18.5.5 Enable Error Interrupt Register High (DMA_EEIH)

The EEI{H,L} registers provide a bit map to enable the error interrupt signal for each of the 64 channels. EEIH supports channels 63-32, while EEIL covers channels 31-00. The state of any given channel's error interrupt enable is directly affected by writes to this register; it is also affected by writes to the SEEI and CEEI registers. The SEEI and CEEI registers are provided so that the error interrupt enable for a single channel can easily be modified without the need to perform a read-modify-write sequence to the EEI{H,L} registers.

Both the eDMA error indicator and error interrupt enable flag must be asserted before an error interrupt request for a given channel is asserted.

18.5.7 Set Enable Request Register (DMA_SERQ)

The SERQ register provides a simple memory-mapped mechanism to set a given bit in the ERQ{H,L} registers to enable the eDMA request for a given channel. The data value on a register write causes the corresponding bit in the ERQ{H,L} register to be set. A data value of 64 to 127 (regardless of the number of implemented channels) provides a global set function, forcing the entire contents of ERQ{H,L} to be asserted. If bit 7 is set, the command is ignored. This allows multiple byte registers to be written as a 32-bit word. Reads of this register return all zeroes.

Address: 0h base + 18h offset = 18h

Bit	0	1	2	3	4	5	6	7
Read	0	SERQ						
Write	NOP							
Reset	0	0	0	0	0	0	0	0

Field	Description
0 NOP	No Op enable

Table continues on the next page...

DMA_SERQ field descriptions (continued)

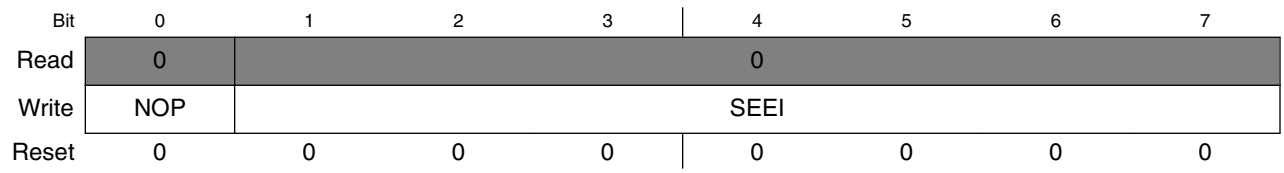
Field	Description
	0 Normal operation 1 No operation, ignore the other bits in this register
1–7 SERQ	Set Enable Request. 0-63: Set the corresponding bit in ERQ{H,L} 64-127: Set all bits in ERQ{H,L}

18.5.8 Clear Enable Request Register (DMA_CERQ)

The CERQ register provides a simple memory-mapped mechanism to clear a given bit in the ERQ{H,L} registers to disable the eDMA request for a given channel. The data value on a register write causes the corresponding bit in the ERQ{H,L} register to be cleared. A data value of 64 to 127 (regardless of the number of implemented channels) provides a global clear function, forcing the entire contents of the ERQ{H,L} to be zeroed, disabling all eDMA request inputs. If the NOP bit is set, the command is ignored. This allows multiple byte registers to be written as a 32-bit word. Reads of this register return all zeroes.

Address: 0h base + 19h offset = 19h

Bit	0	1	2	3	4	5	6	7
Read	0	0						
Write	NOP	CERQ						
Reset	0	0	0	0	0	0	0	0



DMA_CERQ field descriptions

Field	Description
0 NOP	No Op enable. 0 Normal operation 1 No operation, ignore the other bits in this register
1–7 CERQ	Clear enable request. 0-63: Clear corresponding bit in ERQ{H,L} 64-127: Clear all bits in ERQ{H,L}

18.5.9 Set Enable Error Interrupt Register (DMA_SEEI)

The SEEI register provides a simple memory-mapped mechanism to set a given bit in the EEI{H,L} registers to enable the error interrupt for a given channel. The data value on a register write causes the corresponding bit in the EEI{H,L} register to be set. A data value of 64 to 127 (regardless of the number of implemented channels) provides a global set function, forcing the entire contents of EEI{H,L} to be asserted. If the NOP bit is set, the command is ignored. This allows multiple byte registers to be written as a 32-bit word. Reads of this register return all zeroes.

Address: 0h base + 1Ah offset = 1Ah

DMA_SEEI field descriptions

Field	Description
0 NOP	No Op enable 0 Normal operation 1 No operation, ignore the other bits in this register
1–7 SEEI	Set enable error interrupt 0-63: Set the corresponding bit in EEI{H,L} 64-127: Set all bits in EEI{H,L}

18.5.10 Clear Enable Error Interrupt Register (DMA_CEEI)

The CEEI register provides a simple memory-mapped mechanism to clear a given bit in the EEI{H,L} registers to disable the error interrupt for a given channel. The data value on a register write causes the corresponding bit in the EEI{H,L} register to be cleared. A data value of 64 to 127 (regardless of the number of implemented channels) provides a global clear function, forcing the entire contents of the EEI{H,L} to be zeroed, disabling all eDMA request inputs. If the NOP bit is set, the command is ignored. This allows multiple byte registers to be written as a 32-bit word. Reads of this register return all zeroes.

Address: 0h base + 1Bh offset = 1Bh

Bit	0	1	2	3	4	5	6	7
Read	0	0						
Write	NOP	CEEI						
Reset	0	0	0	0	0	0	0	0

DMA_CEEI field descriptions

Field	Description
0 NOP	No Op enable 0 Normal operation 1 No operation, ignore the other bits in this register
1–7 CEEI	Clear Enable Error Interrupt. 0-63: Clear corresponding bit in EEI{H,L} 64-127: Clear all bits in EEI{H,L}

18.5.11 Clear Interrupt Request Register (DMA_CINT)

The CINT register provides a simple memory-mapped mechanism to clear a given bit in the INT{H,L} registers to disable the interrupt request for a given channel. The given value on a register write causes the corresponding bit in the INT{H,L} register to be cleared. A data value of 64 to 127 (regardless of the number of implemented channels) provides a global clear function, forcing the entire contents of the INT{H,L} to be zeroed, disabling all eDMA interrupt requests. If the NOP bit is set, the command is ignored. This allows multiple byte registers to be written as a 32-bit word. Reads of this register return all zeroes.

Address: 0h base + 1Ch offset = 1Ch

Bit	0	1	2	3	4	5	6	7
Read	0	0						
Write	NOP	CINT						
Reset	0	0	0	0	0	0	0	0

DMA_CINT field descriptions

Field	Description
0 NOP	No Op enable. 0 Normal operation 1 No operation, ignore the other bits in this register
1–7 CINT	Clear Interrupt Request. 0-63: Clear the corresponding bit in INT{H,L} 64-127: Clear all bits in INT{H,L}

18.5.12 Clear Error Register (DMA_CERR)

The CERR register provides a simple memory-mapped mechanism to clear a given bit in the ERR{H,L} registers to disable the error condition flag for a given channel. The given value on a register write causes the corresponding bit in the ERR{H,L} register to be cleared. A data value of 64 to 127 (regardless of the number of implemented channels) provides a global clear function, forcing the entire contents of the ERR{H,L} to be zeroed, clearing all channel error indicators. If the NOP bit is set, the command is ignored. This allows multiple byte registers to be written as a 32-bit word. Reads of this register return all zeroes.

Address: 0h base + 1Dh offset = 1Dh

Bit	0	1	2	3	4	5	6	7
Read	0	0						
Write	NOP	CERR						
Reset	0	0	0	0	0	0	0	0

DMA_CERR field descriptions

Field	Description
0 NOP	No Op enable. 0 Normal operation 1 No operation, ignore the other bits in this register
1–7 CERR	Clear Error Indicator. 0-63: Clear corresponding bit in ERR{H,L} 64-127: Clear all bits in ERR{H,L}

18.5.13 Set START Bit Register (DMA_SSRT)

The SSRT register provides a simple memory-mapped mechanism to set the START bit in the TCD of the given channel. The data value on a register write causes the START bit in the corresponding Transfer Control Descriptor to be set. A data value of 64 to 127 (regardless of the number of implemented channels) provides a global set function, forcing all START bits to be set. If the NOP bit is set, the command is ignored. This allows multiple byte registers to be written as a 32-bit word. Reads of this register return all zeroes.

Address: 0h base + 1Eh offset = 1Eh

Bit	0	1	2	3	4	5	6	7
Read	0	0						
Write	NOP	SSRT						
Reset	0	0	0	0	0	0	0	0

DMA_SSRT field descriptions

Field	Description
0 NOP	No Op enable. 0 Normal operation 1 No operation, ignore the other bits in this register
1–7 SSRT	Set START Bit 0-63: Sets the corresponding bit in TCDn_WORD_7[START] 64-127: Set all TCDn_WORD_7[START] bits

18.5.14 Clear DONE Status Bit Register (DMA_CDNE)

The CDNE register provides a simple memory-mapped mechanism to clear the DONE bit in the TCD of the given channel. The data value on a register write causes the DONE bit in the corresponding Transfer Control Descriptor to be cleared. A data value of 64 to 127 (regardless of the number of implemented channels) provides a global clear function, forcing all DONE bits to be cleared. If bit 7 is set, the command is ignored. This allows multiple byte registers to be written as a 32-bit word. Reads of this register return all zeroes.

Address: 0h base + 1Fh offset = 1Fh

Bit	0	1	2	3	4	5	6	7
Read	0	0						
Write	NOP	CDNE						
Reset	0	0	0	0	0	0	0	0

DMA_CDNE field descriptions

Field	Description
0 NOP	No Op enable. 0 Normal operation 1 No operation, ignore the other bits in this register
1–7 CDNE	Clear DONE Status Bit. 0-63: Clears the corresponding bit in TCDn_WORD_7[DONE] 64-127: Clear all TCDn_WORD_7[DONE] bits

18.5.15 Interrupt Request Register High (DMA_INTH)

The INT{H,L} registers provide a bit map for the 64 channels, signaling the presence of an interrupt request for each channel. INTH supports channels 63-32, while INTL covers channels 31-00. The eDMA engine signals the occurrence of a programmed interrupt upon the completion of a data transfer as defined in the transfer control descriptor by setting the appropriate bit in this register. The outputs of this register are directly routed to the platform's interrupt controller. During the execution of the interrupt service routine associated with any given channel, it is software's responsibility to clear the appropriate bit, negating the interrupt request. Typically, a write to the CINT register in the interrupt service routine is used for this purpose.

The state of any given channel's interrupt request is directly affected by writes to this register; it is also affected by writes to the CINT register. On writes to the INT, a one in any bit position clears the corresponding channel's interrupt request. A zero in any bit position has no affect on the corresponding channel's current interrupt status. The CINT register is provided so the interrupt request for a single channel can easily be cleared without the need to perform a read-modify-write sequence to the INT{H,L} registers.

18.5.16 Interrupt Request Register Low (DMA_INTL)

The INT{H,L} registers provide a bit map for the 64 channels, signaling the presence of an interrupt request for each channel. INTH supports channels 63-32, while INTL covers channels 31-00. The eDMA engine signals the occurrence of a programmed interrupt upon the completion of a data transfer as defined in the transfer control descriptor by setting the appropriate bit in this register. The outputs of this register are directly routed to the platform's interrupt controller. During the execution of the interrupt service routine associated with any given channel, it is software's responsibility to clear the appropriate bit, negating the interrupt request. Typically, a write to the CINT register in the interrupt service routine is used for this purpose.

The state of any given channel's interrupt request is directly affected by writes to this register; it is also affected by writes to the CINT register. On writes to the INT, a one in any bit position clears the corresponding channel's interrupt request. A zero in any bit position has no affect on the corresponding channel's current interrupt status. The CINT register is provided so the interrupt request for a single channel can easily be cleared without the need to perform a read-modify-write sequence to the INT{H,L} registers.

18.5.17 Enable Error Interrupt Register High (DMA_ERRH)

The ERR{H,L} registers provide a bit map for the 64 channels, signaling the presence of an error for each channel. ERRH supports channels 63-32, while ERRL covers channels 31-00. The eDMA engine signals the occurrence of an error condition by setting the appropriate bit in this register. The outputs of this register are enabled by the contents of the EEI register, then logically summed across groups of 16, 32, and 64 channels to form several group error interrupt requests which is then routed to the platform's interrupt controller. During the execution of the interrupt service routine associated with any eDMA errors, it is software's responsibility to clear the appropriate bit, negating the error interrupt request. Typically, a write to the CERR register in the interrupt service routine is used for this purpose. Recall the normal eDMA channel completion indicators, setting the transfer control descriptor done flag, and the possible assertion of an interrupt request are not affected when an error is detected.

The contents of this register can also be polled and a non-zero value indicates the presence of a channel error, regardless of the state of the EEI register. The state of any given channel's error indicators is affected by writes to this register; it is also affected by writes to the CERR register. On writes to the ERR, a one in any bit position clears the corresponding channel's error status. A zero in any bit position has no affect on the corresponding channel's current error status. The CERR register is provided so the error indicator for a single channel can easily be cleared.

18.5.19 Hardware Request Status Register High (DMA_HRSH)

The HRS{H,L} registers provide a bit map for the 64 channels to show the current hardware request status for each channel. HRSH supports channels 63-32, while HRSL covers channels 31-00. Hardware request status reflects the current state of the registered and qualified (via the ERQ field) ipd_req lines as seen by the eDMA's arbitration logic. This view into the hardware request signals may be used for debug purposes.

18.5.20 Hardware Request Status Register Low (DMA_HRSL)

The HRS{H,L} registers provide a bit map for the 64 channels to show the current hardware request status for each channel. HRSH supports channels 63-32, while HRSL covers channels 31-00. Hardware request status reflects the current state of the registered and qualified (via the ERQ field) ipd_req lines as seen by the eDMA's arbitration logic. This view into the hardware request signals may be used for debug purposes.

18.5.21 Channel n Priority Register (DMA_DCHPRI*n*)

When the fixed-priority channel arbitration mode is enabled (CR[ERCA] = 0), the contents of these registers define the unique priorities associated with each channel within a group. The channel priorities are evaluated by numeric value, that is, 0 is the lowest priority, 1 is the next higher priority, then 2, 3, etc. Software must program the channel priorities with unique values, otherwise a configuration error will be reported. The range of the priority value is limited to the values of 0–15. When read, the GRPPRI bits of the DCHPRIn register reflect the current priority level of the group of channels in which the corresponding channel resides. GRPPRI bits are not affected by writes to the DCHPRIn registers. The group priority is assigned in the CR. See the Control Register (DMA_CR) definition.

Channel preemption is enabled on a per channel basis by setting the ECP bit in the DCHPRIn register. Channel preemption allows the executing channel's data transfers to be temporarily suspended in favor of starting a higher priority channel. After the preempting channel has completed all of its minor loop data transfers, the preempted channel is restored and resumes execution. After the restored channel completes one read/write sequence, it is again eligible for preemption. If any higher priority channel is requesting service, the restored channel will be suspended and the higher priority channel will be serviced. Nested preemption (attempting to preempt a preempting channel) is not supported. After a preempting channel begins execution, it cannot be preempted. Preemption is only available when fixed arbitration is selected for both group and channel arbitration modes.

A channel's ability to preempt another channel can be disabled by setting the DPA bit in the DCHPRIn register. When a channel's preempt ability is disabled, that channel cannot suspend a lower priority channel's data transfer; regardless of the lower priority channel's ECP setting. This allows for a pool of low priority, large data moving channels to be defined. These low priority channels can be configured to not preempt each other, thus preventing a low priority channel from consuming the preempt slot normally available a true, high priority channel.

Address: 0h base + 100h offset + (1d × i), where i=0d to 63d

Bit	0	1	2	3	4	5	6	7
Read	ECP	DPA	GRPPRI		CHPRI			
Write								
Reset	0	0	*	*	*	*	*	*

* Notes:
- CHPRI field: After reset, the default value of CHPRI bits will be equal to channel number.
- GRPPRI field: See bit field description

DMA_DCHPRI*n* field descriptions

Field	Description
0 ECP	Enable Channel Preemption. 0 Channel n cannot be suspended by a higher priority channel's service request 1 Channel n can be temporarily suspended by the service request of a higher priority channel
1 DPA	Disable Preempt Ability. 0 Channel n can suspend a lower priority channel 1 Channel n cannot suspend any channel, regardless of channel priority
2–3 GRPPRI	Channel n Current Group Priority Group priority assigned to this channel group when fixed-priority arbitration is enabled. These two bits are read only; writes are ignored.

Table continues on the next page...

DMA_DCHPRI*n* field descriptions (continued)

Field	Description
4–7 CHPRI	Channel n Arbitration Priority Channel priority when fixed-priority arbitration is enabled.

18.5.22 Channel n Master ID Register (DMA_DCHMID*n*)

The eDMA master ID replication registers allow the eDMA to use the same protection level and AHB system bus ID of the master programming the eDMA's TCD. When enabled, the eDMA will use the master ID and protection level stored in the DCHMID register instead of the eDMA's default values. When a master (a core for example) programs a TCD, its master ID and protection level are captured when TCD_WORD_7 control attributes are written. Although the scatter/gather operation can change the contents of TCD_WORD_7, that operation does not affect the DCHMIDn registers.

Address: 0h base + 140h offset + (1d × i), where i=0d to 63d

Bit	0	1	2	3	4	5	6	7
Read	EMI	PAL	0		MID			
Write								
Reset	0	0	0	0	0	0	0	0

DMA_DCHMID*n* field descriptions

Field	Description
0 EMI	Enable Master ID replication. 0 Master ID replication is disabled 1 Master ID replication is enabled
1 PAL	Privileged Access Level. The protection level captured in this register reflects the level used when writing the channel's control attributes; TCD_WORD_7, bits 24:31. 0 User protection level for DMA transfers 1 Privileged protection level for DMA transfers
2–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4–7 MID	Master ID. eDMA's master ID when channel n is active and master ID replication is enabled. **NOTE:** The master ID captured in this register reflects the ID used when writing the channel's control attributes; TCD_WORD_7, bits 24-31

18.5.23 TCD Source Address (DMA_TCD*n*_WORD_0)

Each channel requires a 32-byte transfer control descriptor for defining the desired data movement operation. The TCD structure is discussed in detail in Features. The channel descriptors are stored in the local memory in sequential order: channel 0, channel 1, ... channel [n-1]. The definitions of the TCD are presented as eight 32-bit values. The following table is a 32-bit view of the basic TCD structure.

Table 18-154. TCDn 32-bit memory structure

eDMA Offset	TCDn Field	
0x1000 + (32 x n) + 0x00	Source Address (saddr)	
0x1000 + (32 x n) + 0x04	Transfer Attributes (SMOD, SSIZE, DMOD, DSIZE)	Signed Source Address Offset (SOFF)
0x1000 + (32 x n) + 0x08	Signed Minor Loop Offset (SMLOE, DMLOE, MLOF)	Inner “Minor” Byte Count (NBYTES)
0x1000 + (32 x n) + 0x0C	Last Source Address Adjustment (SLAST)	
0x1000 + (32 x n) + 0x10	Destination Address (DADDR)	
0x1000 + (32 x n) + 0x14	Current “Major” Iteration Count (CITER)	Signed Destination Address Offset (DOFF)
0x1000 + (32 x n) + 0x18	Last Destination Address Adjustment/Scatter Gather Address (DLAST_SGA)	
0x1000 + (32 x n) + 0x1C	Beginning “Major” Iteration Count (BITER)	Channel Control/Status BWC, MAJOR.LINKCH, DONE, ACTIVE, MAJOR.E.LINK,E_SG, D_REQ, INT_HALF, INT_MAJ, START

* Notes:
- x = Undefined at reset.

DMA_TCD*n*_WORD_1 field descriptions

Field	Description
0–4 SMOD	Source Address Modulo. 0 Source address modulo feature is disabled ≠0 The value defines a specific address bit which is selected to be either the value after saddr + soff calculation is performed or the original register value. This feature provides the ability to easily implement a circular data queue. For data queues requiring power-of-2 “size” bytes, the queue should be based at a 0-modulo-size address and the smod field set to the appropriate value to freeze the upper address bits. The bit select is defined as ((1 less than smod[4:0]) - 1) where a resulting 1 in a bit location selects the next state address for the corresponding address bit location and a 0 selects the original register value for the corresponding address bit location. For this application, the soff is typically set to the transfer size to implement post-increment addressing with the smod function constraining the addresses to a 0-modulo-size range.
5–7 SSIZE	Source data transfer size. 000 8-bit 001 16-bit 010 32-bit 011 Reserved 100 16-byte 101 32-byte 110 Reserved 111 Reserved
8–12 DMOD	Destination Address Modulo. See the SMOD definition.
13–15 DSIZE	Destination data transfer size See the SSIZE definition
16–31 SOFF	Source address signed offset. Sign-extended offset applied to the current source address to form the next-state value as each source read is completed.

18.5.25 TCD Number of bytes to be transferred (DMA_TCD*n*_WORD_2_NBYTES)

When CR[EMLM] = 0, TCD_Word_2_NBYTES is defined as the number of bytes to be transferred in each service request of the channel.

Address: 0h base + 1008h offset + (32d × i), where i=0d to 63d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	NBYTES

* Notes:
- x = Undefined at reset.

DMA_TCD*n*_WORD_2_NBYTES field descriptions

Field	Description
0–31 NBYTES	Inner "Minor" Byte Transfer Count Number of bytes to be transferred in each service request of the channel. As a channel is activated, the contents of the appropriate TCD is loaded into the eDMA engine, and the appropriate reads and writes performed until the complete byte transfer count has been transferred. This is an indivisible operation and cannot be stalled or halted. After the minor count is exhausted, the current values of the saddr and daddr are written back into the local memory, the major iteration count is decremented and restored to the local memory. If the major iteration count is completed, additional processing is performed. **NOTE:** The NBYTES value 0x0000_0000 is interpreted as 0x1_0000_0000, thus specifying a 4 GB transfer.

18.5.26 TCD Signed Minor Loop Offset (Minor Loop and Offset Enabled) (DMA_TCD*n*_WORD_2_MLOOP)

When CR[EMLM] = 1, TCD WORD_2_MLOOP is defined as four fields: a source minor loop offset enable, a destination minor loop offset enable, a minor loop offset field and a NBYTES field.

Address: 0h base + 1008h offset + (32d × i), where i=0d to 63d

* Notes:
- x = Undefined at reset.

DMA_TCD*n*_WORD_2_MLOOP field descriptions

Field	Description
0 SMLOE	Source minor loop offset enable. This flag selects whether the minor loop offset is applied to the source address upon minor loop completion. 0 The minor loop offset is not applied to the SADDR. 1 The minor loop offset is applied to the SADDR.
1 DMLOE	Destination minor loop offset enable. This flag selects whether the minor loop offset is applied to the destination address upon minor loop completion. 0 The minor loop offset is not applied to the DADDR. 1 The minor loop offset is applied to the DADDR.
2–21 MLOFF	Inner “minor” byte transfer count or Minor loop offset. If both SMLOE and DMLOE are cleared, this field is part of the byte transfer count. If either SMLOE or DMLOE are set, this field represents a sign-extended offset applied to the source or destination address to form the next-state value after the minor loop is completed.

Table continues on the next page...

DMA_TCD*n*_WORD_2_MLOOP field descriptions (continued)

Field	Description
22–31 NBYTES	Inner "Minor" Byte Transfer Count Number of bytes to be transferred in each service request of the channel. As a channel is activated, the contents of the appropriate TCD is loaded into the eDMA engine, and the appropriate reads and writes performed until the complete byte transfer count has been transferred. This is an indivisible operation and cannot be stalled or halted. Once the minor count is exhausted, the current values of the saddr and daddr are written back into the local memory, the major iteration count is decremented and restored to the local memory. If the major iteration count is completed, additional processing is performed. **NOTE:** This field is extended to 30 bits when both SMLOE and DMLOE are cleared (disabled).

18.5.27 TCD Last Source Address Adjustment (DMA_TCD*n*_WORD_3)

Address: 0h base + 100Ch offset + (32d × i), where i=0d to 63d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

* Notes:
- x = Undefined at reset.

DMA_TCD*n*_WORD_4 field descriptions

Field	Description
0–31 DADDR	Destination Address. Memory address pointing to the destination data.

18.5.29 TCD Current Minor Loop Link, Major Loop Count (Channel Linking Enabled) (DMA_TCD*n*_WORD_5)

If TCDn_WORD_5[CITER_E_LINK] is set, the TCDn_WORD_5[CITER] field is defined as follows.

Address: 0h base + 1014h offset + (32d × i), where i=0d to 63d

* Notes:
- x = Undefined at reset.

DMA_TCD*n*_WORD_5 field descriptions

Field	Description
0 CITER_E_LINK	Enable channel-to-channel linking on minor-loop complete. As the channel completes the inner minor loop, this flag enables the linking to another channel, defined by CITER-LINKCH field. The link target channel initiates a channel service request via an internal mechanism that sets the TCDn_WORD_7[START] bit of the specified channel. If channel linking is disabled, the CITER value is extended to 15 bits in place of a link channel number. If the "major" loop is exhausted, this link mechanism is suppressed in favor of the TCDn_WORD_7[MAJOR_E_LINK] channel linking. **NOTE:** This bit must be equal to the TCDn_WORD_7[BITER_E_LINK] bit; otherwise, a configuration error is reported.

Table continues on the next page...

DMA_TCD*n*_WORD_5 field descriptions (continued)

Field	Description
	0 The channel-to-channel linking is disabled 1 The channel-to-channel linking is enabled
1–6 LINKCH_CITER	Current “major” iteration count or Link channel number. If TCDn_WORD_5[CITER_E_LINK] = 0 Then No channel-to-channel linking (or chaining) is performed after the inner "minor" loop is exhausted. LINKCH-CITER are used to form a 15-bit CITER field. Else After the "minor" loop is exhausted, the eDMA engine initiates a channel service request at the channel defined by CITER_LINKCH by setting that channel’s TCDn_WORD_7[START] bit. **NOTE:** The value contained in CITER_E_LINK must not exceed the number of implemented channels.
7–15 CITER	Current Major Iteration Count This 9-bit (ELINK = 1) or 15-bit (ELINK = 0) count represents the current major loop count for the channel. It is decremented each time the minor loop is completed and updated in the transfer control descriptor memory. After the major iteration count is exhausted, the channel performs a number of operations, for example, final source and destination address calculations, optionally generating an interrupt to signal channel completion before reloading the CITER field from the Beginning Iteration Count (BITER) field. **NOTE:** When the CITER field is initially loaded by software, it must be set to the same value as that contained in the BITER field. **NOTE:** If the channel is configured to execute a single service request, the initial values of BITER and CITER should be 0x0001.
16–31 DOFF	Destination address signed offset. Sign-extended offset applied to the current destination address to form the next-state value as each destination write is completed.

18.5.30 TCD Last Destination Address Adjustment/Scatter Gather Address (DMA_TCD*n*_WORD_6)

Address: 0h base + 1018h offset + (32d × i), where i=0d to 63d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

DMA_TCD*n*_WORD_6 field descriptions

Field	Description
0–31 DLAST_SGA	Last destination address adjustment or the memory address for the next transfer control descriptor to be loaded into this channel (scatter/gather).

DMA_TCD*n*_WORD_6 field descriptions (continued)

Field	Description

	If (TCDn_WORD_7[E_SG] = 0)
	Then
	Adjustment value added to the destination address at the completion of the outer major iteration count. This value can be applied to “restore” the destination address to the initial value, or adjust the address to reference the next data structure.
	Else
	This address points to the beginning of a 0-modulo-32 region containing the next transfer control descriptor to be loaded into this channel. This channel reload is performed as the major iteration count completes. The scatter/gather address must be 0-modulo-32, else a configuration error is reported.

18.5.31 TCD Control and Status (DMA_TCD*n*_WORD_7)

Address: 0h base + 101Ch offset + (32d × i), where i=0d to 63d

DMA_TCD*n*_WORD_7 field descriptions

Field	Description
0 BITER_E_LINK	Enable channel-to-channel linking on minor loop complete. This is the initial value copied into the citer.e_link field when the major loop is completed. The CITER_E_LINK field controls channel linking during channel execution. **NOTE:** This bit must be equal to the CITER_E_LINK bit otherwise a configuration error will be reported. 0 The channel-to-channel linking is disabled. 1 The channel-to-channel linking is enabled.

Table continues on the next page...

DMA_TCD*n*_WORD_7 field descriptions (continued)

Field	Description
1–6 BITER_BITER_ LINKCH	"Beginning major iteration count" or "Beginning Link channel number". This is the initial value copied into the citer field or citer.linkch field when the major loop is completed. The CITER fields controls the iteration count and linking during channel execution. If BITER_E_LINK = 0 Then No channel-to-channel linking (or chaining) is performed after the inner "minor" loop is exhausted. BITER-BITER_LINKCH are used to form a 15-bit BITER field. Else After the "minor" loop is exhausted, the eDMA engine initiates a channel service request at the channel defined by BITER_LINKCH by setting that channel's TCD_WORD_7[START] bit. The value contained in BITER_LINKCH must not exceed the number of implemented channels.
7–15 BITER	Beginning "major" iteration count. This is the initial value copied into the CITER field or CITER.LINKCH field when the major loop is completed. The CITER fields control the iteration count and linking during channel execution. This 9- or 15-bit count represents the beginning major loop count for the channel. As the major iteration count is exhausted, the contents of the entire 16-bit BITER entry is reloaded into the 16-bit CITER entry. When the BITER field is initially loaded by software, it must be set to the same value as that contained in the CITER field. If the channel is configured to execute a single service request, the initial values of biter and citer should be 0x0001.
16–17 BWC	Bandwidth Control. This 2-bit field provides a mechanism to effectively throttle the amount of bus bandwidth consumed by the eDMA. In general, as the eDMA processes the inner minor loop, it continuously generates read/write, read/write, ...sequences until the minor count is exhausted. This field forces the eDMA to stall after the completion of each read/write access to control the bus request bandwidth seen by the platform's cross-bar arbitration switch. To minimize start-up latency, bandwidth control stalls are suppressed for the first two AHB bus cycles and after the last write of each minor loop. 00 No eDMA engine stalls 01 Reserved 10 eDMA engine stalls for 4 cycles after each read/write 11 eDMA engine stalls for 8 cycles after each read/write

18–23
MAJOR_LINKCH
	Link Channel Number.
	If (MAJOR_E_LINK = 0,)
	Then
	No channel-to-channel linking (or chaining) is performed after the outer "major" loop counter is exhausted.
	Else
	After the "major" loop counter is exhausted, the eDMA engine initiates a channel service request at the channel defined by MAJOR_LINKCH[5:0] by setting that channel's TCD_START bit.
	NOTE: The value contained in MAJOR_LINKCH[5:0] must not exceed the number of implemented channels.

