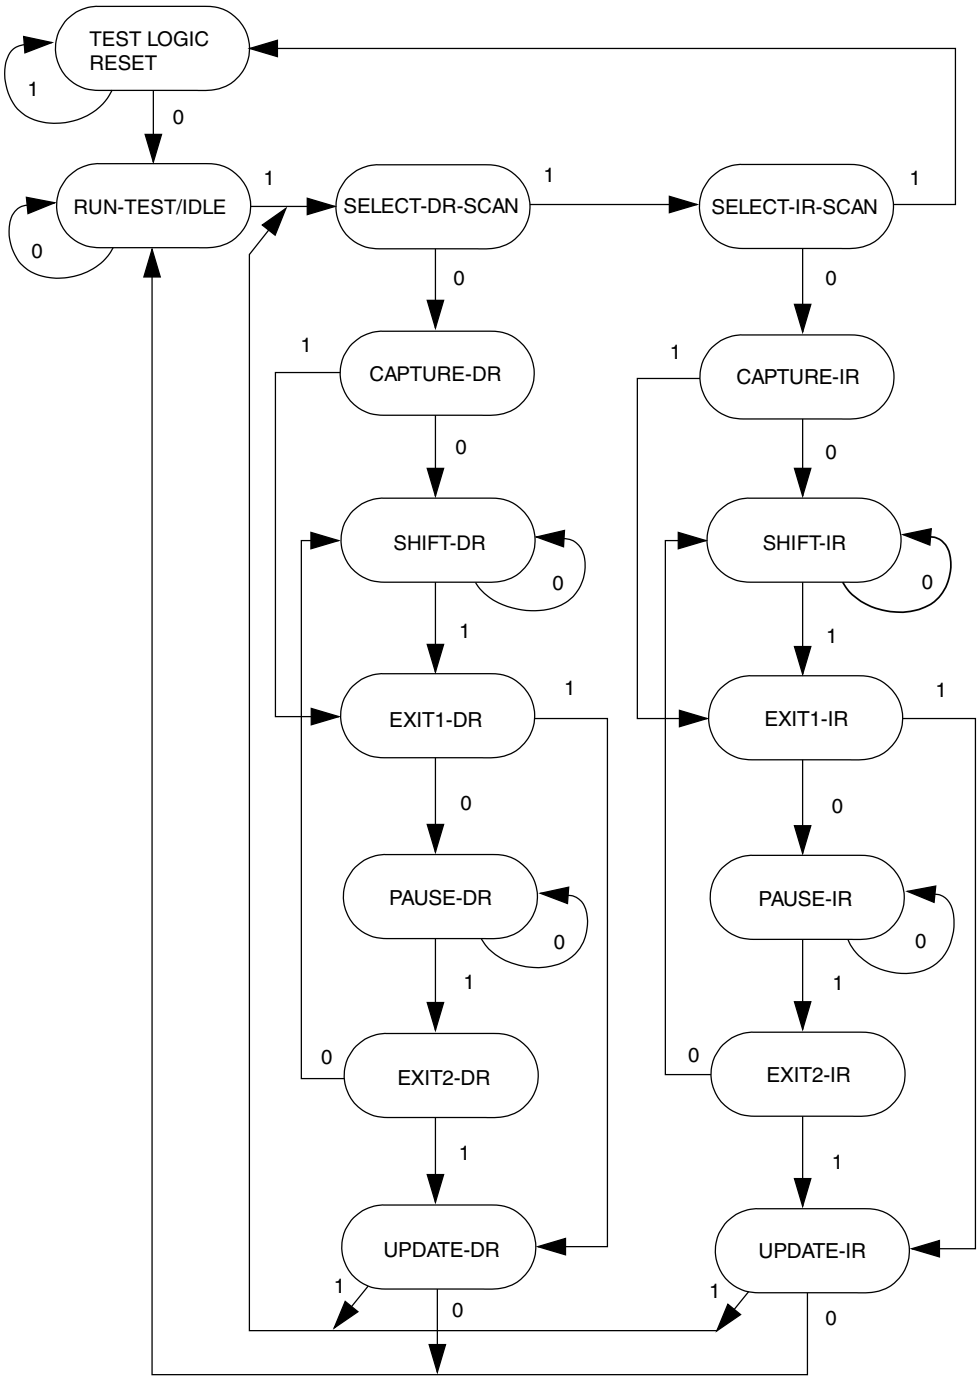


Figure 66-3. Shifting data through a register

66.4.3 TAP controller state machine

The TAP controller is a synchronous state machine that interprets the sequence of logical values on the TMS pin. The following figure shows the machine's states. The value shown next to each state is the value of the TMS signal sampled on the rising edge of the TCK signal. As the following figure shows, holding TMS at logic 1 while clocking TCK through a sufficient number of rising edges also causes the state machine to enter the Test-Logic-Reset state.

The value shown adjacent to each state transition in this figure represents the value of TMS at the time of a rising edge of TCK.

Figure 66-4. IEEE 1149.1-2001 TAP controller finite state machine

66.4.3.1 Enabling the TAP controller

The JTAGC TAP controller is enabled by setting JCOMP to a logic 1 value.

66.4.3.2 Selecting an IEEE 1149.1-2001 register

Access to the JTAGC data registers is achieved by loading the instruction register with any of the JTAGC block instructions while the JTAGC is enabled. Instructions are shifted in via the Select-IR-Scan path and loaded in the Update-IR state. At this point, all data register access is performed via the Select-DR-Scan path.

The Select-DR-Scan path is used to read or write the register data by shifting in the data (LSB first) during the Shift-DR state. When reading a register, the register value is loaded into the IEEE 1149.1-2001 shifter during the Capture-DR state. When writing a register, the value is loaded from the IEEE 1149.1-2001 shifter to the register during the Update-DR state. When reading a register, there is no requirement to shift out the entire register contents. Shifting may be terminated once the required number of bits have been acquired.

66.4.4 JTAGC block instructions

The JTAGC block implements the IEEE 1149.1-2001 defined instructions listed in the following table. This section gives an overview of each instruction; refer to the IEEE 1149.1-2001 standard for more details. All undefined opcodes are reserved.

Table 66-4. General 6-bit JTAG instructions

Instruction	Code[5:0]	Instruction Summary
IDCODE	000001	Selects device identification register for shift
SAMPLE/PRELOAD	000010	Selects boundary scan register for shifting, sampling, and preloading without disturbing functional operation
SAMPLE	000011	Selects boundary scan register for shifting and sampling without disturbing functional operation
EXTEST	000100	Selects boundary scan register and applies preloaded values to output pins. **NOTE:** Execution of this instruction asserts functional reset.
Factory debug reserved	000101	Intended for factory debug only
Factory debug reserved	000110	Intended for factory debug only
ENABLE_JTAG_PASSWORD	000111	Selects JTAG_PASSWORD register
HIGHZ	001001	Selects bypass register and three-states all output pins. **NOTE:** Execution of this instruction asserts functional reset.
Factory debug reserved	001010	Intended for factory debug only
CLAMP	001100	Selects bypass register and applies preloaded values to output pins. **NOTE:** Execution of this instruction asserts functional reset.

Table continues on the next page...

Table 66-4. General 6-bit JTAG instructions (continued)

Instruction	Code[5:0]	Instruction Summary
ENABLE_DCI_CR	001110	Enables access to DCI CR register
ENABLE_DCI_PINCR	001111	Enables access to DCI PINCR register
BYPASS	111111	Selects bypass register for data operations
Reserved[1]	All other opcodes	Decoded to select bypass register
ACCESS_AUX_x	100000-111110	Grants one of the auxiliary TAP controllers ownership of the TAP

1. The manufacturer reserves the right to change the decoding of reserved instruction codes in the future

The ACCESS_AUX instructions are described in the chip configuration debug information.

66.4.4.1 IDCODE instruction

IDCODE selects the 32-bit device identification register as the shift path between TDI and TDO. This instruction allows interrogation of the MCU to determine its version number and other part identification data. IDCODE is the instruction placed into the instruction register when the JTAGC block is reset.

66.4.4.2 SAMPLE/PRELOAD instruction

The SAMPLE/PRELOAD instruction has two functions:

- The SAMPLE portion of the instruction obtains a sample of the system data and control signals present at the MCU input pins and just before the boundary scan register cells at the output pins. This sampling occurs on the rising edge of TCK in the Capture-DR state when the SAMPLE/PRELOAD instruction is active. The sampled data is viewed by shifting it through the boundary scan register to the TDO output during the Shift-DR state. Both the data capture and the shift operation are transparent to system operation.
- The PRELOAD portion of the instruction initializes the boundary scan register cells before selecting the EXTEST or CLAMP instructions to perform boundary scan tests. This is achieved by shifting in initialization data to the boundary scan register during the Shift-DR state. The initialization data is transferred to the parallel outputs of the boundary scan register cells on the falling edge of TCK in the Update-DR state. The data is applied to the external output pins by the EXTEST or CLAMP instruction. System operation is not affected.

66.4.4.3 SAMPLE instruction

The SAMPLE instruction obtains a sample of the system data and control signals present at the MCU input pins and just before the boundary scan register cells at the output pins. This sampling occurs on the rising edge of TCK in the Capture-DR state when the SAMPLE instruction is active. The sampled data is viewed by shifting it through the boundary scan register to the TDO output during the Shift-DR state. There is no defined action in the Update-DR state. Both the data capture and the shift operation are transparent to system operation.

66.4.4.4 EXTEST External test instruction

EXTEST selects the boundary scan register as the shift path between TDI and TDO. It allows testing of off-chip circuitry and board-level interconnections by driving preloaded data contained in the boundary scan register onto the system output pins. Typically, the preloaded data is loaded into the boundary scan register using the SAMPLE/PRELOAD instruction before the selection of EXTEST. EXTEST asserts the internal system reset for the MCU to force a predictable internal state while performing external boundary scan operations.

66.4.4.5 ENABLE_JTAG_PASSWORD instruction

The ENABLE_JTAG_PASSWORD instruction selects the JTAG_PASSWORD register for connection as the shift path between TDI and TDO.

66.4.4.6 HIGHZ instruction

HIGHZ selects the bypass register as the shift path between TDI and TDO. While HIGHZ is active all output drivers are placed in an inactive drive state (e.g., high impedance). HIGHZ also asserts the internal system reset for the MCU to force a predictable internal state.

66.4.4.7 CLAMP instruction

CLAMP allows the state of signals driven from MCU pins to be determined from the boundary scan register while the bypass register is selected as the serial path between TDI and TDO. CLAMP enhances test efficiency by reducing the overall shift path to a

single bit (the bypass register) while conducting an EXTEST type of instruction through the boundary scan register. CLAMP also asserts the internal system reset for the MCU to force a predictable internal state.

66.4.4.8 ACCESS_AUX_x instructions

The JTAGC is configurable to allow other TAP controllers on the device to share the port with it. This is done by providing ACCESS_AUX_x instructions for each of these TAP controllers. When this instruction is loaded, control of the JTAG pins are transferred to the selected TAP controller. Any data input via TDI and TMS is passed to the selected TAP controller, and any TDO output from the selected TAP controller is sent back to the JTAGC to be output on the pins. The JTAGC regains control of the JTAG port during the UPDATE-DR state if the PAUSE-DR state was entered. Auxiliary TAP controllers are held in RUN-TEST/IDLE while they are inactive. Instructions not used to access an auxiliary TAP controller on a device are treated like the BYPASS instruction.

66.4.4.9 BYPASS instruction

BYPASS selects the bypass register, creating a single-bit shift register path between TDI and TDO. BYPASS enhances test efficiency by reducing the overall shift path when no test operation of the MCU is required. This allows more rapid movement of test data to and from other components on a board that are required to perform test functions. While the BYPASS instruction is active the system logic operates normally.

66.4.5 Boundary scan

The boundary scan technique allows signals at component boundaries to be controlled and observed through the shift-register stage associated with each pad. Each stage is part of a larger boundary scan register cell, and cells for each pad are interconnected serially to form a shift-register chain around the border of the design. The boundary scan register consists of this shift-register chain, and is connected between TDI and TDO when the EXTEST, SAMPLE, or SAMPLE/PRELOAD instructions are loaded. The shift-register chain contains a serial input and serial output, as well as clock and control signals.

66.5 Initialization/Application information

The test logic is a static logic design, and TCK can be stopped in either a high or low state without loss of data. However, the system clock is not synchronized to TCK internally. Any mixed operation using both the test logic and the system functional logic requires external synchronization.

To initialize the JTAGC block and enable access to registers, the following sequence is required:

1. Set the JCOMP signal to the JTAGC enable value, thereby enabling the JTAGC TAP controller
2. Load the appropriate instruction for the test or action to be performed

67.3 Introduction

The CJTAG module implements parts of the IEEE 1149.7 standard for test and debug capabilities. IEEE 1149.7 defines enhanced test and debug capabilities which are backwards compatible with IEEE P1149.1. This standard is also known as "Compact JTAG" or "CJTAG".

The module implements the following parts of the IEEE 1149.7 standard:

- IEEE 1149.1 compliant behavior while allowing multiple on-chip TAP controllers
- Ability to assert test reset
- Improved system scan performance with one-bit IR and DR chip bypass paths

- Physical connection of a Debug and Test System (external tool) to a running system without corrupting its operation
- Operation with both 4-pin and 2-pin scan topologies

67.3.1 Types of operation

The 1149.7 standard provides a scalable and flexible solution to meet the needs of varied component and system complexities. There are three types of operation:

- **Compliant**
  - Compliant with the IEEE 1149.1 standard
  - Four-pin operation using the "Standard Protocol" — IEEE 1149.1 signaling where TCK, TMS, TDI and TDO signals transfer control/data information
  - More than one TAPC may be associated with the TAP (once made visible by private instructions)
- **Extended**
  - Compatible with the IEEE 1149.1 standard
  - Four-pin operation using the "Standard Protocol" — IEEE 1149.1 signaling where TCK, TMS, TDI(C) and TDO(C) signals transfer control/data information
  - Additional test/debug functions
- **Advanced**
  - Two-pin operation using the "Advanced Protocol" — signaling where TCK(C) and TMS(C) signals transfer control/data information
  - The TMS(C) signal is operated in a bidirectional manner with the TMS, TDI and TDO TAP information serialized and transferred via this signal

67.3.2 Deployment by class

The TAP.7 capabilities are deployed using five capability classes (T0–T4), each matching the needs of certain scan topologies and mixes of 1149.1 TAPs and 1149.7 TAPs. The classes provide the following capability:

- **Compliant Operation** – provides behavior compliant with the IEEE 1149.1-2001 standard:
  - **Class T0** – 1149.1 compliance when multiple TAPs are used on the same chip.
- **Extended Operation** – extends the capabilities of the IEEE 1149.1-2001 standard:
  - **Class T1** – T0 + Test access port power management, functional reset, and test reset.
  - **Class T2** – T1 + Chip bypass (1-bit) for IR/DR Scans + hot-connection with no errors..
  - **Class T3** – T2 + Star operation (TAPs are paralleled) with series equivalent scans for test.
- **Advanced Operation** – adds capabilities addressing test and debug needs in complex environments:
  - **Class T4** – T3 + Scan with two pins with the Advanced Protocol. A number of protocol optimizations maximize scan performance. TDI(C)/TDO(C) pins are optional and may have programmable function when implemented.

67.3.3 1149.7 TAP signals

The TAP signals for the T0–T4 TAP.7 classes are listed in the following table. Signal names that end in "C" are associated with expanded functionality (above that provided by the IEEE 1149.1 standard).

The notation used in the table is as follows:

- M = Mandatory signal
- MC = Mandatory signal with expanded functionality
- O = Optional signal
- OC = Optional signal with expanded functionality

The CJTAG module provides T4 capability and implements the TCKC, TMSC, TDIC, TDOC and nTRST pins.

Table 67-2. TAP.7 signal list

Signal Name	Description	Class				
		T4	T3	T2	T1	T0
TCK/TCKC	Test clock	MC	M	M	M	M
TMS/TMSC	Test mode select	MC	M	M	M	M

Table continues on the next page...

Table 67-2. TAP.7 signal list (continued)

Signal Name	Description	Class				
		T4	T3	T2	T1	T0
TDI/TDIC	Test data input	OC	MC	M	M	M
TDO/TDOC	Test data output	OC	MC	M	M	M
nTRST	Test reset	O	O	O	O	O
Mandatory signal count (minimum)		2	4	4	4	4

67.3.4 TAP.7 architecture

The TAP.7 hardware architecture is shown in the following figure. It is described with the hardware layers listed below:

- **STL – System Test Logic** – Logic with 1149.1 compliant behavior and underlying TAP hierarchy (T0 capabilities). Provides an IEEE 1149.1 interface for the T0 TAP. 7. This logic is outside the CJTAG module.
- **RSU – Reset and Selection Unit** – A hardware layer that is placed between the APU, EPU, or STL and the TAP.7 signals (Added as an option to support the use of the Control Protocol) Provides reset and TAP.7 Controller selection services.
- **EPU – Extended Protocol Unit** – A hardware layer that is placed between the STL and the TAP.7 signals. (Added for T1, T2, and T3 capabilities). Provides an IEEE 1149.1 interface for the T1–T3 TAP.7s.
- **APU – Advanced Protocol Unit** – A hardware layer that is placed between the STL/ EPU and the TAP.7 signals (added for T4 capabilities). Provides a T4 TAP.7 interface that is either narrow or wide, with the wide version providing an IEEE 1149.1 interface.

The CJTAG module supports T4 functionality that includes STL, RSU, EPU, and APU hardware layers.

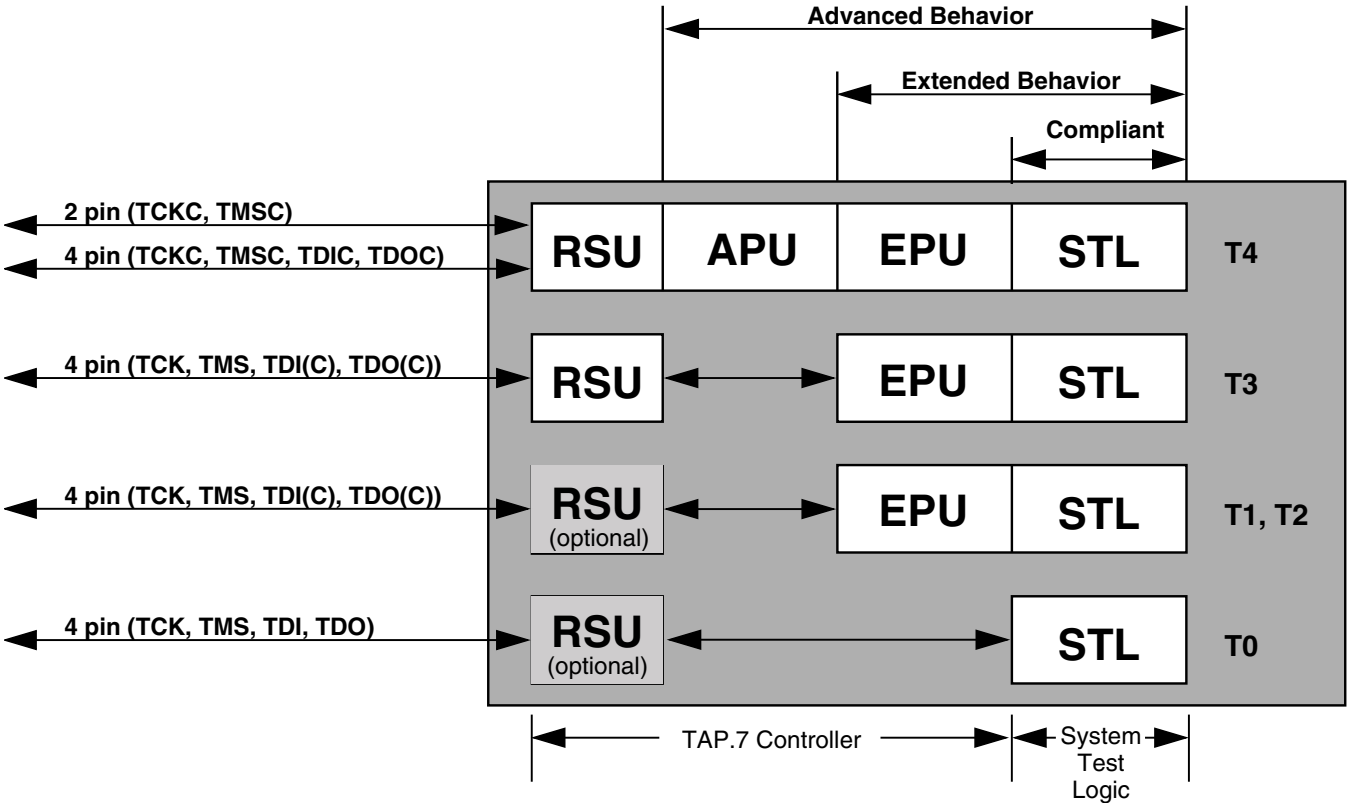

Figure 67-1. TAP.7 Controller Architecture

67.3.5 Protocols

The TAP.7 architecture utilizes the three protocols shown in the following figure.