24 DONE	Channel Done.

Table continues on the next page...

DMA_TCD*n*_WORD_7 field descriptions (continued)

Field	Description
	This flag indicates the eDMA has completed the major loop. The eDMA engine sets it as the CITER count reaches zero. The software or the hardware clears it when the channel is activated. **NOTE:** This bit must be cleared to write the MAJOR_E_LINK or ESG bits.
25 ACTIVE	Channel Active. This flag signals the channel is currently in execution. It is set when channel service begins, and is cleared by the eDMA as the minor loop completes or when any error condition is detected.
26 MAJOR_E_LINK	Enable channel-to-channel linking on major loop complete. As the channel completes the major loop, this flag enables the linking to another channel, defined by MAJOR_LINKCH. The link target channel initiates a channel service request via an internal mechanism that sets the TCDn_CSR[START] bit of the specified channel. **NOTE:** To support the dynamic linking coherency model, this field is forced to zero when written to while the TCDn_CSR[DONE] bit is set. 0 The channel-to-channel linking is disabled 1 The channel-to-channel linking is enabled
27 E_SG	Enable Scatter/Cather Processing. As the channel completes the outer major loop, this flag enables scatter/gather processing in the current channel. If enabled, the eDMA engine uses DLAST_SGA as a memory pointer to a 0-modulo-32 address containing a 32-byte data structure which is loaded as the transfer control descriptor into the local memory. **NOTE:** To support the dynamic scatter/gather coherency model, this field is forced to zero when written to while the TCDn_CSR[DONE] bit is set. 0 The current channel's TCD is normal format. 1 The current channel's TCD specifies a scatter gather format. The DLAST_SGA field provides a memory pointer to the next TCD to be loaded into this channel after the outer major loop completes its execution.
28 DREQ	Disable Request. If this flag is set, the eDMA hardware automatically clears the corresponding ERQ bit when the current major iteration count reaches zero. 0 The channel's ERQ bit is not affected 1 The channel's ERQ bit is cleared when the major loop is complete
29 INT_HALF	Enable an interrupt when major counter is half complete. If this flag is set, the channel generates an interrupt request by setting the appropriate bit in the INT register when the current major iteration count reaches the halfway point. Specifically, the comparison performed by the eDMA engine is (CITER == (BITER >> 1)). This halfway point interrupt request is provided to support double-buffered schemes or other types of data movement where the processor needs an early indication of the transfer's progress. **NOTE:** If BITER = 1, do not use INT_HALT; use INT_MAJOR instead. 0 The half-point interrupt is disabled 1 The half-point interrupt is enabled
30 INT_MAJOR	Enable an interrupt when major iteration count completes.

Table continues on the next page...

DMA_TCD*n*_WORD_7 field descriptions (continued)

Field	Description
	If this flag is set, the channel generates an interrupt request by setting the appropriate bit in the INT register when the current major iteration count reaches zero. 0 The end-of-major loop interrupt is disabled 1 The end-of-major loop interrupt is enabled
31 START	Channel Start. If this flag is set, the channel is requesting service. The eDMA hardware automatically clears this flag after the channel begins execution. 0 The channel is not explicitly started 1 The channel is explicitly started via a software initiated service request

18.6 Functional description

This section provides an overview of the microarchitecture and functional operation of the eDMA module.

18.6.1 eDMA microarchitecture

The eDMA module is partitioned into two major modules:

- the eDMA engine and
- the transfer-control descriptor local memory.

The eDMA engine is further partitioned into four submodules that are shown in the following table.

Table 18-803. eDMA engine submodules

Submodule	Function
Address path	This block implements registered versions of two channel transfer control descriptors, channel x and channel y, and manages all master bus-address calculations. All the channels provide the same functionality. This structure allows data transfers associated with one channel to be preempted after the completion of a read/write sequence if a higher priority channel activation is asserted while the first channel is active. After a channel is activated, it runs until the minor loop is completed, unless preempted by a higher priority channel. This provides a mechanism (enabled by DCHPRI*n*[ECP]) where a large data move operation can be preempted to minimize the time another channel is blocked from execution. When any channel is selected to execute, the contents of its TCD are read from local memory and loaded into the address path channel x registers for a normal start and into channel y registers for a preemption start. After the minor loop completes execution, the address path hardware writes the new values for the TCD*n*_WORD_x[SADDR, DADDR, CITER] back to local memory. If the major iteration count is exhausted, additional processing is performed, including the final address pointer updates, reloading the TCD*n*_WORD_5[CITER] field, and a possible fetch of the next TCD*n* from memory as part of a scatter/gather operation.
Data path	This block implements the bus master read/write datapath. It includes 32 bytes of register storage (matching the maximum transfer size) and the necessary multiplex logic to support any required data alignment. The AMBA-AHB read data bus is the primary input, and the AHB write data bus is the primary output. The address and data path modules directly support the 2-stage pipelined AMBA-AHB bus. The address path module represents the 1st stage of the bus pipeline (address phase), while the data path module implements the 2nd stage of the pipeline (data phase).
Program model/channel arbitration	This block implements the first section of the eDMA programming model as well as the channel arbitration logic. The programming model registers are connected to the slave bus (not shown). The ipd_req[n] inputs and dma_ipi_int[n] outputs are also connected to this module (via the control logic).
Control	This block provides all the control functions for the eDMA engine. For data transfers where the source and destination sizes are equal, the eDMA engine performs a series of source read/ destination write operations until the number of bytes specified in the minor loop byte count has moved. For descriptors where the sizes are not equal, multiple accesses of the smaller size data are required for each reference of the larger size. As an example, if the source size references 16-bit data and the destination is 32-bit data, two reads are performed, then one 32-bit write.

The transfer-control descriptor local memory is further partitioned as shown in the following table:

Table 18-804. Transfer control descriptor memory

Submodule	Description
Memory controller	This logic implements the required dual-ported controller, managing accesses from the eDMA engine as well as references from the slave bus. As noted earlier, in the event of simultaneous accesses, the eDMA engine is given priority and the peripheral slave bus transaction is stalled. The hooks to a BIST controller for the local TCD memory are included in this module.
Memory array	TCD storage is implemented using a single-port, synchronous RAM array.

18.6.2 eDMA basic data flow

The basic flow of a data transfer can be partitioned into three segments. As shown in the following figure, the first segment involves the channel service request. In the diagram, this example uses the assertion of the ipd_req[n] signal to request service for channel n. Channel service request via software and the TCDn_WORD_7[START] bit follows the same basic flow as an ipd_req. The ipd_req[n] input signal is registered internally and then routed to through the eDMA engine, first through the control module, then into the programming model/channel arbitration (pmodel_charb) module. In the next cycle, the channel arbitration is performed, either using the fixed-priority or round-robin algorithm. After the arbitration is complete, the activated channel number is sent through the address path (addr_path) and converted into the required address to access the TCD local memory. Next, the TCD memory is accessed and the required descriptor read from the local memory and loaded into the dma_engine.addr_path.channel_{x,y} registers. The TCD memory is organized 64 bits in width to minimize the time needed to fetch the activated channel's descriptor and load it into the dma_engine.addr_path.channel_{x,y} registers.

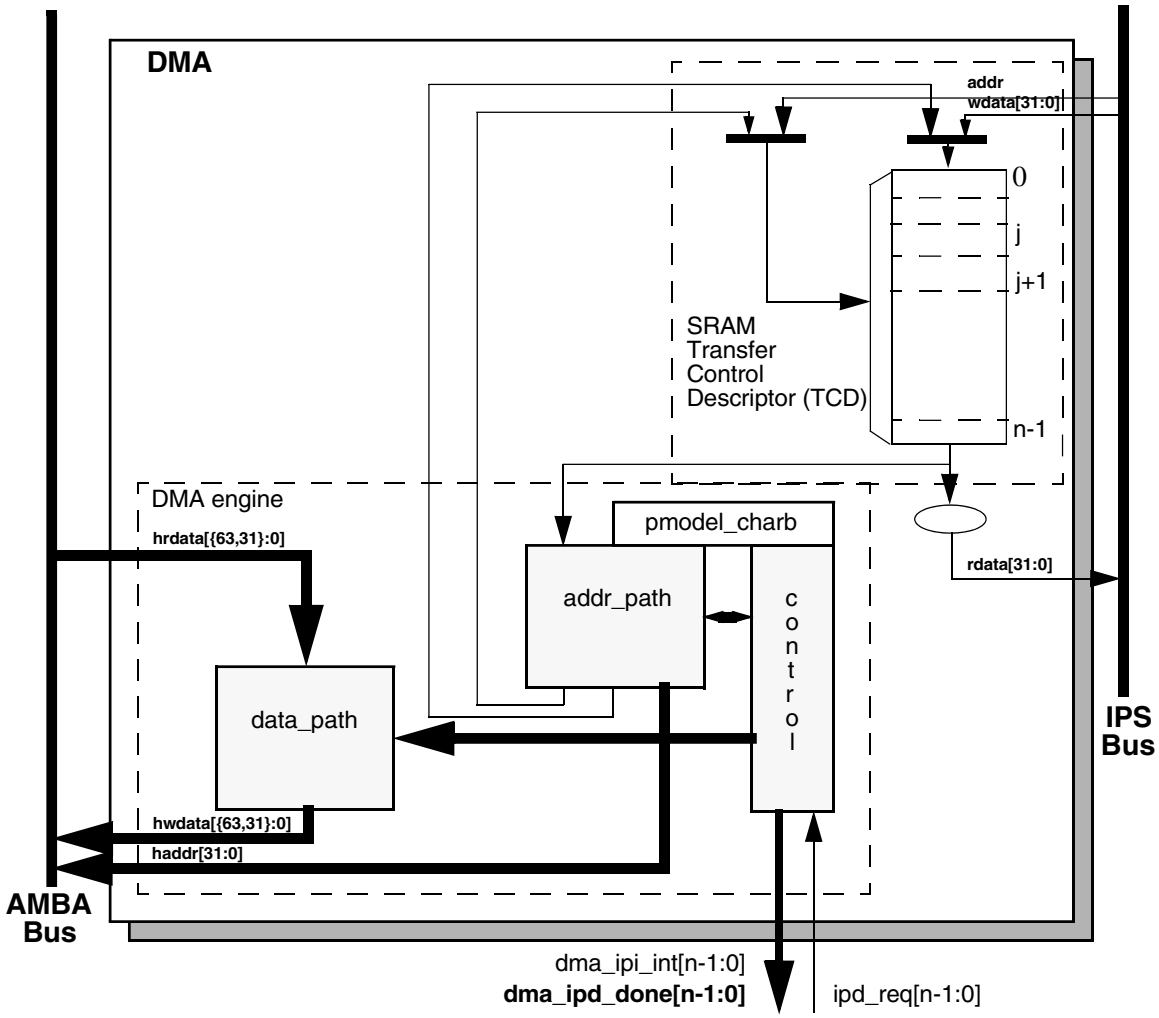

Figure 18-738. eDMA operation, part 1

In the second part of the basic data flow, as shown in the following figure, the modules associated with the data transfer (addr_path, data_path and control) sequence through the required source reads and destination writes to perform the actual data movement. The source reads are initiated and the fetched data is temporarily stored in the data_path module until it is gated onto the AMBA-AHB bus during the destination write. This source read/destination write processing continues until the inner minor byte count has been transferred. The dma_ipd_done[n] signal is asserted at the end of the minor byte count transfer.

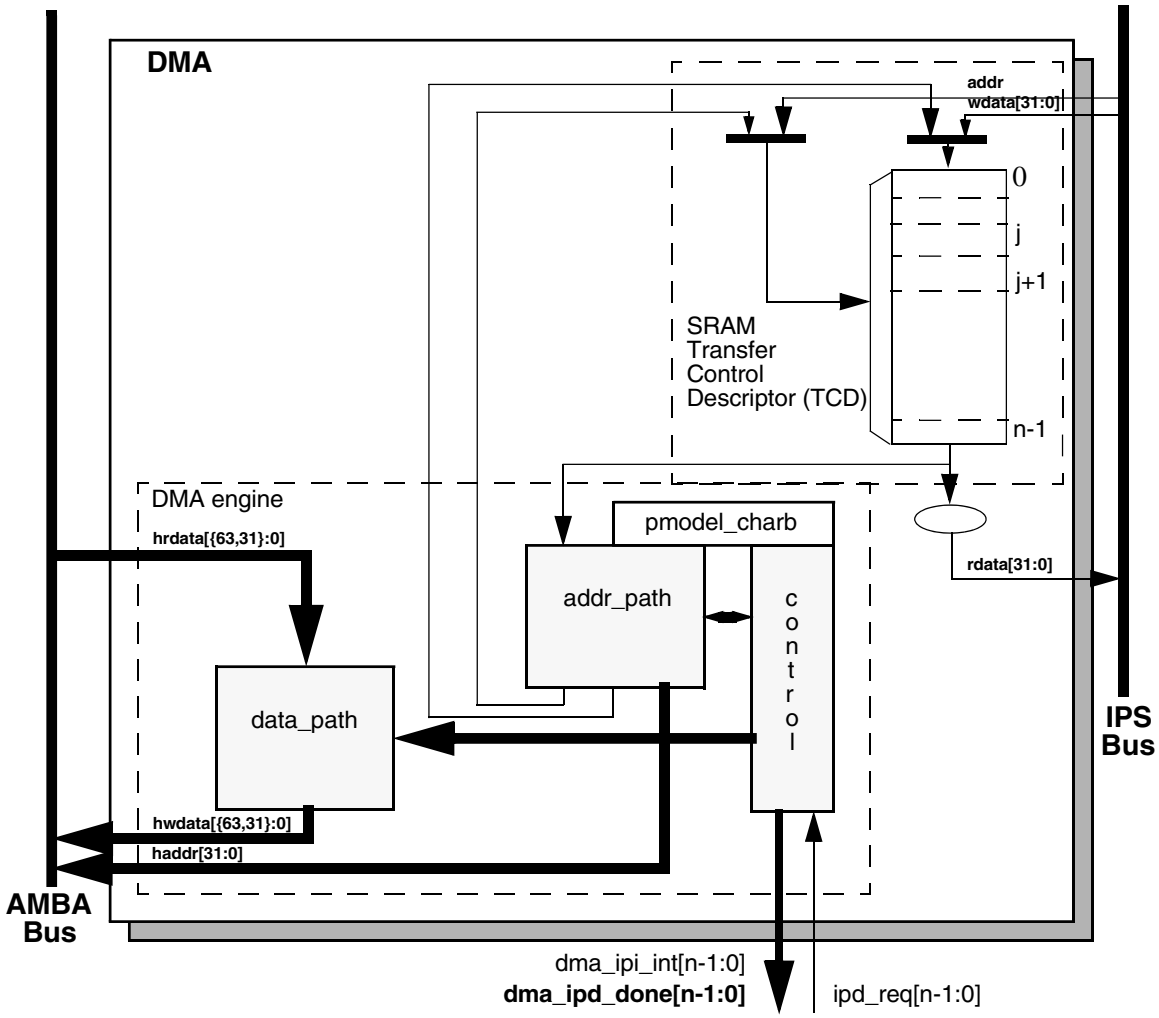

Figure 18-739. eDMA operation, part 2

Once the inner minor byte count has been moved, the final phase of the basic data flow is performed. In this segment, the addr_path logic performs the required updates to certain fields in the channel's TCD, for example, SADDT, DADDR, CITER. If the outer major iteration count is exhausted, then there are additional operations which are performed. These include the final address adjustments and reloading of the BITER field into the CITER. Additionally, assertion of an optional interrupt request occurs at this time, as does a possible fetch of a new TCD from memory using the scatter/gather address pointer included in the descriptor. The updates to the TCD memory and the assertion of an interrupt request are shown in the following figure.

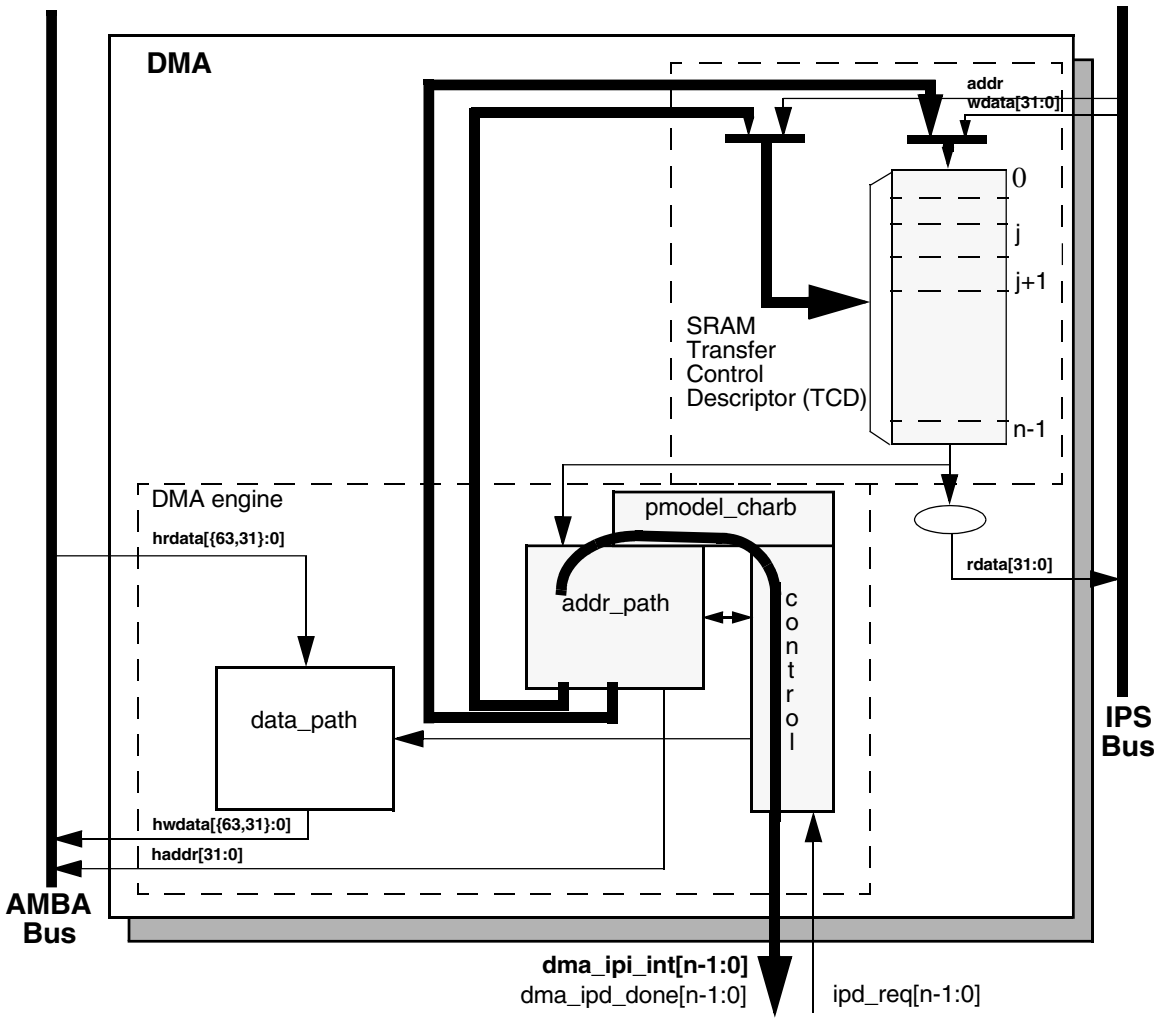

Figure 18-740. eDMA operation, part 3

18.6.3 eDMA performance

This section addresses the performance of the eDMA module, focusing on two separate metrics:

- In the traditional data movement context, performance is best expressed as the peak data transfer rates achieved using the eDMA. In most implementations, this transfer rate is limited by the speed of the source and destination address spaces.
- In a second context where device-paced movement of single data values to/from peripherals is dominant, a measure of the requests that can be serviced in a fixed time is a more relevant metric. In this environment, the speed of the source and destination

address spaces remains important. However, the microarchitecture of the eDMA also factors significantly into the resulting metric.

18.6.3.1 Peak transfer rates

The peak transfer rates for several different sources and destination transfers are shown in the following tables. These tables assume:

- Internal SRAM can be accessed with zero wait-states when viewed from the system bus data phase
- All internal peripheral bus reads require two wait-states, and internal peripheral bus writes three wait-states, when viewed from the system bus data phase
- All internal peripheral bus accesses are 32 bits in size

This table compares peak transfer rates based on different possible system speeds. Specific chips/devices may not support all system speeds listed.

Table 18-805. eDMA peak transfer rates (MB/s)

System Speed, Width	Internal SRAM-to-Internal SRAM	32b internal peripheral bus-to-Internal SRAM	Internal SRAM-to-32b internal peripheral bus
66.7 MHz, 32b	133.3	66.7	53.3
83.3 MHz, 32b	166.7	83.3	66.7
100.0 MHz, 32b	200.0	100.0	80.0
133.3 MHz, 32b	266.7	133.3	106.7
150.0 MHz, 32b	300.0	150.0	120.0

Internal-SRAM-to-internal-SRAM transfers occur at the core's datapath width. For all transfers involving the internal peripheral bus, 32-bit transfer sizes are used. In all cases, the transfer rate includes the time to read the source plus the time to write the destination.

18.6.3.2 Peak request rates

The second performance metric is a measure of the number of DMA requests that can be serviced in a given amount of time. For this metric, assume that the peripheral request causes the channel to move a single internal peripheral bus-mapped operand to/from internal SRAM. The same timing assumptions used in the previous example apply to this calculation. In particular, this metric also reflects the time required to activate the channel.

The eDMA design supports the following hardware service request sequence. Note that the exact timing from Cycle 7 is a function of the response times for the channel's read and write accesses. In the case of an internal peripheral bus read and internal SRAM write, the combined data phase time is 4 cycles. For an SRAM read and internal peripheral bus write, it is 5 cycles.

Table 18-806. Hardware service request process

Cycle		Description
With internal peripheral bus read and internal SRAM write	With SRAM read and internal peripheral bus write	
1		eDMA peripheral request is asserted.
2		The eDMA peripheral request is registered locally in the eDMA module and qualified. TCD*n*_WORD_7[START] bit initiated requests start at this point with the registering of the user write to TCD*n*_WORD_7.
3		Channel arbitration begins.
4		Channel arbitration completes. The transfer control descriptor local memory read is initiated.
5–6		The first two parts of the activated channel's TCD is read from the local memory. The memory width to the eDMA engine is 64 bits, so the entire descriptor can be accessed in four cycles
7		The first system bus read cycle is initiated, as the third part of the channel's TCD is read from the local memory. Depending on the state of the crossbar switch, arbitration at the system bus may insert an additional cycle of delay here.
8–11	8–12	The last part of the TCD is read in. This cycle represents the first data phase for the read, and the address phase for the destination write.
12	13	This cycle represents the data phase of the last destination write.
13	14	The eDMA engine completes the execution of the inner minor loop and prepares to write back the required TCD*n* fields into the local memory. The TCD*n*_WORD_7 is read and checked for channel linking or scatter/gather requests.
14	15	The appropriate fields in the first part of the TCD*n* are written back into the local memory.
15	16	The fields in the second part of the TCD*n* are written back into the local memory. This cycle coincides with the next channel arbitration cycle start.
16	17	The next channel to be activated performs the read of the first part of its TCD from the local memory. This is equivalent to Cycle 4 for the first channel's service request.

Assuming zero wait states on the system bus, DMA requests can be processed every 9 cycles. Assuming an average of the access times associated with internal peripheral bus-to-SRAM (4 cycles) and SRAM-to-internal peripheral bus (5 cycles), DMA requests can

be processed every 11.5 cycles (4 + (4+5)/2 + 3). This is the time from Cycle 4 to Cycle x +5. The resulting peak request rate, as a function of the system frequency, is shown in the following table.

Table 18-807. eDMA peak request rate (Millions of requests per second)

System frequency (MHz)	Request rate with zero wait states	Request rate with wait states
66.6	7.4	5.8
83.3	9.2	7.2
100.0	11.1	8.7
133.3	14.8	11.6
150.0	16.6	13.0

A general formula to compute the peak request rate with overlapping requests is:

PEAKreq = freq / [entry + (1 + read_ws) + (1 + write_ws) + exit], where terms are defined in the following table.

Table 18-808. Peak request formula operands

Operand	Description
PEAKreq	Peak request rate
freq	System frequency
entry	Channel startup (4 cycles)
read_ws	Wait states seen during the system bus read data phase
write_ws	Wait states seen during the system bus write data phase
exit	Channel shutdown (3 cycles)

18.6.3.3 eDMA performance example

Consider a system with the following characteristics:

- Internal SRAM can be accessed with one wait-state when viewed from the system bus data phase
- All internal peripheral bus reads require two wait-states, and internal peripheral bus writes three wait-states viewed from the system bus data phase
- System operates at 150 MHz

For an SRAM to internal peripheral bus transfer,

PEAKreq = 150 MHz / [4 + (1 + 1) + (1 + 3) + 3] cycles = 11.5 Mreq/sec

For an internal peripheral bus to SRAM transfer,

PEAKreq = 150 MHz / [4 + (1 + 2) + (1 + 1) + 3] cycles = 12.5 Mreq/sec

Assuming an even distribution of the two transfer types, the average peak request rate would be:

PEAKreq = (11.5 Mreq/sec + 12.5 Mreq/sec) / 2 = 12.0 Mreq/sec

The minimum number of cycles to perform a single read/write, zero wait states on the system bus, from a cold start where no channel is executing and eDMA is idle are:

- 11 cycles for a software, that is, a TCDn_WORD_7[START] bit, request
- 12 cycles for a hardware, that is, an eDMA peripheral request signal, request

Two cycles account for the arbitration pipeline and one extra cycle on the hardware request resulting from the internal registering of the eDMA peripheral request signals. For the peak request rate calculations above, the arbitration and request registering is absorbed in or overlaps the previous executing channel.

Note

When channel linking or scatter/gather is enabled, a two cycle delay is imposed on the next channel selection and startup. This allows the link channel or the scatter/gather channel to be eligible and considered in the arbitration pool for next channel selection.

18.7 Initialization/application information

18.7.1 eDMA initialization

A typical initialization of the eDMA is:

1. Write the CR register if a configuration other than the default is desired.
2. Write the channel priority levels into the DCHPRIn registers if a configuration other than the default is desired.
3. Enable error interrupts in the EEI registers if so desired.
4. Write the 32-byte TCD for each channel that may request service.
5. Enable any hardware service requests via the ERQ register.
6. Request channel service by either software (setting the TCDn_WORD_7[START] bit) or by hardware (slave device asserting its ipd_req signal).

After any channel requests service, a channel is selected for execution based on the arbitration and priority levels written into the programmer's model. The eDMA engine will read the entire TCD for the selected channel into its internal address path module. As the TCD is being read, the first transfer is initiated on the AHB bus unless a configuration error is detected. Transfers from the source (as defined by the source address, TCDn_WORD_0[SADDR] to the destination (as defined by the destination address, TCDn_WORD_4[DADDR] continue until the specified number of bytes (TCDn_WORD_2[NBYTES] have been transferred. When the transfer is complete, the eDMA engine's local TCDn_WORD_0[SADDR], TCDn_WORD_4[DADDR], and TCDn_WORD_5[CITER] are written back to the main TCD memory and any minor loop channel linking is performed, if enabled. If the major loop is exhausted, further post processing is executed, that is, interrupts, major loop channel linking, and scatter/gather operations, if enabled.

18.7.2 eDMA programming errors

The eDMA performs various tests on the Transfer Control Descriptor to verify consistency in the descriptor data. Most programming errors are reported on a per channel basis with the exception of two errors; Group Priority Error and Channel Priority Error, GPE and CPE in the ES register respectively.

For all error types other than Group or Channel Priority Errors, the channel number causing the error is recorded in the ES register. If the error source is not removed before the next activation of the problem channel, the error will be detected and recorded again.

The sequence listed below is correct. For item 2, the dma_ipd_ack{done} lines will assert only if the selected channel is requesting service via the ipd_req signal. I think the typical application will enable error interrupts for all channels. So the user will get an error interrupt, but the channel number for the ERR register and the error interrupt request line may be wrong because they reflect the selected channel.

Channel priority errors are identified within a group after that group has been selected as the active group. For example:

1. The eDMA is configured for fixed group and fixed channel arbitration modes.
2. Group3 is the highest priority and all channels are unique in that group.
3. Group2 is the next highest priority and has two channels with the same priority level.
4. If Group3 has any service requests, those requests will be executed.
5. Once all of the Group3 requests have completed, Group2 will be the next active group.
6. If Group2 has a service request, then an undefined channel in Group2 will be selected and a channel priority error will occur.

7. This will repeat until the all of Group2 requests have been removed or a higher priority Group3 request comes in.

A group priority error is global and any request in any group will cause a group priority error.

In general, if priority levels are not unique, the highest (channel/group) priority that has an active request will be selected, but the lowest numbered (channel/group) with that priority will be selected by arbitration and executed by the eDMA engine. The hardware service request handshake signals, error interrupts and error reporting will be associated with the selected channel.

18.7.3 eDMA arbitration mode considerations

18.7.3.1 Fixed group arbitration, fixed channel arbitration

In this mode, the channel service request from the highest priority channel in the highest priority group will be selected to execute. If the eDMA is so programmed that the channels within one group use “fixed” priorities, and that group is assigned the highest “fixed” priority of all groups, it is possible for that group to take all the bandwidth of the eDMA controller — that is, no other groups will be serviced if there is always at least one eDMA request pending on a channel in the highest priority group when the controller arbitrates the next eDMA request.

The advantage of this scenario is that latency can be small for channels that need to be serviced quickly.

Preemption is available in this scenario only.

18.7.3.2 Round-robin group arbitration, fixed channel arbitration

The occurrence of one or more eDMA requests from one or more groups, the channel with the highest priority from a specific group will be serviced first. Groups are serviced starting with the highest group number with a service request and rotating through to the lowest group number containing a service request.

Once the channel request is serviced, the group round-robin algorithm will select the highest pending request from the next group in the round-robin sequence. Servicing continues round robin, always servicing the highest priority channel in the next group in the sequence, or just skipping a group if it has no pending requests.

If a channel requests service at a rate that equals or exceeds the round-robin service rate, then that channel will always be serviced before lower priority channels in the same group, and thus the lower priority channels will never be serviced.

The advantage of this scenario is that a single group cannot use all the eDMA bandwidth.

The highest priority channel selection latency is potentially greater than fixed/fixed arbitration.

Excessive request rates on high priority channels can prevent the servicing of lower priority channels in the same group.

18.7.3.3 Round-robin group arbitration, round-robin channel arbitration

Groups will be serviced as described in Round-robin group arbitration, fixed channel arbitration, but this time channels will be serviced in channel number order. Only one channel is serviced from each requesting group for each round-robin pass through the groups.

Within each group, channels are serviced starting with the highest channel number and rotating through to the lowest channel number without regard to channel priority levels.

Because channels are serviced in round-robin manner, any channel that generates eDMA requests faster than a combination of the group round robin service rate and the channel service rate for its group will not prevent the servicing of other channels in its group. Any eDMA requests that are not serviced are simply lost, but at least one channel will be serviced.

This scenario ensures that all channels will be guaranteed service at some point, regardless of the request rates. However, the potential latency could be quite high.

All channels are treated equally. Priority levels are not used in round-robin/round-robin mode.

18.7.3.4 Fixed group arbitration, round-robin channel arbitration

The highest priority group with a request will be serviced. Lower priority groups will be serviced if no pending requests exist in the higher priority groups.

Within each group, channels are serviced starting with the highest channel number and rotating through to the lowest channel number without regard to the channel priority levels assigned within the group.

This scenario could cause the same bandwidth consumption problem as indicated in Fixed group arbitration, fixed channel arbitration, but all the channels in the highest priority group will be serviced.

Service latency will be short on the highest priority group, but can become much longer as the group priority decreases.

18.7.4 Transfer

18.7.4.1 Single request

To perform a simply transfer of ‘n’ bytes of data with one activation, set the major loop to one (TCDn_WORD_5[CITER] = TCDn_WORD_7[BITER] = 1). The data transfer will begin after the channel service request is acknowledged and the channel is selected to execute. Once the transfer is complete, the TCDn_WORD_7[DONE] bit will be set and an interrupt will be generated if properly enabled.

For example, the following TCD entry is configured to transfer 16 bytes of data. The eDMA is programmed for one iteration of the major loop transferring 16 bytes per iteration. The source memory has a byte wide memory port located at 0x1000. The destination memory has a word wide port located at 0x2000. The address offsets are programmed in increments to match the size of the transfer; one byte for the source and four bytes for the destination. The final source and destination addresses are adjusted to return to their beginning values.

- TCDn_WORD_5[CITER] = TCDn_WORD_7[BITER] = 1
- TCDn_WORD_2[NBYTES] = 16
- TCDn_WORD_0[SADR] = 0x1000
- TCDn_WORD_1[SOFF] = 1
- TCDn_WORD_1[SSIZE] = 0
- TCDn_WORD_3[SLAST] = -16
- TCDn_WORD_4[DADDR] = 0x2000
- TCDn_WORD_5[DOFF] = 4
- TCDn_WORD_1[DSIZE] = 2
- TCDn_WORD_6[DLAST_SGA] = -16
- TCDn_WORD_7[INT_MAJOR] = 1
- TCDn_WORD_7[START] = 1 (TCDn_WORD_7 should be written last after all other fields have been initialized)
- All other TCD fields = 0

The eDMA is programmed for one iteration of the major loop transferring 16 bytes per iteration. The source memory has a byte wide memory port located at 0x1000. The destination memory has a word wide port located at 0x2000. The address offsets are programmed in increments to match the size of the transfer; one byte for the source and four bytes for the destination. The final source and destination addresses are adjusted to return to their beginning values.

The TCD values above generate the following sequence of events:

1. Slave bus write to the TCDn_WORD_7[START] bit requests channel service
2. The channel is selected by arbitration for servicing
3. eDMA engine writes:
   - TCDn_WORD_7[DONE] = 0,
   - TCDn_WORD_7[START] = 0,
   - TCDn_WORD_7[ACTIVE] = 1
4. eDMA engine reads: channel TCD data from local memory to internal register file
5. The source to destination transfers are executed as follows:
   a. read_byte(0x1000), read_byte(0x1001), read_byte(0x1002), read_byte(0x1003)
   b. write_word(0x2000) -> first iteration of the minor loop
   c. read_byte(0x1004), read_byte(0x1005), read_byte(0x1006), read_byte(0x1007)
   d. write_word(0x2004) -> second iteration of the minor loop
   e. read_byte(0x1008), read_byte(0x1009), read_byte(0x100A), read_byte(0x100B)
   f. write_word(0x2008) -> third iteration of the minor loop
   g. read_byte(0x100C), read_byte(0x100D), read_byte(0x100E), read_byte(0x100F)
   h. write_word(0x200C) -> last iteration of the minor loop -> major loop complete
6. eDMA engine writes:
   - TCDn_WORD_0[SADR] = 0x1000,
   - TCDn_WORD_4[DADDR] = 0x2000,
   - TCDn_WORD_5[CITER] = 1 (TCDn_WORD_7[BITER])
7. eDMA engine writes:
   - TCDn_WORD_7[ACTIVE] = 0,
   - TCDn_WORD_7[DONE] = 1,
   - INT[n] = 1
8. The channel retires

The eDMA goes idle or services next channel.

18.7.4.2 Multiple requests

The next example is the same as the previous example, with the exception of transferring 32 bytes via two hardware requests. The only fields that change are the major loop iteration count and the final address offsets. The eDMA is programmed for two iterations

of the major loop transferring 16 bytes per iteration. After the channel's hardware requests is enabled in the ERQ register, channel service requests are initiated by the slave device.

- TCDn_WORD_5[CITER] = TCD.biter = 2
- TCDn_WORD_3[SLAST] = -32
- TCDn_WORD_6[DLAST_SGA] = -32

This would generate the following sequence of events:

1. First hardware (ipd_req) request for channel service
2. The channel is selected by arbitration for servicing
3. eDMA engine writes:
   - TCDn_WORD_7[DONE] = 0,
   - TCDn_WORD_7[START] = 0,
   - TCDn_WORD_7[ACTIVE] = 1
4. eDMA engine reads: channel TCD data from local memory to internal register file
5. The source to destination transfers are executed as follows:
   a. read_byte(0x1000), read_byte(0x1001), read_byte(0x1002), read_byte(0x1003)
   b. write_word(0x2000) ≥ first iteration of the minor loop
   c. read_byte(0x1004), read_byte(0x1005), read_byte(0x1006), read_byte(0x1007)
   d. write_word(0x2004) ≥ second iteration of the minor loop
   e. read_byte(0x1008), read_byte(0x1009), read_byte(0x100A), read_byte(0x100B)
   f. write_word(0x2008) ≥ third iteration of the minor loop
   g. read_byte(0x100C), read_byte(0x100D), read_byte(0x100E), read_byte(0x100F)
   h. write_word(0x200C) ≥ last iteration of the minor loop
6. eDMA engine writes:
   - TCDn_WORD_0[SADDR] = 0x1010,
   - TCDn_WORD_4[DADDR] = 0x2010,
   - TCDn_WORD_5[CITER] = 1
7. eDMA engine writes: TCDn_WORD_7[ACTIVE] = 0
8. The channel retires ≥ one iteration of the major loop

   The eDMA goes idle or services the next channel.

9. Second hardware (ipd_req) requests channel service
10. The channel is selected by arbitration for servicing
11. eDMA engine writes:
    - TCDn_WORD_7[DONE] = 0,
    - TCDn_WORD_7[START] = 0,
    - TCDn_WORD_7[ACTIVE] = 1
12. eDMA engine reads: channel TCD data from local memory to internal register file
13. The source to destination transfers are executed as follows:
    a. read_byte(0x1010), read_byte(0x1011), read_byte(0x1012), read_byte(0x1013)
    b. write_word(0x2010) ≥ first iteration of the minor loop

c. read_byte(0x1014), read_byte(0x1015), read_byte(0x1016), read_byte(0x1017)
d. write_word(0x2014) ≥ second iteration of the minor loop
e. read_byte(0x1018), read_byte(0x1019), read_byte(0x101A), read_byte(0x101B)
f. write_word(0x2018) ≥ third iteration of the minor loop
g. read_byte(0x101C), read_byte(0x101D), read_byte(0x101E), read_byte(0x101F)
h. write_word(0x201C) ≥ last iteration of the minor loop ≥ major loop complete

14. eDMA engine writes:
    - TCDn_WORD_0[SADDR] = 0x1000,
    - TCDn_WORD_4[DADDR] = 0x2000,
    - TCDn_WORD_5[CITER] = 2 (TCDn_WORD_5TCDn_WORD_7[BITER])
15. eDMA engine writes:
    - TCDn_WORD_7[ACTIVE] = 0,
    - TCDn_WORD_7[DONE] = 1,
    - INT[n] = 1
16. The channel retires ≥ major loop complete.

    The eDMA goes idle or services the next channel.

18.7.5 TCD status

18.7.5.1 Minor loop complete

There are two methods to test for minor loop completion when using software initiated service requests. The first method is to read the TCD.citer field and test for a change. Another method may be extracted from the sequence shown below. The second method is to test the TCD.start bit AND the TCD.active bit. The minor loop complete condition is indicated by both bits reading zero after the TCD.start was written to a one. Polling the TCD.active bit may be inconclusive because the active status may be missed if the channel execution is short in duration.

The TCD status bits execute the following sequence for a software activated channel:

1. TCD.start = 1, TCD.active = 0, TCD.done = 0 (channel service request via software)
2. TCD.start = 0, TCD.active = 1, TCD.done = 0 (channel is executing)
3. Either TCD.start = 0, TCD.active = 0, TCD.done = 0 (channel has completed the minor loop and is idle) or TCD.start = 0, TCD.active = 0, TCD.done = 1 (channel has completed the major loop and is idle)

The best method to test for minor loop completion when using hardware initiated service requests is to read the TCD.citer field and test for a change. The hardware request and acknowledge handshakes signals are not visible in the programmer's model.

The TCD status bits execute the following sequence for a hardware activated channel:

1. ipd_req asserts (channel service request via hardware)
2. TCD.start = 0, TCD.active = 1, TCD.done = 0 (channel is executing)
3. Either TCD.start = 0, TCD.active = 0, TCD.done = 0 (channel has completed the minor loop and is idle) or TCD.start = 0, TCD.active = 0, TCD.done = 1 (channel has completed the major loop and is idle)

For both activation types, the major loop complete status is explicitly indicated via the TCD.done bit.

The TCD.start bit is cleared automatically when the channel begins execution regardless of how the channel was activated.

18.7.5.2 Active channel TCD reads

The eDMA will read back the 'true' TCD.saddr, TCD.daddr, and TCD.nbytes values if read while a channel is executing. The 'true' values of the saddr, daddr, and nbytes are the values the eDMA engine is currently using in its internal register file and not the values in the TCD local memory for that channel. The addresses (saddr and daddr) and nbytes (decrements to zero as the transfer progresses) can give an indication of the progress of the transfer. All other values are read back from the TCD local memory.

18.7.5.3 Preemption status

Preemption is only available when fixed arbitration is selected for both group and channel arbitration modes. A preempt-able situation is one in which a preempt-enabled channel is running and a higher priority request becomes active. When the eDMA engine is not operating in fixed group, fixed channel arbitration mode, the determination of the relative priority of the actively running and the outstanding requests become undefined. Channel and/or group priorities are treated as equal (constantly rotating) when round-robin arbitration mode is selected.

The TCD.active bit for the preempted channel remains asserted throughout the preemption. The preempted channel is temporarily suspended while the preempting channel executes one iteration of the major loop. Two TCD.active bits set at the same time in the overall TCD map indicates a higher priority channel is actively preempting a lower priority channel.

The worst case latency when switching to a preempt channel is the summation of:

- arbitration latency (2 cycles)
- bandwidth control stalls (if enabled)
- the time to execute two read/write sequences (including AHB bus holds; a system dependency driven by the slave devices or the crossbar).

18.7.6 Channel linking

Channel linking (or chaining) is a mechanism where one channel sets the TCD.start bit of another channel (or itself) thus initiating a service request for that channel. This operation is automatically performed by the eDMA engine at the conclusion of the major or minor loop when properly enabled.

The minor loop channel linking occurs at the completion of the minor loop (or one iteration of the major loop). The TCD.citer.e_link field are used to determine whether a minor loop link is requested. When enabled, the channel link is made after each iteration of the major loop except for the last. When the major loop is exhausted, only the major loop channel link fields are used to determine if a channel link should be made. For example, with the initial fields of:

- TCD.citer.e_link = 1
- TCD.citer.linkch = 0xC
- TCD.citer value = 0x4
- TCD.major.e_link = 1
- TCD.major.linkch = 0x7

will execute as:

1. minor loop done -> set channel 12 TCD.start bit
2. minor loop done -> set channel 12 TCD.start bit
3. minor loop done -> set channel 12 TCD.start bit
4. minor loop done, major loop done -> set channel 7 TCD.start bit

When minor loop linking is enabled (TCD.citer.e_link = 1), the TCD.citer field uses a nine bit vector to form the current iteration count.

When minor loop linking is disabled (TCD.citer.e_link = 0), the TCD.citer field uses a 15 bit vector to form the current iteration count. The bits associated with the TCD.citer.linkch field are concatenated onto the citer value to increase the range of the citer.

NOTE

The TCD.citer.e_link bit and the TCD.biter.e_link bit must equal or a configuration error will be reported. The citer and biter vector widths must be equal to calculate the major loop, half-way done interrupt point.

18.7.7 Dynamic programming

18.7.7.1 Dynamic priority changing

The following two options are recommended for dynamically changing channel priority levels:

1. Switch to round-robin channel arbitration mode, change the channel priorities, then switch back to fixed arbitration mode.
2. Disable all the channels within a group, then change the channel priorities within that group only, then enable the appropriate channels.

The following two options are available for dynamically changing group priority levels:

1. Switch to round-robin group arbitration mode, change the group priorities, then switch back to fixed arbitration mode.
2. Disable all channels, change the group priorities, then enable the appropriate channels.

18.7.7.2 Dynamic channel linking

Dynamic channel linking is the process of setting the TCD.major.e_link bit during channel execution. This bit is read from the TCD local memory at the end of channel execution, thus allowing the user to enable the feature during channel execution.

Because the user is allowed to change the configuration during execution, a coherency model is needed. Consider the scenario where the user attempts to execute a dynamic channel link by enabling the TCD.major.e_link bit at the same time the eDMA engine is retiring the channel. The TCD.major.e_link would be set in the programmer's model, but it would be unclear whether the actual link was made before the channel retired.

The coherency model in the following table is recommended when executing a dynamic channel link request.

Step #	Action
1	Write 1b to the TCD.major.e_link bit.
2	Read back the TCD.major.e_link bit.
3	Test the TCD.major.e_link request status: • If TCD.major.e_link = 1b, the dynamic link attempt was successful. • If TCD.major.e_link = 0b, the attempted dynamic link did not succeed (the channel was already retiring).

For this request, the TCD local memory controller forces the TCD.major.e_link bit to zero on any writes to a channel's TCD.word7 after that channel's TCD.done bit is set, indicating the major loop is complete.

NOTE

The user must clear the TCD.done bit before writing the TCD.major.e_link bit. The TCD.done bit is cleared automatically by the eDMA engine after a channel begins execution.

18.7.7.3 Dynamic scatter/gather

Dynamic scatter/gather is the process of setting the TCD.e_sg bit during channel execution. This bit is read from the TCD local memory at the end of channel execution, thus allowing the user to enable the feature during channel execution.

Because the user is allowed to change the configuration during execution, a coherency model is needed. Consider the scenario where the user attempts to execute a dynamic scatter/gather operation by enabling the TCD.e_sg bit at the same time the eDMA engine is retiring the channel. The TCD.e_sg would be set in the programmer's model, but it would be unclear whether the actual scatter/gather request was honored before the channel retired.

Two methods for this coherency model are shown in the following subsections. Method 1 has the advantage of reading the major.linkch field and the e_sg bit with a single read. For both dynamic channel linking and scatter/gather requests, the TCD local memory controller forces the TCD.major.e_link and TCD.e_sg bits to zero on any writes to a channel's TCD.word7 if that channel's TCD.done bit is set indicating the major loop is complete.

NOTE

The user must clear the TCD.done bit before writing the TCD.major.e_link or TCD.e_sg bits. The TCD.done bit is cleared automatically by the eDMA engine after a channel begins execution.

18.7.7.3.1 Method 1 (channel not using major loop channel linking)

For a channel not using major loop channel linking, the coherency model in the table below may be used for a dynamic scatter/gather request.

When the TCD.major.e_link bit is zero, the TCD.major.linkch field is not used by the eDMA. In this case, the TCD.major.linkch bits may be used for other purposes. This method uses the TCD.major.linkch field as a TCD identification (ID).

Step	Action
1	When the descriptors are built, write a unique TCD ID in the TCD.major.linkch field for each TCD associated with a channel using dynamic scatter/gather.
2	Write 1b to theTCD.d_req bit. **NOTE:** Should a dynamic scatter/gather attempt fail, setting the d_req bit will prevent a future hardware activation of this channel. This stops the channel from executing with a destination address (daddr) that was calculated using a scatter/gather address (written in the next step) instead of a dlast final offest value.
3	Write theTCD.dlast_sga field with the scatter/gather address.
4	Write 1b to the TCD.e_sg bit.
5	Read back the 16 bit TCD control/status field.
6	Test the TCD.e_sg request status and TCD.major.linkch value: • If e_sg = 1b, the dynamic link attempt was successful. • If e_sg = 0b and the major.linkch (ID) did not change, the attempted dynamic link did not succeed (the channel was already retiring). • If e_sg = 0b and the major.linkch (ID) changed, the dynamic link attempt was successful (the new TCD's e_sg value cleared the e_sg bit).

18.7.7.3.2 Method 2 (channel using major loop linking)

For a channel using major loop channel linking, the coherency model in the following table may be used for a dynamic scatter/gather request. This method uses the TCD.dlast_sga field as a TCD identification (ID).

Table 18-811. Coherency model for Method 2

Step	Action
1	Write 1b to theTCD.d_req bit. **NOTE:** Should a dynamic scatter/gather attempt fail, setting the d_req bit will prevent a future hardware activation of this channel. This stops the channel from executing with a destination address (daddr) that was calculated using a scatter/gather address (written in the next step) instead of a dlast final offest value.
2	Write theTCD.dlast_sga field with the scatter/gather address.
3	Write 1b to the TCD.e_sg bit.
4	Read back the TCD.e_sg bit.
5	Test the TCD.e_sg request status: • If e_sg = 1b, the dynamic link attempt was successful. • If e_sg = 0b, read the 32 bit TCD dlast_sga field. • If e_sg = 0b and the dlast_sga did not change, the attempted dynamic link did not succeed (the channel was already retiring). • If e_sg = 0b and the dlast_sga changed, the dynamic link attempt was successful (the new TCD's e_sg value cleared the e_sg bit).

18.7.7.4 Hardware request release timing

This section provides a timing diagram for deasserting the ipd_req hardware request signal. The following figure shows two read write sequences with shadowing that indicates the release of the ipd_req hardware request signal.

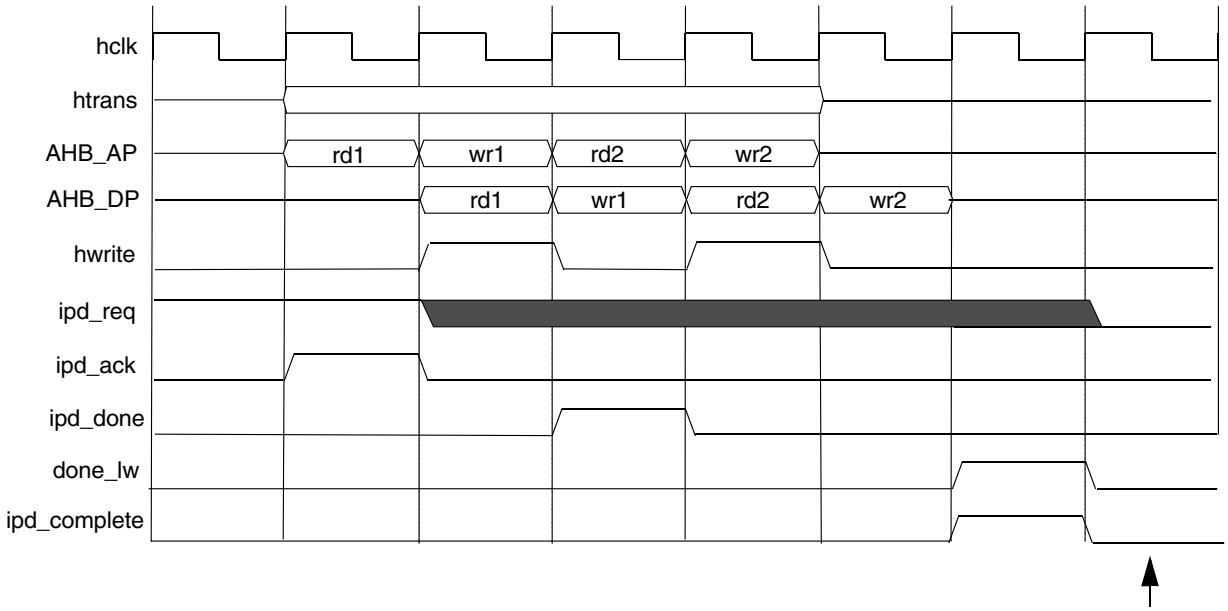

Figure 18-741. ipd_req hardware handshake

Chapter 19
Direct Memory Access Multiplexer (DMACHMUX)

19.1 DMACHMUX chip-specific module information

The peripheral DMA requests are serviced by a DMA controller. A static multiplexing scheme allows the support of more peripheral requests than available DMA channels.

19.1.1 DMA channel assignment

This device has four multiplexers. The following table lists which DMA channels apply to each multiplex.

Table 19-1. DMA multiplexer and channel list

DMAMUX instance	DMA channel
0	0-15
1	16-31
2	32-47
3	48-63

19.1.2 DMA channel multiplexing block diagram

The connections of the DMA channel multiplexors to the eDMA are shown in the following figure. One DMAMUX is instantiated for every 16 DMA channels.

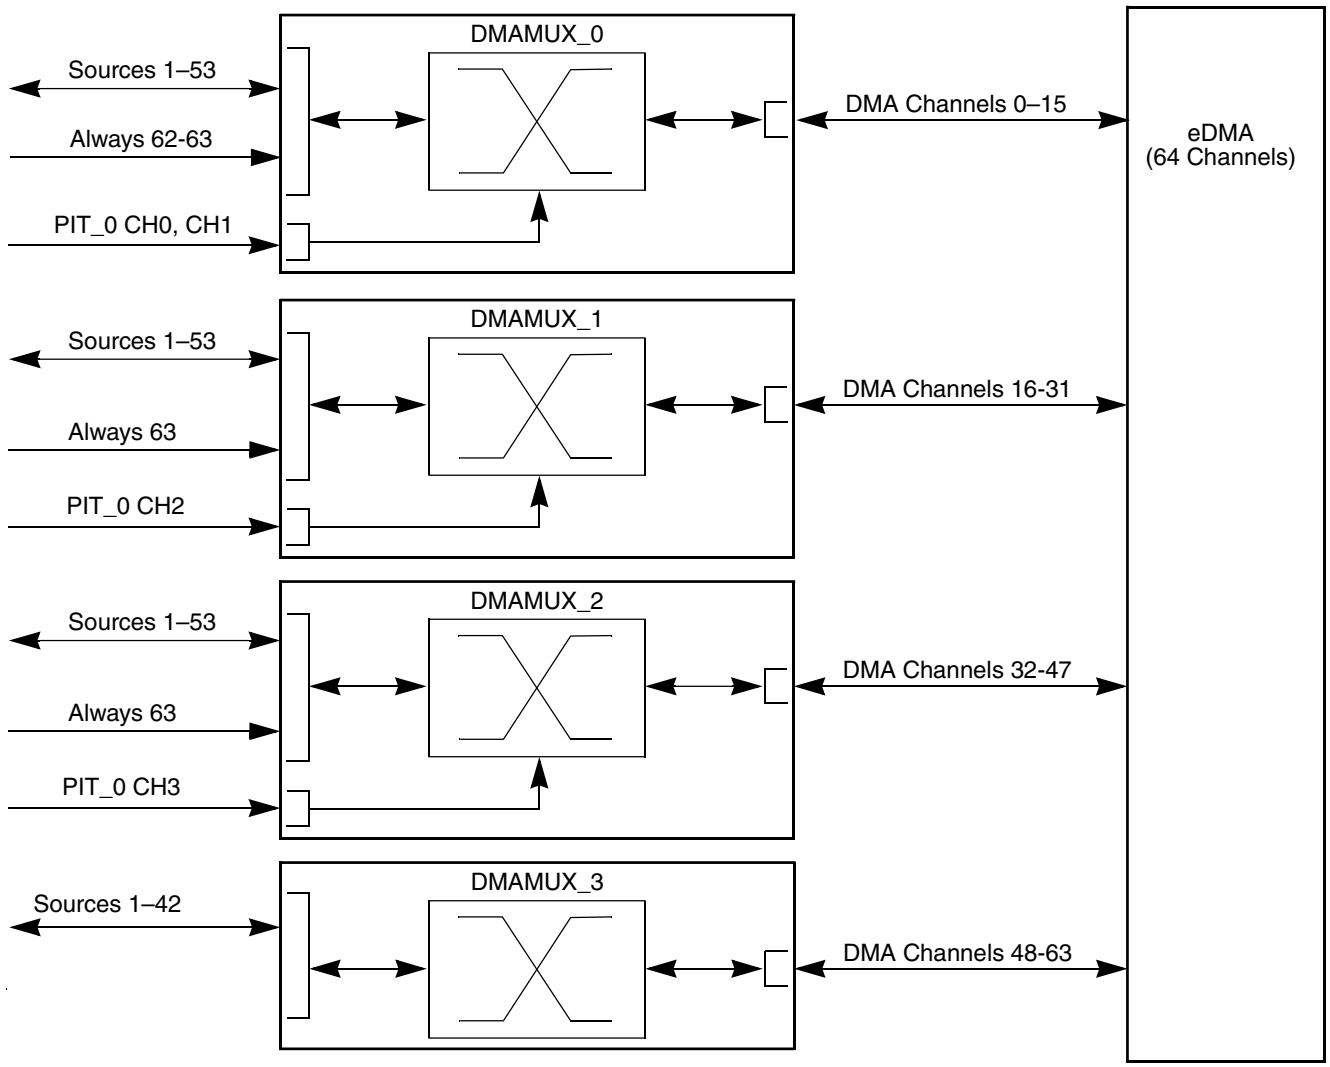

Figure 19-1. DMA channel multiplexing

19.1.3 DMA request mapping

The mapping of the peripheral DMA requests to the DMA_CH_MUX input sources is shown in the following table.

Table 19-2. DMA request mapping

Source	DMAMUX_0	DMAMUX_1	DMAMUX_2	DMAMUX_3

NOTE

Multiple CHCONFIG registers, whether within the same DMAMUX instance or among multiple DMAMUX instances, must not select the same source value.

The mapping of the PIT periodic triggers to the DMA channel sources is shown in the following table.

Table 19-3. PIT_0 periodic trigger to DMA channel mapping

PIT_0 channel	PIT_0 periodic trigger	DMA Channel
0	DMAMUX_0 Trigger 0	0
1	DMAMUX_0 Trigger 1	1
2	DMAMUX_1 Trigger 0	16
3	DMAMUX_2 Trigger 0	32

The DMAMUX_CHCFGn[TRIG] field is only available in the following DMAMUX instances.

Table 19-4. DMAMUX instance with TRIG field

DMAMUX instance	DMAMUX_CHCFGn register with TRIG field
DMAMUX_0	DMAMUX_CHCFG0 and DMAMUX_CHCFG1
DMAMUX_1	DMAMUX_CHCFG0
DMAMUX_2	DMAMUX_CHCFG0

19.1.4 DMAMUX Memory map

Each of the four instances of DMAMUX (0–3) is allocated 512 bytes of memory space. The DMAMUX address offsets are shown in the following table. Offsets are from the DMAMUX base address.

Table 19-5. DMAMUX memory map

Offset	Register	Access
0x0000	DMAMUX_0 CHCONFIG0-CHCONFIG15	R/W
0x0200	DMAMUX_1 CHCONFIG0-CHCONFIG15	R/W
0x0400	DMAMUX_2 CHCONFIG0-CHCONFIG15	R/W
0x0600	DMAMUX_3 CHCONFIG0-CHCONFIG15	R/W

Each channel must be configured separately via settings in a dedicated configuration register. There is one configuration register per channel for each DMAMUX.

19.2 Introduction

19.2.1 Overview

The Direct Memory Access Multiplexer (DMAMUX) routes DMA sources, called slots, to any of the 16 DMA channels. This process is illustrated in the following figure.