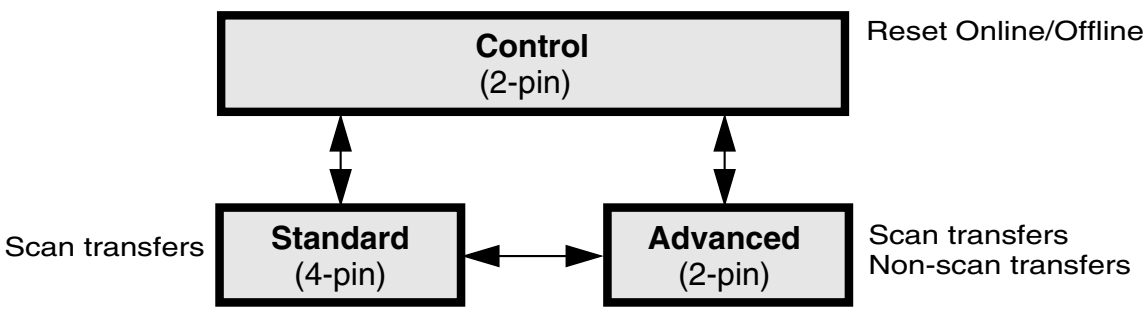

Figure 67-2. TAP.7 Behaviors

The Standard Protocol transfers data with the TMS(C) signal value being sampled with a TCK(C) edge. The Advanced and Control Protocols use both data transferred with the TMS(C) signal value being sampled with a TCK(C) signal edge and escape sequences. The Standard Protocol may be used to switch to the use of the Advanced Protocol and

vice versa. The Control Protocol can also be used to switch between the use of the Standard and the Advanced Protocol. The mandatory and optional deployment of these protocols with the TAP.7 classes is shown in the following table.

Table 67-3. Class/protocol relationship

Class	Protocol		
	Standard	Control	Advanced
T0 – T2	Mandatory	Optional	N/A
T3	Mandatory	Mandatory	N/A
T4	Mandatory	Mandatory	Mandatory

The CJTAG module implements T4 functionality and supports the Standard, Advanced, and Control Protocols.

67.3.5.1 Standard Protocol

The Standard Protocol is the signaling defined by the IEEE 1149.1 standard. This protocol is also used to implement TAP.7 commands using only the TCK(C) and TMS(C) signals in a manner that does not require either TAP.7 controller instruction or data registers. The TAP.7 controller does not add bits to the scan paths of underlying technology. The Standard Protocol can be used to manage the TAP.7 controller functionality independent of the function associated with the availability of the TDI and TDO signals. The Standard Protocol supports STL data transfers only when these signals are present and provide the 1149.1 functionality defined by the IEEE 1149.1 standard.

67.3.5.2 Advanced Protocol

The Advanced Protocol supports both STL data transfers and management of the TAP.7 controller functionality with both the 2-signal (narrow) and 4-signal (wide) configurations. The Advanced Protocol serializes the TMS, TDI, and TDO information used with the Standard Protocol using only the TCK(C) and TMS(C) signals. A number of additional scan formats provide bit sequences optimized for specific use cases. Each of these additional scan formats affects the TMSC signaling sequences.

67.3.5.3 Control Protocol

The Control Protocol uses Escape sequences to reset the TAP.7 controller, place a TAP.7 controller offline or online, and indicate End of Transmission (EOT) with the Advanced Protocol. The characteristics of this protocol provide Hot-Connect-Protection by requiring a preamble of alternating ones and zeroes preceding a selection escape when a TAP controller is started up offline.

67.4 Operating models

The following figure illustrates a simplified view of the CJTAG operating model.

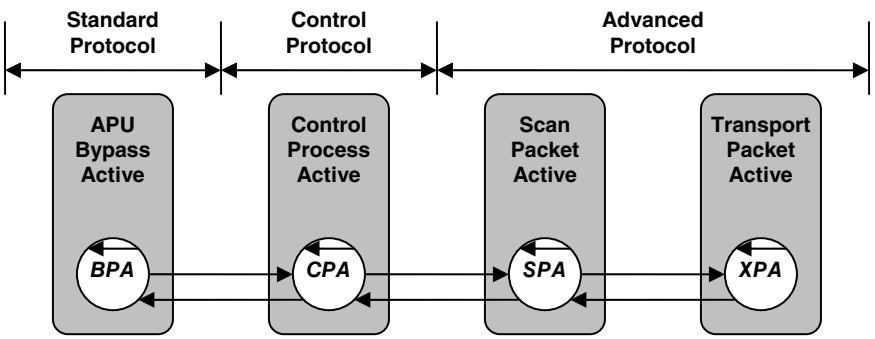

Figure 67-3. CJTAG operating model

67.5 CJTAG implementation summary

The CJTAG module is a T4 TAP.7 controller that implements the following functions.

67.5.1 T0 functions

- IDCODE. - implemented in chip level TAPC (JTAGC module)
- 1149.1 Compliance at start-up
- Isolating / Excluding of embedded TAPs – implemented in chip level TAPC (JTAGC module)
- Operation with other technologies and scan topologies
- Multiple embedded TAPs

67.5.2 T1 functions

- EPU Command processing
- EPU Class-Specific Registers
- Asserting a test reset to the STL (TRESET Register)

67.5.3 T2 functions

- "Super Bypass" function – JScan0, JScan1, JScan2 scan formats. Allows the STL to be coupled or decoupled.

67.5.4 T3 functions

- Generation of a TAP.7 controller reset with a Reset Escape Sequence
- JScan3 Scan Format

67.5.5 T4 functions

- TMSC sampling on rising edge or falling edge of TCKC
- MScan (For test and debug)
- OScan 0-7
- TDIC and TDOC / Alternate pin function multiplexing (wide 4 only)

67.6 Ancillary services

67.6.1 Overview

Ancillary services are pertinent to any TAP.7 controller implemented with an RSU, such as the CJTAG module.

Ancillary services include:

- Resets
- Start-up options

- Escape sequences
- TAPC state machine

67.6.2 Resets

The TAP.7 controller reset function expands the reset function provided by the IEEE 1149.1 standard to provide additional reset types. It supports six reset types, Type-0 – Type-5, listed below. It can be implemented with as few as two reset types (Type-2 and Type-4), or as many as six reset types (all types) of reset inputs: This is determined by the class and options implemented.

The CJTAG module utilizes Type-0, Type-2, Type-3, Type-4, and Type-5 resets.

- **Type-0** – Reset of the TAP.7 by power management logic (power-on reset)
- **Type-1** – Chip level generated Test Reset. (equivalent to Type-2)
- **Type-2** – Externally generated Test Reset (nTRST/nTRST_PD pin)
- **Type-3** – TAP.7 controller generated reset
- **Type-4** – *Test-Logic-Reset* state
- **Type-5** – TAP.7 Controller TReset Register reset of the CLTAPC.

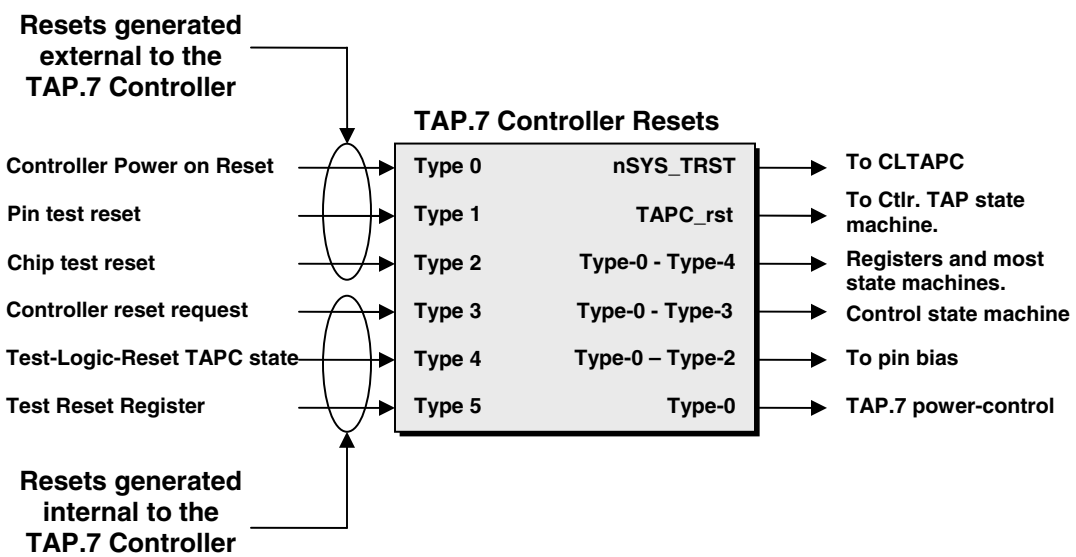

Figure 67-4. Conceptual view of the EPU reset logic and state machines

67.6.2.1 Type 5 reset

A Type-5 reset affects only the STL via the nSYS_TRST pin. It is asserted when the TRESET Register value is a logic 1. This register is set to its inactive state by reset Types 0-4.

67.6.2.2 Type 4 reset

A Type-4 reset is created by the *Test-Logic-Reset* state. It does not affect the TAP.7 TAPC state machine state as this state is the source of this reset, nor does it cause the assertion of the nSYS_TRST signal. It does however affect the coupling and decoupling of the STL. The Type-4 reset initializes the TAP.7 registers and most controller state machines. It affects but does not initialize the control state machine managing TAP.7 controller selection. It also establishes the default operating conditions.

67.6.2.3 Type 3 reset

A Type-3 reset is created by reset requests generated by the TAP.7 controller. A Type-3 reset performs the functions associated with a Type-4 reset and creates the *Test-Logic-Reset* state.

A Type-3 reset is generated in response to reset requests generated by EPU and APU logic

- A reset escape sequence
- Reset protocol sequences (delay packet directive, check packet directive)

A Type-3 reset request is generated with a reset escape sequence. This function is similar to but not the same as the reset function generated by a test reset pin. The Advanced Protocol includes certain bit patterns that initiate Type-3 resets. These bit patterns assist in the initialization of the TAP.7 controller when the TCKC signal is sourced by the TS and the external tool/TS connection is broken. The external tool may also generate these sequences, if desired, while the external tool/TS connection remains intact. These reset requests cause a Type-3 reset that is one clock wide.

With this being the case, consideration may be given to integrating the CJTAG module without the use of the Test Reset signal (nTRST/nTRST_PD pin).

67.6.2.4 Type 2 reset

A Type-2 reset is created by chip level logic to initialize the TAP.7 controller when TAP.7 power control is not implemented. It is unimplemented otherwise. It performs all of the functions of the Type-3 reset in addition to initializing the escape sequence detection logic.

67.6.2.5 Type 1 reset

A Type-1 reset is created with either the nTRST or nTRST_PD pin. It is not created when neither of these pins is implemented. It performs all of the functions of the Type-2 reset. It initiates TAP.7 controller power down provided the TAP.7 power control mode permits power down.

67.6.2.6 Type 0 reset

A Type-0 reset is implemented when TAP.7 controller power down is implemented. It performs all of the functions of a Type-1 reset and also initializes the TAP.7 power control logic.

67.6.2.7 Reset State Machine

The Reset State Machine assists in the translation of the reset inputs to the reset outputs. It handles Type-3 reset controller reset requests. The state machine state assures Type-0, Type-1, and Type-2 resets are forwarded to the STL without modifying their duration.

This state machine allows a Type-3 reset only when its state is “T3 Reset” (two TCK(C) falling edges have occurred in the absence of a Type-0, Type-1, and Type-2 reset).

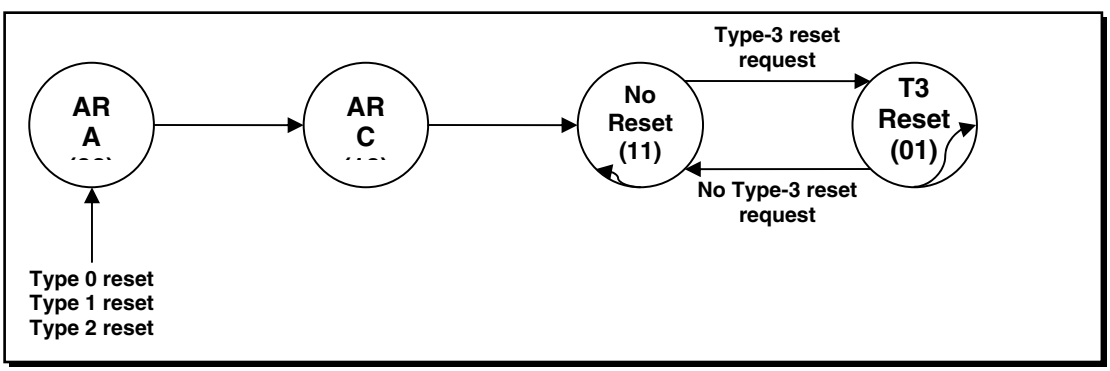

Figure 67-5. Reset state machine

Table 67-4. Reset state descriptions

Reset state		Description
ARA	Async. Reset Asserted	An async. reset has occurred or is occurring
ARC	Async. Reset Completed	An async. reset has occurred and has been released
No Reset	No Reset	No Reset
T3 Reset	Type-3 Reset	A Type-3 reset request has been processed.

Type-0, Type-1, and Type-2 resets are fully asynchronous. These resets are passed directly to nSYS_TRST without modification. The Type-3, Type-4, and Type-5 resets are fully synchronous.

The effects of the TAP.7 controller reset types are shown in the following table.

Table 67-5. Reset effects

Reset	CLTAPC	Pin-Hi-Z	State Machines other than CSM	Control State Machine (CSM)	TAPC SM State	Escape Sequence Detection	Power Control State
Type-5	Yes	–	–	–	–	–	–
Type-4	–	Yes	Yes	–	–	–	–
Type-3	Yes	Yes	Yes	Yes	Yes	–	–
Type-2	Yes	Yes	Yes	Yes	Yes	Yes	–
Type-1	Yes	Yes	Yes	Yes	Yes	Yes	–
Type-0	Yes	Yes	Yes	Yes	Yes	Yes	Yes

67.6.3 Start-up Options

67.6.3.1 Overview

The TAP.7 start-up options are shown in the following table. The only startup option currently supported by the CJTAG module is 1149.1 Compliant.

Table 67-6. Start-up Options

Start-up Option	Description
1149.1 Compliant	TAP.1 signal functionality, the CLTAPC is coupled
1149.1 Compatible	TAP.7 signal functionality, the CLTAPC is decoupled

Table continues on the next page...

Table 67-6. Start-up Options (continued)

Start-up Option	Description
1149.1 Protocol Compatible	No, or alternate TDIC/TDOC signal functionality, the CLTAPC is decoupled.
Offline-at-Start-up (Dormant)	The TAP.7 controller is offline and awaits synchronization to external tool operation so as to be placed online, the CLTAPC is decoupled after its state is moved to *Run-Test/Idle*

67.6.3.2 1149.1 Compliant start-up

Start-up behavior with the 1149.1 Compliant behavior start-up option:

- 1149.1-specific behavior / Standard protocol
- The TAPC finite state machine operated in lock step with the CLTAPC finite state machine.
- The TDIC and TDOC pins are present and provide the TDI and TDO function.
- The CLTAPC is coupled at start-up.

With this start-up option, the TAP.7 controller may be programmed and the scan topology may be interrogated. If the scan topology is known to be the Series Scan Topology at power-up, the TAP.7 can be operated as though it is a TAP.1.

Table 67-7. Reset values for TAP.7 startup options

Start-up Option	Type-0 – Type-3 Reset?	Default TAP.7 and TAP.7 controller characteristics				
		TAP.7 Controller online	CLTAPC Coupled	SGC Reg. == 1	SCNFMT	Initial TMSC pin bias
1149.1 Compliant	x	Yes	Yes	Yes	JScan0	PU

67.6.4 RSU operation

The RSU uses TCKC and TMSC with the control protocol for configuration control.

67.6.4.1 General Operation

From a very high level, the RSU enables the remainder of the TAP.7 functionality when the TAP.7 controller is Online and disables the remainder of the TAP.7 functionality otherwise. The RSU either consumes or discards the TMS(C) information while the TAP. 7 controller is Offline. The relationship of the escape sequence detection, technology selection logic, and the underlying technology is shown in the following figure.

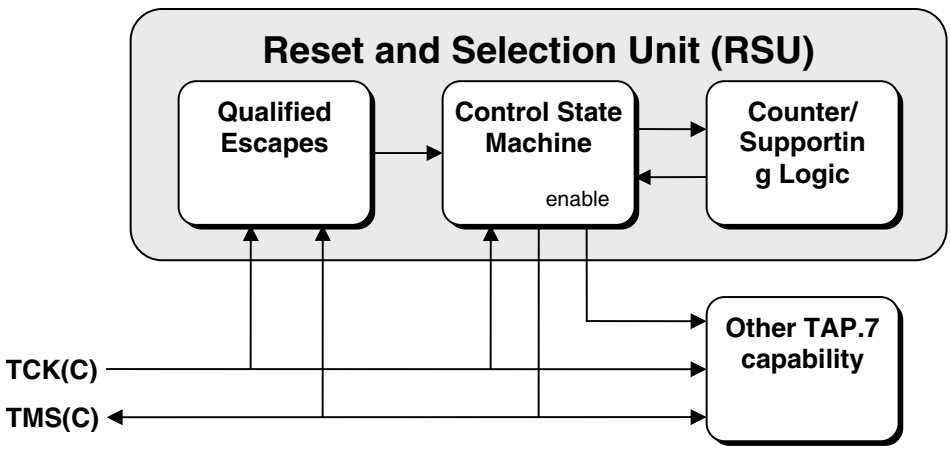

Figure 67-6. Conceptual view of technology selection mechanism

67.6.4.2 Common Signaling Across Technologies

With the TAP.7 architecture, the signaling conventions chosen for technology selection is multiple data transitions of the TMS(C) signal while the TCK(C) signal is a logic 1. The common signaling space is available when the external tool sources the TCK(C) signal as it is capable of creating these signaling conventions. It is unavailable when the TS sources the TCK(C) signal as the external tool cannot stop the TCKC signal at a logic 1 to create these signaling conventions.

67.6.4.3 Escape Sequence Detection

TAP.7 TAPC interprets the count of the number of TMS(C) edges while TCK(C) is a logic 1 as one of four escape sequences. Each escape sequence has a different function and TMSC edge count. These escape sequences, their edge counts, and their functions are described below:

- **Custom** (2 or 3 edges) – Ends scan and transport transfers with a TAP.7 controller, may be used for other purposes with another technology.
- **Reset** (> 7 edges) – Resets all technologies (generates a Type-3 TAP.7 TAPC reset)

The external tool creates an escape sequence by generating one or more TMS(C) edge pairs while the TCK(C) signal is a logic 1 value. Even and odd TMS(C) edge counts beginning with two are given the same meaning.

An escape sequence:

- Can be detected only when a Type-0, Type-1 or Type-2 reset is **not** asserted.
- Begins and ends while the TCK(C) is a logic 1.
- Uses TMS(C) as a clock while the TCK(C) is a logic 1.
- Overlays additional control information onto the normal information that is transferred with the TCK(C) and the TMS(C) without changing the normal information.
- Must be detected when TCK(C) is a logic 1 regardless of the TCK(C) and TMS(C) drive histories.

67.6.4.3.1 Custom escape sequence

An online technology can use the custom escape sequence in any manner it chooses. It is used as the End of Transmission (EOT) of certain data types (formats OScan4-7) with T4 and above TAP.7s.