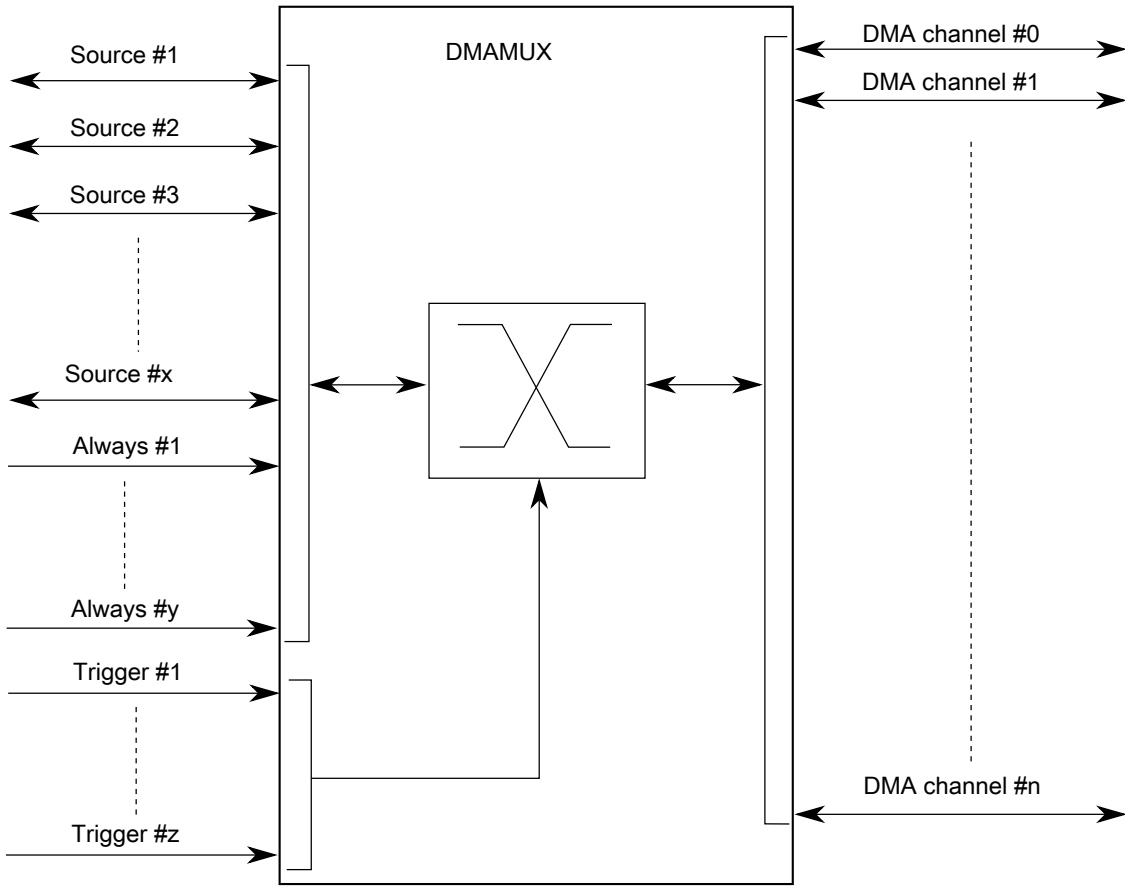

Figure 19-2. DMAMUX block diagram

19.2.2 Features

The DMAMUX module provides these features:

- Up to 61 peripheral slots and up to two always-on slots can be routed to 16 channels.
- 16 independently selectable DMA channel routers.
  - The first four channels additionally provide a trigger functionality.
- Each channel router can be assigned to one of the possible peripheral DMA slots or to one of the always-on slots.

19.2.3 Modes of operation

The following operating modes are available:

- Disabled mode

In this mode, the DMA channel is disabled. Because disabling and enabling of DMA channels is done primarily via the DMA configuration registers, this mode is used mainly as the reset state for a DMA channel in the DMA channel MUX. It may also be used to temporarily suspend a DMA channel while reconfiguration of the system takes place, for example, changing the period of a DMA trigger.

- Normal mode

  In this mode, a DMA source is routed directly to the specified DMA channel. The operation of the DMAMUX in this mode is completely transparent to the system.

- Periodic Trigger mode

  In this mode, a DMA source may only request a DMA transfer, such as when a transmit buffer becomes empty or a receive buffer becomes full, periodically.

  Configuration of the period is done in the registers of the periodic interrupt timer (PIT). This mode is available only for channels 0–3.

19.3 External signal description

The DMAMUX has no external pins.

19.4 Memory map/register definition

This section provides a detailed description of all memory-mapped registers in the DMAMUX.

DMAMUX memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	Channel Configuration register (DMAMUX_CHCFG0)	8	R/W	00h	19.4.1/614
1	Channel Configuration register (DMAMUX_CHCFG1)	8	R/W	00h	19.4.1/614

19.4.1 Channel Configuration register (DMAMUX_CHCFG*n*)

Each of the DMA channels can be independently enabled/disabled and associated with one of the DMA slots (peripheral slots or always-on slots) in the system.

NOTE

Setting multiple CHCFG registers with the same source value will result in unpredictable behavior. This is true, even if a channel is disabled (ENBL==0).

Before changing the trigger or source settings, a DMA channel must be disabled via CHCFGn[ENBL].

Address: 0h base + 0h offset + (1d × i), where i=0d to 15d

Bit	0	1	2	3	4	5	6	7
Read Write	ENBL	TRIG	SOURCE					
Reset	0	0	0	0	0	0	0	0

DMAMUX_CHCFG*n* field descriptions

Field	Description
0 ENBL	DMA Channel Enable Enables the DMA channel. 0 DMA channel is disabled. This mode is primarily used during configuration of the DMAMux. The DMA has separate channel enables/disables, which should be used to disable or reconfigure a DMA channel. 1 DMA channel is enabled
1 TRIG	DMA Channel Trigger Enable Enables the periodic trigger capability for the triggered DMA channel.

Table continues on the next page...

DMAMUX_CHCFG*n* field descriptions (continued)

Field	Description
	0 Triggering is disabled. If triggering is disabled and ENBL is set, the DMA Channel will simply route the specified source to the DMA channel. (Normal mode) 1 Triggering is enabled. If triggering is enabled and ENBL is set, the DMAMUX is in Periodic Trigger mode.
2–7 SOURCE	DMA Channel Source (Slot) Specifies which DMA source, if any, is routed to a particular DMA channel. See the chip-specific DMAMUX information for details about the peripherals and their slot numbers.

19.5 Functional description

The primary purpose of the DMAMUX is to provide flexibility in the system's use of the available DMA channels.

As such, configuration of the DMAMUX is intended to be a static procedure done during execution of the system boot code. However, if the procedure outlined in Enabling and configuring sources is followed, the configuration of the DMAMUX may be changed during the normal operation of the system.

Functionally, the DMAMUX channels may be divided into two classes:

- Channels that implement the normal routing functionality plus periodic triggering capability
- Channels that implement only the normal routing functionality

19.5.1 DMA channels with periodic triggering capability

Besides the normal routing functionality, the first 4 channels of the DMAMUX provide a special periodic triggering capability that can be used to provide an automatic mechanism to transmit bytes, frames, or packets at fixed intervals without the need for processor intervention.

The trigger is generated by the periodic interrupt timer (PIT); as such, the configuration of the periodic triggering interval is done via configuration registers in the PIT. See the section on periodic interrupt timer for more information on this topic.

Note

Because of the dynamic nature of the system (due to DMA channel priorities, bus arbitration, interrupt service routine lengths, etc.), the number of clock cycles between a trigger and the actual DMA transfer cannot be guaranteed.

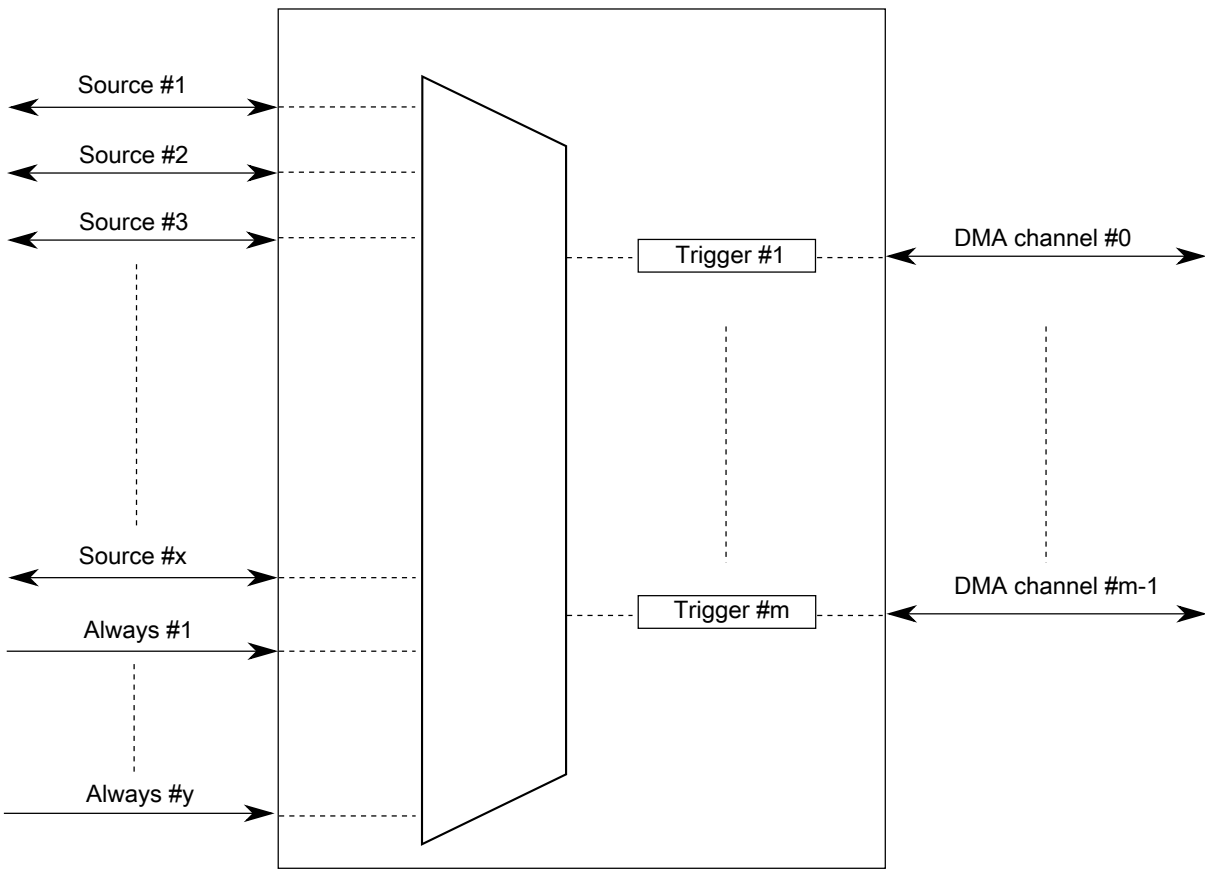

Figure 19-20. DMAMUX triggered channels

The DMA channel triggering capability allows the system to schedule regular DMA transfers, usually on the transmit side of certain peripherals, without the intervention of the processor. This trigger works by gating the request from the peripheral to the DMA until a trigger event has been seen. This is illustrated in the following figure.

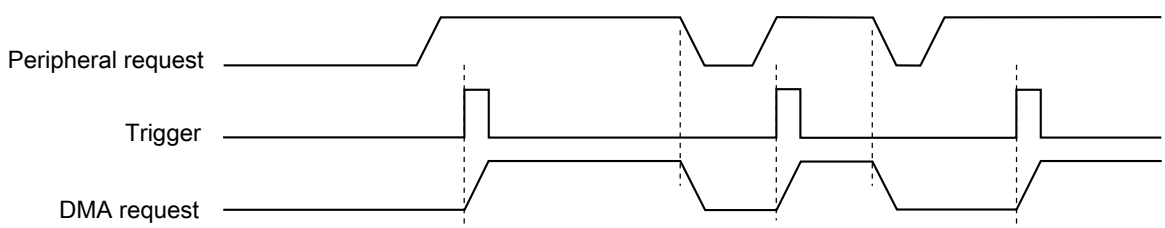

Figure 19-21. DMAMUX channel triggering: normal operation

After the DMA request has been serviced, the peripheral will negate its request, effectively resetting the gating mechanism until the peripheral reasserts its request and the next trigger event is seen. This means that if a trigger is seen, but the peripheral is not requesting a transfer, then that trigger will be ignored. This situation is illustrated in the following figure.

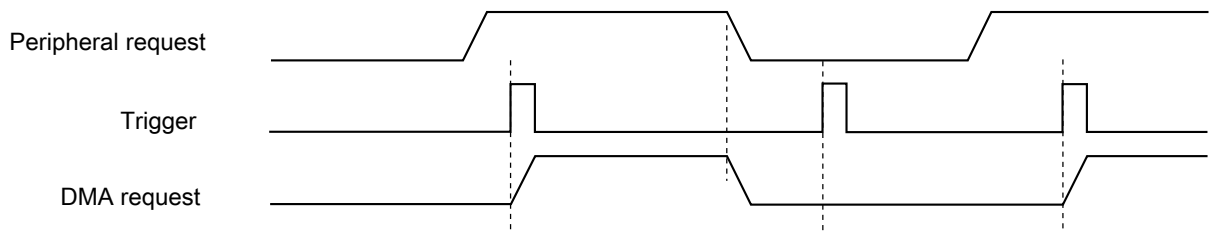

Figure 19-22. DMAMUX channel triggering: ignored trigger

This triggering capability may be used with any peripheral that supports DMA transfers, and is most useful for two types of situations:

- Periodically polling external devices on a particular bus

  As an example, the transmit side of an SPI is assigned to a DMA channel with a trigger, as described above. After it has been set up, the SPI will request DMA transfers, presumably from memory, as long as its transmit buffer is empty. By using a trigger on this channel, the SPI transfers can be automatically performed every 5 µs (as an example). On the receive side of the SPI, the SPI and DMA can be configured to transfer receive data into memory, effectively implementing a method to periodically read data from external devices and transfer the results into memory without processor intervention.

- Using the GPIO ports to drive or sample waveforms

  By configuring the DMA to transfer data to one or more GPIO ports, it is possible to create complex waveforms using tabular data stored in on-chip memory. Conversely, using the DMA to periodically transfer data from one or more GPIO ports, it is possible to sample complex waveforms and store the results in tabular form in on-chip memory.

A more detailed description of the capability of each trigger, including resolution, range of values, and so on, may be found in the periodic interrupt timer section.

19.5.2 DMA channels with no triggering capability

The other channels of the DMAMUX provide the normal routing functionality as described in Modes of operation.

19.5.3 Always-enabled DMA sources

In addition to the peripherals that can be used as DMA sources, there are two additional DMA sources that are always enabled. Unlike the peripheral DMA sources, where the peripheral controls the flow of data during DMA transfers, the sources that are always enabled provide no such "throttling" of the data transfers. These sources are most useful in the following cases:

- Performing DMA transfers to/from GPIO—Moving data from/to one or more GPIO pins, either unthrottled (that is, as fast as possible), or periodically (using the DMA triggering capability).
- Performing DMA transfers from memory to memory—Moving data from memory to memory, typically as fast as possible, sometimes with software activation.
- Performing DMA transfers from memory to the external bus, or vice-versa—Similar to memory to memory transfers, this is typically done as quickly as possible.
- Any DMA transfer that requires software activation—Any DMA transfer that should be explicitly started by software.

In cases where software should initiate the start of a DMA transfer, an always-enabled DMA source can be used to provide maximum flexibility. When activating a DMA channel via software, subsequent executions of the minor loop require that a new start event be sent. This can either be a new software activation, or a transfer request from the DMA channel MUX. The options for doing this are:

- Transfer all data in a single minor loop.

  By configuring the DMA to transfer all of the data in a single minor loop (that is, major loop counter = 1), no reactivation of the channel is necessary. The disadvantage to this option is the reduced granularity in determining the load that the DMA transfer will impose on the system. For this option, the DMA channel must be disabled in the DMA channel MUX.

- Use explicit software reactivation.

  In this option, the DMA is configured to transfer the data using both minor and major loops, but the processor is required to reactivate the channel by writing to the DMA registers *after every minor loop*. For this option, the DMA channel must be disabled in the DMA channel MUX.

- Use an always-enabled DMA source.

In this option, the DMA is configured to transfer the data using both minor and major loops, and the DMA channel MUX does the channel reactivation. For this option, the DMA channel should be enabled and pointing to an "always enabled" source. Note that the reactivation of the channel can be continuous (DMA triggering is disabled) or can use the DMA triggering capability. In this manner, it is possible to execute periodic transfers of packets of data from one source to another, without processor intervention.

19.6 Initialization/application information

This section provides instructions for initializing the DMA channel MUX.

19.6.1 Reset

The reset state of each individual bit is shown in Memory map/register definition. In summary, after reset, all channels are disabled and must be explicitly enabled before use.

19.6.2 Enabling and configuring sources

To enable a source with periodic triggering:

1. Determine with which DMA channel the source will be associated. Note that only the first 4 DMA channels have periodic triggering capability.
2. Clear the CHCFG[ENBL] and CHCFG[TRIG] fields of the DMA channel.
3. Ensure that the DMA channel is properly configured in the DMA. The DMA channel may be enabled at this point.
4. Configure the corresponding timer.
5. Select the source to be routed to the DMA channel. Write to the corresponding CHCFG register, ensuring that the CHCFG[ENBL] and CHCFG[TRIG] fields are set.

NOTE

The following is an example. See the chip configuration details for the number of this device's DMA channels that have triggering capability.

To configure source #5 transmit for use with DMA channel 1, with periodic triggering capability:

1. Write 0x00 to CHCFG1.

2. Configure channel 1 in the DMA, including enabling the channel.
3. Configure a timer for the desired trigger interval.
4. Write 0xC5 to CHCFG1.

The following code example illustrates steps 1 and 4 above:

```
void DMAMUX_Init(uint8_t DMA_CH, uint8_t DMAMUX_SOURCE)
{
    DMAMUX_0.CHCFG[DMA_CH].B.SOURCE = DMAMUX_SOURCE;
    DMAMUX_0.CHCFG[DMA_CH].B.ENBL   = 1;
    DMAMUX_0.CHCFG[DMA_CH].B.TRIG   = 1;
}
```

To enable a source, without periodic triggering:

1. Determine with which DMA channel the source will be associated. Note that only the first 4 DMA channels have periodic triggering capability.
2. Clear the CHCFG[ENBL] and CHCFG[TRIG] fields of the DMA channel.
3. Ensure that the DMA channel is properly configured in the DMA. The DMA channel may be enabled at this point.
4. Select the source to be routed to the DMA channel. Write to the corresponding CHCFG register, ensuring that CHCFG[ENBL] is set while CHCFG[TRIG] is cleared.

NOTE

The following is an example. See the chip configuration details for the number of this device's DMA channels that have triggering capability.

To configure source #5 transmit for use with DMA channel 1, with no periodic triggering capability:

1. Write 0x00 to CHCFG1.
2. Configure channel 1 in the DMA, including enabling the channel.
3. Write 0x85 to CHCFG1.

The following code example illustrates steps 1 and 3 above:

```
In File registers.h:
#define DMAMUX_BASE_ADDR     0x40021000/* Example only ! */
/* Following example assumes char is 8-bits */
volatile unsigned char *CHCFG0 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0000);
volatile unsigned char *CHCFG1 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0001);
volatile unsigned char *CHCFG2 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0002);
volatile unsigned char *CHCFG3 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0003);
volatile unsigned char *CHCFG4 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0004);
volatile unsigned char *CHCFG5 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0005);
volatile unsigned char *CHCFG6 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0006);
volatile unsigned char *CHCFG7 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0007);
volatile unsigned char *CHCFG8 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0008);
volatile unsigned char *CHCFG9 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0009);
volatile unsigned char *CHCFG10= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000A);
volatile unsigned char *CHCFG11= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000B);
volatile unsigned char *CHCFG12= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000C);
volatile unsigned char *CHCFG13= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000D);
```

```
volatile unsigned char *CHCFG14= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000E);
volatile unsigned char *CHCFG15= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000F);

In File main.c:
#include "registers.h"
:
:
*CHCFG1 = 0x00;
*CHCFG1 = 0x85;
```

To disable a source:

A particular DMA source may be disabled by not writing the corresponding source value into any of the CHCFG registers. Additionally, some module-specific configuration may be necessary. See the appropriate section for more details.

To switch the source of a DMA channel:

1. Disable the DMA channel in the DMA and reconfigure the channel for the new source.
2. Clear the CHCFG[ENBL] and CHCFG[TRIG] bits of the DMA channel.
3. Select the source to be routed to the DMA channel. Write to the corresponding CHCFG register, ensuring that the CHCFG[ENBL] and CHCFG[TRIG] fields are set.

To switch DMA channel 8 from source #5 transmit to source #7 transmit:

1. In the DMA configuration registers, disable DMA channel 8 and reconfigure it to handle the transfers to peripheral slot 7. This example assumes channel 8 doesn't have triggering capability.
2. Write 0x00 to CHCFG8.
3. Write 0x87 to CHCFG8. (In this example, setting CHCFG[TRIG] would have no effect due to the assumption that channel 8 does not support the periodic triggering functionality.)

The following code example illustrates steps 2 and 3 above:

```
In File registers.h:
#define DMAMUX_BASE_ADDR     0x40021000/* Example only ! */
/* Following example assumes char is 8-bits */
volatile unsigned char *CHCFG0 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0000);
volatile unsigned char *CHCFG1 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0001);
volatile unsigned char *CHCFG2 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0002);
volatile unsigned char *CHCFG3 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0003);
volatile unsigned char *CHCFG4 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0004);
volatile unsigned char *CHCFG5 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0005);
volatile unsigned char *CHCFG6 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0006);
volatile unsigned char *CHCFG7 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0007);
volatile unsigned char *CHCFG8 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0008);
volatile unsigned char *CHCFG9 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0009);
volatile unsigned char *CHCFG10= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000A);
volatile unsigned char *CHCFG11= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000B);
volatile unsigned char *CHCFG12= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000C);
volatile unsigned char *CHCFG13= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000D);
volatile unsigned char *CHCFG14= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000E);
volatile unsigned char *CHCFG15= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000F);
```

```
In File main.c:
#include "registers.h"
:
:
*CHCFG8 = 0x00;
*CHCFG8 = 0x87;
```

Chapter 20
Wakeup Unit (WKPU)

20.1 Introduction

The Wakeup Unit (WKPU) supports one external source that can cause non-maskable interrupts to on-chip cores and wakeup events to the system. The following figure is a block diagram of the WKPU and its interfaces to other system components.

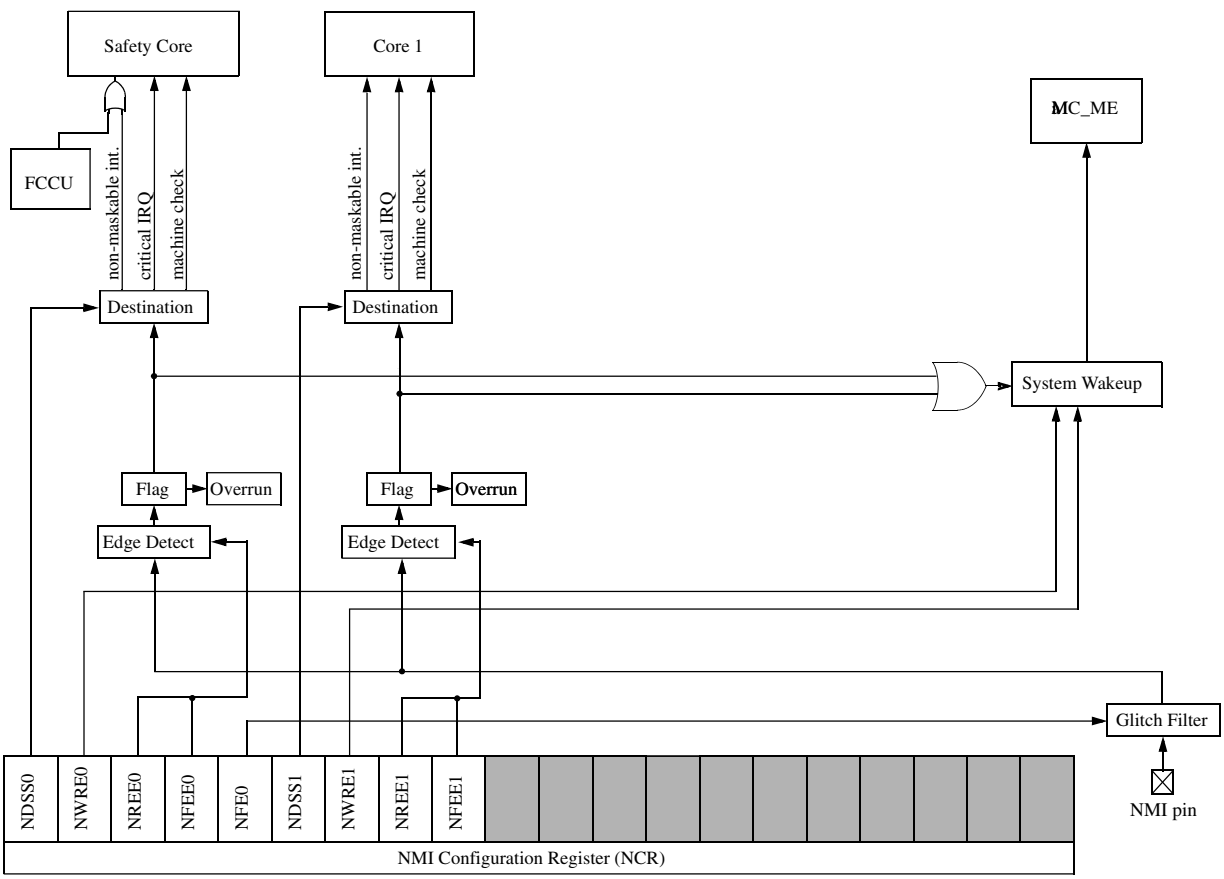

Figure 20-1. WKPU block diagram

20.1.1 Features

The WKPU supports these features:

- One external NMI source
- One analog glitch filter
- Independent interrupt destination for each core (as shown in figure above):
  - Non-maskable interrupt
  - Critical interrupt
  - Machine check request
- Active edge selection control for events to each core
- Configurable wakeup event to exit from low-power mode to the MC_ME
- Configurable wakeup event to exit from Stop mode to the MC_ME
- WKPU register configuration lock

20.2 External Signal Description

There is a single, active-edge selectable, NMI pin on the device that connects to the WKPU block. See this chip's signal description information for details on this pin.

20.3 WKPU memory map and registers

This section provides a detailed description of all registers accessible in the WKPU module.

NOTE

Reserved registers will read as 0, writes will have no effect. A transfer error will be issued when trying to access completely reserved register space.

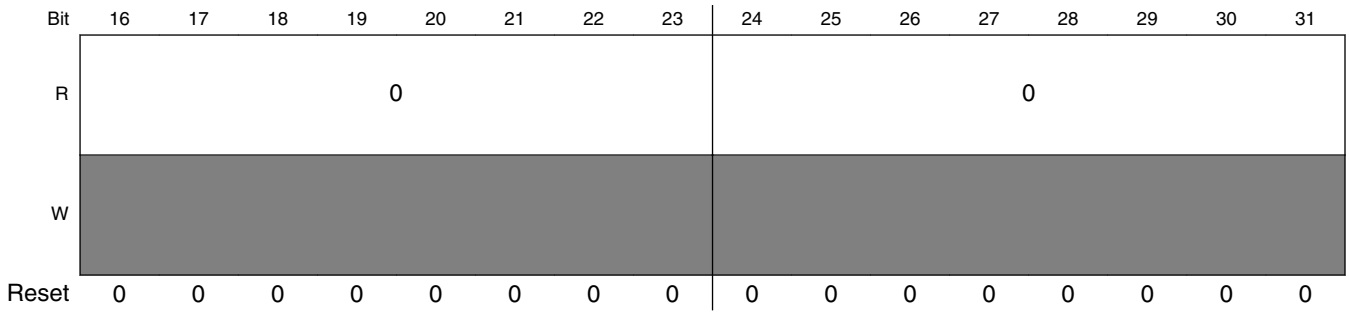
WKPU memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	NMI Status Flag Register (WKPU_NSR)	32	R/W	0000_0000h	20.3.1/625
8	NMI Configuration Register (WKPU_NCR)	32	R/W	0000_0000h	20.3.2/627

20.3.1 NMI Status Flag Register (WKPU_NSR)

This register holds the status flags of the NMI external source pin. This register is a clear-by-write-1 register type, preventing inadvertent overwriting of other flags in the same register. The status flag is set whenever an NMI event is detected. The overrun flag is set whenever an NMI event is detected and the status flag is set (i.e., has not yet been cleared).

The status flags are set independently of the NDSS bits. Therefore, these flags can set but not generate a non-maskable interrupt or system wakeup if NWRE = 0 or if NDSS is set to “no request”.



NOTE

The overrun flag is cleared by writing a ‘1’ to the appropriate overrun bit in the NSR. If the status bit is cleared and the overrun bit is still set, the pending interrupt will not be cleared.

Also see the notes in NMI Configuration Register (WKPU_NCR).