67.6.4.3.2 Reset escape sequences

A reset event initializes all technologies sharing the TCK(C) and TMS(C) connectivity. A reset escape sequence resets the technology. It is recommended that this reset occur with the falling edge of TCKC. With a TAP.7 controller a reset escape sequence generates a Type-3 reset beginning with the falling edge of TCK(C) following the asynchronous detection of the event.

67.6.5 TAPC State Machine

T1 and above TAP.7s require knowledge of the TAPC state machine state. With T2 and above TAPs this knowledge must be developed independently of the CLTAPC. This is generally accomplished by implementing a TAPC state machine within the EPU. This TAPC state machine provides the function of the state machine within a standard 1149.1 TAPC. It is recommended that this state machine is implemented to change state on the falling edge of TCK(C) as this has numerous advantages to a TAP.7 controller. The EPU does not contain 1149.1 Instruction or Data Registers. The APU controls the state changes of this TAPC state machine with T4 and above TAP.7s.

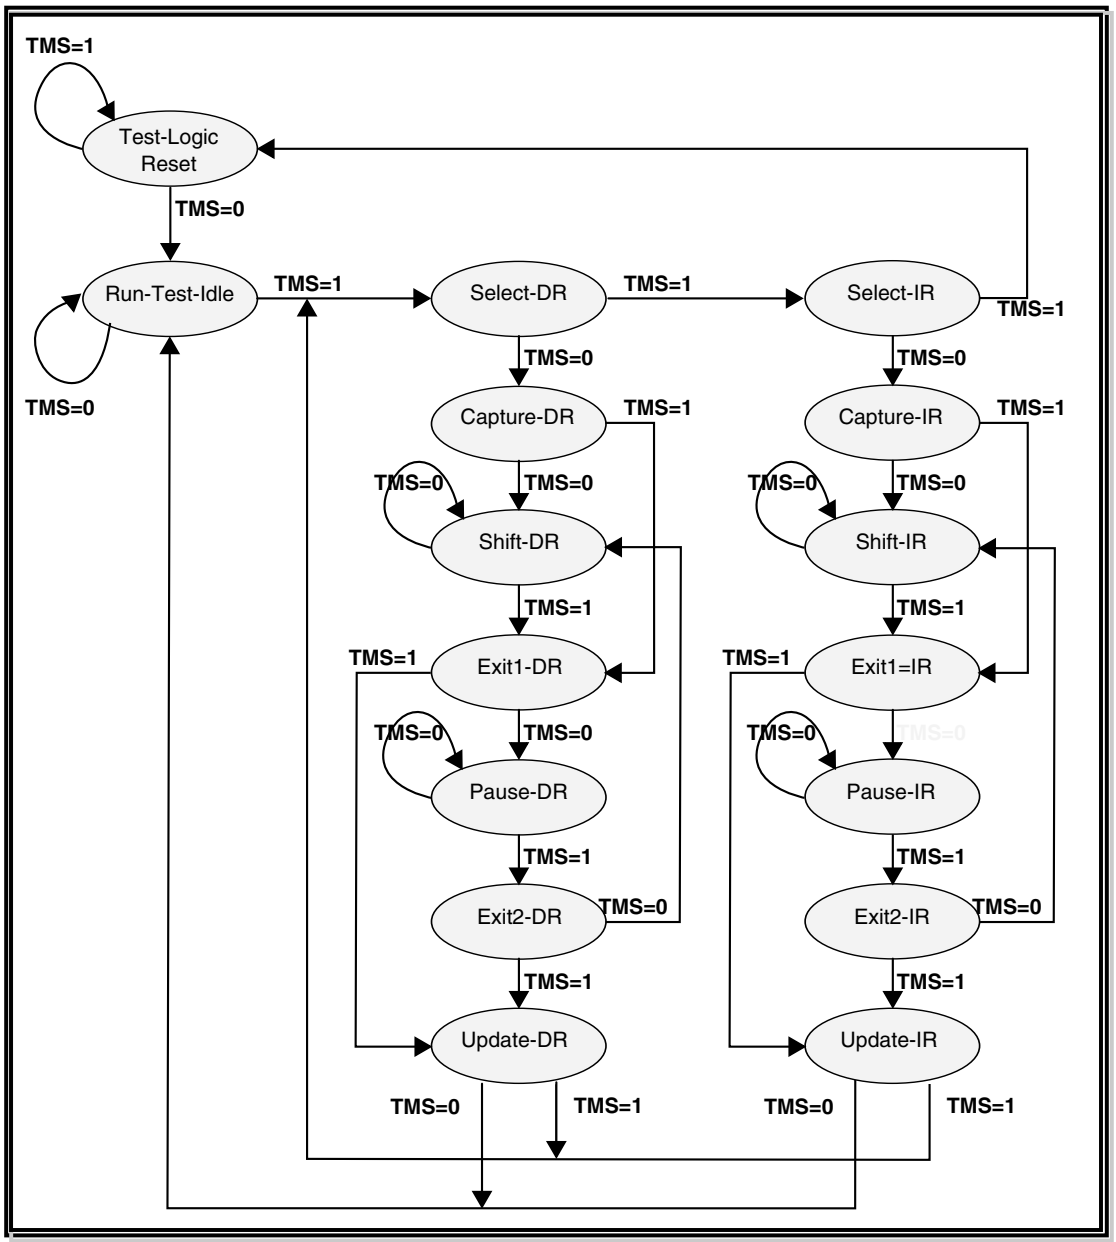

Figure 67-7. Falling edge TAP controller state machine

67.7 EPU (Extended Protocol Unit) Operation

67.7.1 EPU Operation

The EPU adds functionality to the BYPASS and IDCODE instructions.

67.7.1.1 Zero-bit DR-Scans (ZBS)

A zero-bit DR-Scan (ZBS) is a TAPC-state sequence that begins with the *Select-DR-Scan* state and ends with an exit from the *Update-DR* state without an intervening *Shift-DR* state. The external tool controls the EPU using ZBSs.

The use of ZBSs can begin immediately following the *Test-Logic-Reset* state since this state initializes the Instruction Registers of TAPs with either the *BYPASS* or *IDCODE* instructions.

67.7.1.2 Utilizing ZBSs for TAP.7 Controller Functionality

Beginning with a ZBS count of zero, the ZBS count is incremented with each consecutive occurrence of a ZBS without encountering a *Shift-DR* state. This count cannot be incremented past seven. *Run-Test/Idle* is the only state that may occur between consecutive occurrences of ZBSs without terminating the count of consecutive ZBSs.

67.7.1.3 Locking the ZBS Count

When a DR-Scan containing a *Shift-DR* state occurs, and the ZBS count is greater than zero, the ZBS count is not incremented when the *Update-DR* state is reached. It is instead locked at its current value. ZBSs occurring after locking the ZBS count do not affect the locked ZBS count. Locking the ZBS count is the equivalent of storing the count for subsequent use.

67.7.1.4 Control levels

Locking the ZBS count activates a control level that is equal to the locked ZBS count (1-7) when ZBSs are being used for TAP.7 functionality and merely locks the ZBS count otherwise.

1. ZBSs may be used by the STL or another function
2. TAP.7 command generation
3. Reserved control level
4. Accesses to optional TAP.7 scan paths
5. Accesses to optional TAP.7 scan paths

6. Force offline operation (optional)
7. External tool uses

Control level one may be used by the STL since there is no TAP.7 controller functionality associated with this control level.

Control level two enables DR-Scans to create TAP.7 commands. A portfolio of these commands supports the deployment of TAP.7 controllers in the Series or Star Scan Topologies. These commands manage TAP.7 controller registers and perform other functions.

Control level three is reserved for use with a subsequent specification revision.

Control levels four and five provide access to custom (private) scan paths when access to these paths is permitted by a TAP.7 register bit used for this purpose. The EPU provides a 1-bit scan path otherwise. No other EPU functionality is associated with these control levels. The CJTAG module does not support the use of this control level.

Control level six may be optionally used to force offline operation with a TAP.7 controller that supports this capability. The EPU provides a 1-bit scan path for this control level. The CJTAG module does not support the use of this control level.

Control level seven is reserved for external tool use. With this control level, external tool capabilities may be managed using the same infrastructure used to manage TAP.7 controller capability. The EPU provides a 1-bit scan path for this control levels.

67.7.1.5 Exiting a Control Level

A control level is exited when one of the following occurs:

- The *Select-IR-Scan* TAP.7 controller state
- The *Test-Logic-Reset* state
- Certain TAP.7 controller commands (Exit Control Level – ECL register bit)
- An event that synchronizes the operation of TAP.7 controllers

67.7.1.6 Zeroing the ZBS Count

Events causing an exit from a control level also zero the ZBS count. Scan Selection Directives (SSDs) associated with T3 and above TAP.7s zero the ZBS count when the control level has not been locked.

67.7.1.7 Utilizing ZBSs within the STL

After the *Test-Logic-Reset* state, ZBSs are used for basic EPU control. ZBSs that are intended for TAP.7 use are henceforth called "***TAP.7 ZBSs***". ZBSs that are intended for other uses are henceforth called "***Other ZBSs***". Two TAP.7 registers enable the STL's use of ZBSs. Storing these registers causes a control level exit, zeroes the ZBS count, and enables the use of Other ZBSs. Storing the Suspend Register (**SUSPEND**) suspends the use of control levels. Storing the ZBS Inhibit Register (**ZBSINH**) inhibits ZBS detection.

When either of these methods is used, the *Test-Logic-Reset* state enables the use of TAP. 7 ZBSs in addition to initializing the TAP.7 controller.

The operation of the TAP.7 controller changes with the use of these two paths.

When the System Path is used:

- A count of eight consecutive ZBSs is used to create a logic 0 SUSPEND Register value.
- The CLTAPC supplies the TAP.7 scan path and controls the drive of TDO(C), provided it is not bypasses.
- The EPU supplies the TAP.7 scan path (a one bit bypass) when the CLTAPC is bypassed.
- Functions supporting Boundary Scan in a Star Scan Topology are enabled.

When the EPU Path is used:

- When the control level has not been locked, the TDO(C) signal remains high-impedance.
- The command control level may be created
- When commands are used, the TDO(C) signal remains high-impedance except during *Shift-DR* states within CR-Scans, and remains high impedance at other times.
- Auxiliary scan paths may be accessed with control levels four and five.

67.7.2 EPU Registers

67.7.2.1 Global

A global register is a register whose value is stored at the same time and with the same value as registers with the same name in all TAP.7 TAPCs sharing an external tool connection. They are stored using TAP.7 TAPC commands dedicated for this purpose. These commands store a single global register. Global registers manage TAP.7 TAPC functions that affect the synchronized operation of a TAP.7 TAPC. An example of a global register is the Scan Format (SCN_FMT) Register used to define the TAPC signal protocol.

A second means of storing all global registers is available. The selection of the TAP.7 TAPC with the technology selection function stores either the Scan Format register value (short form) or all global registers (long form). Storing all global registers provides a simple means to synchronize the values of all global registers when Technology Selection causes a non-operating TAP.7 TAPC to become operational while other TAPCs are operational.

67.7.2.2 Local

Local registers manage TAP.7 TAPC functions that do not affect the synchronized operation of TAP.7 TAPCs. Local registers are conditionally stored using TAP.7 controller commands dedicated for this purpose. These commands provide for changing the value of these registers one a time with a unique value in a Series Scan Topology based on the TAPC's position on the scan chain. Local registers are stored with a unique value in a Star Scan Topology based on a TAPC address assigned to the TAPC.

Registers programmed with commands are described in this section. The CJTAG module implements all mandatory T4 registers as well as the optional APFC, TRESET, and RDBACK0 registers.There are 16 mandatory and 10 optional registers that can be grouped in classes as shown in Read-only – Configuration and register read back..

- **Control** – TAP.7 controller behaviors and characteristics.
- **Options** – Control of optional functions.
- **Select** – Controls the selection of a TAP.7 for Scan and execution of conditional commands.
- **Read-only** – Configuration and register read back.

Table 67-8. TAP.7 controller register list (managed with commands)

Register type	Global/local	Width	Register mnemonic	Name
Control	Global	1	ECL	Exit Control Level
		1	SUSPEND	Suspend
		1	ZBSINH	ZBS Detect Inhibit
		5	SCNFMT	Scan Format
		1	SSDE	SSD Enable
		2	DLYC	Delay control
		2	RDYC	Ready Control
Options	Local	1	TRESET	Test Reset
		2	APFC	Aux. Pin Func. Cntl.
Select	Local	1	CGM	Cond. Group Member
		1	SGC	Scan Group Candidate
		1	SEDGE	Sampling Edge
Read-only	Local	32	RDBACK0	Read-back 0
		32	RDBACK1	Read-back 1
		32	CNFG0	Configuration Register 0

M = Mandatory register

O = Optional register

67.7.2.3 Register Descriptions

67.7.2.3.1 Exit Control Level (ECL)

Storing this register zeroes the ZBS count and unlocks the control level.

This register is set using the STMC command. It remains logic 1 only momentarily before immediately returning to logic 0.

This register is cleared by a global register load.

67.7.2.3.2 Suspend (SUSPEND)

Setting this register suspends the use of control levels. When this register is a logic 1, the "System Path" (STL) is used.

1 – Suspend use of control levels. Enables "System Path."

0 – Enable use of control levels.

SUSPEND is set with the STMC command.

This register is cleared when 8 consecutive ZBSs are detected without the locking of the ZBS count.

This register is cleared by a global register load.

67.7.2.3.3 ZBS Inhibit (ZBSINH)

Storing to ZBSINH inhibits ZBS detection.

1 – Inhibit ZBS detection.

0 – Enable ZBS detection.

ZBSINH is set with the STMC command.

This register is cleared by a global register load.

67.7.2.3.4 Scan Format (SCNFMT[4:0])

Set using Store Scan Format (STFMT) command.

Read using Scan String (SCNS) command.

Table 67-9. Scan Format Register Values

TAPC.7 Class	SCNFMT	Description
T2–T4	00000	**JScan0:** • 1149.1 Compliant Operation. • Requests the coupling of the CLTAPC when the Run-Test/Idle state is reached.
	00001	**JScan1:** • 1149.1 Compatible Operation • Requests the decoupling of the CLTAPC when the Run-Test/Idle state is reached.
	00010	**JScan2:** • 1149.1 Compatible Operation. • Requests the coupling or decoupling of the CLTAPC when the Run-Test/Idle state is reached based on the value of the CACT register

Table continues on the next page...

Table 67-9. Scan Format Register Values (continued)

TAPC.7 Class	SCNFMT	Description
T3–T4	00011	**JScan3:** • Non-compatible 1149.1 Operation • Allows the detection of a T2 TAP.7 controller that is deployed in a Star-4 topology. • Enables TDOC signal behavior that prevents drive conflicts in a Star-4 Scan Topology. • Enables the use of SSDs
T4	01000	**OScan0** • Data rate dependent components • Single TAP.7 communication • Debug and Test applications
	01001	**OScan1** • TAP.1 components • Single/Multi-TAP.7 communication • Debug and Test applications
	01010	**OScan2** • TAP.1 components • No TDI or TDO in non-shift states • Debug applications
	01011	**OScan3** • TAP.1 components • No TDI in non-shift states • No TDO in any state

Table continues on the next page...

Table 67-9. Scan Format Register Values (continued)

TAPC.7 Class	SCNFMT	Description
T4	01100	**OScan4** • Data rate dependent components • Single TAP.7 communication • Debug and Test applications
	01101	**OScan5** • TAP.1 components • Single/Multi-TAP.7 communication • Debug and Test applications
	01110	**OScan6** • TAP.1 components • No TDI or TDO in non-shift states • Debug applications
	01111	**OScan7** • TAP.1 components • No TDI in non-shift states • No TDO in any state
	10000	**MScan** • Data rate dependent components • Multi TAP.7 communication • Directed CID assignment • Virtually any IP with compliant or non-compliant 1149.1 behavior
	10001 – 11111	**Reserved**

The use of a Scan Format value other than 00000b – 10000 shall not change the value of the SCNFMT Register.

67.7.2.3.5 Scan Selection Directive Enable (SSDE)

This register specifies whether the Scan Selection State may be managed using the scan selection directives.

0 – Scan selection directives are not enabled.

1 – Scan selection directives are enabled.

This register is set using the STMC command.

This register is read using SCNS (Scan String), RDBACK0.

67.7.2.3.6 Delay Control (DLYC[1:0])

The Delay Control register provides a means for the external tool to delay the completion of an SP. This delay is essentially an external tool stall. This delay may be zero, one, two, or n TCKC periods. This delay is especially useful when the TCKC is sourced by the TS and a Standard-to-Advanced Protocol adapter is added to an external tool supporting only the Standard Protocol. It allows an external tool design additional time to receive TDO, advance the external tool TAPC state, receive TMS and TDI information, and begin generation of a new SP payload. The DLYC register should be programmed before the use of the Advanced Protocol begins after the use of the Standard Protocol.

Set using the STMC command.

Read using SCNS, RDBACK0

Bits 18-17 of the "Global Register."

67.7.2.3.7 Ready Control (RDYC[1:0])

The Ready Control register defines behavior exhibited in the SP payload output bit frames when the STL stall opportunities (RDY bits) are included as control information. This register defines the number of additional bits inserted in these bit frames. These bits provide more time for a high-performance external tool to ascertain whether the TAP.7 controller is ready to complete the SP payload. The use of these bits makes a high-performance external tool design easier as input and output buffer delays play less of a role in limiting the TAP.7 controller performance. The RDYC register should be programmed before the use of the Advanced Protocol begins.

Set using the STMC command.

Read using SCNS, RDBACK0.

Bits 18-17 of the Global register state.

67.7.2.3.8 Test Reset (TRESET)

Asserts a test reset to the STL.

0 – The nSYS_TRST and SYS_TMS signals presented to the STL is not influenced by this bit.

1 – The nSYS_TRST presented to the STL is asserted and the SYS_TMS signal is a logic 1.

Set using the STC1 command.

The effects of the TRESET Register may be modified by a private TAP.7 controller register. When this private register is unimplemented or has a value of zero, the TRESET register causes the maximum initialization of the STL with nSYS_TRST and the SYS_TMS logic 1 value. Otherwise, the value of the private register may modify the function of the TRESET Register bit.

When the TRESET Register is a logic 1, the STL scan path appears broken as the state of CLTAPC remains *Test-Logic-Reset* while the EPUTAPC state progression continues. When the operation of the EPUTAPC and CLTAPC controllers is coupled, as with a T1 TAP.7, the state of these two TAPCs may be resynchronized to the *Run-Test/Idle* state by:

- An STC1 Command that sets the TRESET Register value to a logic 0.
- A stay in the Run-Test/Idle state of two or more SYS_TCK periods immediately following the Update-DR state of this command

A failure to follow the guidelines is considered a programming error and will result in erroneous system operation. The EPUTAPC and CLTAPC states will not be synchronized as they progress through the state diagram.

67.7.2.3.9 Auxiliary Pin Function Control (APFC[1:0])

This register enables TDI and TDO alternate functions when 2-pin TAP.7 operation is selected.

0x – TDI and TDO have JTAG function.

1x – TDI and TDO have alternate function.

Set using STC2 command.

Read using SCNS, RDBACK0.

67.7.2.3.10 Conditional Group Member (CGM)

Used by STC1, STC2, STTESTM, and EXC3 – EXC0 commands as the “condition” for updating registers.

Set and cleared using MCM and SCNB commands.

Read using SCNS, RDBACK0.

67.7.2.3.11 Scan Group Candidate (SGC)

This register determines whether the STL is coupled when the *Run-Test/Idle* state is reached when scan formats other than JScan0 and JScan1 are used.

- **0** – Decoupling action.
- **1** – Coupling action.

Set and cleared using STMC, MSC, and SCNB commands.

Read using SCNS, RDBACK0.

67.7.2.3.12 Sampling Edge (SEDGE)

The Sampling Edge register defines the TCKC edge used to sample the TMSC input.

- **0** – Sample TMSC on the TCKC falling edge.
- **1** – Sample TMSC on the TCKC rising edge.

Set and cleared using STC1 command.

Read using SCNS, RDBACK0

67.7.2.3.13 Read Back 0 (RDBACK0)

Non-transport related register information.

Read using SCNS command.

Unimplemented registers shall read back as "0".