Address: 0h base + 0h offset = 0h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

WKPU_NSR field descriptions

Field	Description
0 NIF0	NMI Status Flag 0 (safety core) If enabled (i.e., NCR[NREE0] or NCR[NFEE0] is set), an NMI input event will set NIF0. NIF0 causes an interrupt request based on the NMI destination, as configured by NCR[NDSS0], and/or a system wakeup request based on NCR[NWRE0]. 0 No event has occurred on the pad 1 An event as defined by NCR[NREE0] and NCR[NFEE0] has occurred
1 NOVF0	NMI Overrun Status Flag 0 (safety core) This field is a copy of the current NIF0 value whenever a NMI event occurs, thereby indicating to the software that an NMI occurred while the last one was not yet serviced. NOVF0 causes an interrupt request based on the NMI destination, as configured by NCR[NDSS0], and/or a system wakeup request based on the NCR[NWRE0] bit configuration. 0 No overrun has occurred on NMI input 0 1 An overrun has occurred on NMI input 0
2–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8 NIF1	NMI Status Flag 1 (Core 1) If enabled (i.e., NCR[NREE1] or NCR[NFEE1] is set), an NMI input event will set NIF1. NIF1 causes an interrupt request based on the NMI destination, as configured by NCR[NDSS1], and/or a system wakeup request based on NCR[NWRE1]. 0 No event has occurred on the pad 1 An event as defined by NCR[NREE1] and NCR[NFEE1] has occurred
9 NOVF1	NMI Overrun Status Flag 1 (Core 1) This field is a copy of the current NIF1 value whenever a NMI event occurs, thereby indicating to the software that an NMI occurred while the last one was not yet serviced. NOVF1 causes an interrupt request based on the NMI destination, as configured by the NCR[NDSS1] bits, and/or a system wakeup request based on the NCR[NWRE1] bit configuration. 0 No overrun has occurred on NMI input 1 1 An overrun has occurred on NMI input 1
10–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

WKPU_NSR field descriptions (continued)

Field	Description
24–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

20.3.2 NMI Configuration Register (WKPU_NCR)

This register holds the configuration bits for the non-maskable interrupt settings.

NOTE

Writing a '0' to both NREE*n* and NFEE*n* disables the NMI functionality completely (i.e. no system wakeup or interrupt will be generated on any pad activity).

NOTE

Writing to the NCR when NIF = 1 or NOVF = 1 causes an interrupt to the destination source/system wakeup to be generated independent of an NMI wakeup event.

	1. Set MSR[ME], Machine Check Enable field of the core's Machine State Register, to 1. 2. Set HID0[EMCP] to 1. 00 A non-maskable interrupt will occur if NSR[NIF0] or NSR[NOVF0] is set. 01 A critical interrupt will occur if NSR[NIF0] or NSR[NOVF0] is set. 10 A machine check request will occur if NSR[NIF0] or NSR[NOVF0] is set. 11 No reaction
3 NWRE0	NMI Wakeup Request Enable 0 **NOTE:** If wakeup requests are disabled, the corresponding NDSS field must be set to 11 to disable wakeups from an NMI, critical interrupt, or machine check. 0 System wakeup requests from the corresponding NSR[NIF0] bit are disabled 1 A set NSR[NIF0] bit or set NSR[NOVF0] bit causes a system wakeup request
4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5 NREE0	NMI Rising-edge Events Enable 0 0 Rising-edge event is disabled 1 Rising-edge event is enabled
6 NFEE0	NMI Falling-edge Events Enable 0 0 Falling-edge event is disabled 1 Falling-edge event is enabled
7 NFE0	NMI Filter Enable Enable analog glitch filter on the NMI pad input. 0 Filter is disabled 1 Filter is enabled
8 NLOCK1	NMI Configuration Lock Register 1 0 Writing 0 to this bit has no effect. 1 Writing a 1 to this bit locks the configuration for the NMI until it is unlocked by a system reset.
9–10 NDSS1	NMI Destination Source Select 1 00 A non-maskable interrupt will occur if NSR[NIF1] or NSR[NOVF1] is set. 01 A critical interrupt will occur if NSR[NIF1] or NSR[NOVF1] is set. 10 A machine check request will occur if NSR[NIF1] or NSR[NOVF1] is set. 11 No reaction
11 NWRE1	NMI Wakeup Request Enable 1 0 System wakeup requests from the corresponding NSR[NIF1] bit are disabled 1 A set NSR[NIF1] bit or set NSR[NOVF1] bit causes a system wakeup request
12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13 NREE1	NMI Rising-edge Events Enable 1

Table continues on the next page...

WKPU_NCR field descriptions (continued)

Field	Description
	0 Rising-edge event is disabled 1 Rising-edge event is enabled
14 NFEE1	NMI Falling-edge Events Enable 1 0 Falling-edge event is disabled 1 Falling-edge event is enabled
15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

20.4 Functional Description

This section provides a functional description of the WKPU features.

20.4.1 Non-Maskable Interrupts

The WKPU allows the external NMI pin to assert the non-maskable interrupts of the cores on the device. These interrupts include non-maskable interrupts, critical interrupts, or machine check requests to any of the cores including the main core and safety core. The safety core's non-maskable interrupt line from the WKPU is routed through the FCCU block, where is it combined with the FCCU internal NMI interrupt event arising due to fault management logic.

The NMI destination interrupt is controlled by the user through the configuration of NCR[NDSS*n*].

The enabling of rising-edge, falling-edge, or either-edge reaction to the NMI pin is independent for each core, and is controlled by NCR[NFEE*n*] and NCR[NREE*n*].

The WKPU supports the capturing of a second event per NMI input before the interrupt is cleared, thus reducing the chance of losing an NMI event.

The NMI supports a status flag, NSR[NIF*n*], and an overrun flag, NSR[NOVF*n*].

20.4.2 System Wakeup

The WKPU allows the external NMI pin to assert a system wakeup from STOP to the MC_ME module on the chip. The system wakeup is enabled through the NWRE bits in the NCR register.

20.4.3 Glitch Filter

An analog glitch filter, between the NMI pin and the WKPU module, is enabled by NCR[NFE0]. See the chip's data sheet for the glitch filter's electrical specifications.

20.4.3.1 Edge Detect

Each NMI request can be enabled or disabled independently. This can be performed using the NCR register, which contains all configuration bits for a given NMI in a single byte. The user can configure interrupts with an active rising edge, an active falling edge, or either edge being active. Disabling both edge events results in no interrupt being propagated from the WKPU block.

The active NMI edge is controlled by the user through the configuration of the NREE and NFEE bits.

NOTE

After reset, all rising-/falling-edge enable bits set to 0, therefore the NMI functionality is disabled after reset and must be enabled explicitly by software.

20.5 Initialization Information

This section discusses initialization for the following features:

- Glitch Filter and Pad Configuration
- Non-Maskable Interrupts

20.5.1 Glitch Filter and Pad Configuration

Glitch filter control and pad configuration should be performed while the NMI is disabled in order to avoid erroneous triggering by glitches caused by the configuration process itself.

When enabling the glitch filter, do not enable the rising-/falling-edge events bits, i.e., the NREEand NFEE bits in the same register write.

20.5.2 Non-Maskable Interrupts

When an NMI interrupt pin is first enabled, it is possible to get a false interrupt flag. To prevent a false interrupt request during pin interrupt initialization the user must do the following:

1. Mask interrupts by clearing NSR[NIF*n*] and NSR[NOVF*n*].
2. Clear NCR[NFEE*n*] and NCR[NREE*n*], preferably by writing 0 to all bits in the register.
3. Configure the analog glitch filter using NCR[NFE0].
4. Write appropriate bit values to the NCR register to configure:
    - NMI source (NDSS*n*).
    - Wakeup request (NWRE*n*).
    - Glitch filter (NFE0)
    - Rising/falling edge events enable (NFEE*n* and NREE*n*).
    - NMI configuration lock (NLOCK*n*).

Chapter 21
Error Injection Module (EIM)

21.1 Error Injection Module (EIM) chip-specific module information

The EIM provides error injection for the DMA memory Error Correcting Code (ECC).

21.2 Introduction

The Error Injection module is mainly used for diagnostic purposes. It provides a method for diagnostic coverage of the peripheral memories. See the chip-specific EIM information to determine which peripheral memories are supported by this method.

21.2.1 Overview

The Error Injection Module (EIM) provides support for inducing single-bit and multi-bit inversions on read data when accessing peripheral RAMs. Injecting faults on memory accesses can be used to exercise the SEC-DED ECC function of the related system.

NOTE

The following diagram shows an example EIM implementation with a 64-bit read data bus and an 8-bit checkbit bus.

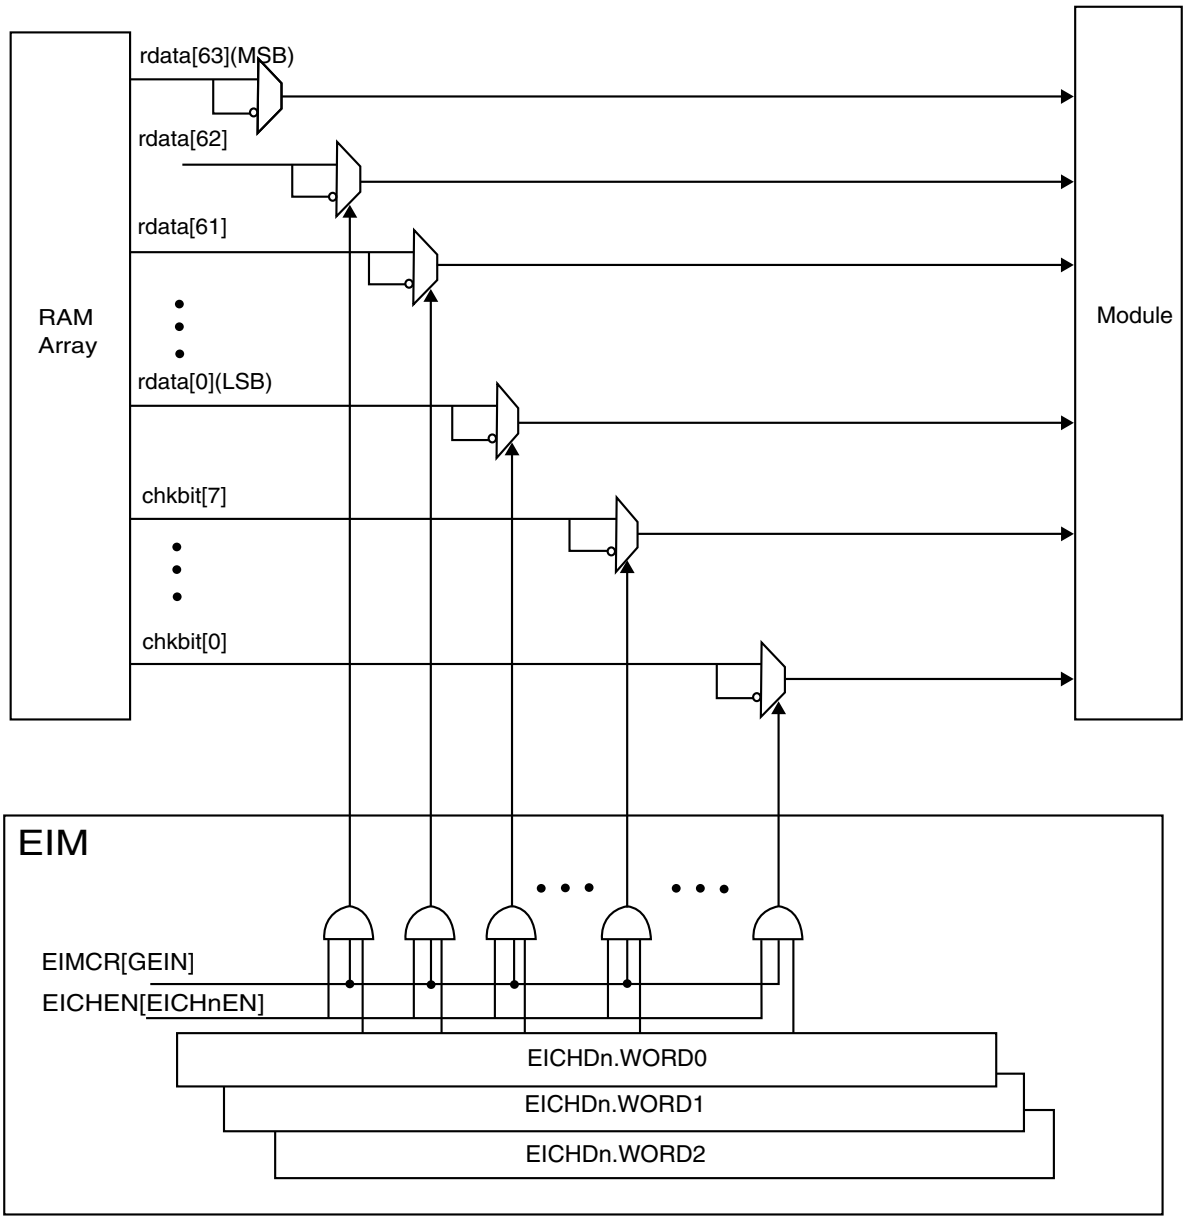

Figure 21-1. EIM functional block diagram (64-bit read data bus and 8-bit checkbit bus)

21.2.2 Features

The EIM includes these features:

- Supports 1 error injection channel
- Protection against accidental enable and reconfiguration error injection function via two-stage enable mechanism

21.3 Memory map and register definition

The EIM provides an IPS programming model mapped to an on-platform peripheral slot.

Programming model access

All system bus masters can access the programming model:

- Only in supervisor mode
- Using only 32-bit (word) accesses

Any of the following attempted references to the programming model generates an IPS error termination:

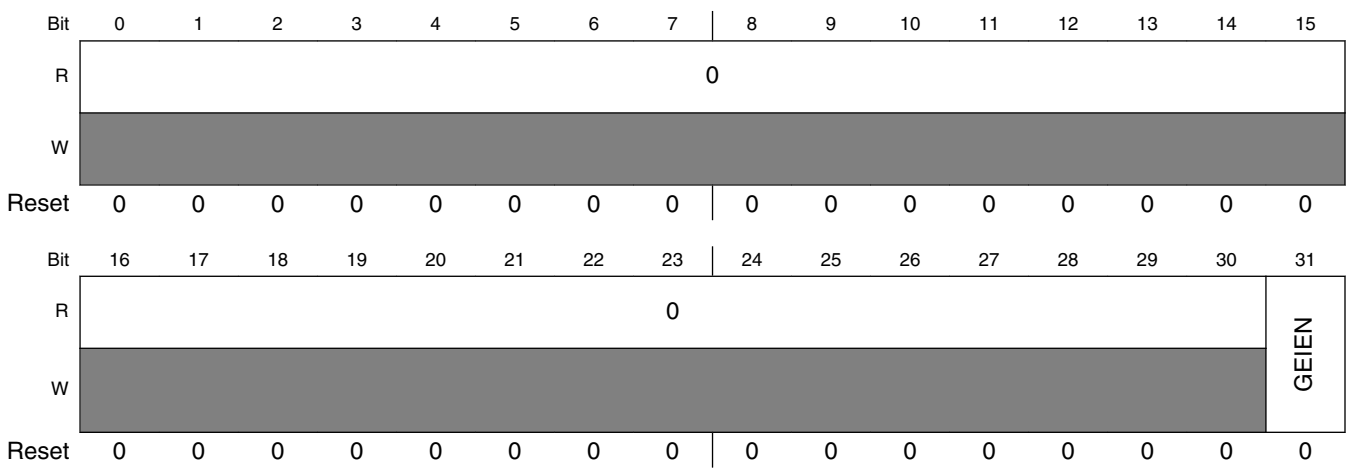
- In user mode
- Using non-32-bit access sizes
- To undefined (reserved) addresses

Attempted updates to the programming model while the EIM is in the midst of an operation will result in non-deterministic behavior.

Error injection channel descriptor: function and structure

Each error injection channel descriptor:

- Specifies a mask that defines which bits of the read data and checkbit bus from target RAM are inverted on a read access.
- Consists of a 128-bit (16-byte) structure, composed of four 32-bit words, in the EIM programming model.
    - Each descriptor consists of Error Injection Channel Descriptor Word0-1 (EICHD*n*_WORD0-1) and, depending on the implementation, Word2 (EICHD*n*_WORD2).
    - When Word2 is unused, the corresponding word in the 16-byte structure is unused.
    - The fourth word in the 16-byte structure is always unused.



EIM memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	Error Injection Module Configuration Register (EIM_EIMCR)	32	R/W	0000_0000h	21.3.1/636
4	Error Injection Channel Enable register (EIM_EICHEN)	32	R/W	0000_0000h	21.3.2/637
100	Error Injection Channel Descriptor, Word0 (EIM_EICHD0_WORD0)	32	R/W	0000_0000h	21.3.3/638
104	Error Injection Channel Descriptor, Word1 (EIM_EICHD0_WORD1)	32	R/W	0000_0000h	21.3.4/639
108	Error Injection Channel Descriptor, Word2 (EIM_EICHD0_WORD2)	32	R/W	0000_0000h	21.3.5/639

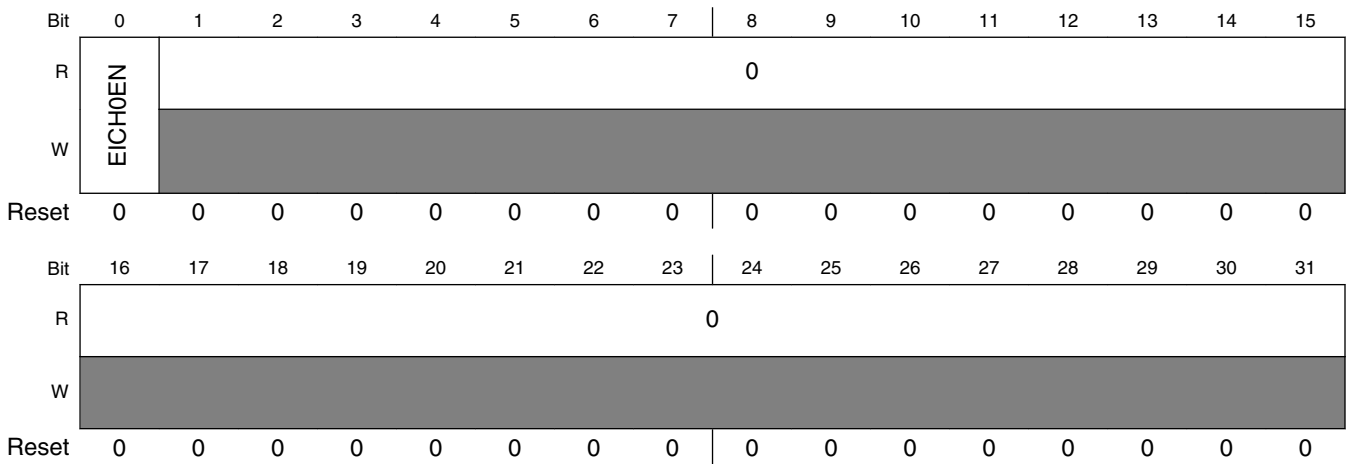
21.3.1 Error Injection Module Configuration Register (EIM_EIMCR)

The EIM Configuration Register is used to globally enable/disable the error injection function.

Address: 0h base + 0h offset = 0h

EIM_EIMCR field descriptions

Field	Description
0–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 GEIEN	Global Error Injection Enable This bit globally enables or disables the error injection function of the EIM. This field is initialized by hardware reset. 0 Disabled 1 Enabled



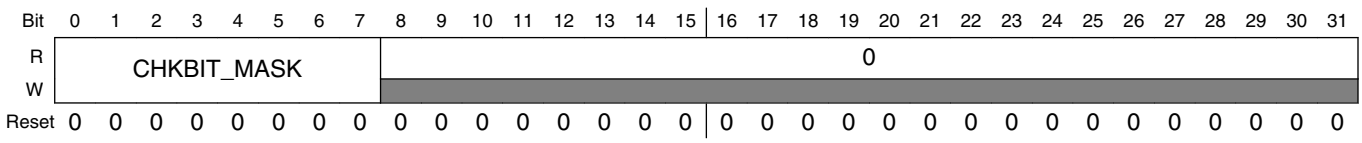
21.3.2 Error Injection Channel Enable register (EIM_EICHEN)

Each field of the Error Injection Channel Enable register (EICHEN) is used to enable or disable the corresponding error injection channel.

NOTE

To enable an error injection channel, the Global Error Injection Enable (EIMCR[GEIEN]) field must also be asserted.

Address: 0h base + 4h offset = 4h



EIM_EICHEN field descriptions

Field	Description
0 EICH0EN	Error Injection Channel 0 Enable This field enables the corresponding error injection channel. The Global Error Injection Enable (EIMCR[GEIEN]) field must also be asserted to enable error injection. After error injection is enabled, all subsequent read accesses incur one or more bit inversions as defined in the corresponding EICHD*n*_WORD registers. Error injection remains in effect until the error injection channel is manually disabled via software. Any write to the corresponding EICHD*n*_WORD registers clears the corresponding EICHEN[EICH*n*EN] field, disabling the error injection channel. This field is cleared by power-on reset and unaffected by other types of system reset. 0 Error injection is disabled on Error Injection Channel 0 1 Error injection is enabled on Error Injection Channel 0
1–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

21.3.3 Error Injection Channel Descriptor, Word0 (EIM_EICHD*n*_WORD0)

The first word of the Error Injection Channel Descriptor defines a left-justified mask field (CHKBIT_MASK) whose width is up to 8 bits. Each bit of CHKBIT_MASK specifies whether the corresponding bit of the checkbit bus from the target RAM should be inverted or remain unmodified on read accesses. Successful writes to this field clear the corresponding error injection channel valid bit, EICHEN[EICH*n*EN].

Address: 0h base + 100h offset + (256d × i), where i=0d to 0d

EIM_EICHD*n*_WORD0 field descriptions

Field	Description
0–7 CHKBIT_MASK	Checkbit Mask This field defines a bit-mapped mask that specifies whether the corresponding bit of the checkbit bus from the target RAM should be inverted or remain unmodified. The width of the field for the channel is defined in the chip-specific EIM information. 0 The corresponding bit of the checkbit bus remains unmodified. 1 The corresponding bit of the checkbit bus is inverted.
8–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

21.3.4 Error Injection Channel Descriptor, Word1 (EIM_EICHD*n*_WORD1)

The second word of the Error Injection Channel Descriptor defines the bits in the mask corresponding to bytes 0–3 of the read data bus. Each bit specifies whether the corresponding bit of the read data bus from the target RAM should be inverted or remain unmodified on read accesses. Successful writes to this field clear the corresponding error injection channel valid field, EICHEN[EICH*n*EN].

Address: 0h base + 104h offset + (256d × i), where i=0d to 0d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

EIM_EICHD*n*_WORD1 field descriptions

Field	Description
0–31 B0_3DATA_ MASK	Data Mask Bytes 0-3 This field defines a bit-mapped mask that specifies whether the corresponding bit of the read data bus from the target RAM should be inverted or remain unmodified. For details about which bits in this field are implemented for the applicable channel and how the bits map to bytes 0-3 of the read data bus, see the chip-specific EIM information. 0 The corresponding bit of bytes 0-3 on the read data bus remains unmodified 1 The corresponding bit of bytes 0-3 on the read data bus is inverted.

21.3.5 Error Injection Channel Descriptor, Word2 (EIM_EICHD*n*_WORD2)

The third word of the Error Injection Channel Descriptor, when present, defines the bits in the mask corresponding to bytes 4–7 of the read data bus. Each bit specifies whether the corresponding bit of the read data bus from the target RAM should be inverted or remain unmodified on read accesses. Successful writes to this field clear the corresponding error injection channel valid field, EICHEN[EICH*n*EN].

Address: 0h base + 108h offset + (256d × i), where i=0d to 0d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

EIM_EICHD*n*_WORD2 field descriptions

Field	Description
0–31 B4_7DATA_ MASK	Data Mask Bytes 4-7 This field defines a bit-mapped mask that specifies whether the corresponding bit of the read data bus from the target RAM should be inverted or remain unmodified. For details about which bits in this field are implemented for the applicable channel and how the bits map to bytes 4-7 of the read data bus, see the chip-specific EIM information. 0 The corresponding bit of bytes 4-7 on the read data bus remains unmodified. 1 The corresponding bit of bytes 4-7 on the read data bus is inverted.

21.4 Functional description

The EIM provides protection against accidental enabling and reconfiguration of the error injection function by enforcing a two-stage enablement mechanism. To properly enable the error injection mechanism for a channel, execute both of the following:

- Assert the EICHEN[EICH*n*EN] field, where *n* denotes the channel number.
- Assert EIMCR[GEIEN].

NOTE

When the use case for a channel requires writing any EICHD*n*_WORD register, write the EICHD*n*_WORD register before executing the two-stage enablement mechanism. A successful write to any EICHD*n*_WORD register clears the corresponding EICHEN[EICH*n*EN] field.

The EIM supports 1 error injection channel. Each channel:

- is assigned to a single memory array interface.
- intercepts the assigned memory read data bus and checkbit bus and injects errors by inverting the value transmitted for selected bits on each bus line.

On a memory read access, the applicable EICHD*n*_WORD registers define which bits of the read data and/or checkbit bus to invert.

Figure 21-1 depicts the interception and override of a 64-bit read data bus and an 8-bit checkbit data bus for an example memory array.

Chapter 22
Clocking

22.1 Introduction

This chapter describes the architecture for the system level clocks and includes the following information:

- System clock specifics
- Clock architecture
- Clock sources
- Clock monitoring
- Programmable clock dividers
- Clock control registers
- Progressive Clock Switching

NOTE

This chapter covers only clocks that are generated on the device. Protocol clocks that are provided by external devices are covered in the respective chapters where they are used.

The clock (system clock) for the computational shell (which includes the checker and two computational cores as well as all modules that run in the high speed domain), memories, and debug logic is independent from the peripheral clocks. This allows the system clock to be a frequency modulated clock to reduce electromagnetic emissions, while having a precise clock for the peripheral timer and communication functions. It also allows the system clock to be reduced during low computational activity periods to help reduce power consumption, while providing a fixed frequency to the communication interfaces and timers.

The MPC5746R boots from the internal 16 MHz RC oscillator (IRCOSC), and uses this as a backup clock in the event of a PLL or XOSC failure (if backup clock is enabled).

There are three possible ways to provide the source clock:

- External oscillator

- External crystal
- Internal 16 MHz RC oscillator.

The internal clocks are generated from one of these input sources. These output clocks of the PLLs, along with the XOSC and IRCOSC, can be selected to drive system peripherals depending on the configuration of the Auxiliary Clock Selectors (in the MC_CGM). The PHI1 output of PLL0 can also be used as the clock source for PLL1. A total of eleven clock selectors allows developers to select the PLL reference clocks, drive various system peripherals with an independent clock source, and select a clock source to drive the CLKOUT signal for off-chip use. One of the clock selectors is used exclusively for the system clock.

Each of the outputs of the module clock selectors has dividers which allows for even more clock frequency granularity with division factors up to 128 for a given group of peripherals. On selected outputs of the clock dividers are Clock Monitor Units (CMU) that are used to test the integrity of the clocks making sure that their frequencies stay within necessary operating limits. If any of the eleven CMUs detects an issue with the clock signal that is being monitored, an interrupt or system reset can be generated, depending on the CMUs configurations.

22.2 Clock generation

The top-level clock generation architecture is given in the following figure. All clock selectors and dividers in the figure are located and programmed in the Clock Generation Module (MC_CGM). All dividers are integer dividers (1, 2, 3, …, n) with the ranges shown in Clock generation .

NOTE

CMU_0…CMU_9, CMU_12 in Clock generation use IRCOSC for their reference clock. However, the user can select XOSC as the reference in CMU_0 for monitoring IRCOSC.

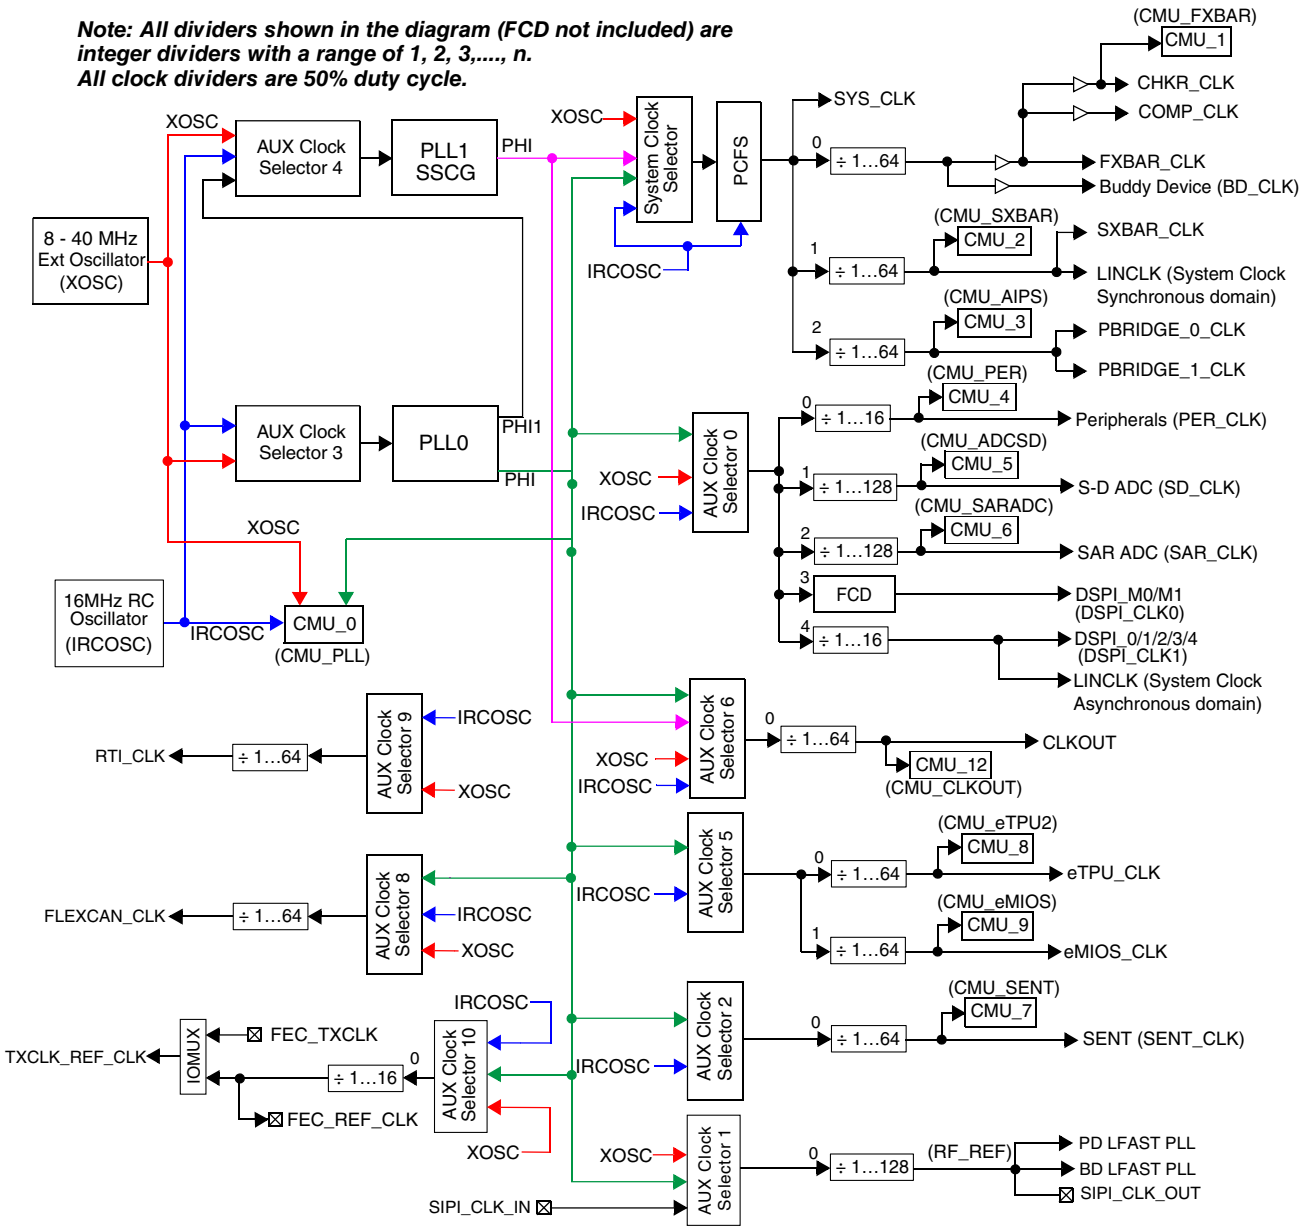

Figure 22-1. Clock generation

NOTE

Default clock source for all Auxillary Clock Selectors is the IRCOSC. User must configure MC_CGM_AC*n*_SC[SELCTL] before enabling the corresponding module functionality.