Table 67-10. RDBACK register format

Bit	Width	Register Mnemonic	Name

NC = No Change

DF = Default Scan Format

DM = Default Power Control Mode

DCA = Default Coupling Action

DT = Default Topology

DP = Default Pin Function

67.7.3 EPU Commands

There are two command types:

- Two Part Commands
- Three Part Commands

Any number of two-part and three part commands may be issued in any combination before the command control level is exited. If the command control level is exited before a two- or three-part command is completed, the command is aborted and becomes a NOP.

67.7.3.1 Two Part Commands

TAP.7 controller commands are 10-bit values. The 10-bit commands are created by two consecutive DR-Scans when the control level is locked at the command control level (two). The first DR-Scan provides a five-bit command opcode. The second DR-Scan provides a five-bit operand. These two scans are called the command part one (CP1) and command part two (CP2), respectively. A command created entirely with these two scans is called a two-part command.

67.7.3.2 Three Part Commands

Some commands are used to send and/or receive data values other than values embedded in the command's operand. These commands are called three-part commands. With these commands, CP1 and CP2 are followed by an additional DR-Scan to transport a data value to or from an EPU scan path. When used for this purpose, the DR-Scan is called a Control Register Scan (CR-Scan). The CR-Scan is a minimum of zero bits in length with there being no maximum length. The CR-Scan path is described in SECTION.

67.7.3.3 Command Sequence

The two 5-bit values concatenated to create the 10-bit command represent the number of Shift-DR states between the *Capture-DR* and *Update-DR* states of CP1 and CP2. The count within CP1 creates the MSBs of the command while the count within CP2 creates the LSBs of the command. The command is decoded when the *Update-DR* state of the second DR-Scan is reached. A determination as to whether the command is a two- or three-part command is made at this point. The command format is shown in the following figure.

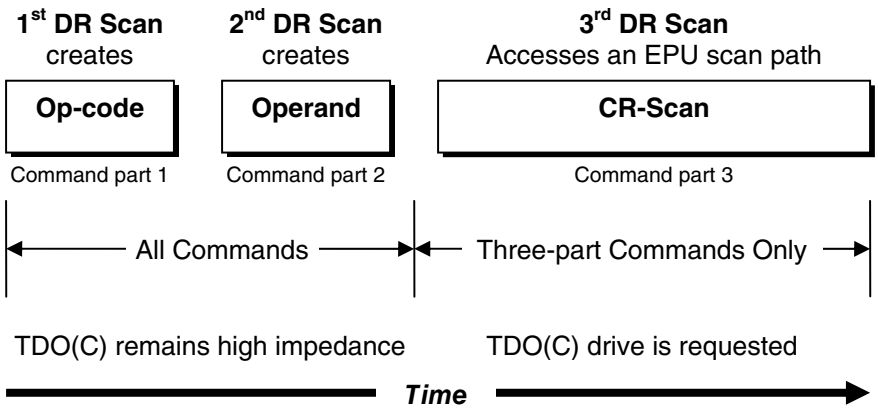

Figure 67-8. DR_Scan sequence used for command creation

The 10-bit command created by CP1 and CP2 determines the command's function and whether the command is a two- or three-part command. If the command is a two part command, the function specified by the command is performed when command part 2 completes. If the command is a three-part command, the DR-Scan following CP2 performs a TAP.7 controller function designated by the 10-bit controller command. This DR-Scan is called a ***Control-Register Scan*** (CR-Scan) and can be any length. A CR-Scan has many of the attributes of the DR-Scan as it moves data between the external tool and TAP.7 controller and accesses various EPU scan paths. There are many two part commands, but only three three-part commands, each having a special purpose.

67.7.3.4 Commands

There are 11 mandatory and 5 optional commands that can be grouped in classes as shown in the following list:

- Store – The operand is stored in a register or causes an action.
- Select – Controls participation of Scan and conditional command execution.
- Scan – Inputs and outputs with a CR-Scan.
- Enumerate – Controller ID allocation and de-allocation.
- Private – Commands available for chip-specific definition.

The definition of the commands with their operands is shown in the following table.

Table 67-13. – TAP.7 controller command list

Command class	Opcode count	Mnemonic	Name	TAP.7 class			
				1	2	3	4
Store	0x00	STMC	Store Miscellaneous Control	M	M	M	M
	0x01	STC1	Store Conditional 1-bit	M	M	M	M
	0x02	STC2	Store Conditional 2-bit	M	M	M	M
	0x03	STFMT	Store Format	-	M	M	M
	0x04	STDCST	Store Data Channel State	-	-	-	-
Select	0x06	MCM	Make Cond. Group Member	M	M	M	M
	0x07	MSC	Make Scan Group Candidate	-	M	M	M
Scan	0x08	SCNB	Scan Bit	M	M	M	M
	0x09	SCNS	Scan String	M	M	M	M
Enumerate[1]	0x0A	CIDA	Allocate Controller ID	-	-	M	M
	0x0B	CIDD	De-allocate Controller ID	-	-	M	M
Reserved	0x0C–0x1F	Reserved	Reserved	-	-	-	-

1. Enumerate commands are not currently supported by the CJTAG module.

67.7.3.4.1 Store Commands

Store commands are two-part commands that are available in both Star and Series Scan Topologies. The Store Miscellaneous Control (STMC) Command performs control functions that affect all TAP.7 controllers sharing an external tool connection. It stores values in one-bit and two-bit registers.

The Store Conditional 1 bit (STC1) and Store Conditional 2 bit (STC2) Commands store one-bit and two-bit values in registers, respectively. These commands operate two ways:

1. Unconditionally storing registers in all TAP.7 controllers or
2. Storing registers in only the TAP.7 controllers that have a logic 1 Conditional Group Member (CGM) Register value.

The Store Format (STFMT) Command unconditionally stores a five-bit Scan Format value.

The Store Data Channel State (STDCST) Command stores a five-bit value identifying the states supporting transport.

67.7.3.4.2 Select Commands

Select commands are two-part commands that are available in both Star and Series Scan Topologies. Their primary use is to select TAP.7 controllers of interest in a Star Scan Topology. These commands define the TAP.7 controller(s) participating in scans and the TAP.7 controllers that conditionally execute STC1 and STC2 Commands.

The Make Conditional Group Member (MCM) Command specifies which TAP.7 controllers execute store conditional commands as it manages the Command and Path Enable (CAPE) Register. This register also affects the execution of private commands and is utilized in EPU scan path selection.

The Make Scan Group Candidate (MSC) command manages the SGC register. This register determines whether the STL is coupled when the *Run-Test/Idle* state is reached when scan formats other than JScan0 and JScan1 are used. Select commands execute only when the CIDI Register is a logic 0, indicating the TAP.7 controller's CID is valid, and are treated as no operations otherwise.

67.7.3.4.3 Scan Commands

Scan commands are three-part commands that are available in both Star and Series Scan Topologies. The CR-Scan portion of Scan Bit (SCNB) and Scan String (SCNS) Commands is used to set and test bits (SCNB) or transfer strings of bits (SCNS). The commands may be used to access both public and private registers.

67.7.3.5 Command Definitions

67.7.3.5.1 Store Commands

67.7.3.5.1.1 Store Miscellaneous Control Command (STMC)

Table 67-14. Store Miscellaneous Control

STMC		Store Miscellaneous Control				
Opcode	**Operand**	**bbb**		**x**	**y**	**Description**
00000	bbb x y	000	StateCtl	0	0	NOP
				0	1	ExitCmdLev(ECL)
				1	0	Exit/Suspend (SUSPEND) = 1
				1	1	ZBS Inhibit (ZBSINH) = 1
		001	ScanCtl	0	-	SGC = y
				1	-	CGM = y
		010	RdyCtl	-	-	RDYC = xy
		011	DlyCtl	-	-	DLYC = xy
		100	ScnFunc	0	-	SSDE = y
				1	0	Star-4 Topology Test
				1	1	Reserved
		101	Reserved	-	-	Reserved
		110				
		111				

67.7.3.5.1.2 Store Conditional 1-bit (STC1)

Table 67-15. Store Conditional 1 bit (STC1)

STC1		Store Conditional 1 bit			
Opcode	**Operand**	**c**	**bbb**	**CAPE**	**Description**
00001	c bbb v	0	000	-	SREDGE = v
			001	-	Reserved
			010	-	TRESET = v
			011 – 111	-	Reserved
		1	–-	0	No change
			000	1	SREDGE = v
			001	1	Reserved
			010	1	TRESET = v
			011 – 111	1	Reserved

67.7.3.5.1.3 Store Conditional 2-bit (STC2)

Table 67-16. Store Conditional 2 bit (STC2)

STC2		Store Conditional 2 bit			
Opcode	**Operand**	**c**	**bb**	**CAPE**	**Description**
00010	c bb vv	0	00	-	Reserved
			01	-	STCKDC = vv
			10	-	APFC = vv
			11	-	Reserved
		1	–-	0	No change
			00	1	Reserved
			01	1	STCKDC = vv
			10	1	APFC = vv
			11	1	Reserved

67.7.3.5.1.4 Store Scan Format (STFMT)

Table 67-17. Store Scan Format (STFMT)

STFMT		Store Scan Format
Opcode	**Operand**	
00011	nnnnn	SCNFMT = nnnnn

67.7.3.5.2 Select Commands

This section describes the select commands with their operands.

67.7.3.5.2.1 Make Conditional Group Member (MCM)

This command operates as a no operation when the CIDI Register is a logic 1 (The Controllers CID is invalid). Otherwise it sets the CGM bit in a TAP.7 controller that has a valid CID and the CID matches the operand CID field (iiii). The CGM Register is also stored with the STMC and SCNB commands.

Table 67-18. Make Conditional Group Member (MCM)

MCM		Conditional Group Member	
Opcode	**Operand**	**m**	**Description**
00110	m iiii	0	CGM bit of the non-targeted controller is cleared
		1	CGM bit of the targeted controller is set. CGM bit of a non-targeted controller is unaffected.

67.7.3.5.2.2 Make Scan Group Candidate (MSC)

This command operates as a no operation when the CIDI Register is a logic 1 (The Controllers CID is invalid). Otherwise it sets the SGC bit in a TAP.7 controller that has a valid CID and the CID matches the operand CID field (iiii). The SGC Register is also stored with the STMC and SCNB commands.

Table 67-19. Make Scan Group Candidate (MSC)

MSC		Make Scan Group Candidate	
Opcode	**Operand**	**m**	**Description**
00111	m iiii	0	SGC bit of the non-targeted controller is cleared
		1	SGC bit of the targeted controller is set. SGC bit of a non-targeted controller is unaffected.

67.7.3.5.3 Scan Commands

67.7.3.5.3.1 Scan Bit (SCNB)

This is a 3-part command. The operand chooses the bit to be read or written by the CR-Scan.

Table 67-20. Scan Bit (SCNB)

SCNB			Scan Bit		
Opcode	**Operand**	**CR-Scan**	**yyyyy**	**Description**	**R/W**
01000	yyyyy	-	0	Scan Group Candidate (SGC)	Write only
		-	1	Conditional Group Member (CGM)	Write only
		-	2	CNFG[0]	Read only
		-	3	CNFG[1] (not implemented)	Read only
		-	4	CNFG[2] (not implemented)	Read only
		-	5	CNFG[3] (not implemented)	Read only
		-	6	Functional reset requested (FRESETR) (not implemented)	Read only
		-	7	Series topology detect	Write only
		-	15 – 8	Reserved	Read only

67.7.3.5.3.2 Scan String (SCNS)

This is a 3-part command. The operand chooses the string to be read or written by the CR-Scan.

Table 67-21. Scan String (SCNS)

SCNS			Scan String		
Opcode	Operand	CR-Scan	yyyyy	Description	R/W
01001	yyyyy	-	0	RDBACK[0] Register [31:0]	Read only
		-	1	RDBACK[1] Register [31:0] (not implemented)	Read only
		-	2	CNFG[0] Register [31:0]	Read only
		-	3	CNFG[1] Register [31:0] (not implemented)	Read only
		-	4	CNFG[2] Register [31:0] (not implemented)	Read only
		-	5	CNFG[3] Register [31:0] (not implemented)	Read only
		-	6 - 7	Reserved (read logic 0)	Read only
		-	31 - 8	Private – available for customization	

67.7.4 EPU operating states

The TAP.7 controller and STL share the use of ZBSs. The EPU has three operating states as shown in the following figure:

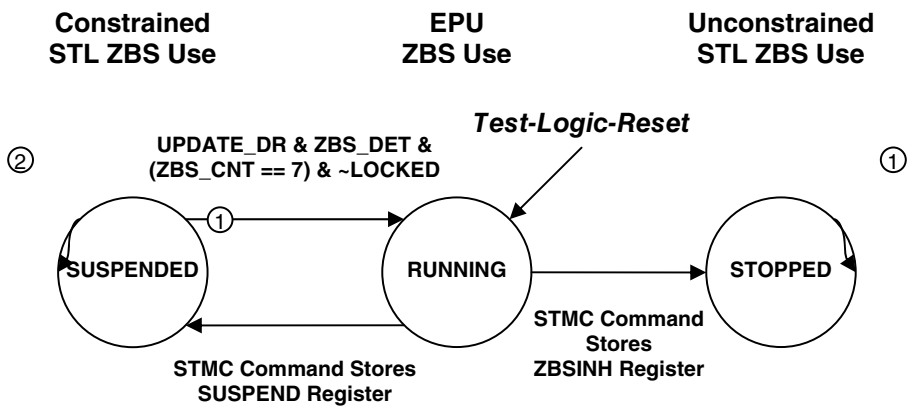

Figure 67-9. EPU operating states

The values of the SUSPEND and ZBSINH Registers determine the type of operation as shown in the following table. The Test-Logic-Reset state sets the SUSPEND and ZBSINH Register values to a logic 0.

Table 67-22. ZBS use state characteristics with both TAP.7 and other ZBS use

ZBSINH	SUSPEND	EPU operating State	ZBS use by:	Until
0	0	RUNNING	EPU	Command allocates to STL
0	1	SUSPENDED	STL	ZBS sequence allocates to EPU
1	0	STOPPED	STL	Test-Logic-Reset state allocates to EPU
1	1	Not possible		

67.7.5 System and EPU Paths

The System path is utilized when the external tool requires access to system (STL) resources. This path is used when either the SUSPEND Register is a logic 1 or the ZBS count is less than or equal to one. The EPU path is used otherwise.

The EPU scan path is constructed from five types of EPU scan paths:

- **Bypass** – A 1-bit scan path
- **Bit** – Supports set and test bit operations (a 1-bit shift register)
- **String** – Support 32-bit reads or 32-bit writes
- **Enumerate** – A 36-bit scan path that transports a TAPC address with T3 and above TAP.7s
- **Auxiliary** – An n-bit scan path that transports 1 – n bits using a conventional IEEE 1149.1 style DR-Scan path using Control Levels 4 and 5.

67.8 APU (Advanced Protocol Unit) Operation

67.8.1 Overview

The Advanced Protocol Unit (APU) is placed between the EPU and the RSU to create the T4 TAP.7 controller. The APU delivers advanced capabilities with a number of operating modes (new scan formats) that utilize the Standard Protocol and the Advanced Protocol in both the narrow and wide T4 TAP.7 versions.

The APU enables scan transfers with two signals by serializing the information related to a TAPC state machine state. It provides a number of serialization formats to balance scan flexibility and scan performance. It multiplexes the use of the TMSC signal for T4 TAP.7 controller functions. The serialization is bypassed to provide T3 TAP.7 capability.

With a wide TAP.7, the chip architect may choose to implement the TDIC and TDOC signal functions as fixed functionality (the T3 TDIC and TDOC functions) or as programmable between the T3 TDIC and TDOC signal functions and an alternate function using a TAP.7 controller register. In this case, the default signal function may be either of the programmable choices. Programmable TDIC and TDOC functionality provides a means to fully utilize these signals in any scan topology as the T3 TAP.7 functionality is fully supported.

The entire EPU infrastructure (i.e., ZBS detection, control-level management, and command generation) is utilized when either the Standard Protocol or the Advanced Protocol is used, as these TAP.7 controller attributes are controlled entirely from the TAPC state machine state progression. The EPU is unaware of the APU's existence. All T4 features are managed outside of the EPU.

The TAP.7 serialization schemes are specified with scan formats that complement the JScan 0-3 Scan Formats inherited from the T3 TAP.7. The scan formats are called advanced scan formats as they support two-signal operation.

Two groups of scan formats (MScan and OScan0-7) provide a number of options for the serialization of scan information for use in a Star-2 scan topology. The OScan Scan Format is broken into two groups with the same function, one group has better performance but may only be used with an external tool sourced TCKC. The external tool chooses a scan format that matches the constraints imposed by the application, chip components, and possibly the external tool itself.

The MScan and OScan formats address Test and Debug use cases. The mandatory MScan and OScan0-1 formats emphasize flexibility over performance. The remaining optional Oscan2-7 formats emphasize performance over flexibility by not transmitting unneeded information such as TDI and TDO in non-shift TAPC state machine states.

The optional capabilities added with T4 and above TAP.7s change the bit sequences seen at the TAP.7 signals. A TAP.7 controller comprehends only the bit sequences generated by the use of the features it supports. It is never exposed to bit sequences it does not comprehend. A check for supporting an enabled feature is made before the feature is used (alters the bit sequences). When a T4 TAP.7 controller detects the use of an unsupported scan format, it halts its operation and places itself in a state where its operation may be resumed. This state is henceforth called "offline". A TAP.7 controller that is not offline is henceforth called "online". While offline the TAP.7 controller awaits the detection of a

special signaling sequence called the Online Activation Protocol. This protocol sequence places an offline TAP.7 controller online and synchronizes the operation of all online TAP.7s.

The Advanced Protocol Unit supports the stall of a transfer by both the external tool and STL at any TAPC state.

The APU provides the following functions:

- Bypass (for operation with the Standard Protocol)
- Scan control (for SP use)
- Configuration Control (for CP use)

The Scan Control, Configuration Control, and Transport Control functions are idled when the Standard Protocol is used as the Bypass Function connects the TCKC and TMSC pins to the EPU.

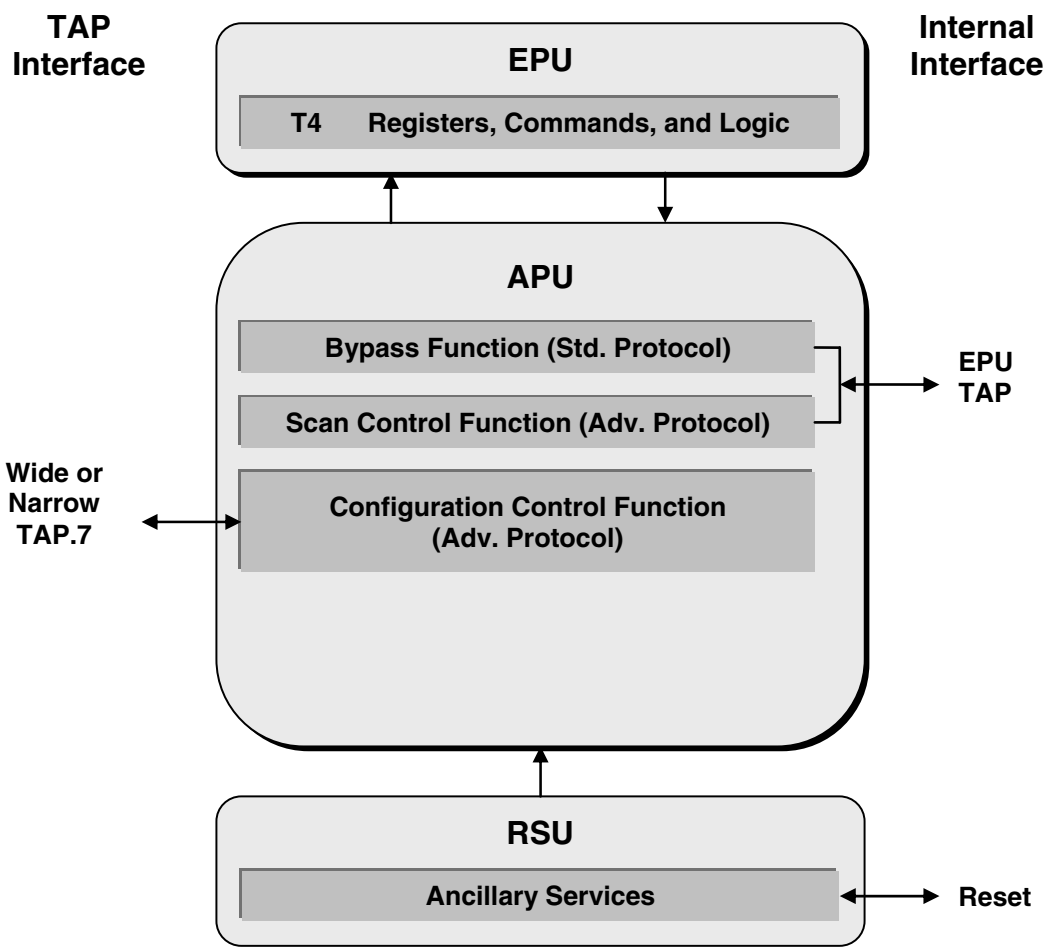

Figure 67-10. Conceptual block diagram of the APU functions

The APU's internal interface includes a connection to EPU registers, the EPU's TAP interface, connections to chip-level data channels (when they are implemented), and reset signaling with the EPU. The APU's TAP interface provides mutually exclusive use of the TMSC pin for:

- Bypass Function
- Scan Control Function
- Configuration Control Function

When the Standard Protocol is used, the APU's Bypass function connects the EPU directly to the TAP.7 pins. When the TDIC and TDOC pin functions are not available (narrow TAP.7 or TDIC and TDOC pin functions are an alternate function), the APU sources a logic 1 to the EPU inputs associated with these pins.

When the Advanced Protocol is used, the APU multiplexes the use of the TMSC pin between the other APU functions. Scan Control acts as a serial to parallel converter, translating the parallel information at the EPU's TAP interface into bidirectional serial transfers. Since the Scan Control is literally a protocol adaptor, the entire EPU infrastructure (ZBS detection, control-level management, and command generation) is utilized when either the Standard or Advanced Protocol is used, as these TAP.7 controller attributes are controlled entirely from the TAPC state progression.

67.8.2 Operation

The conceptual view of the APU operation is shown in the following figure.

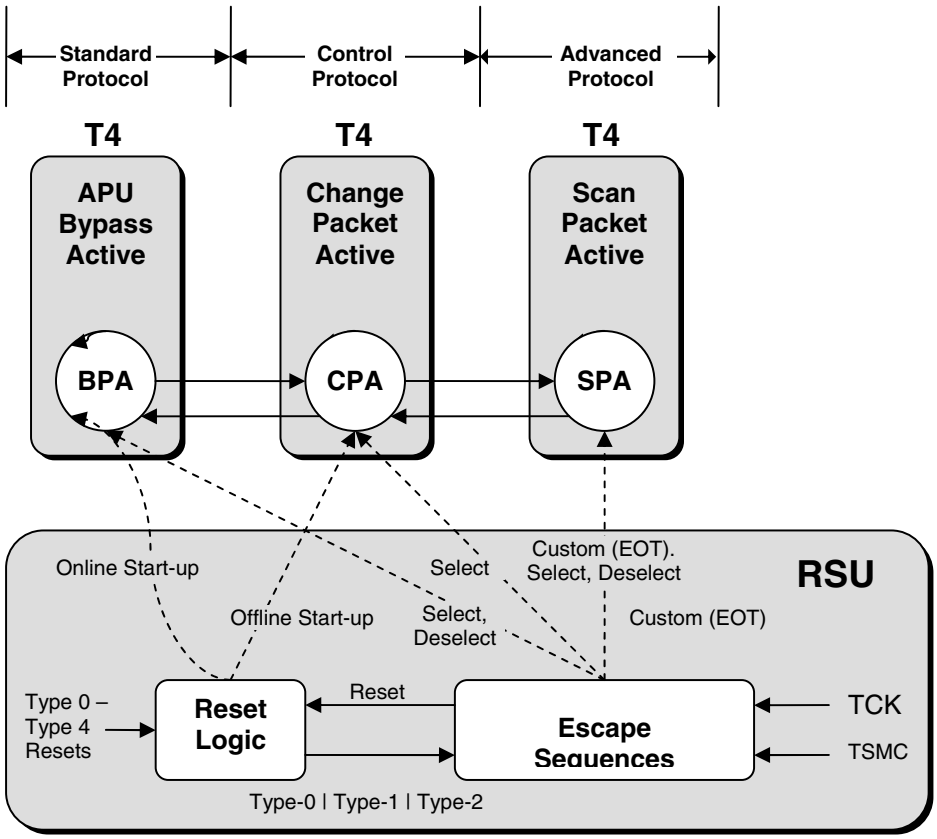

Figure 67-11. Conceptual view of APU operation

The APU operating states managing the use of the TAP pins and the ancillary (RSU) services use of the TMSC pin.

APU operating states:

- ***BPA*** – **B**y**P**ass **A**ctive
- ***CPA*** – **C**hange **P**acket **A**ctive
- ***SPA*** – **S**can **P**acket **A**ctive

67.8.2.1 BPA

The *BPA* state allocates the use of the TMSC pin to the Standard Protocol. This state is entered two ways:

- As a result of a TAP.7 controller reset when the TAP.7 controller starts up online.
- From the CPA state when a TAP.7 controller register write specifies the use of the Standard Protocol.

67.8.2.2 CPA

The *CPA* state allocates the use of the TMSC pin to a CP. This state is entered in one of three ways:

- As a result of a TAP.7 controller reset when the TAP.7 controller starts up offline.
- A value specifying the use of the Advanced Protocol is written to the SCNFMT Register when using the Standard Protocol.
- A TAP.7 controller register write occurs when using the Advanced Protocol.

67.8.2.3 SPA

The SPA state allocates the use of the TMSC pin to an SP. This state is entered when the SCNFMT Register specifies the use of the Advance Protocol when a CP ends.

67.8.3 Escape sequences

Escape-sequence detection provides services to the Reset Logic, Scan, Configuration Control, and Transport Control functions as outlined below:

- **Scan and Transport Control** – End of Transfer (EOT) escape sequence detected.
- **Configuration Control** – Synchronize Advanced Protocol (SAP) escape sequence.
- **Reset Logic** – Reset (RES) escape sequence detected.

An EOT escape sequence is used to increase the efficiency of OScan Scan formats.

An SAP escape sequence is used to place TAP.7 controllers online.

A RES escape sequence asynchronously causes generation of a Type-3 Reset. Following a RES escape sequence, the drive of the TMSC pin is inhibited so it is not driven when TCKC becomes a logic 0 immediately following the RES escape sequence.

67.8.4 Signal behaviors

The TCKC signal:

- The test clock

The TMSC signal:

- An input when the Standard Protocol is used
- Bi-directional when the Advanced Protocol is used

The TDI and TDO signals:

- Deleted with a narrow TAP.7
- One of two functions with a wide TAP.7
  - Fixed – as the TAP.7 TDIC and TDOC pin functions, or
  - Programmable – as the TAP.7 TDIC and TDOC signal functions or alternate functions with a TAP.7 controller reset establishing the default signal function.

67.8.5 APU Functions

67.8.5.1 Bypass Active (BPA) Function

When the Standard Protocol is used, the APU connects the EPU inputs and outputs directly to the TAP.7 pins. If the TDIC and TDOC pin functions are not present (e.g., a narrow TAP.7 or the TDIC and TDOC pins have an alternate function assigned to them), the APU provides a logic 1 to the EPU for unsupported pin functions and ignores the EPU's TDO output data.

67.8.5.2 Scan Packet Active (SPA) Function

The Scan Control function is encapsulated within the Scan Packet Active (SPA) state. With the Standard Protocol, the external tool and TAP.7 exchange the scan information associated with a single TAPC state machine state in one TCK period using the TMS(C), TDI(C), and TDO(C) pins. With the Advanced Protocol all or part of this information is exchanged serially within a Scan Packet (SP) as shown in . There is a one to one correspondence between SPs and TAPC state machine state changes, except when the SPA state precedes the CPA state. In this case the SP preceding a CP does not advance the TAPC state machine state.

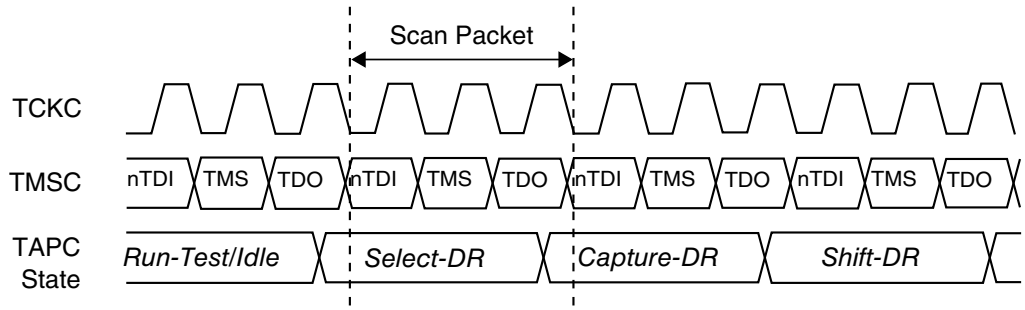

Figure 67-12. Scan Packet Sequence

A comparison of the parallel transfer of TAP information with the Standard Protocol and the serialization and de-serialization of the TAP information using the TCKC and TMSC pins with the Advanced Protocol is shown in FIGURE. The IEEE 1149.1 signals between the EPU and STL are prefixed with SYS_.

The APU manages the serialization and de-serialization of the scan information. The APU converts the TDI and TMS information within a Scan Packet (SP) into the TMS and TDI information presented to the EPU. It converts the combination of the EPU TDO and EPU TDO_OE signals into the TDO information in the same SP. If the EPU indicates that the TDO pin drive is not enabled, logic 1 TDO data is created, otherwise the TDO data is the supplied by either the EPU or STL.

Information within a Scan Packet is first passed from the external tool to the TAP.7 followed by information passed from the TAP.7 to the external tool. In this example the scan format specifies the exchange of the TMS, TDI, and TDO TAPC information. Each TAPC state machine state takes three TCKC periods. Other scan formats specify the exchange of different mixes of information. Control information is added with the most flexible scan formats. Some scan formats send less information and consequently take fewer TCKC periods.

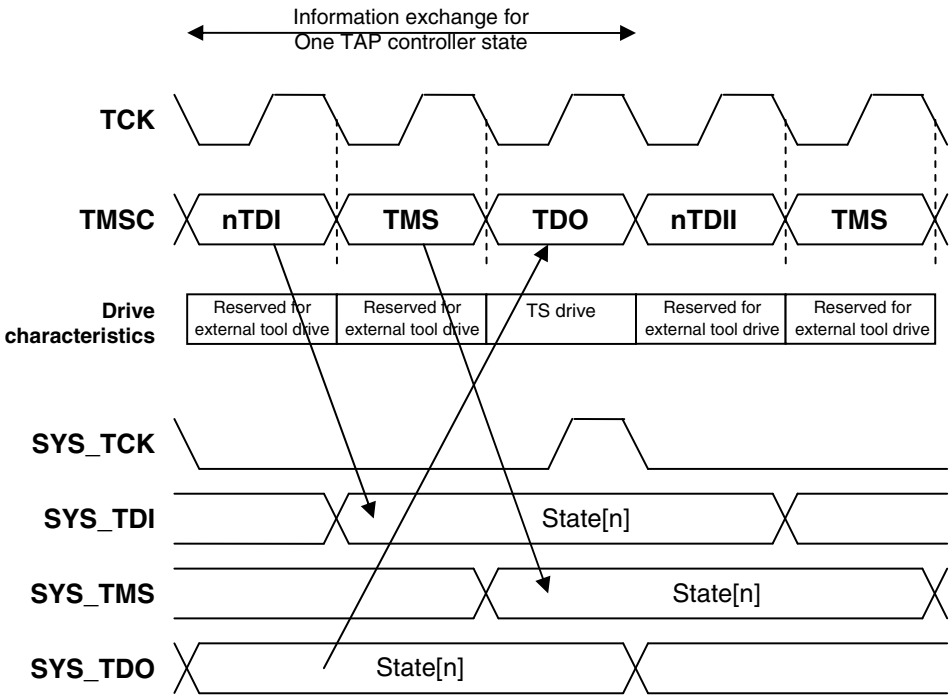

Figure 67-13. Serialization and De-serialization of Scan Packet Information

In order to produce comparable TAPC state machine state rates with a TAP.1 and TAP.7 controller:

- Full-cycle timing between the external tool and TAP.7 allows operation at higher TCKC frequencies.
- The number of bits transferred to advance a TAPC state machine is minimized. (reaching as few as one for some scan formats.)

The TAP.7 controller provides both full-cycle bit timing (falling TCKC edge to falling TCKC edge) and half-cycle bit timing (falling TCKC edge to rising TCKC edge), with a TAP.7 register used to define the type of timing used. Half-cycle timing is used as the default following a TAP.7 controller reset. The TCKC frequency is reduced to accommodate half-cycle timing.

With full-cycle timing, the TMSC input and output data are both output with and sampled with the falling edge of the TCKC. This means that the entire TCKC period may be spent transferring a bit from the external tool to the TAP.7 or vice-versa. The TCKC frequency can therefore be maximized when full-cycle timing is used. With half-cycle timing, the APU samples the TMSC input data with the rising edge of the TCKC and outputs TMSC data with the falling edge of TCKC.

Minimizing the number of bits transferred per TAPC state machine state is affected by a number of factors. The information that must be transferred per TAPC state machine state varies for different test and debug applications. Also, with some test and debug

applications, all TAPC state machine states do not require that the same amount of information be transferred. This is especially true with debug applications where specialized use of the TAP is more likely.

67.8.5.3 Control Process Active (CPA) Function

While using the Advanced Protocol, all TAP.7 configuration changes occur within the CPA state. All online and offline transitions also occur while in the CPA state. When entering the CPA state from the BPA or SPA state, the CPA state checks for the use of supported features affecting the Advanced Protocol. The CPA state is exited when the enabled features affecting the Advanced Protocol are supported.

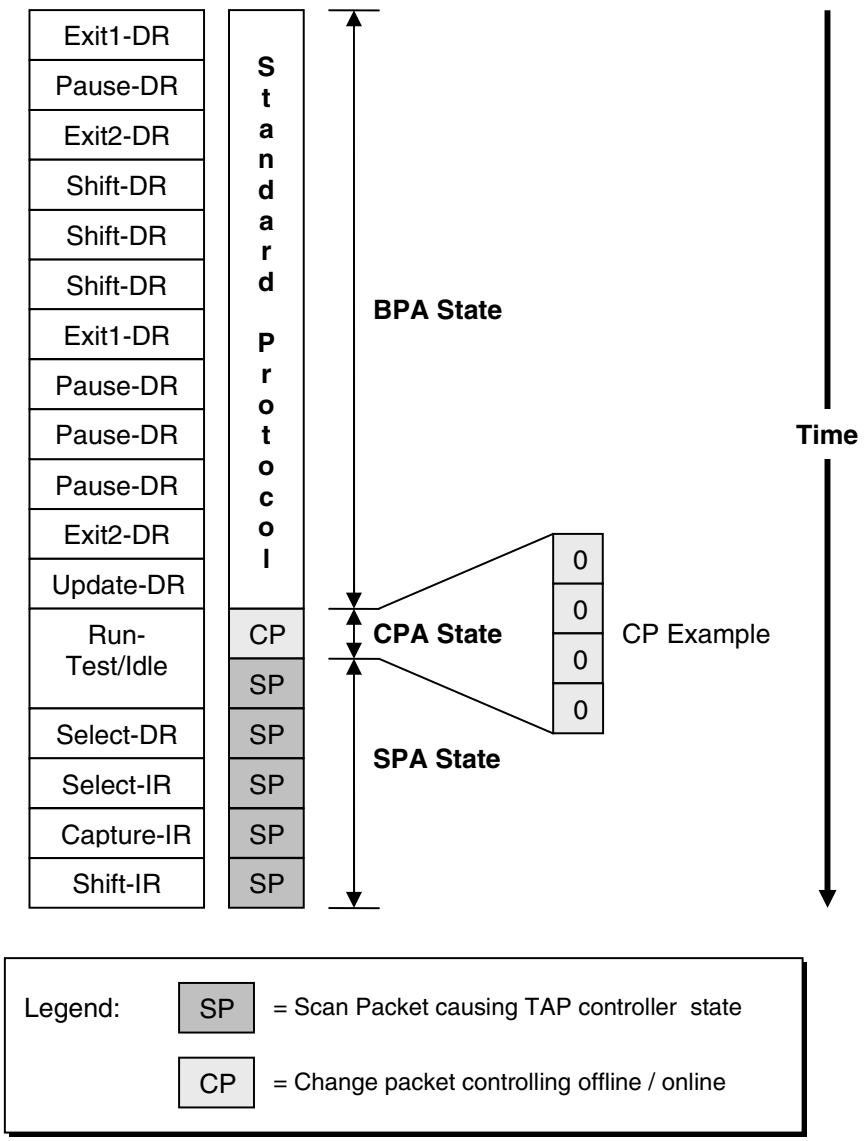

Figure 67-14. CPA State Entry from BPA State with Continued Online Operation

An SP preceding a CP does not advance the TAPC state machine state. This SP performs housekeeping functions that assure the contents of the SP preceding this SP have been fully utilized. This has significance when the SP contains control information that allows the STL to stall the completion of a SP.

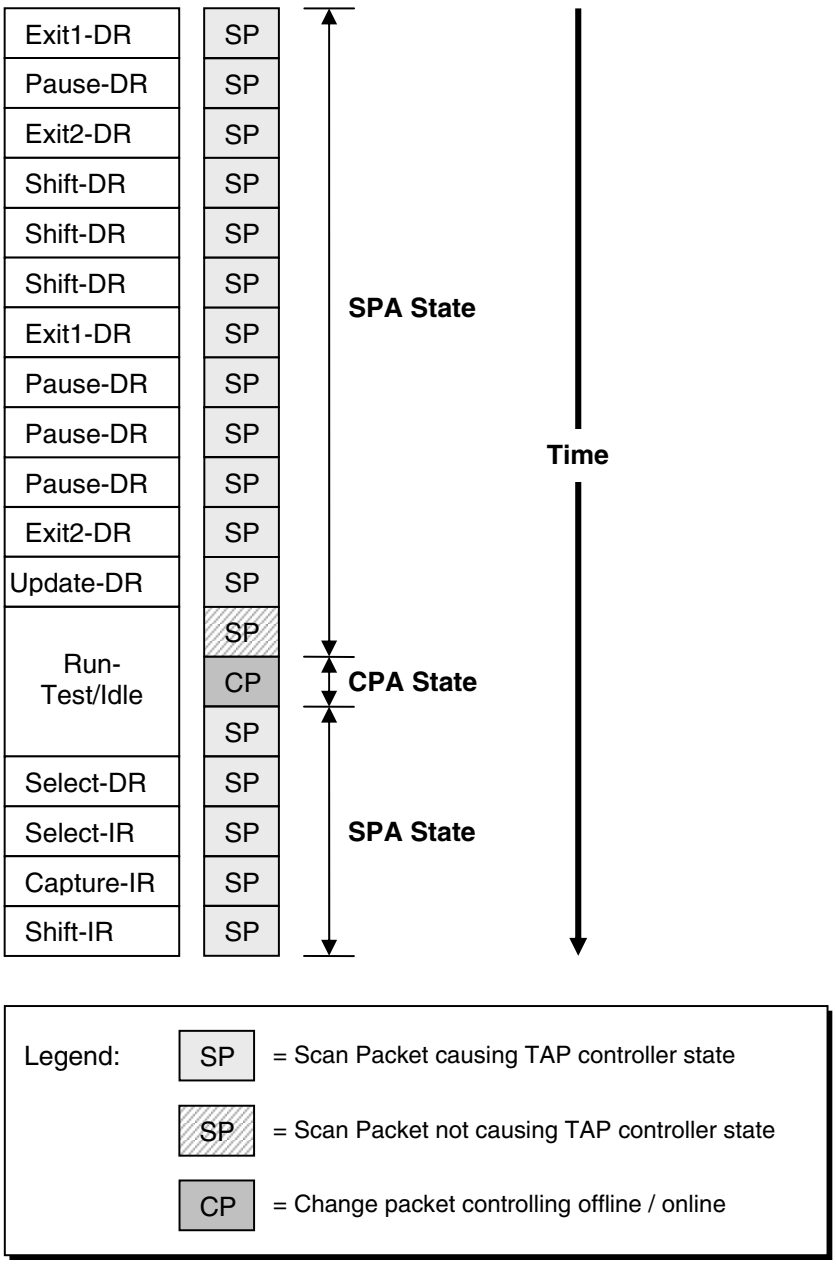

Figure 67-15. CPA State Entry from the SPA State with Continued Online Operation

When an unsupported feature is enabled, the TAP.7 controller is placed offline. This suspends the TAP.7 controller's operation at a point where its operation may later be synchronized to the remainder of the system. The APU stops advancing the EPU's and CLTAPC's TAPC state machine state while offline. It also suspends Data Channels activity while offline. The detection of the appropriate Online Activation Protocol while

the TAP.7 controller is offline places the TAP.7 controller online and causes an exit from the CPA state to the SPA state. An offline to online transition initiates the use of a predefined set of mandatory features in all online TAP.7 controllers to assure they operate synchronously.