IRCOSC is the default clock for PLL1, but a PLL lock cannot be achieved using IRCOSC as the reference for PLL1.

NOTE

PBRIDGE_x_CLK may be referred to as "AIPS_CLK" elsewhere in this document.

NOTE

Do not bring out the ADC clock (XOSC + PLL0) or its component (XOSC and PLL0) on the CLKOUT pad when the ADC is in use using the same clock.

22.2.1 MC_CGM registers

Table 22-1 shows the relationship between the clocks in Clock generation and the MC_CGM registers.

NOTE

See Clock Generation Module (CGM) for specifics on register configurations.

Table 22-1. MC_CGM relationship to clocks

MC_CGM Registers	Register Description	Output Clock	CMU
MC_CGM_SC_DC0	System Clock Divider Configuration 0	Checker Core Computational Cores SYSCLK[1], (FXBAR, BD_CLK)	CMU_1 (CMU_FXBAR)
MC_CGM_SC_DC1	System Clock Divider Configuration 1	SXBAR_CLK	CMU_2 (CMU_SXBAR)

MC_CGM_AC10_DC MC_CGM_AC10_SC	Aux Clock 10 Divider Configuration 0 Aux Clock 10 Select Control	FEC_REF_CLK[3]	—

1. SYSCLK output is before the divider, so it is not directly monitored by CMU_1 (CMU_FXBAR).
2. MC_CGM_AC0_DC3 is a FCD.
3. FEC_REF_CLK is the output for the divider, but the IOMUX can select either FEC_TXCLK input signal or FEC_REF_CLK for TXCLK_REF_CLK generation.

22.3 System clock frequency limitations

The maximum frequency of operation for the device system level clocks is given in the following table.

NOTE

It is the responsibility of the user not to exceed these values.

Table 22-2. Maximum system level clock frequencies

System clock	Max frequency (MHz)
Cores (CHKR_CLK, COMP_CLK)	200
FXBAR, BD_CLK, System Ram Ctrl	200
SXBAR, System Ram Array, LINCLK (System Clock Synchronous domain)	100
PBRIDGE_0	50
PBRIDGE_0 (eTPU2 Slot)	200
PBRIDGE_1	50
eDMA	100
INTC (Interrupt Controller)	50
FLEXCAN_CLK	40

Table continues on the next page...

Table 22-2. Maximum system level clock frequencies (continued)

System clock	Max frequency (MHz)
DSPI_CLK0, DSPI_CLK1	80
PER_CLK	80
LINCLK (System Clock Asynchronous domain)	80
SAR_CLK	80
SD_CLK	16
SENT_CLK	80
FEC_REF_CLK, TXCLK, RXCLK	50, 25, 25
RF_REF (BD_LFAST_PLL, PD_LFAST_PLL)	26
RTI_CLK	50
eMIOS_CLK	100
CTU	100

In order to maintain synchronization between the different system clock branches (for example, SYS_CLK output from the System Clock Selector), there are limitations on the frequencies of those clocks. The system clocks must be binary multiples of each other with the frequency relationships described in the electrical specifications.

NOTE

The MC_CGM_SC_DCn registers must be configured with dividers that respect the clock ratios 1:2:4, for FXBAR_CLK, SXBAR_CLK, and PBRIDGE_n_CLK respectively.

Table 22-3. Examples of valid clock domain combinations (FXBAR_CLK / SXBAR_CLK / PBRIDGE_n_CLK)

FXBAR_CLK	SXBAR_CLK	PBRIDGE_n
200 MHz	100 MHz	50 MHz
160 MHz	80 MHz	40 MHz
100 MHz	50 MHz	25 MHz

22.3.1 JTAG frequencies

The following table shows the maximum frequencies of the JTAG interface.

Table 22-4. JTAG frequencies

Device	Configuration	e200z4 max. internal JTAG frequency	Buddy Device max. RWA internal frequency	Maximum external JTAG frequency	Notes
PD[1]	Unconfigured clock	—	—	See electrical characteristics for maximum usable external JTAG frequency	Assumes 16 MHz clock with +/- 1.5% tolerance, and JTAG usable at 1/2 CPU frequency
	Clock configured to 200 MHz	100 MHz			JTAG usable at 1/2 CPU frequency
ED[2]	BD only powered	—	22.4 MHz		BD clocked by internal 64 MHz RC clock (RCOSC64) with +/- 30% tolerance and BD RWA usable at 1/2 frequency.
	PD and BD powered, unconfigured clock	—	—		ED clocked by internal 8 MHz RC clock (IRC) with +/- 1.5% tolerance, and BD RWA usable at 1/2 frequency
	PD and BD powered, PD clock configured to 200 MHz	100 MHz	100 MHz		100 MHz JTAG achievable using LFAST mode debug, or s/w mode JTAGM. JTAG messages are generated internally by JTAGM and stay within BD and PD domain. The external tool interface is LFAST only

1. PD = Production Die
2. ED = Emulation and Debug devices = Production die + Buddy die

22.4 Default clock configuration

At power up, the IRCOSC is the default clock for the entire system. All system clock dividers are set to divide by two at power-on reset.

22.5 Clock sources

The following clock sources are described in this section:

- PLL0
- PLL1 (FMPLL)
- External Oscillator (XOSC)
- External Clock (EXTAL Bypass)
- Internal 16 MHz RC Oscillator (IRCOSC)

22.5.1 PLL

The PLL system in the MPC5746R is a Dual PLL that provides separate system and peripheral clocks. The PLLs are disabled after power on and must be enabled by software. The block diagram for the Dual PLL appears in Figure 22-2.

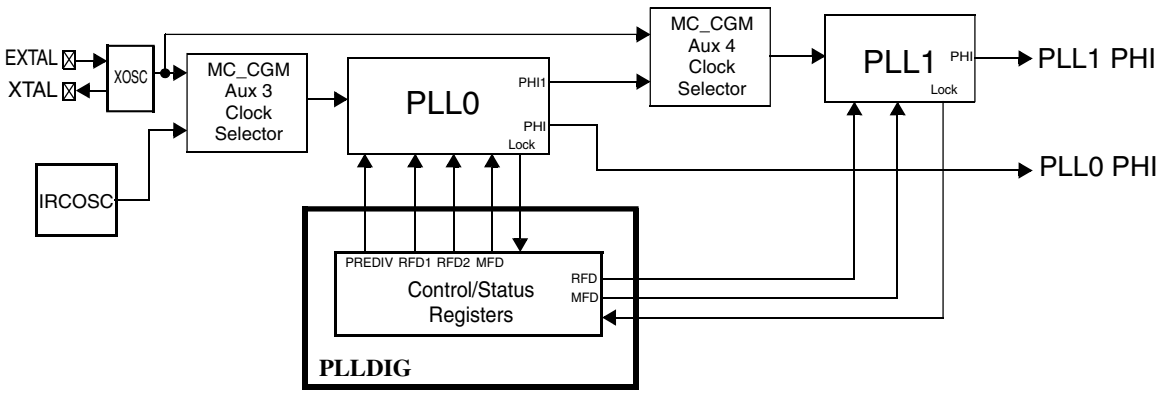

Figure 22-2. MPC5746R Dual PLL digital interface block diagram

22.5.1.1 PLL0 - base PLL (non-FM)

PLL0 is the primary PLL. This PLL is used to source a non-FM clock to the MPC5746R peripherals and also the reference clock to PLL1.

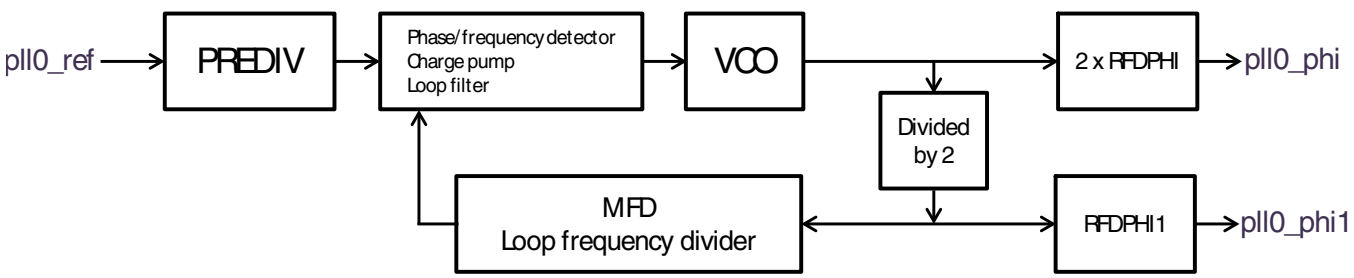

Figure 22-3. PLL0 Block Diagram

22.5.1.1.1 PLL0 input clocks

The possible input clock sources for PLL0 are the XOSC, IRCOSC, and EXTAL Bypass. The EXTAL Bypass input is the EXTAL pin. AUX Clock Selector 3 selects which input clock will be used as the source for PLL0. The selection between XOSC and EXTAL Bypass is made via the XOSC_CTL register of the XOSC module.

22.5.1.1.2 PLL0 output clocks

The output clocks from PLL0 are PHI and PHI1. The PHI output clock drives various peripheral clocks and the system clock when selected in the MC_CGM. The PHI1 output provides one of the input references for PLL1.

22.5.1.2 PLL1 - FMPLL

PLL1 is a Frequency Modulated PLL (FMPLL) that is typically used to drive the system clock. PHI is the output of PLL1 which drives the System Clock Selector of the MC_CGM.

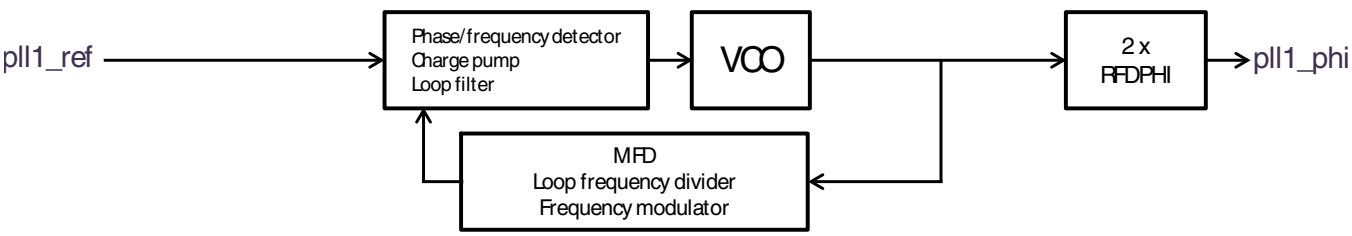

Figure 22-4. PLL1 Block Diagram

22.5.1.2.1 PLL1 input clocks

The possible input clock sources for PLL1 are XOSC, PLL0_PHI, and EXTAL Bypass. The EXTAL Bypass input is the EXTAL pin, which "bypasses" the XOSC output. AUX Clock Selector 4 selects which input clock is used as the source for PLL1. The selection between XOSC and EXTAL Bypass is made via the XOSC_CTL register of the XOSC module.

22.5.1.2.2 PLL1 output clocks

The output clock from PLL1 is the PHI clock, which can drive the system clock if the System Clock Selector of the MC_CGM is configured to do so. The PHI output clock contains a fractional divider that can be applied to the loop divide of the PLL to achieve good granularity in the PLL1 PHI output clock frequency.

22.5.1.2.3 PLL register interface

This device has a single digital interface for the dual PLLs. The digital interface provides register control of all features of PLL0 and PLL1. Details are provided in the "Dual PLL Digital Interface" chapter.

22.5.1.2.4 PLL register write protection

The PLL registers with write protection are defined in PLL_DIG protected registers.

22.5.1.3 PLL register reset values

All reset values for the PLLDIG registers that are device specific are shown in the following table. All other register reset values are shown in the Dual PLL Digital Interface chapter.

Table 22-5. Dual PLL Digital Interface register reset values

Offset	Register	Reset Value
0008h	PLL0DV – PLL0 Divider Register	0000_0000h
0028h	PLL1DV – PLL1 Divider Register	0000_0000h

22.5.1.4 PLL initialization information

Coming out of reset PLL0 and PLL1 are disabled per the DRUN mode configuration register, MC_ME_DRUN_MC.

1. Configure PLL0 and related modules.
   a. With PLL0 disabled, program the PLL0 clock source in MC_CGM_AC3_SC[SELCTL]. Default source is the 16 MHz IRCOSC. Write MC_CGM_AC3_SC[SELCTL] = 1 to select the XOSC as source.
   b. Program PLL0DV[PREDIV], PLL0DV[RFDPHI1], PLL0DV[MFD], and PLL0DV[RFDPHI].
   c. If desired, modify the XOSC_CTL[EOCV] to adjust the external oscillator stabilization count, used when the external oscillator is turned on (by the MC_ME).
   d. If necessary, modify the CMU frequency meter values (CMU_MDR and CMU_FDR) used to monitor the XOSC frequency. The XOSC frequency is compared to the IRCOSC source when the XOSC is turned on.
2. Turn on the XOSC and PLL0.
   a. Configure a mode configuration for turning on PLL0 and the XOSC. In a mode configuration register (for example, MC_ME_DRUN_MC) set MC_ME_<*mode*>_MC[XOSCON] = 1 and

MC_ME_<*mode*>_MC[PLL0ON] = 1. If desired, also set MC_ME_<*mode*>_MC[SYSCLK] = 2 for this new mode configuration to use PLL0 (PLL0 PHI output) as the sysclk.

b. Enter that mode by two writes to MC_ME_CTRL register to enter that mode. This is required even if entering the same mode.

3. Wait for the mode transition to complete.

a. Wait for the mode transition to complete by polling MC_ME_GS[S_MTRANS] or enabling an interrupt for flag MC_ME_IS[I_MTC]. A timer, even if it is the watchdog, should be used to make sure the mode transition completes. Mode transition will NOT complete until:

- The XOSC counter expires (if the new mode configuration changes MC_ME_<*mode*>_MC[XOSCON] = 1), and
- PLL is locked (if the new mode configuration changes MC_ME_<*mode*>_MC[PLL0ON] = 1)

b. Confirm the desired target mode was entered by checking the status of MC_ME_GS[S_CURRENT_MODE].

4. Configure PLL1 and related modules.

a. With PLL1 disabled, program PLL1 clock source in MC_CGM_AC4_SC[SELCTL]. Default is MC_CGM_AC4_SC[SELCTL] = 1 which selects XOSC.

b. Program PLL1DV[MFD] and PLL1DV[RFDPHI].

c. If required, program the PLL1FM register with the desired frequency modulation parameters and enable FM modulation, PLL1FM[MODEN] = 1. The PLL1FM register must not be written after PLL1 is enabled and operating in normal mode.

5. Turn on PLL1.

a. Configure a mode configuration for turning on PLL1, and keeping the XOSC and PLL0 on. In a mode configuration register (for example, MC_ME_DRUN_MC), initialize MC_ME_<*mode*>_MC[XOSCON] = 1, MC_ME_<*mode*>_MC[PLL0ON] = 1 and MC_ME_<*mode*>_MC[PLL1ON] = 1. If desired, also set MC_ME_<*mode*>_MC[SYSCLK] = 4 for this new mode configuration to use PLL1 as the sysclk.

b. Enter that mode by two writes to ME_CTRL register to enter that mode. This is required even if re-entering the same mode.

6. Wait for the mode transition to complete.
   a. Wait for the mode transition to complete by polling MC_ME_GS[S_TRANS] or enabling an interrupt for flag MC_ME_IS[I_MTC]. A timer, even if it is the watchdog, should be used to make sure the mode transition completes. Mode transition will NOT complete until:
      - XOSC counter expires (if the new mode configuration changes XOSCON to 1), and
      - PLL1 is locked (if the new mode configuration changes MC_ME_<*mode*>_MC[PLL1ON] = 1).
   b. Confirm the desired target mode was entered by checking the status of MC_ME_GS[S_CURRENT_MODE].

NOTE

See the "Mode Entry Module (MC_ME)" chapter in this *Reference Manual* for details.

22.5.2 External oscillator (XOSC)

The external oscillator (XOSC) is provided as a reference for the on-chip PLLs. It can also can be used as a clock source to the ADCs, timer, serial interfaces, RTI, LFAST, and PLL reference as well as a system clock source. It is available for observation on the CLKOUT pin, and is used as a reference to calibrate the IRCOSC frequency.

The external oscillator allows a crystal or external clock to be used as the reference clock for the microcontroller. The XOSC has the following features:

- Reference clock to PLL0 and PLL1
- Reference clock to CMU_0 (IRCOSC trimming)
- Option to drive the FlexCAN protocol clock from the XOSC through AUX Clock Selector 8
- Provides support for 8 MHz to 40 MHz crystal inputs

22.5.2.1 XOSC register write protection

The XOSC registers have write protection as shown in OSC_DIG protected registers.

22.5.2.2 XOSC reset value

The following table shows the default reset value for the XOSC registers.

Table 22-6. XOSC register reset values

Offset	Register	Reset Value
0x00	XOSC_CTL-XOSC Control Register	0030_0000h

22.5.3 Internal 16 MHz RC Oscillator (IRCOSC)

The MCU has a 16 MHz RC oscillator which is always enabled and can be used as the clock source for both PLLs. It is used as the clock source for the FCCU, SWT, and SIUL2 input filters, and it can also be used as a clock source for LINFlex, DSPI both ADCs and peripheral clock as well as the system clock. The IRCOSC is the default system clock after reset. The register interface is used for user trimming of the oscillator and dividing the output from 1 to 32.

22.5.3.1 IRCOSC register interface

This device has a dedicated digital interface for the IRCOSC. The digital interface provides a register for fine tuning the IRCOSC, 6-bit factory trim value frequency by the user. Other registers allow reading of the settings of IRCOSC temperature sensor, voltage regulator and capacitor trimming values that are set by the factory. The IRCOSC is always enabled when the device is powered.

22.5.3.2 IRCOSC reset value

The following table shows the default reset value for the IRCOSC registers.

Table 22-7. IRCOSC register reset values

Offset	Register	Reset Value
0004	NT-IRCOSC Native Trimming Register	0000_0000h

22.5.3.3 IRCOSC register write protection

The IRCOSC registers do not utilize write protection.

22.5.3.4 IRCOSC trimming

The IRCOSC requires trimming to meet accuracy requirements. During the initial phases of a reset sequence triggered by a power-on or destructive reset, the IRCOSC runs at its untrimmed frequency value. A trim value that was determined during factory test, and subsequently stored in flash memory, is loaded during reset via the SSCM to the IRCOSC_CTL[USER_TRIM] (see the "IRCOSC Digital Interface" chapter for details).

22.6 Peripheral Clocks

The following figure shows the clock distribution to the core and peripheral modules.

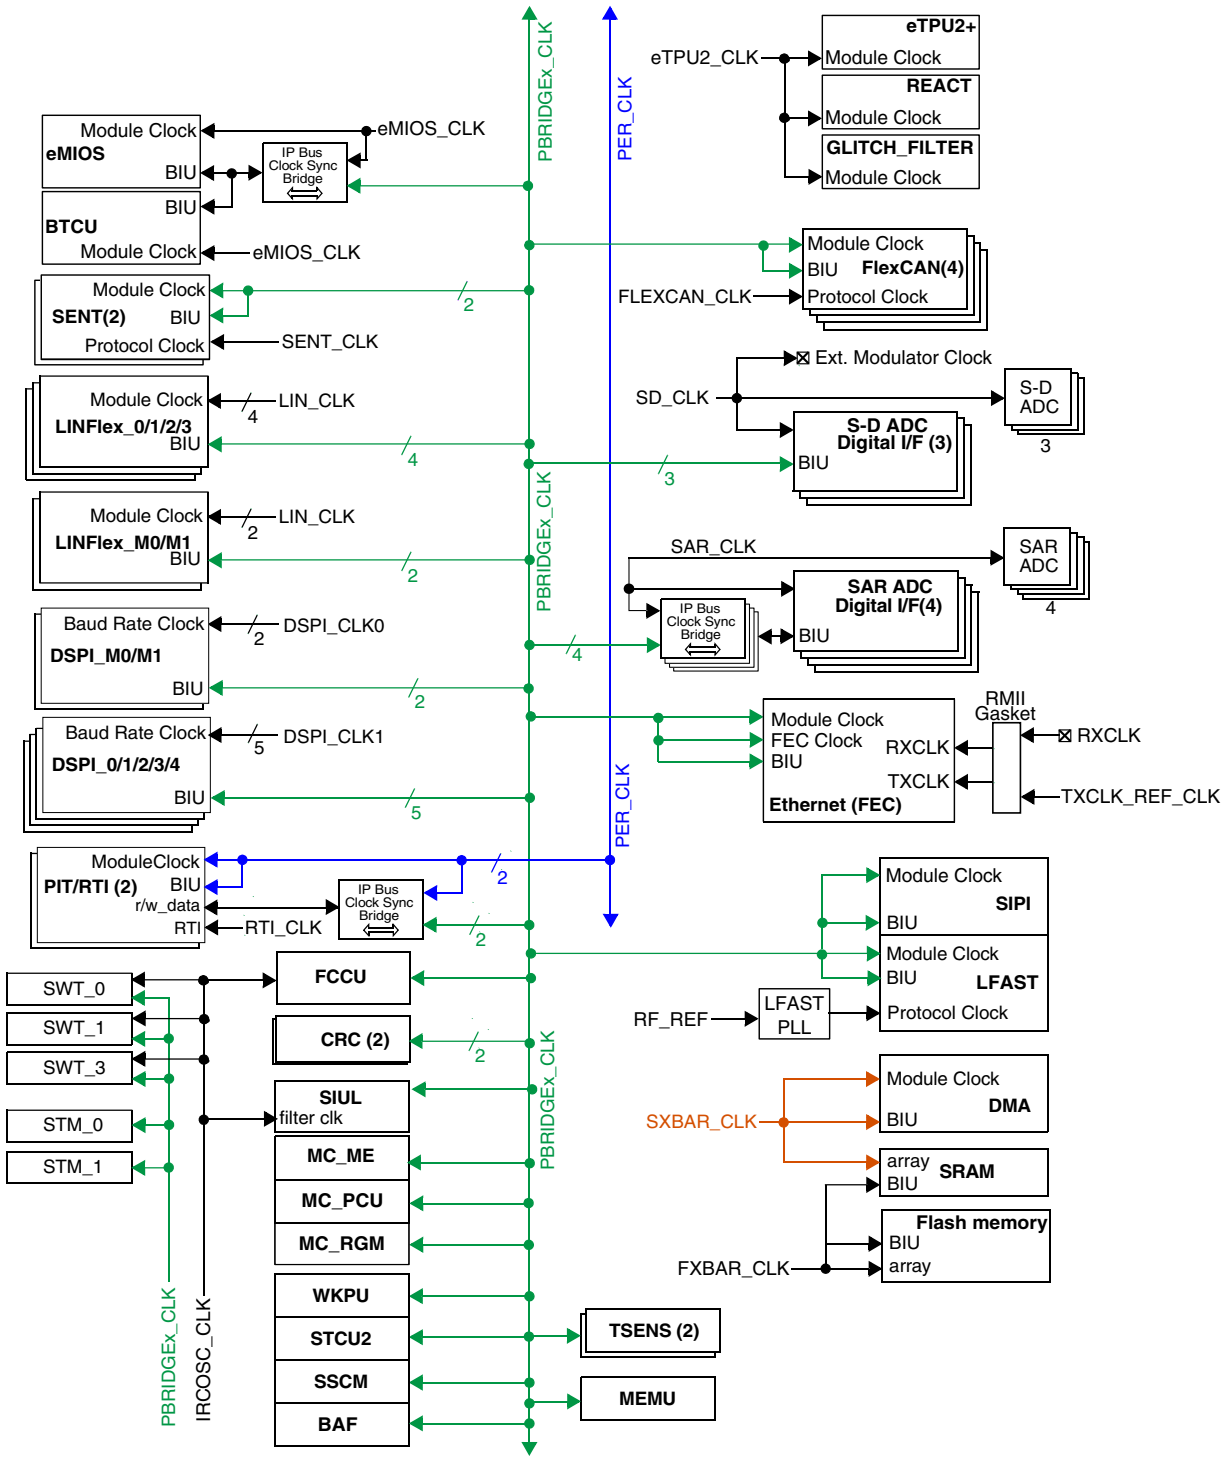

Figure 22-5. Clock distribution

22.6.1 LFAST clocking

The MPC5746R includes an LFAST module to support high speed device communications. A single LFAST PLL supports high speed operation of the LFAST module. For low speed LFAST operation, the reference clock is used directly by the LFAST module.

The source of the LFAST PLL may be the PLL0_PHI or the external oscillator (XOSC) or input from the external LFAST device via the SIPI_CLK_IN package signal. When this reference clock is generated internally, it can also be output on the SIPI_CLK_IN signal. The SIPI_CLK_IN signal connection appears in the following figure. Input/ Output direction of the SIPI_CLK_IN/OUT signal is controlled by the MSCR in the SIUL2.

On Emulation and Debug Devices (ED), the LFAST module on the Buddy Die (BD) is used and connected to the package debug pins instead of the Production Die (PD) debug LFAST module. This module has a separate dedicated LFAST PLL, although as with non EDs', the SIPI_CLK_OUT/IN pin only supports output of the reference clock to a connected LFAST capable tool.

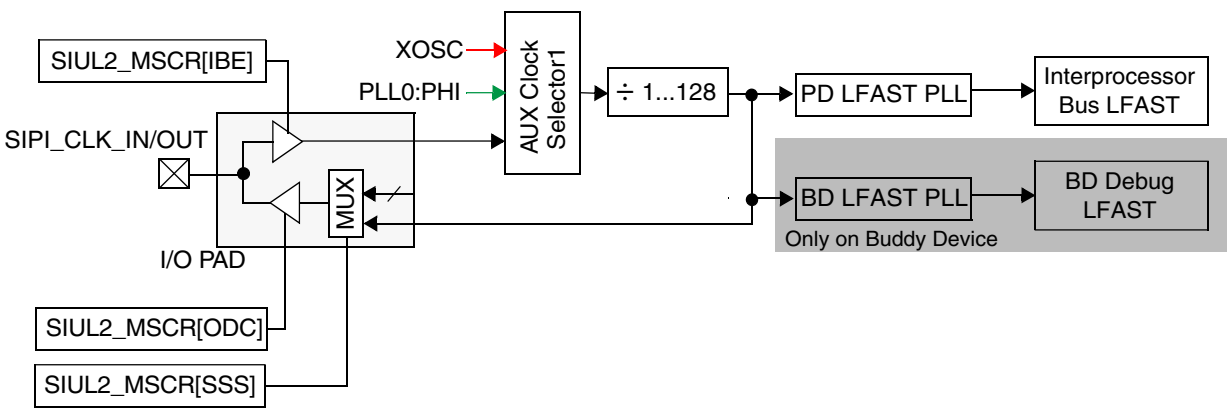

Figure 22-6. Device LFAST SysClk

22.6.2 Ethernet clocking

Both internal and external clocks sources for both MII and RMII Ethernet interface modes are supported. The MII clocks (TXCLK/RXCLK) are 25 MHz, and the RMII clock (REF_CLK) is 50 MHz. Figure 22-7 shows the connections for the Ethernet clocks.

The RXCLK pin is an input, used in MII mode only, and ignored by the RMII gasket in RMII mode.

The TXCLK pin is an input, used in MII mode only, but is shared with the REF_CLK input of the RMII gasket. Therefore, the Aux clock selector is required to select between TXCLK and REF_CLK for MII and RMII modes.

The REF_CLK can be generated internally or input to the device. For MII mode, the FEC_REF_CLK can be used for the 25 MHz reference for the external Ethernet PHY, which provides the TXCLK/RXCLK clocks back to the device. For RMII mode, FEC_REF_CLK can be generated internally and fed to both the PHY device and to the RMII gasket by enabling the REF_CLK pad input and output buffers. REF_CLK can also be provided externally as an input to the device.