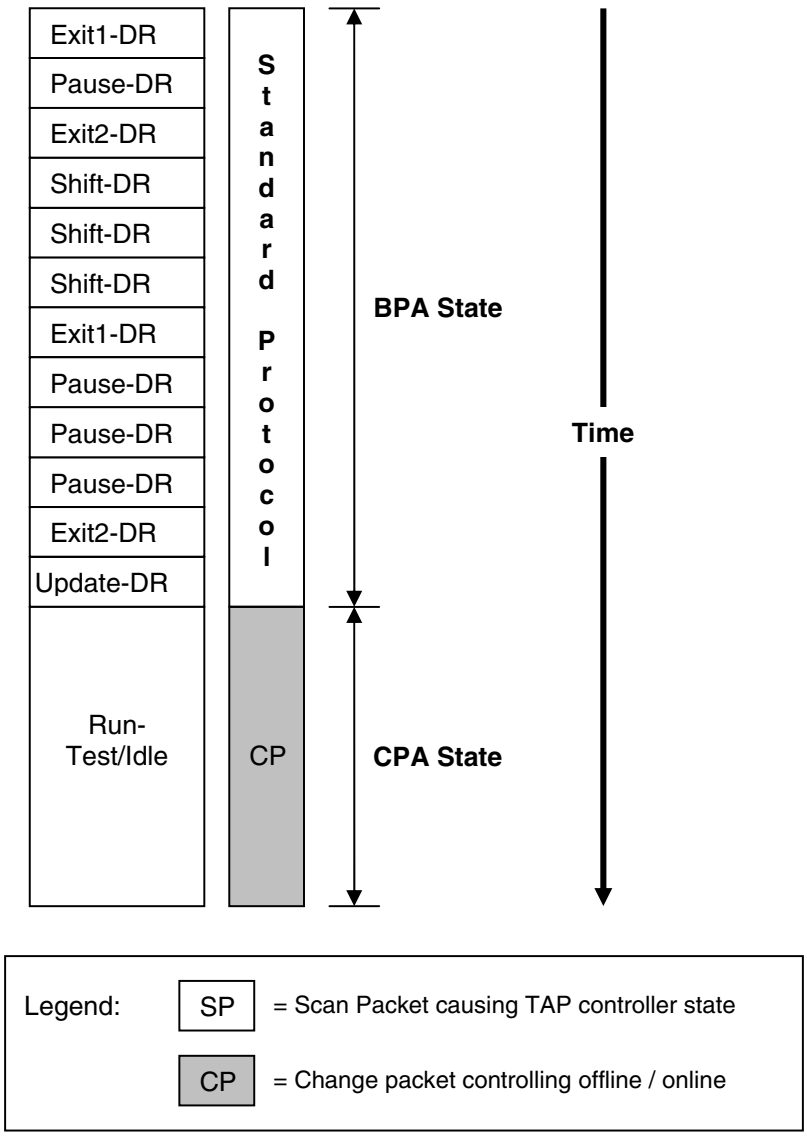

Figure 67-16. CPA State Entry from the BPA State with Offline Operation

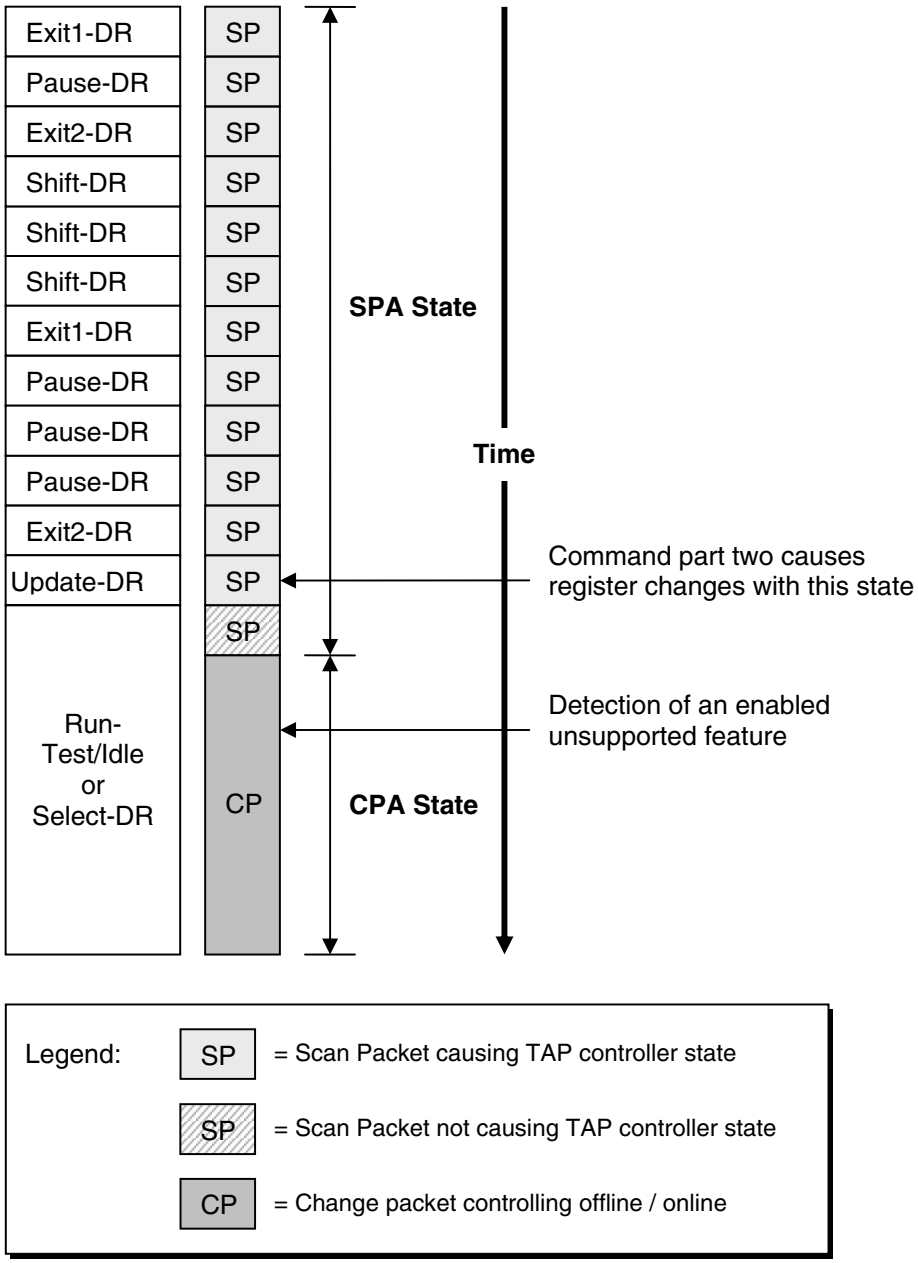

Figure 67-17. CPA State Entry from the SPA State with Offline Operation

A TAP.7 controller reset places the TAP.7 controller offline when the offline at start-up option is used. From this point the TAP.7 controller awaits being placed online.

67.8.6 Configuration Change Packets (CP)

A Change Packet (CP) is composed of three element types:

- **Preamble** – A 1-bit value that is a don't care. This bit facilitates a Standard to Advanced Protocol change with some external tool implementations.

- **Body** – Two or more bits representing one or more CP directives
  - **00** – CP_END
  - **01** – CP_NOP (extends the body by 1-bit)
  - **10** – CP_NOP (extends the body by 1-bit)
  - **11** – CP_RES (Generate a Type-3 TAP.7 controller reset coincident with the post amble bit.
- **Post amble** – A 1-bit value that is a don't care. This bit facilitates and Advanced to Standard Protocol change with some external tool implementations.

A minimum-length CP has a Preamble, a 2-bit Body, and a Post amble. This can be as simple as four logic zero values.

67.8.7 Scan Packet

A Scan Packet defines the period of TMSC pin activity where control information exchanged by the external tool and TAP.7 controller affects the TAPC state, except when the SP precedes a Change Packet. The external tool should view the Scan Packet as:

- Exchanging only the necessary TAPC information (TMS, TDI, and TDO or some subset thereof)
- Causing an advance of the TAP.7 TAPC state when it is not followed by a Change Packet.
- Causing an advance of the STL TAPC state when it is not followed by a Change Packet and when the STL is coupled.

With this perspective, the external tool views Scan Packets as running a virtual TAPC state machine at the TAP.7 pins. The effects of each Scan Packet take effect when the Scan Packet completes. The real TAP.7 and STL controller state machine states may change state before or after the virtual state machine.

67.8.8 SP Format

A SP serially exchanges the TDI, TMS, and TDO or a subset thereof, between the external tool and TAP.7 controller. Control information may be added to this exchange. A SP has three parts:

- **Payload** – Data + Control information (all scan formats), the payload content is varied to trade-off performance and flexibility. RDY bit(s) within the payload are included with some scan formats to provide the STL a means to stall progression of the TAPC state.
- **Delay** – Control information (optional) providing separation of adjacent payloads in time. Delay elements support simple external tool implementations where a delay element is used to stall progression of the TAPC state while it develops a new SP following the completion of the prior payload.

The header elements, delay elements, and control information within the payload element is consumed by the TAP.7 controller. This and other control information within the SP payload is not visible to the EPU and STL TAPCs.

67.8.8.1 Payload Element Content

67.8.8.1.1 Input and Output Bit Frames

An input bit frame is sourced by the external tool and an output bit frame is sourced by the TAP.7 controller. The payload may contain and input bit frame, an output bit frame, or both. When an input bet frame arrives at the TAP.7 controller, the TDI and TMS information within it is presented in parallel to the TAP.1 controllers within the EPU and STL. The output bit frame begins when the input frame is completed. The payload is completed when the EPU and STL are ready to utilize this information and the TDO data needed to complete the output bit frame is available. This process is repeated for each SP.

With input bit frames, MScan and OScan scan formats have no control bits input bit frames.

With output bit frames:

- TDO information passed to the external tool is a logic 1 when the EPU indicates the TDO pin would be high impedance.
- RDY bits provide TAP.7 stall opportunities with MScan and some OScan formats.
- PC0 and PC1 bits are added to MScan scan formats to allow Wire-ANDed output.

67.8.8.1.2 Varying the content of input and output bit frames

The various scan formats (MScan, OScan0-7) provide a number of options for the serialization of scan information for use in a Star-2 scan topology. These scan formats vary the content of SPs to balance flexibility and performance for different use cases. The amount of information transferred per TAPC state is based on the constraints imposed by these use cases. The MScan and OScan scan formats determine the factors affecting the payload content as shown in the following table.

Table 67-23. Factors determining the SP payload content

Scan format	Payload content determined by the:	
	TAPC state	Header
MScan	–	–
OScan	Yes	–

67.8.8.2 Delay Element Content

A delay element can be zero, one, two, or n bits in length. One and two bit delay elements are fixed length with neither the external tool or TAP.7 controller driving the TMSC pin. The TMSC pin is kept at the last value driven by either the external tool or TS. With an n-bit delay elements, the external tool drives the TMSC pin for the first n-1 bits and may drive the TMSC pin the nth bit. With an n-bit delay element the string of delay element bits is a series of directives virtually the same as those used by a CP (DLY_NOP, DLY_END, and DLY_RES).

67.8.8.3 Scan Formats

67.8.8.3.1 Overview

Scan formats utilizing the Advanced Protocol address different use cases. The amount of information transferred per TAPC state is based on the constraints imposed by these use cases. In one extreme two types of control information, the first allowing the stall of the completion of the Scan Packet, and the second supporting the Wire-AND of TAP.7 controller output are added to the TMS, TDI, and TDO information within the Scan Packet. In the other extreme, the external tool may minimize the information transferred for each TAPC state using its understanding of the application and transfer only the data of interest. In some cases the transfer of only one bit of information per TAPC is

required. There are a number of scan formats that operate between these two extremes. The external tool chooses a scan format that best matches the performance/functionality needs of the application.

The scan formats added to specify the use of the Advance Protocol are listed below:

- **MScan** – Maximum flexibility.
- **OScan0-7** – Optimized for test and debug applications.

These scan formats provide seven different functions. Five factors have influenced the definition of these scan formats:

- Supporting the capabilities of the IEEE1149.x and IEEE 1532 Standards.
- Providing the STL and external tool an opportunity to stall the TAPC state progression.
- Providing a minimum pin count and scalable functionality.
- Maximizing the efficiency of scan operations utilized for applications debug operations.
- Providing a rich set of capability for high end applications debug.

The performance and flexibility of MScan and OScan scan formats are shown in Table 67-24 and Table 67-26. The performance and flexibility of these scan formats are given subjective/approximate ratings in these tables. These ratings range from least to best. Use cases for these scan formats are also included in these tables.

67.8.8.3.2 MScan scan formats

The MScan scan format provides a universal scan function. It is the most flexible but lowest-performance scan format. The Scan Packets used by these scan formats are packed with data and control information and is the same for all TAPC states. This scan format accommodates the deployment of IEEE 1149.1 IP with non-compliant behavior within the STL. The STL is allowed to stall the TAPC state progression (to pace the arrival of Scan Packets with its ability to process them), and uses Wire-ANDed Output.

Table 67-24. MScan scan format use case summary

Scan format	Supporting	Performance	Flexibility	TCKC source
MScan	STL Stalls	Least	Best	External tool or TS
	Test			
	Non-compliant behavior STL IP			
	Multi-chip debug communication			
	Controller ID Allocation			

Table 67-25. MScan Scan Packet content

	Non-shift TAP controller states							Shift TAP controller states					
MScan	nTDI	TMS	PC0	RDY	PC1	TDO		nTDI	TMS	PC0	RDY	PC1	TDO

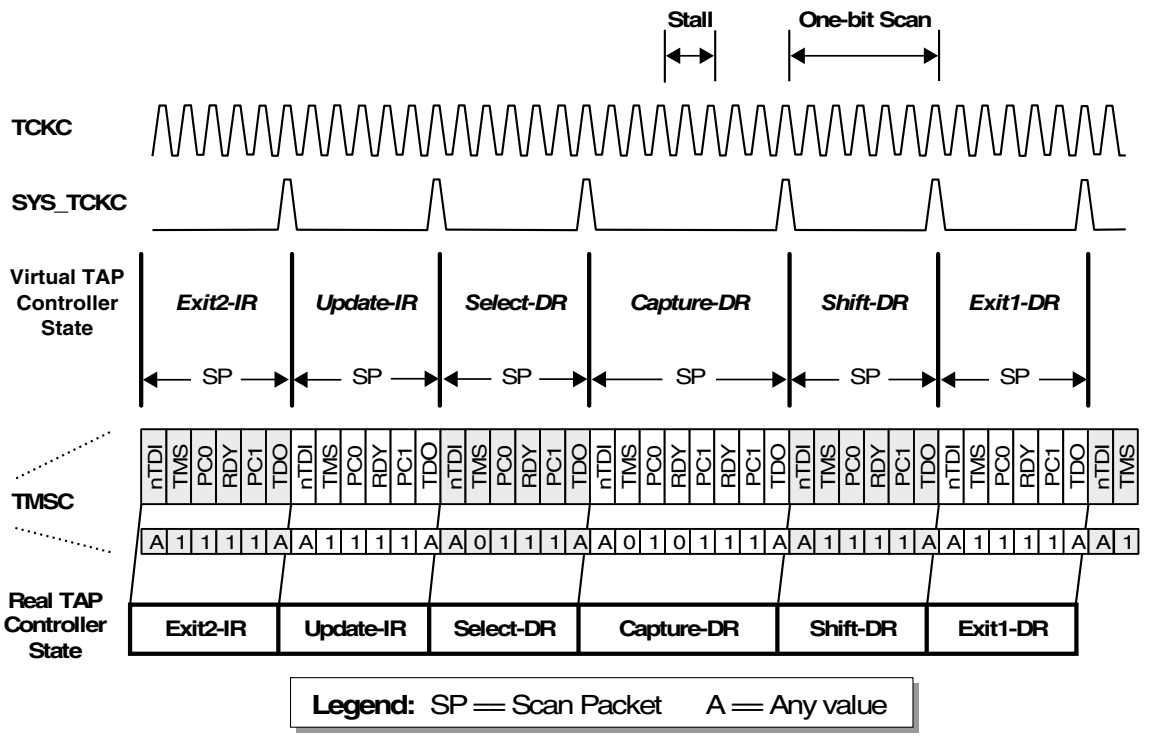

Figure 67-18. MScan Transaction

67.8.8.3.3 OScan Scan Formats

The OScan scan formats provide optimization choices where no knowledge of the data content of the scan exchange is needed. The Scan Packet content of these scan formats is modulated by a combination of the scan format and the TAPC state for some OScan scan formats. For instance, TDI data and TDO data is not exchanged for non-shift TAPC states and included in shift TAPC states in certain OScan formats. The modulation of Scan Packet content with TAPC state varies by scan format.

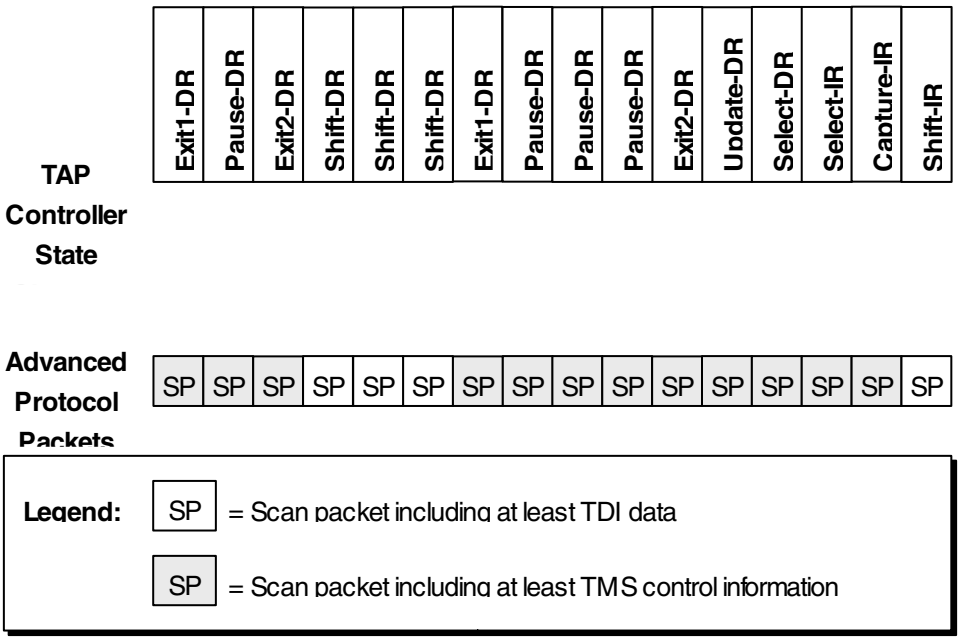

Figure 67-19. OScan Scan Packet content/TAPC state relationships

OScan scan formats replicate four functions in two forms:

- **OScan0 – OScan3:** Providing the best performance for a test clock source by the target system.
- **OScan 4 – OScan7:** Providing the best performance for a test clock sourced by the external tool.