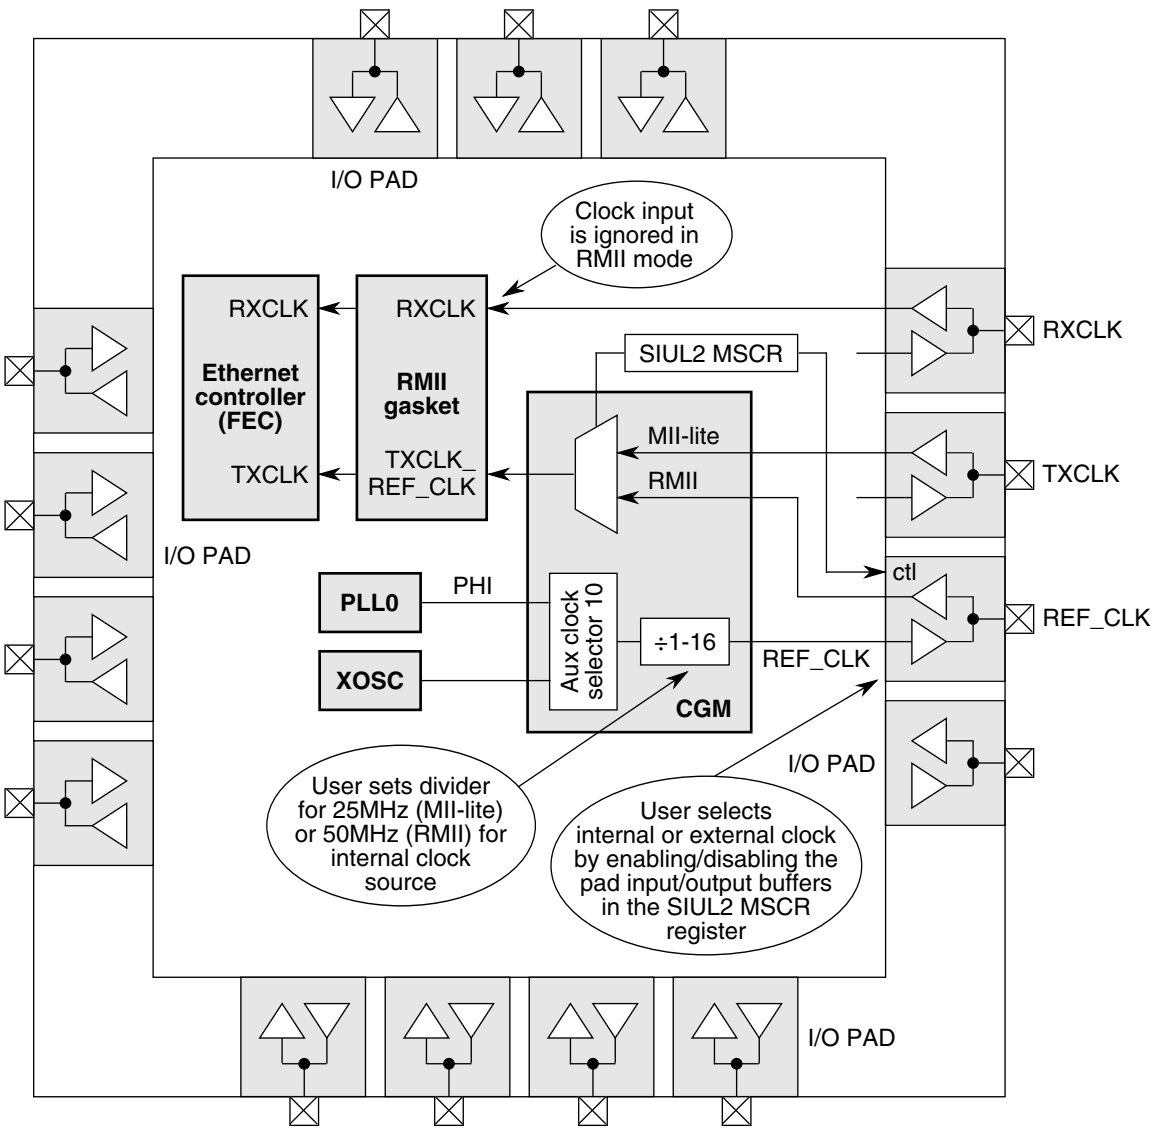

Figure 22-7. Ethernet clocking diagram

22.6.3 Sigma-Delta ADC clocking

The analog portion of the Sigma-Delta ADC on the device works only with an internal modulator. The internal clock (SD_CLK, see Figure 22-5) is always used when the internal modulator in the S-D ADC is enabled.

Each S-D ADC is connected as shown in Figure 22-8, with the SD_CLK being common to all modules.

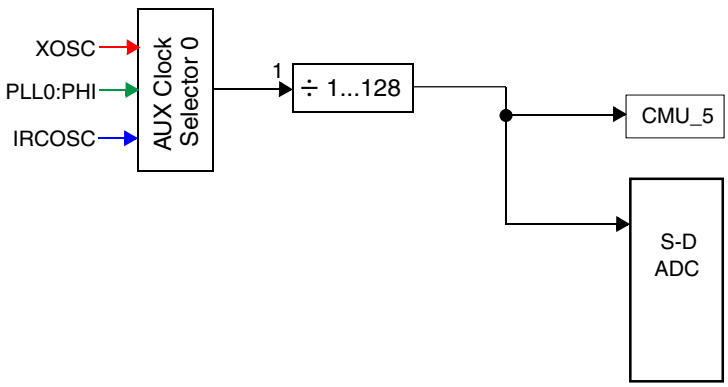

Figure 22-8. Device S-D ADC clocking

22.6.4 LINFlex clocking

The LINFlex protocol clock (LINCLK) domain selection may be configured via soft DCF client programming, as described in LINCLK_DOMAIN_SELECTION - BAF LINCLK Synch/Asynch Clock domain selection DCF Client.

Depending on the application's LINCLK source selection, the LinFlex protocol clock will operate as follows:

- System Clock Synchronous mode: the LINCLK source is connected to the Synchronous System Clock Selector / Clock Divider 1

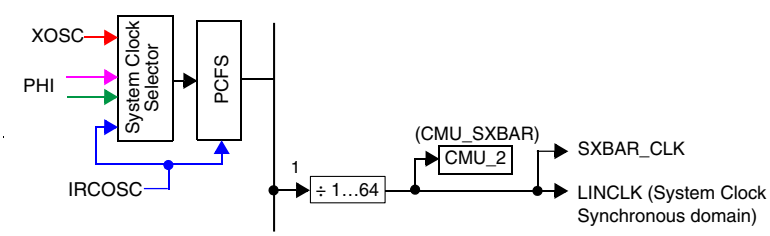

Figure 22-9. System Clock Synchronous domain

- System Clock Asynchronous mode: the LINCLK source is connected to the Auxiliary Clock Selector 0/ Clock Divider 4

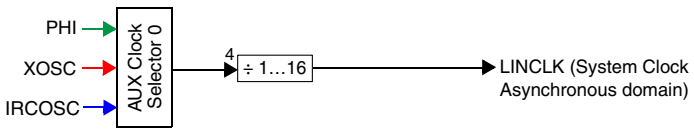

Figure 22-10. System Clock Asynchronous domain

In either mode the LINCLK must be enabled by setting the Auxiliary Clock 0 Divider Configuration Register (MC_CGM_AC0_DC4) Divider Enable (DE) bit to 0b1.

NOTE

The System Clock Selector / Clock Divider 1 (MC_CGM_SC_DC1) Divider Enable (DE) bit only controls SXBAR_CLK.

The Auxiliary Clock Selector 0 / Clock Divider 4 (MC_CGM_AC0_DC4) Divider Enable (DE) bit always controls LINCLK, regardless of the selected LINFlex operation mode, and defaults to 0b0 (LINCLK disabled).

22.7 Clock monitoring

For all safety critical clocks, the microcontroller detects a missing clock or incorrect frequency. To achieve this clock monitoring units (CMUs) are used. Each CMU is programmed independently. The IRCOSC and XOSC are used as the clock monitor references. Detailed information on the CMUs can be found in the Clock Monitor Unit chapter.

22.7.1 CMU configuration

This section explains the CMU configuration.

Figure 22-11 shows the block diagram for CMU_0 on the MPC5746R.

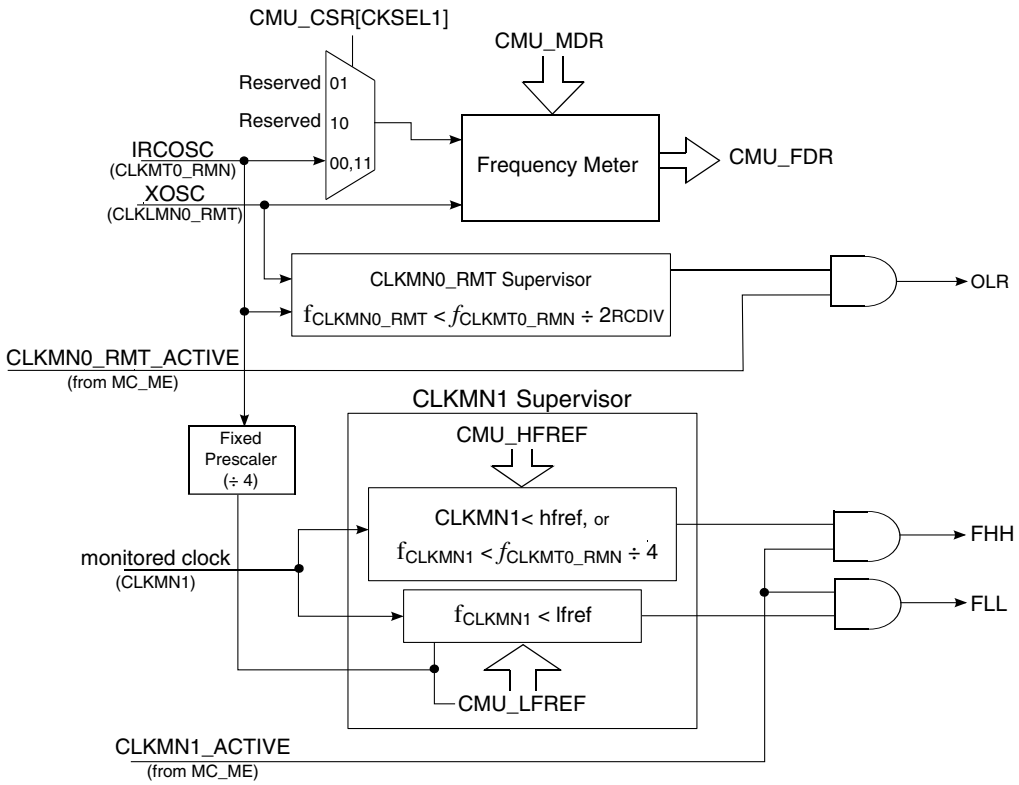

Figure 22-11. CMU_0 Block Diagram

Figure 22-12 shows the block diagram for CMU_[1:9,12] on the MPC5746R.

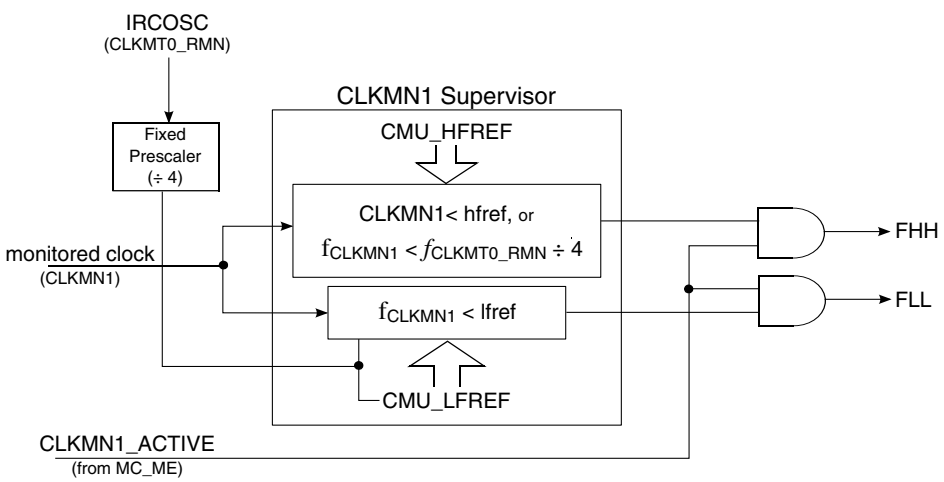

Figure 22-12. CMU_[1:9,12] Block Diagram

22.7.1.1 Clock input sources

The following table shows the clocks that are monitored by each CMU. These signals are connected internally on the chip, but are not accessible via pins on the boundary of the device. IRCOSC is the reference clock for all clock monitors. Only CMU_0 implements the XOSC monitor. CMU_0 uses the IRCOSC clock to measure if the XOSC is too low. CMU_0 can also be used to calibrate the IRCOSC frequency using the XOSC. All other CMUs are configured identically.

Table 22-8. Clock input sources

Clock module	Monitored clock
CMU_0 (CMU_PLL)	XOSC, IRCOSC, PLL0:PHI
CMU_1 (CMU_FXBAR)	CHKR_CLK
CMU_2 (CMU_SXBAR)	SXBAR_CLK
CMU_3 (CMU_AIPS)	PBRIDGE_0_CLK, PBRIDGE_1_CLK
CMU_4 (CMU_PER)	PER_CLK
CMU_5 (CMU_ADCSD)	SD_CLK
CMU_6 (CMU_SARADC)	SAR_CLK
CMU_7 (CMU_SENT)	SENT_CLK
CMU_8 (CMU_eTPU2)	eTPU_CLK
CMU_9 (CMU_eMIOS)	eMIOS_CLK
CMU_12 (CMU_CLKOUT)	CLKOUT

22.7.1.2 CMU registers and field availability

This table specifies which registers and fields are available on a given CMU for this device

Table 22-9. CMU registers availability

Address Offset	Register	CMU Instance	Note
0000h	CMU_CSR	All	CMU_CSR[SFM], CMU_CSR[RCDIV], and CMU_CSR[CLSEL1] are only used in CMU_0. CMU_CSR reset value is 0x06 for CMU_0 and 0x00 for all other CMU instances.
0004h	CMU_FDR	CMU0	—
0008h	CMU_HFREFR	All	—
000Ch	CMU_LFREFR	All	—
0010h	CMU_ISR	All	CMU_ISR[OLRI] is only used in CMU_0.

Table continues on the next page...

Table 22-9. CMU registers availability (continued)

Address Offset	Register	CMU Instance	Note
0014h	Reserved	—	—
0018h	CMU_MDR	CMU0	—

22.7.1.3 CMU register write protection

The CMU registers have write protection as shown in CMU protected registers.

22.7.2 External oscillator (XOSC) monitor

The XOSC frequency is compared to a minimum value limit. If the measured XOSC frequency is below the limit, a flag is set, and an interrupt is generated, if enabled. Frequency limits are given in the MPC5746R Data Sheet.

22.7.3 Internal RC oscillator (IRCOSC) monitor

The period of the IRCOSC can be measured in CMU_0, using the XOSC as a reference. This allows for application trimming of the IRCOSC frequency.

22.8 Loss of system clock behavior

This device has built-in mechanisms for detecting loss of the oscillator or PLL clocks, and provides several options for reaction to a loss of clock in the application. Figure 22-13 gives a high-level view of the loss of clock logic.

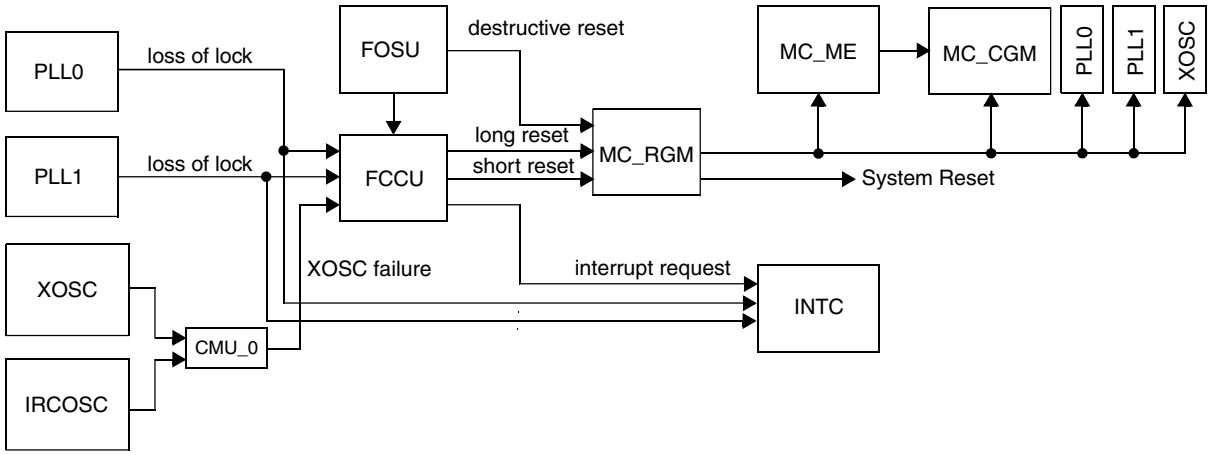

Figure 22-13. Loss of clock logic

22.8.1 Loss of PLL or XOSC

As shown in Figure 22-13, each loss of lock signal from the PLLs or XOSC failure are monitored by the FCCU. For the event when a clock failure occurs, the FCCU can be programmed to generate a short or long reset sequence or simply to generate an interrupt. In the case of the interrupt, only the unpredictable free running clock is still provided by the PLL. There is no automatic system clock switch in this case, and the user is required to program the switch through the Mode Entry module (MC_ME). Therefore, it is strongly recommended that the interrupt reaction to a PLL loss of lock is not selected when the PLL is used as the source of the system clock.

If a long or short reset is selected: the PLL, XOSC, MC_ME, and MC_CGM are reset to their default states, and the system clock is switched to the IRCOSC.

22.8.2 Loss of IRCOSC

The frequency of the IRCOSC is monitored by the frequency meter in CMU_0. There is no automated trigger of an FCCU error condition if the IRCOSC fails. Since the IRCOSC is the boot and backup clock, a failure is a catastrophic failure.

22.8.3 PLL loss of lock interrupt

Always write 1 to both PLL0CR[LOLIE] and PLL1CR[LOLIE] to keep the loss of lock interrupt function enabled.

The main interrupt functionality is determined by the FCCU via fault input NCF[32] for PLL0 and fault input NCF[33] for PLL1.

22.9 Progressive clock switching

The Progressive Clock Frequency Switching (PCFS) blocks are shown in the system-level clock diagram in Clock generation . They are used for ramping the system and peripheral clocks and for obtaining the precise clock frequency input for the SXBAR, FXBAR and Buddy Device (BD_CLK) module. See the "Progressive system clock switching" section in the "Clock Generation Module (MC_CGM)" chapter for details on PCFS.

Chapter 23
Dual PLL Digital Interface (PLLDIG)

23.1 Introduction

The Dual PLL system composed of PLL0 and PLL1 analog blocks and the digital interface (PLLDIG). The two analog PLL blocks are cascaded, with the PHI1 output of PLL0 feeding the clock input of PLL1.

A key feature of the dual PLL architecture is the ability to drive peripherals from the PLL0 PHI output, which is non-modulated and independent of the core clock frequency. The core and platform clocks are driven by PLL1.

23.2 Block Diagram

Please refer to the “Clocking chapter” of this *Reference Manual* to see the block diagram.

23.3 Features

The Dual PLLDIG has the following features:

- Supports dual PLL in cascaded mode with PLL0 clock out as reference clock to PLL1.
- Reference clock pre-divider for finer frequency synthesis resolution.
- Reduced frequency divider for decreasing the PLL0/PLL1 output clock frequency without causing the PLLs to lose lock.
- Programmable frequency modulation on PLL1.
- Lock detect circuitry reports when the PLLs have achieved frequency lock, and continuously monitors lock status to report loss of lock conditions.
    - The loss of lock indication is sent to the FCCU via the system glue logic.

23.4 Modes of operation

The operating mode of the PLLs is determined by the value of PLL*n*CR[CLKCFG]. The various modes of operation for the PLL are:

- Bypass mode with reference, and both PLLs disabled
- Normal mode with reference, and either PLL0 or both PLLs enabled

NOTE

Mode changes are controlled by configuring the MC_ME Mode Configuration registers (MC_ME_<*mode*>_MC).

Bypass mode is defined as the mode where all clocks are driven by an external clock driving the EXTAL signal. Normal mode is defined as the mode where the clocks are driven by the PLLs. When using a crystal for the reference clock, reset should remain asserted until the oscillator has stabilized.

When PLL0:PHI1 is the source for PLL1, and PLL0 is powered down and working in bypass mode, PLL1 should be bypassed and powered down. PLL1 should be configured to work in normal mode only after PLL0 has achieved lock (for example, bypass with PLL0 running or PLL0 in normal mode, PLL*n*SR[LOCK] = 1).

23.4.1 Bypass mode with reference, both PLLs disabled

In this mode, the PLLs are bypassed and system and peripheral clocks (PLL clock outputs) are driven from the external clock reference. The user must supply a clock that is within the appropriate frequency range. This mode is indicated by PLL0CR[CLKCFG] = 00b and PLL1CR[CLKCFG] = 00b. This is also the default power up mode of the PLLs.

23.4.2 Normal mode with reference, PLL0 or both PLLs enabled

In normal mode, PLL0 receives an input clock from the reference which can be prescaled by the pre-divider. PLL0 multiplies the frequency to create the PLL0 output clock. The user must supply a crystal that is within the appropriate frequency range, the crystal manufacturer recommended external support circuitry and short signal route from the MCU to the crystal.

PLL0 generates a non-modulated clock which drives PLL0 PHI1. PLL1 can generate a frequency modulated clock or a non-modulated clock (for example, locked on a single frequency). The modulation rate, modulation depth, and modulation enable are programmed by configuring the PLLFM register.

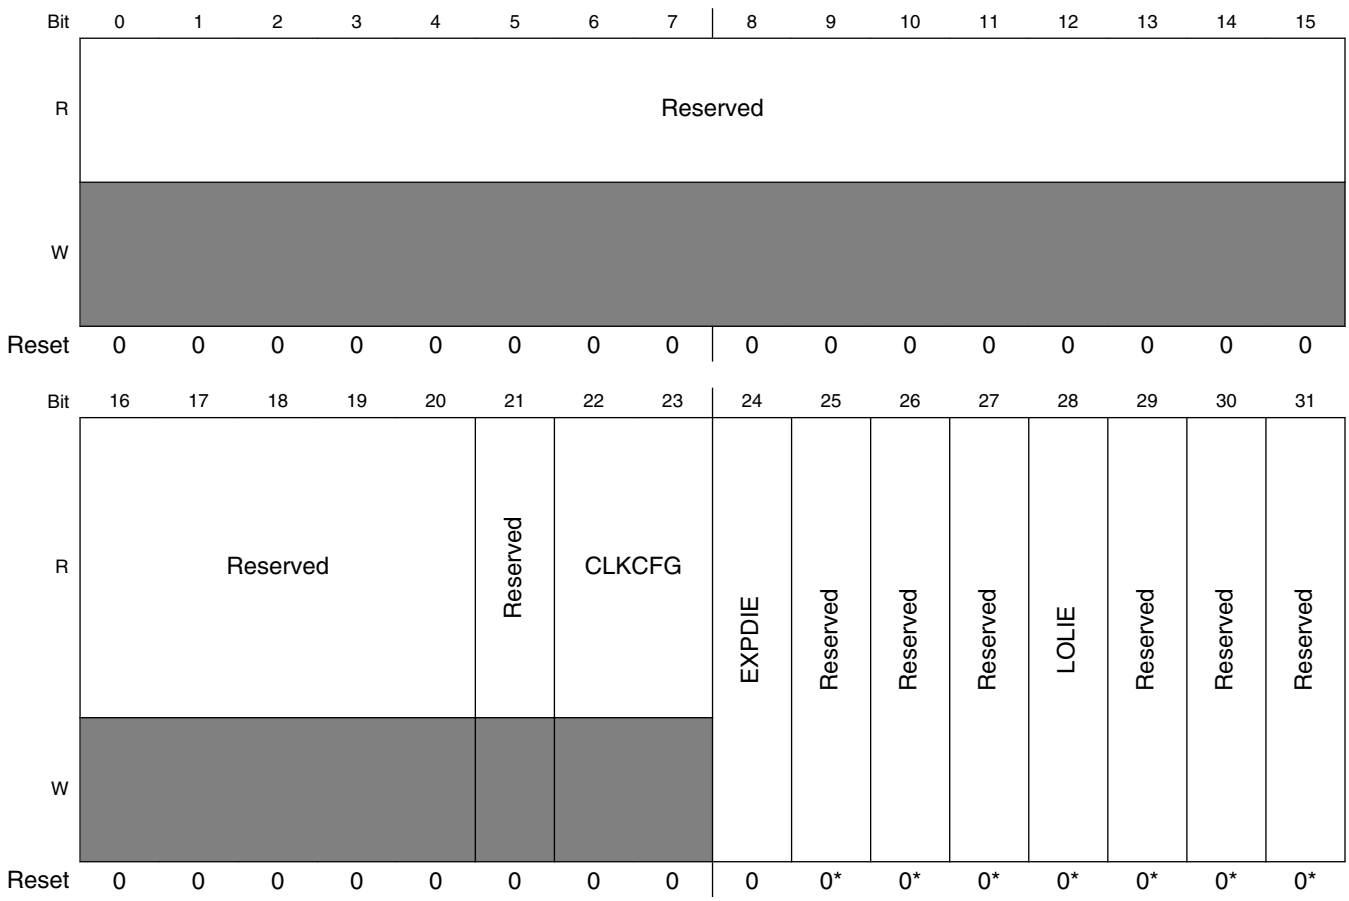
NOTE

While powering down the PLLs and if PLL0:PHI1 is used as the source for PLL1, user must ensure that PLL1 is powered down first followed by powering down PLL0 for proper shut off.

Configuring the appropriate MC_ME_<*mode*>_MC register to start PLL1 should only be done after PLL0 has achieved lock.

23.5 Memory map and register definition

This section provides the memory map and detailed descriptions of all registers for configuring the PLLs. The table below shows the memory map. Addresses are given as offsets from the module base address. All registers can be accessed using 8-bit, 16-bit or 32-bit addressing.



PLLDIG memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	PLLDIG PLL0 Control Register (PLLDIG_PLL0CR)	32	R/W	See section	23.5.1/668
4	PLLDIG PLL0 Status Register (PLLDIG_PLL0SR)	32	R/W	See section	23.5.2/670
8	PLLDIG PLL0 Divider Register (PLLDIG_PLL0DV)	32	R/W	See section	23.5.3/672
20	PLLDIG PLL1 Control Register (PLLDIG_PLL1CR)	32	R/W	See section	23.5.4/674
24	PLLDIG PLL1 Status Register (PLLDIG_PLL1SR)	32	R/W	See section	23.5.5/676
28	PLLDIG PLL1 Divider Register (PLLDIG_PLL1DV)	32	R/W	See section	23.5.6/677
2C	PLLDIG PLL1 Frequency Modulation Register (PLLDIG_PLL1FM)	32	R/W	See section	23.5.7/679
30	PLLDIG PLL1 Fractional Divide Register (PLLDIG_PLL1FD)	32	R/W	0000_0000h	23.5.8/681

23.5.1 PLLDIG PLL0 Control Register (PLLDIG_PLL0CR)

The PLL0CR is shown in the following table.

Address: 0h base + 0h offset = 0h

* Notes:
- This field can be written at any time, but writes are ignored. Read returns previously written value.
- LOLIE field: See the "Clocking" chapter for details on configuring this field.

PLLDIG_PLL0CR field descriptions

Field	Description
0–20 Reserved	This field is reserved.
21 Reserved	This field is reserved.
22–23 CLKCFG	Clock Configuration This field indicates the operational state of PLL.

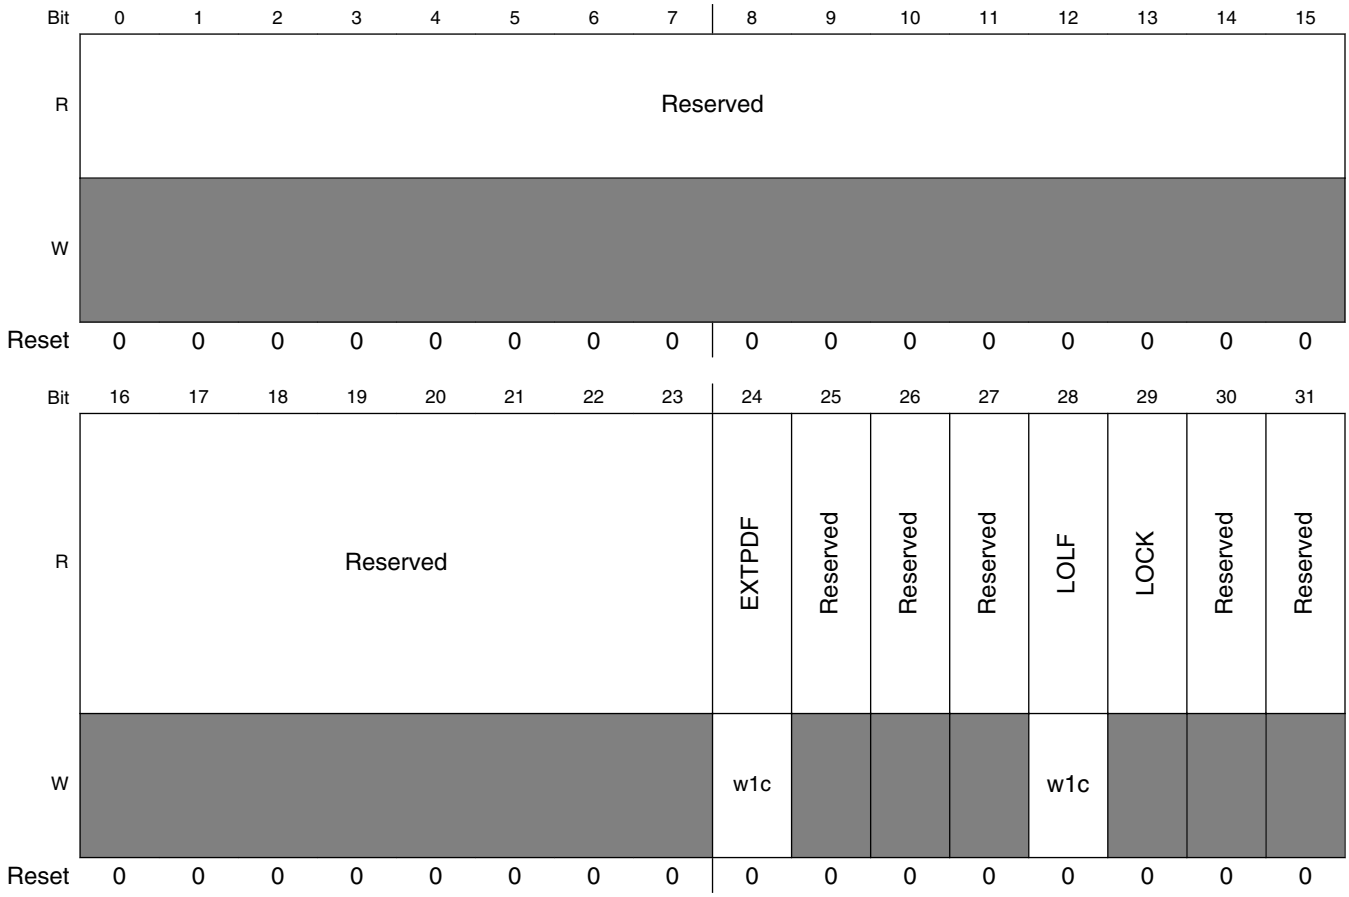


Table continues on the next page...