The OScan4 – OScan7 scan formats are more efficient, as EOT escape sequences are used to identify an exit from the Shift-xR TAPC state. A Scan Packet associated with the Shift-xR TAPC state does not include a TMS bit. Instead, and EOT escape sequence overlaid on an nTDI bit causes an exit from shift TAPC state with no exit from this state occurring otherwise. A look at the 32-bit DR-Scan shows the impact of this optimization. A total of 96 bits are required when each Scan Packet associated with a Shift TAPC state when TMS is included in these Scan Packets while a total of 64 bits are required when TMS is not included in these Scan Packets. Assuming the EOT escape adds the equivalent of three bit periods, the number of TCK periods fo this transfer is 67/96 or roughly 70% of the total without this optimization.

These scan formats may only be used with an external tool sourced TCKC as EOTs are utilized to improve its performance. The OScan0 – OScan3 Scan Formats always have a TMS bit included in the Scan Packet. The OScan scan format use case summary is shown in the following table.

Table 67-26. OScan scan format use case summary

Scan Format	Supporting	Performance	Flexibility	TCKC Source
OScan0	Stalls	↓	Best	External tool
OScan1	Test		↑	
OScan2	Debug Performance			
OScan3	Debug Downloads (input only)	Best		
OScan4	Stalls	↓	Best	External tool or TS
OScan5	Test		↑	
OScan6	Debug Performance			
OScan7	Debug Downloads (input only)	Best		

Certain OScan optimizations are applied in a hierarchical manner.

- **Optimization I:** OScan1/OScan5 – RDY bit(s) and their trailing ONE bits are deleted from all Scan Packets.
- **Optimization II:** OScan2/OScan6 – Optimization I + nTDI and TDO bits are deleted from Scan Packets associated with non-shift TAPC states.
- **Optimization III:** OScan3/OScan7 – Optimization II + TDO bits are deleted from Scan Packets.
- **Optimization IV:** OScan4 – OScan7 – TMS bits are deleted from Scan Packets associated with shift TAPC states.

Table 67-27. OScan Scan Format "Payload"

Scan Format	Non-shift TAP controller states					Shift TAP controller states			
OScan0	nTDI	TMS	RDY	TDO		nTDI	TMS	RDY	TDO

67.9 Functional Description

This section combines the information given in the Ancillary Services, EPU Operation, and APU Operation sections into a single reference for performing common TAP.7 tasks.

67.9.1 Switching from Standard Protocol to Advanced Protocol

Upon exit of Type-0 to Type-4 reset, the CJTAG begins operation in Standard Protocol 4-pin mode. The following steps are required to move from Standard Protocol 4-pin mode to Advanced Protocol (either 4-pin or 2-pin) mode.

The first step required to move to the Advanced Protocol is to change the CJTAG control level to control level 2 via zero-bit scans (ZBS), as described in Control levels.

After the control level is set tocontrol level 2, TAP.7 commands can be executed as described in EPU Commands. Execution of the Store Scan Format (STFMT) to set the scan format to any OSCAN0-7 or MSCAN format begins the switch from the Standard Protocol to the Advanced Protocol.

Once the STFMT command is executed selecting an Advanced Protocol scan format, the CJTAG transitions to the intermediate Control Protocol mode. The Control Protocol uses TMS inputs to control Configuration Change Packets as described in Control Process Active (CPA) Function and Configuration Change Packets (CP). Loading a change packet body value of 00 (CP_END) results in the switch to the Advanced Protocol.

If Advanced Protocol 2-pin operation is desired, the APFC register should be written to a value of 10 or 11 prior to the execution of the STFMT command that selects an advanced scan format. The APFC register is written via the Store Conditional 2-bit (STC2) command described in Store Conditional 2-bit (STC2).

Chapter 68
JTAG Data Communication (JDC)

68.1 Introduction

The JTAG Data Communication (JDC) module provides the capability to move register data between the IPS and JTAG domains. This facilitates communication between internal resources that access memory mapped register space and an external tool that accesses the JTAG port.

68.2 Overview

The JDC module consists of IPS accessible registers, JTAG accessible registers, and associated logic to coordinate movement of data from one register domain to another.

The JDC implements the following IPS data registers, occupying separate memory space:

- 32-bit memory mapped register that can be read or written via IPS (JOUT_IPS), and whose contents are ported out for capture into a JTAG register (JOUT) to be read via the JTAG port.
- 32-bit memory mapped register that can only be read via IPS (JIN_IPS), and whose contents are loaded from a JTAG register (JIN).

In addition to the data registers themselves, logic is implemented to indicate when new data has been shifted in via the JTAG port and is ready to be read from the JIN_IPS register, and when new data has been written to the JOUT_IPS register and is ready to be read via the JTAG port. The state of these flags is captured into a status register (MSR), and also provided to a JTAG register (JOUT) for tool visibility.

There is a single bus interface to port register data out to the JTAGC, and a single bus interface to port data in from the JTAGC. The architecture is shown in the following figure.

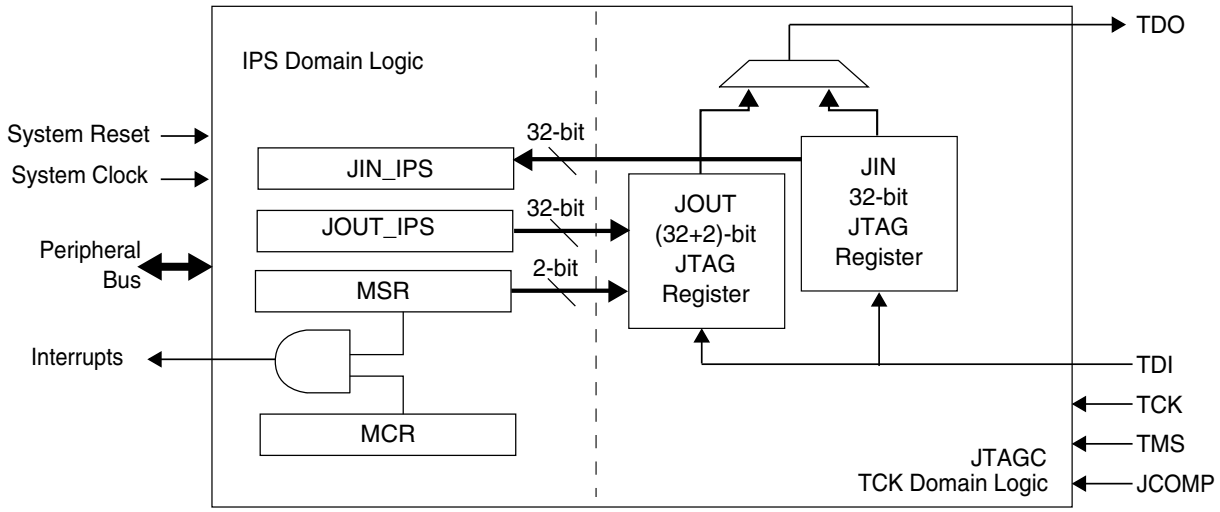

Figure 68-1. JDC block diagram

68.3 Memory mapped registers

Four 32-bit registers are implemented. Only 32-bit accesses are valid. The effects of access that are not 32 bits are not defined.

JDC memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	Module Configuration Register (JDC_MCR)	32	R/W	0000_0000h	68.3.1/2957
4	Module Status Register (JDC_MSR)	32	R/W	0000_0000h	68.3.2/2958
8	JTAG Output Data Register (JDC_JOUT_IPS)	32	R/W	0000_0000h	68.3.3/2959
C	JTAG Input Data Register (JDC_JIN_IPS)	32	R	0000_0000h	68.3.4/2960

68.3.1 Module Configuration Register (JDC_MCR)

The MCR is used to enable the interrupt outputs of the JDC. This register is reset by system destructive reset.

Address: 0h base + 0h offset = 0h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	Reserved															JIN_IEN

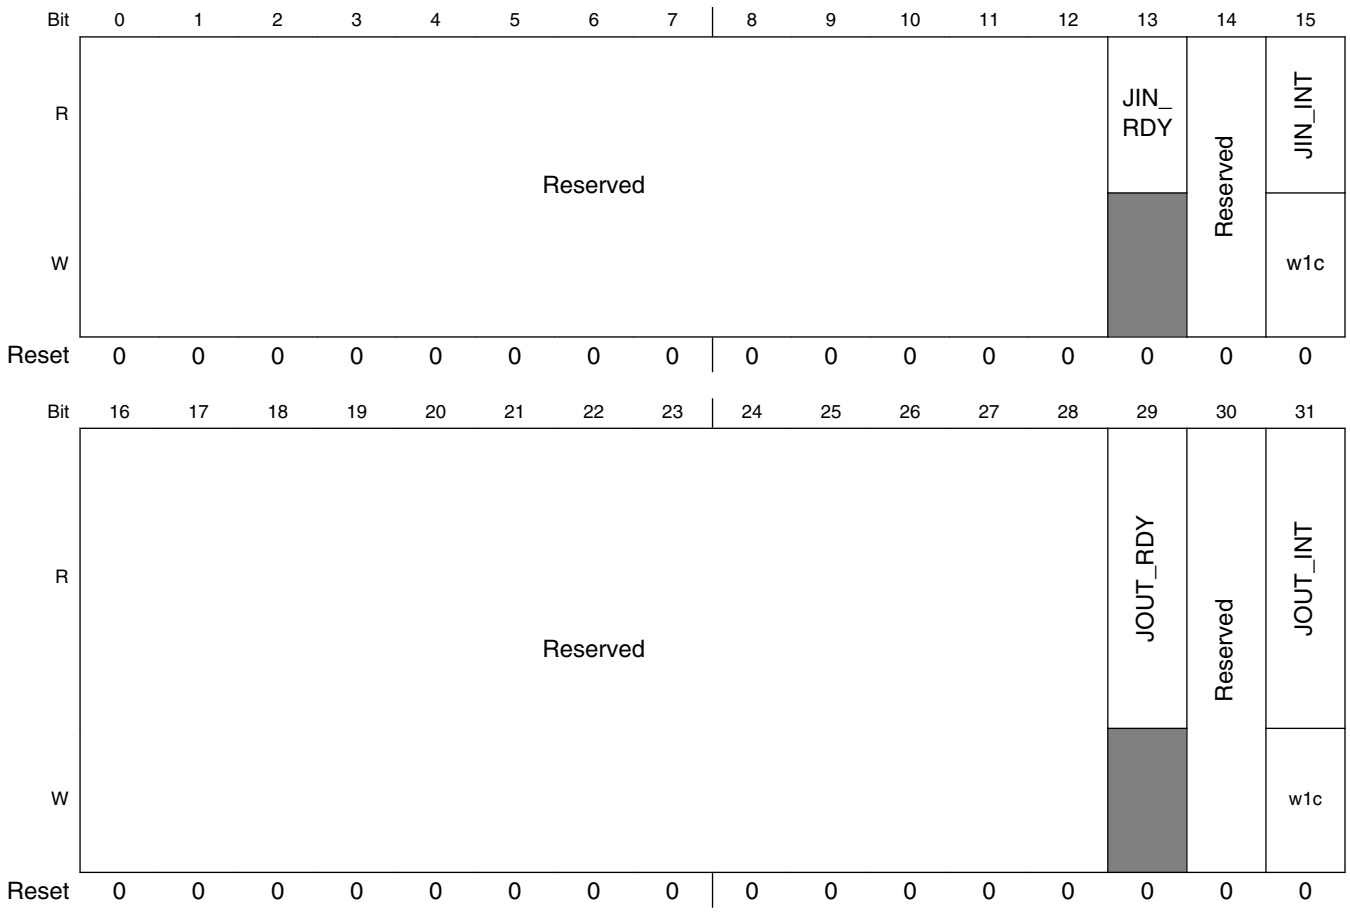
R	Reserved															JOUT_IEN
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0



JDC_MCR field descriptions

Field	Description
0–14 Reserved	This field is reserved.
15 JIN_IEN	JIN Interrupt Enable. 0 Setting of MSR[JIN_INT] bit does not assert the JIN interrupt 1 Setting of MSR[JIN_INT] bit asserts the JIN interrupt
16–30 Reserved	This field is reserved.
31 JOUT_IEN	JOUT Interrupt Enable. 0 Setting of MSR[JOUT_INT] bit does not assert the JOUT interrupt 1 Setting of MSR[JOUT_INT] bit asserts the JOUT interrupt

68.3.2 Module Status Register (JDC_MSR)

The MSR holds the JTAG register status and interrupt bits. This register is reset by system destructive reset.

Address: 0h base + 4h offset = 4h

JDC_MSR field descriptions

Field	Description
0–12 Reserved	This field is reserved.
13 JIN_RDY	JIN Ready (read only). 0 Cleared upon software read of JIN_IPS contents via IPS 1 Set when new data is written to the JIN_IPS register
14 Reserved	This field is reserved.
15 JIN_INT	JIN Interrupt.

Table continues on the next page...

JDC_MSR field descriptions (continued)

Field	Description
	0 Cleared by writing logic 1 1 Set when new data is written to the JIN_IPS register
16–28 Reserved	This field is reserved.
29 JOUT_RDY	JOUT Ready (read only). 0 Cleared upon tool read of JOUT register via JTAG port 1 Set when new data is written to the JOUT_IPS register
30 Reserved	This field is reserved.
31 JOUT_INT	JOUT Interrupt. 0 Cleared by writing logic 1 1 Set when JOUT_RDY bit is cleared by tool reading JOUT register

68.3.3 JTAG Output Data Register (JDC_JOUT_IPS)

The JOUT_IPS register holds data written via IPS. The JOUT_IPS contents are ported out and captured into the JOUT register to be read via the JTAG port. This register is reset by system destructive reset.

Address: 0h base + 8h offset = 8h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	Data

JDC_JIN_IPS field descriptions

Field	Description
0–31 Data	JIN_IPS data.

68.4 Non-Memory mapped register definition

The JDC also implements two JTAG accessible registers that are not memory mapped. One JTAG register is used to shift in data to be placed in the JIN_IPS register. The other JTAG register captures data from the JOUT_IPS register and ready status from the MSR to be shifted out via the JTAG port.

68.4.1 JTAG output data register (JOUT)

The JOUT register captures data from the JOUT_IPS register upon execution of the JOUT_READ JTAG instruction. It also holds the JIN_RDY and JOUT_RDY status bits. This register is reset by system destructive reset and JTAG reset. The following figure shows the format of the JOUT register.

	33	…	2	1	0
R W	JOUT_IPS Data			JIN_RDY	JOUT_RDY
Reset	*[1]	*	*	*	*

1. The reset value of the JOUT register is 34'b0.

The JOUT register is described in the following table.

Table 68-6. JOUT JTAG register field descriptions

Field	Description
JOUT_IPS Data	Data value from JOUT_IPS register
JIN_RDY	State of JIN_RDY bit from MSR
JOUT_RDY	State of JOUT_RDY bit from MSR

68.4.2 JTAG input data register (JIN)

Data is written to the JIN register via JTAG during execution of the JIN_WRITE JTAG instruction. The JIN data is later captured in the JIN_IPS register to be read via IPS. This register is reset by system destructive reset and JTAG reset. The following figure shows the format of the JIN register.

	31	…	0
R W	JIN Data		
Reset	*[1]	*	*

1. The reset value of the JIN register is 32'b0.

The JIN register is described in the following table.

Table 68-7. JIN JTAG register field descriptions

Field	Description
JIN Data	Contains data to be captured in JIN_IPS register upon exit of Update-DR state when executing WRITE_JIN JTAG instruction.

68.5 Functional description

The JDC module provides the ability to shift in data via the JTAG port and capture that data into a memory mapped register that can be accessed via IPS. It also provides the ability to capture data written to a memory mapped register into a JTAG shift register for output via the JTAG port. An overview of the module functionality is described below.

- A software write to the JOUT_IPS register sets the JOUT_RDY flag bit, indicating new data is available to be read from the JOUT register via the JTAG port. The state of the JOUT_RDY bit is reflected in the MSR and also ported out to the JOUT register. A JTAG read of the JOUT register via execution of the JOUT_READ

instruction with a JOUT_RDY bit whose value is logic 1 indicates the register contains new data. The JOUT_RDY flag bit is cleared upon exit of the Capture-DR JTAG state during execution of the JOUT_READ instruction. Clearing the JOUT_RDY bit indicates to software that a new data value can be written to the JOUT_IPS register.

- A JTAG write to the JIN register via execution of the JIN_READ JTAG instruction updates the contents of the JIN_IPS register upon exit of the Update-DR state. An update of the JIN_IPS register sets the JIN_RDY flag bit, indicating new data is available to be read via IPS. The state of the JIN_RDY bit is reflected in the MSR register and also ported out to the JOUT register. The JIN_RDY flag bit is cleared upon software read of the JIN_IPS register. A JTAG read of the JOUT register with a JIN_RDY value of logic 0 indicates new data can be written to the JIN register.

68.5.1 JTAG register access

Refer to the JTAGC documentation for information on how to access the JTAG registers.

68.5.1.1 JDC block instructions

The JDC block implements the IEEE 1149.1-2001 defined instructions listed in the following table. This section gives an overview of each instruction; refer to the IEEE 1149.1-2001 standard for more details. All undefined opcodes are reserved.

Table 68-8. JTAG instructions

Instruction	Code[4:0]	Instruction Summary
Reserved	00001	Factory debug reserved
JOUT_READ	00010	Selects JOUT data register. Data from JOUT_IPS is captured into JOUT data register upon entry to Capture-DR state while JOUT_READ is active.
JIN_WRITE	01110	Selects JIN data register. Data from JIN is captured into JIN_IPS upon exit of Update-DR state while JIN_WRITE is active.
BYPASS	11111	Selects bypass register for data operations
Reserved	All other opcodes	Decoded to select bypass register

Chapter 69
Sequence Processing Unit (SPU)

69.1 Sequence Processing Unit (SPU) chip-specific module information

Although SPU_SS[25] is reserved, it will be automatically asserted when SPU is enabled (SPU_SE[SED]=1).

69.2 Introduction

The Sequence Processing Unit (SPU) provides an on-device trigger functions similar to those found on a logic analyzer. In a complex SoC, performance monitor functions are available at two levels: system level and CPU level. Complex trigger and system performance monitor functions are implemented in the SPU module. System level performance monitor functions are integrated into the SPU complex trigger logic, and thus allow counting and timing of any debug trigger combinations supported by the SPU.

Various clients such as the cores or crossbar switch, generate watchpoints and triggers when operating in their debug mode. The SPU collects these triggers (such as interrupt occurrence, address watchpoint, and so on) and uses them as conditions to sequence through states, with resultant actions (such as start/stop trace, start/stop counter, capture timebase, and so on) The SPU provides the capability to create complex debug triggers. By configuring each of the events to trigger specific actions, complex logic-analyzer-like behavior can be achieved, providing vital real-time visibility and debug ability of the activities of the system.

69.2.1 SPU block diagram

The following figure shows a top-level block diagram of the SPU.

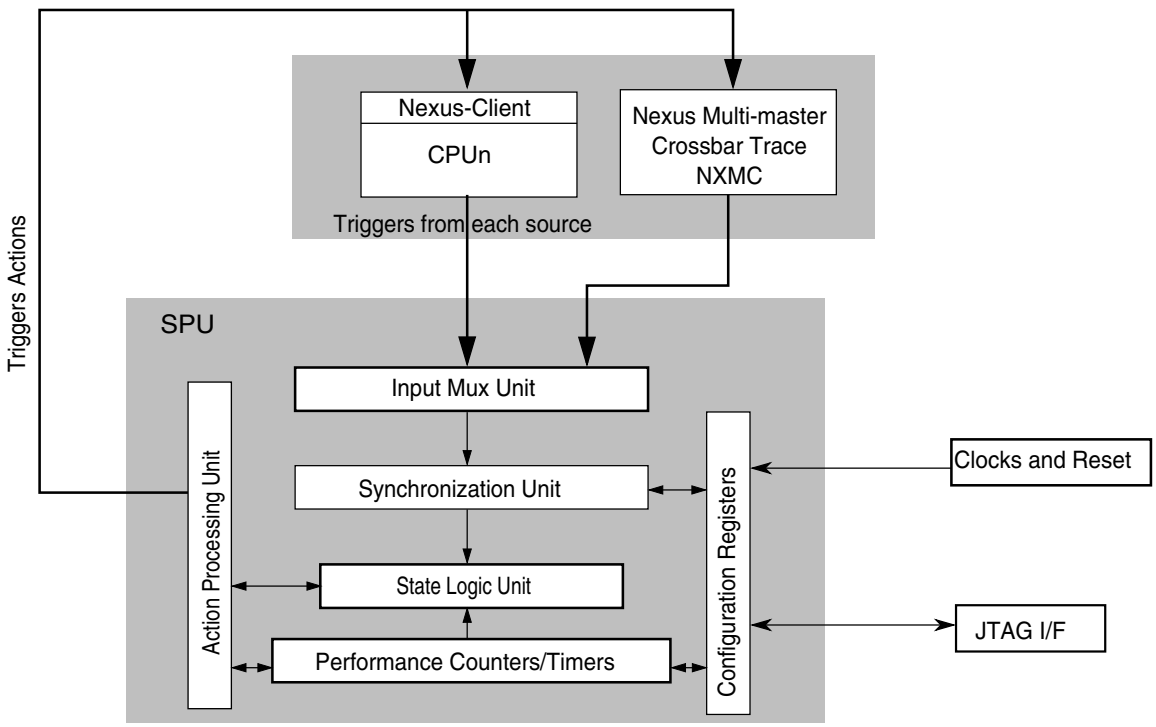

Figure 69-1. SPU block diagram

69.2.2 Overview

The SPU is able to generate complex debug events, based upon input events from sources (CPUs and system bus clients) throughout the SoC. The SPU has the ability to create a state machine to trigger a debug action. Single or multiple actions can be triggered by a state machine, which results in debug events being created. There are a selection of timers and counters available to assist comparison events.

Complex trigger support is implemented in the State Logic Unit (SLU). There are numerous inputs coming from different clients. Users can choose 63 inputs from a set of 167 inputs at the level one Mux. There are actually 64 inputs to the Muxes but one of the inputs is permanently connected to a high level, so users can only choose 63 of the inputs. Out of these 63 inputs, users can select 16 inputs for each SLU. This is shown in Figure 69-4.

One SLU consists of four input AND gates, the output of which are ORed together. One of the inputs of each AND gate has the option to invert it. Also, the output of each AND gate can be optionally inverted. Finally, the output of each SLU has the option of inversion. The block diagram for one SLU state is shown in Figure 69-5. The SPU includes eight SLUs states.

Users can utilize these states to form a configurable state machine. This allows users to join states together with the if-then-else operations to create a sequence. Each state in a sequence has the ability to move to another state based on the true condition from the state logic, and the ability to route to another state based on the a false condition from the state logic. This is shown in Figure 69-6 and Figure 69-7. At a given time, a maximum of four sequences are allowed. Each sequence can have one state or maximum of eight states. Each state can only be used in one unique sequence. The number of states in all the sequences cannot exceed eight. Each state has the ability to trigger one to four actions based on a true/false condition in the active sequence.

An example of typical complex trigger for the SPU would be: if FunctionA is entered, monitor CPU0 writes to VariableB. If CPU0 writes a value to VariableB which is 0x100, then enable trace for CPU1 and halt CPU0.

The SPU consists of the following sub-blocks:

- Input Mux Unit—receives the numerous triggers from various clients and reduces them down into a user selected set. The muxing unit selects sixteen inputs for each sequencing SLU from a set of 63 static inputs. This selection is done using two levels of muxing. At the first level of muxing, users select 63 out of 167 inputs. At the second level of muxing, out of these 63 inputs, one input can be selected for each of the four input AND gates. There are 128 64 × 1 Muxes to cater the needs of 128 inputs of all the eight states. This input mux selection logic is shown in Figure 69-4.
- State Logic Units (SLU)—responsible for performing operations on the selected input events to produce desired events. Each SLU has a control register that manages how the various inputs are combined to produce a desired event. Only one input of each four input AND gate can be independently inverted. The combined event can also be optionally inverted. These optional inversions coupled with DeMorgan's law allows for generalized signal combinations. This is shown in Figure 69-5.
- Action Processing Unit—takes an action request from a SLU state and converts this into one or multiple actions. The action unit can be programmed to trigger various actions in response to each processed event from the SLU unit. The user can define the actions associated with each state from each SLU.
- Counters/Timers—The SPU implements 16 32-bit timer/counter functionality. Timer or counter selection is done via a configurable register in the SPU. Each counter/timer has its own control register. A 32-bit comparator value can optionally be compared against the timer/counter. These registers are accessible via JTAG.

69.2.3 Features

The features of the SPU are as follows:

- Clients:
  - 2 CPU(s)
  - 2 System Bus clients (NXMC)
- Input watchpoints/triggers selection
- Input debug triggers for instruction execution selection
- Input interrupt selection
- Sequences and states criteria
  - Up to 4 user programmable number of active/simultaneous sequences
  - Up to 8 user programmable states that can be split between all four sequences
  - Each state can only be used in one unique sequence
  - A sequence can consist of a single state or any number of states up to 8
- State logic
  - Each state logic consist of sum of products (SOP)
  - SOP consist of four 4-input AND gates, and one 4-input OR gate
  - Optional inversion on one input of each AND gate of each state logic
  - Optional inversion on output of each AND gate.
  - Optional inversion on output of OR gate of each state
  - States are joined together with if-then-else statement to create a sequence
- SLU events
  - Up to 8 user programmable derived events/actions
  - Any state can optionally trigger of 1 to 4 actions based on a true condition
  - Any state can optionally trigger of 1 to 4 actions based on a false condition
  - User selection of trigger actions generated in response to each programmed trigger
- SPU counters/timers

    - 16 32-bit counters/timers
    - Timer/counter configurability selection via a register
    - Start/increment when used as timer/counter respectively
    - Reset when used as timer/counter respectively
    - Counter value compare match
    - Counter overflow event status
    - Generation of a greater than condition against a 32-bit comparator value (no support for range condition from single counter)
    - Range support using two counters
    - Use of counter/timer registers to generate counted or timed triggers
    - Use of counter/timer registers to capture system performance statistics
    - Each timer/counter value has the ability to be inserted into the Nexus trace stream upon an SPU action
    - Access to timer/counter values via JTAG
- Prescaler for timer mode only
    - Configurable prescaler of /1, /4, /16 or /32 of the clock for timer operation inside the SPU
- Asynchronous interfaces
    - SPU to/from CPU (fastest clock)
    - SPU to/from NXMC
    - SPU to/from NAR
    - SPU to/from DCI
    - SPU to/from JTAGM
- Interfaces
    - CPU
    - System bus
    - NAR
    - DCI

- Configuration registers—32-bit double word aligned configuration registers (byte, halfword access not supported)
- SPU actions—SPU block triggers various actions based on the derived events, these actions are defined in SPU actions.

69.3 SPU actions

Sequence actions describe what is triggered. A sequence state may only have a GoTo action to determine the next sequence state. The complete set of actions are as follows:

- Start/stop trace for a source
- Start/stop/increment counter/timer counter/timer[0–15]
- Reset counter/timer[0–15]
- Capture counter/timer values[0–15]—place the specified counter/timer value into the trace stream for counters[0–15]
- Halt1—single signal (EVTI0) that can be used to halt a pre-configured DCI group1
- Halt2—single signal (EVTI1) that can be used to halt a pre-configured DCI group2
- Generate a watchpoint trigger for a respective ID field the NXMC (global timestamp must be enabled from the NAR)
- Capture the global timebase and place it into the trace stream with a watchpoint ID field of respective watchpoints at the NXMC (send TIMESTAMPx where x is related to an watchpoint ID field of NXMC only)
- Single interrupt for INTC to interrupt a CPU—de-assert (cleared) via JTAGM
- Generate a pulse on the EVTO pin—output pulse over EVTO1 and EVTO2
- Start or Stop Performance Counters (PMC) for a CPU source—Start/Stop CPUn
- Optional trace group 1 (Start/Stop Trace a pre-configured set of trace signals)—four (DTM,PTM,WTM,OTM) independent start/stop trace groups can be formed. One or more clients (CPUn and Nexus) can be part of a particular group.

Note

GoTo is not part of the Action list described above but it is implemented in the state logic to move from one state to another. If there is nothing defined for GoTo, it signifies the end of the sequence.

In the condition where a state (State n) updates a counter and the next state in the sequence (State n+1) evaluates the value of the same counter (for example, to compare if the counter is less-than a certain value), the update to the counter (from State n) is not applied before the counter evaluation in the next state (State n+1). This results in the old value of the counter being evaluated (in State n+1), rather than the desired updated value. This is due to hardware limitations of the SPU as the update to the counter does not complete until the clock cycle after the evaluation of the next state. This limitation is only applicable in Div1 mode and not in Div4 mode.

To workaround this hardware limitation, a delay should be inserted between the update to a counter and the evaluation of this counter. A dummy state can be used between the counter update (State n) and the counter evaluation (State n+1). A dummy state is a state with any input, that on both then/else conditions, the action proceeds to the next state (State n+1) where the counter evaluation occurs. The insertion of this dummy state provides sufficient time for the update of the counter to be applied, in time for the counter evaluation. The same outcome is also possible in a complex sequence with multiple states by scheduling states so that counter update and counter evaluation are not performed on consecutive states in a sequence.

69.4 SPU enable/disable mode

By default, the SPU is in disabled mode. In this state, all events/inputs are disabled such that no counting or other actions occur. All of the SPU control registers are accessible in this state. All of the configurations must be done before enabling the SPU by programming the SPU Enable/Disable register.

69.5 SPU module interface

The SPU is connected to many clients such as the cores, system bus, NAR and Nexus clients. The SPU also interfaces to the DCI and the JTAG modules as shown in the following figure.

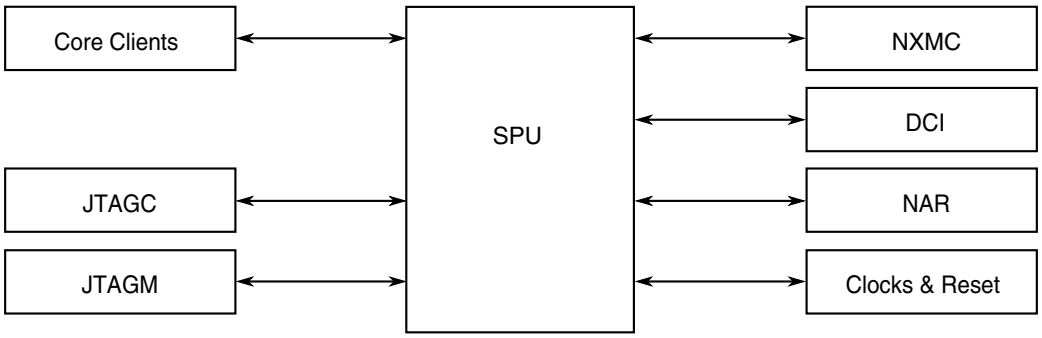

Figure 69-2. SPU module interface

69.6 Register definition

The SPU contains 32-bit aligned registers (byte and half-word access are not supported). All configuration registers in the SPU are JTAG registers such that these registers are accessible via JTAG interface only. Write access to reserved locations have no impact while read access to reserved locations always return 0. These registers have Nexus reset and JTAG reset control.

Note

The SPU does not check for correctness of the programmed values in the registers and programmers must ensure that correct values are being written.

The following table lists the memory mapped registers which control the operation of the SPU. There are two instructions for the SPU registers:

- Instruction to enable the SLU (first set of registers with offsets 0x1–0x49) registers is 4'h3
- Instruction to enable the Counter Control Unit (second set of registers with offsets 0x1–0x48) is 4'h2

Table 69-1. SPU register summary

Offset (hex)	Register	Access	Reset Value
1	Level1 Mux Selection 0 (L1SEL0)	R/W	32'h0
2	Level1 Mux Selection 1 (L1SEL1)	R/W	32'h0
3	Level1 Mux Selection 2 (L1SEL2)	R/W	32'h0

69.6.1 Level1 input Mux configurations registers

A set of input Mux control registers is used to narrow down the large number of SPU watchpoints to a manageable set. There are sixty-four 8 × 1 (eight inputs and one output) multiplexers. Three bits per Mux are used to select one input out of 8 inputs. 8 Muxes are configured with each 32-bit register; in other words, 8 out of 64 inputs for each register. This provides the flexibility to the programmer to route any input trigger to any state input. The detail of this selection is shown in Figure 69-4.

Note

Users cannot program MUX 63 in L1SEL7 (the 64th mux). All eight inputs of the 63rd mux are tied to high and the output is always high (1'b1).

69.6.1.1 Level1 Mux Selection 0 (L1SEL0)

The following table shows the format of the L1SEL0 register. The values for the fields of the L1SEL0 register are device dependent. For a description of these fields, see the device-specific chapter that describes how the modules are configured.

Offset: 0x01 Access: User read/write

69.6.1.9 Input triggers level detection control 2 (ITLD2)

Only a rising edge is detected on the outputs of the first 32 level1 Muxes and therefore these values are not programmable. The last 32 level1 Muxes (Mux 32–63) trigger level is programmable in the Input Triggers Level Detection Control 2 and 3 registers. The following table shows the format of the ITLD2 register. All of the MUX fields in the ITLD2 register have the same description as shown in Table 69-2.

The ITLD registers Mux field is described in the following table.

Table 69-2. ITLD register field descriptions

Field	Description
Mux*	Mux Output Signal Detection.
	00 Level is passed after synchronization (default)
	01 Posedge detection
	10 Toggle detection
	11 Level is passed after synchronization

69.6.1.10 Input triggers level detection control 3 (ITLD3)

Only a rising edge is detected on the outputs of the first 32 level1 Muxes and therefore these values are not programmable. The last 32 level1 Muxes (Mux 32–63) trigger level is programmable in the Input Triggers Level Detection Control 2 and 3 registers. The following table shows the format of the ITLD3 register. All of the MUX fields in the ITLD3 register have the same description as shown in Table 69-2.

Offset					0x0C								Access: User read/write

69.6.1.11 CPU0 processor exception vector prefix (C0PEVP)

The SPU captures the exception vector from CPU0 when the exception enable signal is asserted. The exception vector decoding is defined in Table 69-28. The SPU compares this captured vector with the value in the C0PEVP register. The following table shows the format of the C0PEVP register.

Offset: 0x0D Access: User read/write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

The C0PEVP register is described in the following table.

Table 69-3. C0PEVP register field descriptions

Field	Description
15:0 CPU0	CPU0 processor exception vector. Program this field with one of the vector values from Table 69-28 to select the corresponding processor exception. **Note:** This field must use the byte swapped values in the CnPEVP register CPUn field value column in Table 69-28.
31:16	Reserved

69.6.1.12 CPU1 processor exception vector prefix (C1PEVP)

The SPU captures the exception vector from CPU1 when the exception enable signal is asserted. The exception vector decoding is defined in Table 69-28. The SPU compares this captured vector with the value in the C1PEVP register. The following table shows the format of the C1PEVP register.

Offset: 0x0E Access: User read/write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
W	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	CPU1															
R																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The C1PEVP register is described in the following table.

Table 69-4. C1PEVP register field descriptions

Field	Description
15:0 CPU1	CPU1 processor exception vector. Program this field with one of the vector values from Table 69-28 to select the corresponding processor exception. **Note:** This field must use the byte swapped values in the CnPEVP register CPUn field value column in Table 69-28.
31:16	Reserved

69.6.1.13 CPU0 interrupt priority selection (C0PIS)

The following table shows the format of the C0PIS register. The SPU compares the input CPR vector from CPU0 with the value programmed to the C0PIS register and generates a match signal if necessary. The typical use case would be for posedge detection on match (to detect when the priority level is set to the compare value) or high detection while match remains.

Offset: 0x012 Access: User read/write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
W	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	CPU0

The C1PIS register is described in the following table.

Table 69-6. C1PIS register field descriptions

Field	Description
7:0 CPU1	CPU1 Priority Interrupt Selection.
31:8	Reserved

69.6.2 Level2 input Mux configurations registers

At level1, the set of input Mux control registers (described in Level1 input Mux configurations registers) narrows down the large number of SPU watchpoints to a manageable set using sixty-four 8 × 1 multiplexers. At Level2, 16 inputs are selected for each SLU from the 64 level1 outputs using 16 64 × 1 multiplexers. Six bits per Mux select one input out of 64 (in fact 63) inputs. Each 32-bit register configures the AND gates of one state; therefore, eight registers are used to configure inputs for the 8 SLUs. All the 63 inputs are static for all the eight states. Any 16 inputs can be selected from the 63 input triggers for a state.

The detail selection is shown in the following figure for State0. Similar logic is provided for States 1–7.

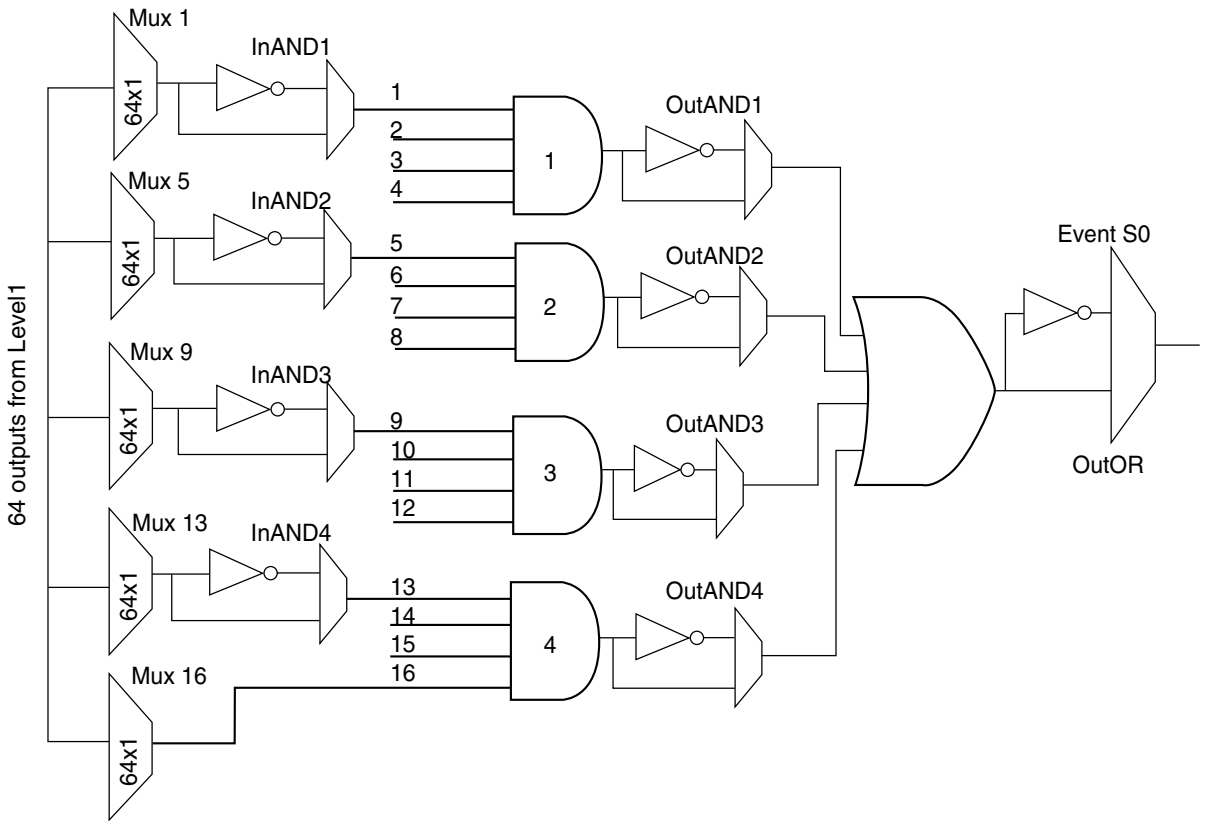

Figure 69-3. Level2 Mux AND gates input pin routing for State0

Note

If any SLU AND gate is unused, then its output is logic low (1'b0). Thus, if all four inputs of a particular AND gate are at the default value 1'b1 (none of the inputs have been routed from the Level 2 mux to the inputs of AND gates), then the output of that AND gate is logic low. This provides protection to avoid the masking of other inputs to the OR gate.

69.6.2.1 Level2 Mux state n selection 0 (L2nSEL0)

The following table shows the format of the L2nSEL0 register, where n, the state number, is equal to 0–7.

Offset:	0x17 (State0)	Access: User read/write
	0x1B (State1)	
	0x1F (State2)	
	0x23 (State3)	
	0x27 (State4)	
	0x2B (State5)