PLLDIG_PLL0CR field descriptions (continued)

Field	Description
	When PLLs are externally powered down the CLKCFG field changes to 00b. **NOTE:** In cascaded PLL configuration (PLL0 driving the reference clock for PLL1) the external power down signal for PLL1 must be removed only when PLL0 has locked, PLL0SR[LOCK] = 1. **NOTE:** CLKCFG can be written, but writes have no effect. Mode changes are implemented by writing to the appropriate MC_ME_< *mode* >_MC register (see the "Mode Entry Module (MC_ME)" chapter and Clock configuration for details). 00 Bypass mode with PLL off 01 Reserved 10 Reserved 11 Normal mode with PLL running.
24 EXPDIE	External Power Down Cycle Complete indication interrupt enable. This bit enables generation of an interrupt when the external power down of the PLL is complete (for example, PLLs are powered down and powered back up). 0 Ignore interrupt. Interrupt not requested 1 Enable interrupt request on power down cycle completion
25 Reserved	This field is reserved.
26 Reserved	This field is reserved.
27 Reserved	This field is reserved.
28 LOLIE	Loss-of-lock interrupt enable. The LOLIE bit enables a loss-of-lock interrupt request when PLL0SR[LOLF] = 1. If PLL0SR[LOLF] = 0 or PLL0CR[LOLIE] = 0, the interrupt request is ignored. The interrupt request only occurs in normal mode, therefore LOLIE bit has no effect in bypass mode. 0 Ignore loss-of-lock. Interrupt not requested. 1 Enable interrupt request upon loss-of-lock.
29 Reserved	This field is reserved.
30 Reserved	This field is reserved.
31 Reserved	This field is reserved.

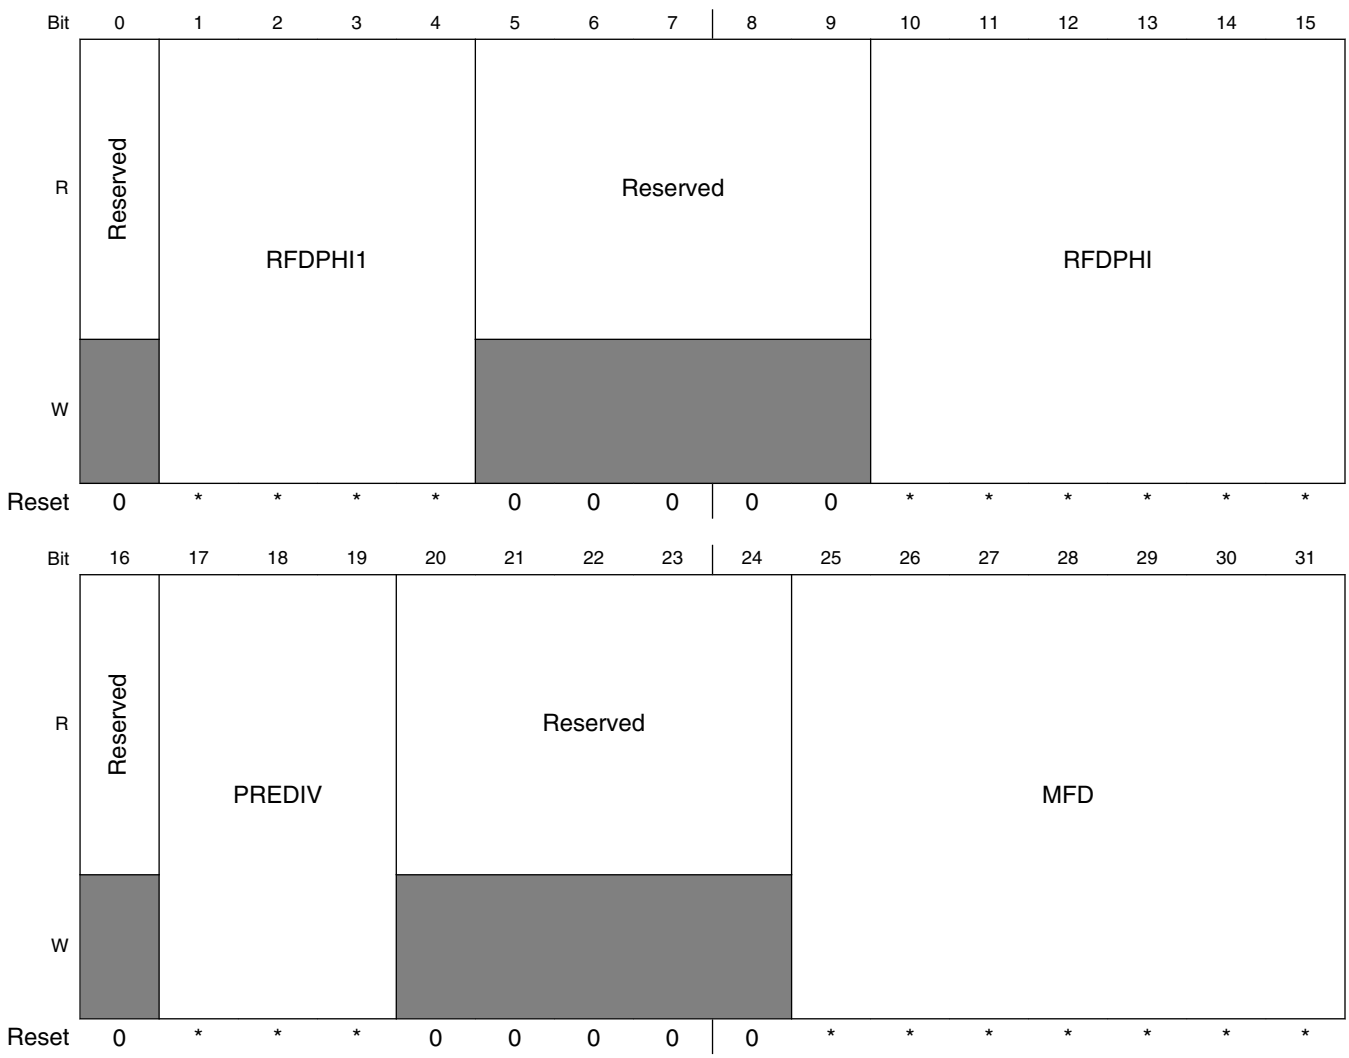
23.5.2 PLLDIG PLL0 Status Register (PLLDIG_PLL0SR)

Address: 0h base + 4h offset = 4h

PLLDIG_PLL0SR field descriptions

Field	Description
0–23 Reserved	This field is reserved.
24 EXTPDF	External Power Down Cycle Complete indication interrupt flag. This bit indicates that the external power down of the PLL is complete (for example, PLLs are powered down and then powered up). User must write 1 to clear this bit. 0 PLLs not power cycled. Interrupt not requested 1 PLLs power down cycle is complete. Interrupt is requested
25 Reserved	This field is reserved.
26 Reserved	This field is reserved.
27 Reserved	This field is reserved.

Table continues on the next page...



PLLDIG_PLL0SR field descriptions (continued)

Field	Description
28 LOLF	Loss-of-lock flag. This bit provides the interrupt request flag for the loss-of-lock condition. Software must write 1 to LOLF to clear it, writing 0 has no effect. This flag bit is sticky in the sense that if lock is reacquired, the bit will remain set until cleared by either writing 1 or asserting reset. LOLF is not asserted if the loss-of-lock condition was detected while the PLL is in bypass mode, but changing from normal to bypass mode will not automatically clear the LOLF if it was previously asserted while the PLL was in normal mode. 0 No loss of lock detected. Interrupt service not requested. 1 Loss of lock detected. Interrupt service requested.
29 LOCK	Lock status bit. Indicates whether PLL has acquired lock. If operating in bypass mode, the LOCK bit will still operate normally (for example, assert when the PLL acquires lock or negate when it loses lock). 0 PLL is unlocked. 1 PLL is locked.
30 Reserved	This field is reserved.
31 Reserved	This field is reserved.

23.5.3 PLLDIG PLL0 Divider Register (PLLDIG_PLL0DV)

The PLL0DV register provides the PHI/PHI1 output clock reduced frequency dividers, pre-divider, and loop divider. PLL0DV can be modified at anytime, but the changes become effective only after the PLL is disabled, then reenabled. If these fields are changed without powering down the PLL, the PLL will lose lock and generate either a reset or interrupt based on which is enabled. The reduced frequency divider bitfields (RFDPHI, RFDPHI1) can be modified at anytime, but the changes only become effective when PLL0 is disabled, then reenabled.

Address: 0h base + 8h offset = 8h

* Notes:

- MFD field: See Clocking chapter for reset value
- PREDIV field: See Clocking chapter for reset value
- RFDPHI field: See Clocking chapter for reset value

- RFDPHI1 field: See Clocking chapter for reset value

PLLDIG_PLL0DV field descriptions

Field	Description
0 Reserved	This field is reserved.
1–4 RFDPHI1	PHI1 reduced frequency divider. This 4-bit field determines the VCO clock post divider for driving the PHI1 output clock. RFDPHI1 has a range of 4..15 (4h..Fh). All other values are reserved.
5–9 Reserved	This field is reserved.
10–15 RFDPHI	PHI reduced frequency divider. This 6-bit field determines the VCO clock post divider for driving the PHI output clock. RFDPHI has a range of 1..63 (1h..3Fh). All other values are reserved.
16 Reserved	This field is reserved.
17–19 PREDIV	Input clock predivider. This field controls the value of the divider on the input clock. The output of the predivider circuit generates the reference clock to the PLL analog loop. The PREDIV value 000b causes the input clock to be inhibited. 000 Clock inhibit 001 Divide by 1 010 Divide by 2 011 Divide by 3 100 Divide by 4 101 Divide by 5 110 Divide by 6 111 Divide by 7
20–24 Reserved	This field is reserved.
25–31 MFD	Loop multiplication factor divider. This field controls the value of the divider in the feedback loop. The value specified by the MFD bits establishes the multiplication factor applied to the reference frequency. Divider value = MFD, where MFD has the range 8...127 (8h...7Fh). All other values are reserved (see Clock configuration for details).

23.5.4 PLLDIG PLL1 Control Register (PLLDIG_PLL1CR)

The PLL1CR is shown in the following table. It contains the operational state of PLL1, and is used to enable/disable PLL specific interrupts.

Address: 0h base + 20h offset = 20h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

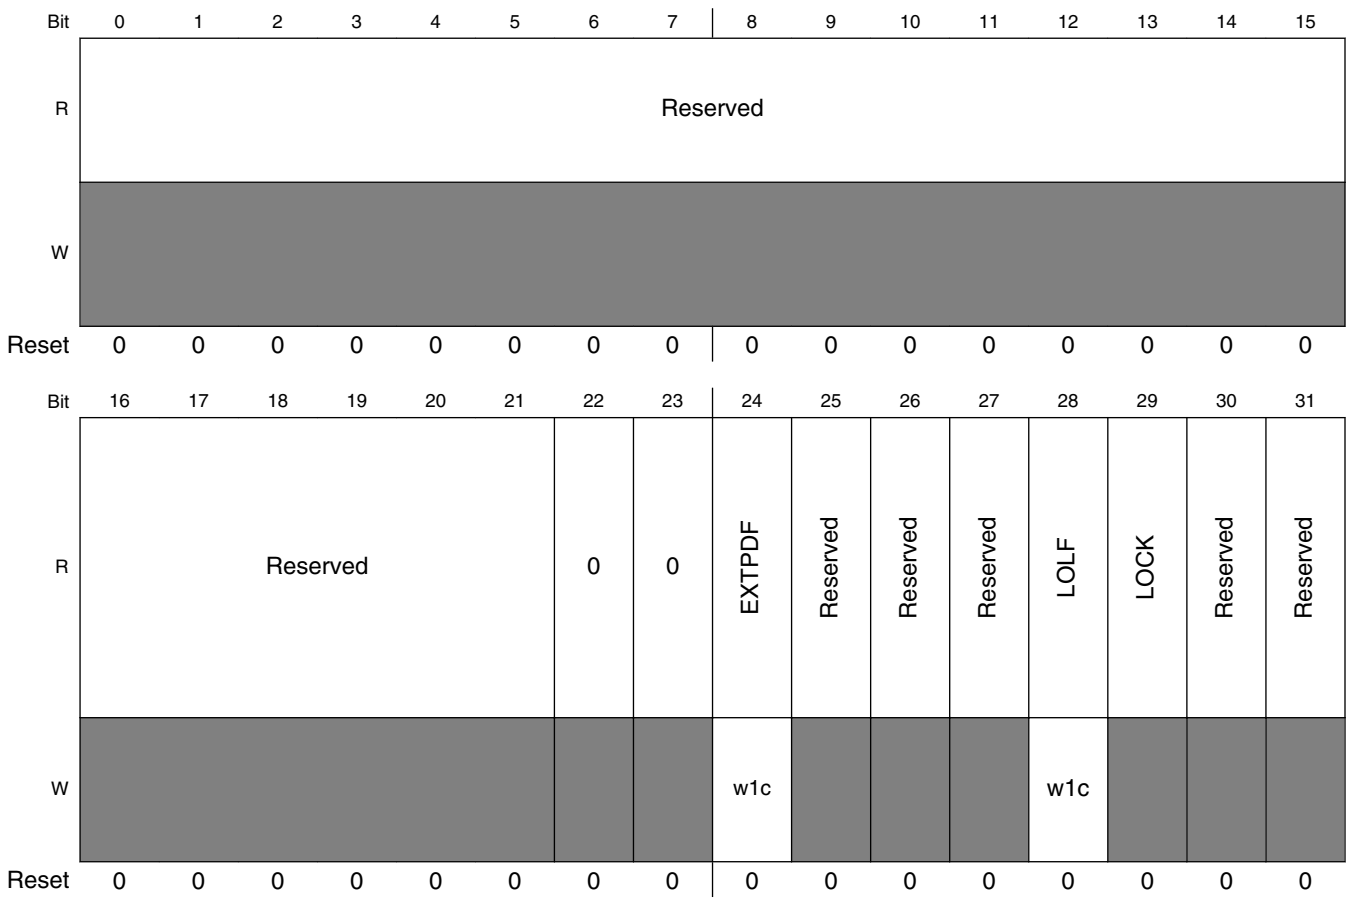
* Notes:
- This field can be written at any time, but writes are ignored. Read returns previously written value.
- LOLIE field: Please refer to device "Clocking" chapter for details on configuring this field.

PLLDIG_PLL1CR field descriptions

Field	Description
0–20 Reserved	This field is reserved.
21 Reserved	This field is reserved.
22–23 CLKCFG	Clock Configuration This field indicates the operational state of the PLL. When the PLLs are externally powered down the CLKCFG field changes to 00b. **NOTE:** In cascaded PLL configuration (PLL0 driving the reference clock for PLL1) the external power down signal for PLL1 must be removed only when PLL0 has locked, PLL0SR[LOCK] = 1.

Table continues on the next page...



PLLDIG_PLL1CR field descriptions (continued)

Field	Description
	NOTE: CLKCFG can be written, but writes have no effect. Mode changes are implemented by writing to the appropriate MC_ME_< *mode* >_MC register (see the "Mode Entry Module (MC_ME)" chapter and Clock configuration for details). 00 Bypass mode with PLL off 01 Reserved 10 Reserved 11 Normal mode with PLL running.
24 EXPDIE	External Power Down Cycle Complete indication interrupt enable. This bit enables generation of an interrupt when external power down of the PLL is complete (for example, PLLs are powered down and powered back up). 0 Ignore interrupt. Interrupt not requested 1 Enable interrupt request on power down cycle completion
25 Reserved	This field is reserved.
26 Reserved	This field is reserved.
27 Reserved	This field is reserved.
28 LOLIE	Loss-of-lock interrupt enable. The LOLIE bit enables a loss-of-lock interrupt request when PLL1SR[LOLF] = 1. If PLL1SR[LOLF] = 0 or PLL1CR[LOLIE] = 0, the interrupt request is ignored. The interrupt request only occurs in normal mode, therefore LOLIE bit has no effect in bypass mode. 0 Ignore loss-of-lock. Interrupt not requested. 1 Enable interrupt request upon loss-of-lock.
29 Reserved	This field is reserved.
30 Reserved	This field is reserved.
31 Reserved	This field is reserved.

23.5.5 PLLDIG PLL1 Status Register (PLLDIG_PLL1SR)

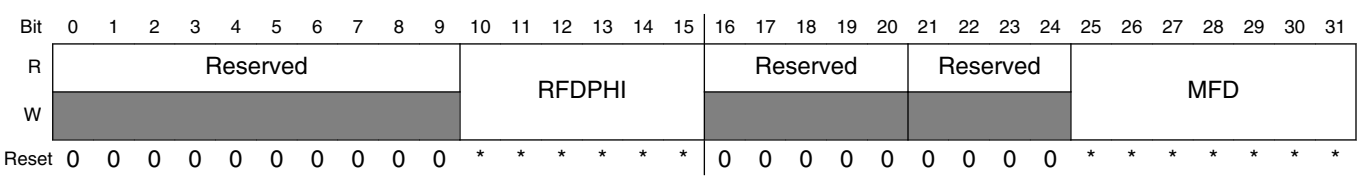
PLL1SR contains status flags showing the current state of the PLL.

Address: 0h base + 24h offset = 24h

PLLDIG_PLL1SR field descriptions

Field	Description
0–21 Reserved	This field is reserved.
22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24 EXTPDF	External Power Down Cycle Complete indication interrupt flag. This bit indicates that the external power down of the PLL is complete (for example, PLLs are powered down and then powered up). 0 PLLs not power cycled. Interrupt not requested 1 PLLs power down cycle is complete. Interrupt is requested

Table continues on the next page...



PLLDIG_PLL1SR field descriptions (continued)

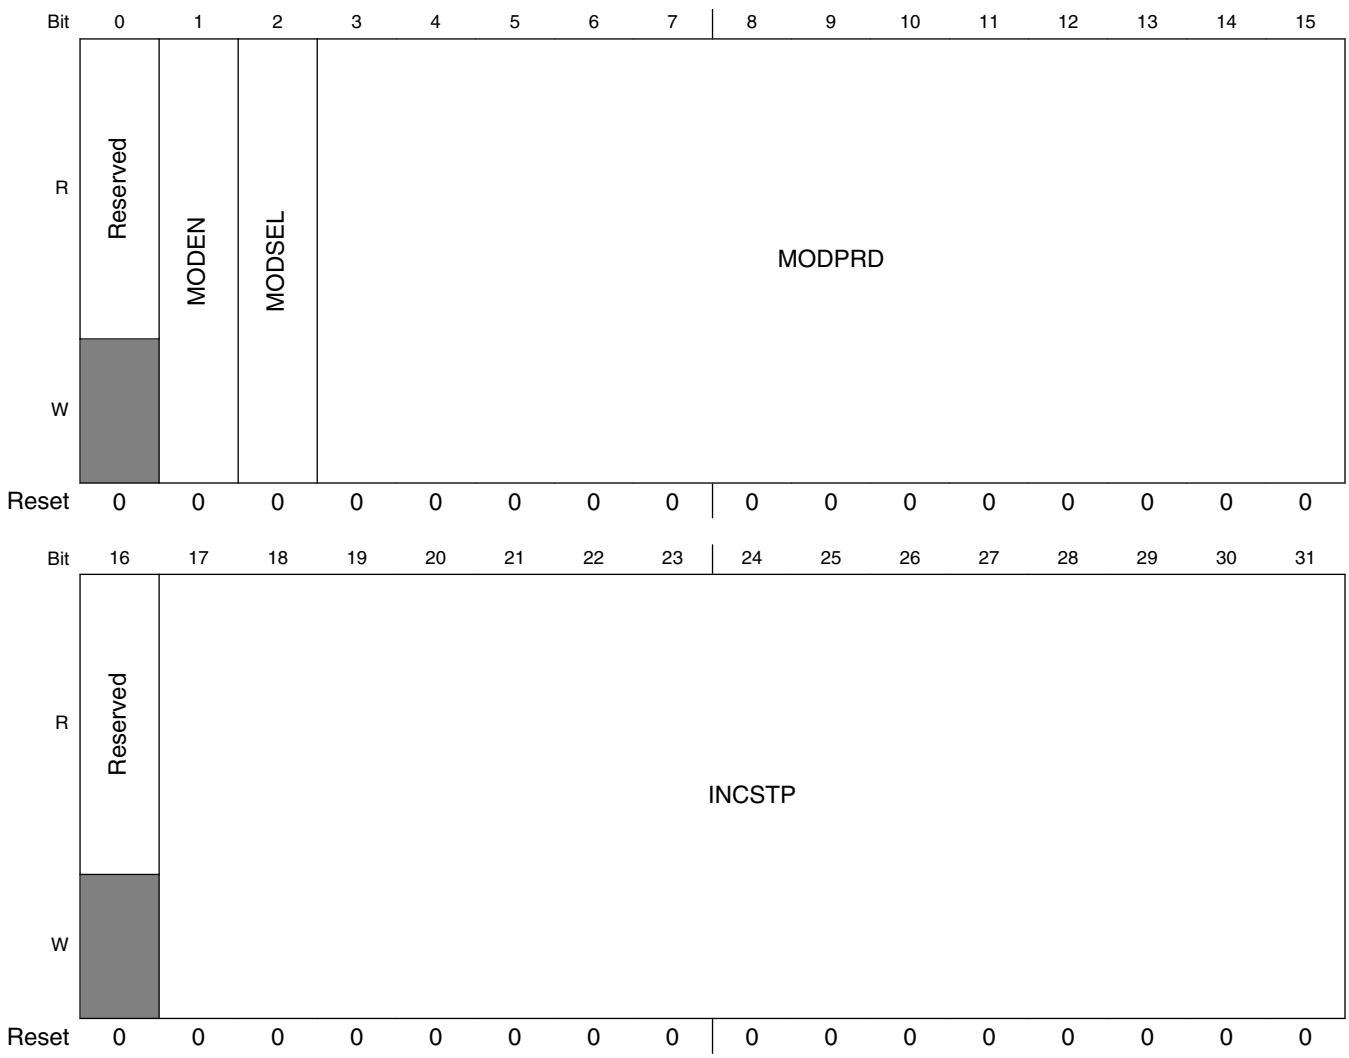
Field	Description
25 Reserved	This field is reserved.
26 Reserved	This field is reserved.
27 Reserved	This field is reserved.
28 LOLF	Loss-of-lock flag. This bit provides the interrupt request flag for the loss-of-lock condition. Software must write 1 to LOLF to clear it, writing 0 has no effect. This flag bit is sticky in the sense that if lock is reacquired, the bit will remain set until cleared by either writing 1 or asserting reset. LOLF is not asserted if the loss-of-lock condition was detected while the PLL is in bypass mode, but changing from normal to bypass mode will not automatically clear the LOLF if it was previously asserted while the PLL was in normal mode. 0 No loss of lock detected. Interrupt service not requested. 1 Loss of lock detected. Interrupt service requested.
29 LOCK	Lock status bit. Indicates whether PLL has acquired lock. If operating in bypass mode, the LOCK bit will still operate normally (for example, assert when the PLL acquires lock or negate when it loses lock). 0 PLL is unlocked. 1 PLL is locked.
30 Reserved	This field is reserved.
31 Reserved	This field is reserved.

23.5.6 PLLDIG PLL1 Divider Register (PLLDIG_PLL1DV)

The values of the reduced frequency divider (RFDPHI) and loop multiplication factor divider (MFD) can be modified at anytime, but the new values only become effective after the PLL is disabled, then reenabled.

Address: 0h base + 28h offset = 28h

* Notes:
- MFD field: See Clocking chapter for reset value
- RFDPHI field: See Clocking chapter for reset value



PLLDIG_PLL1DV field descriptions

Field	Description
0–9 Reserved	This field is reserved.
10–15 RFDPHI	PHI reduced frequency divider. This 6-bit field determines the VCO clock post divider for driving the PHI output clock. RFDPHI has a range of 1..63 (1h..3Fh). All other values are reserved.
16–20 Reserved	This field is reserved.
21–24 Reserved	This field is reserved.
25–31 MFD	Loop multiplication factor divider. This field controls the value of the divider in the feedback loop. The value specified by the MFD bits establishes the multiplication factor applied to the reference frequency. Divider value = MFD, where MFD has the range 16...34 (10h...22h). All other values are reserved.

23.5.7 PLLDIG PLL1 Frequency Modulation Register (PLLDIG_PLL1FM)

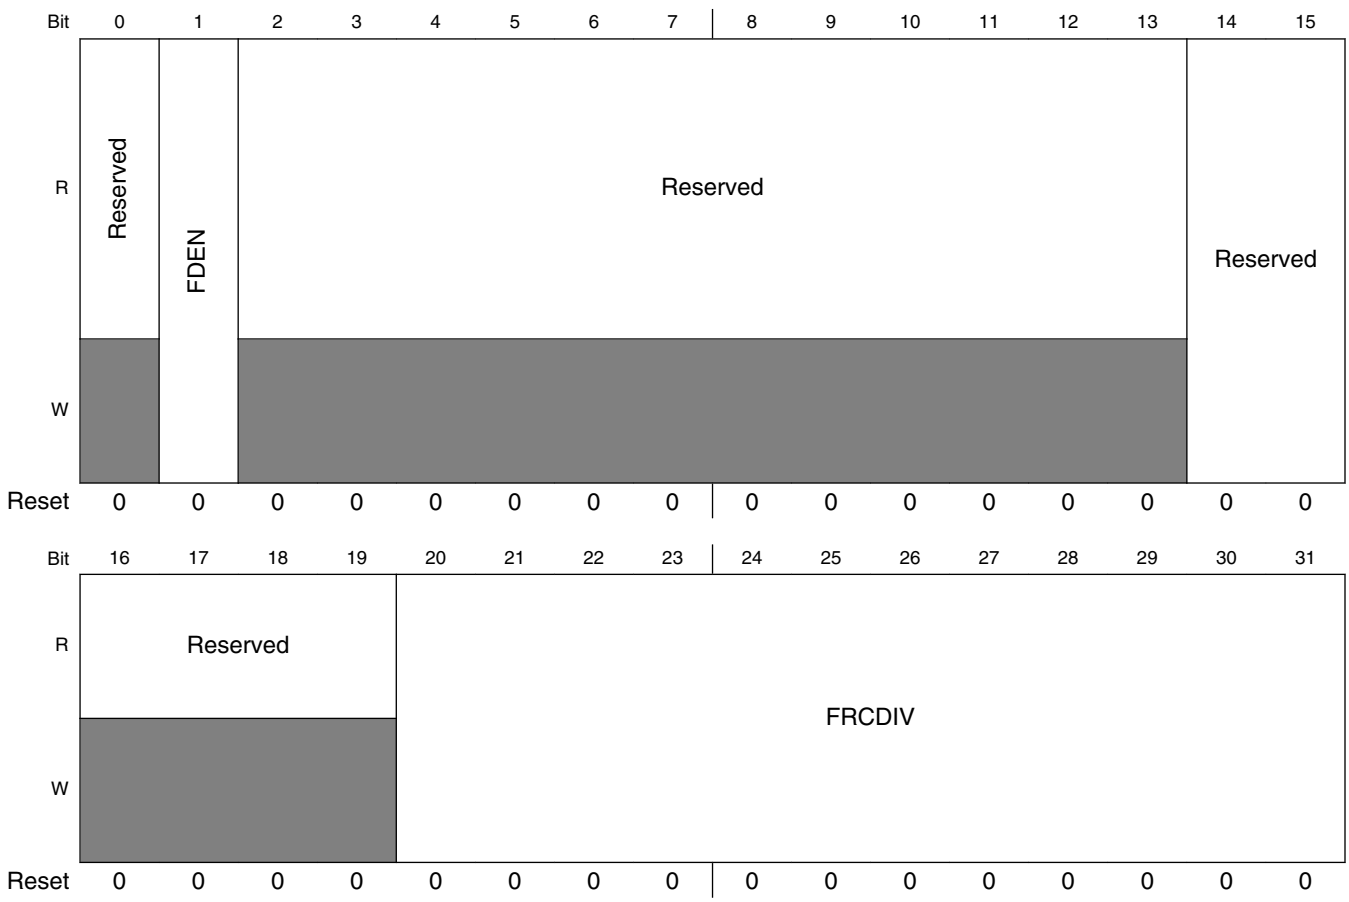
The PLL1FM register controls enables frequency modulation, and provides controls for modulation mode selection, modulation depth and modulation rate. This register should be written when PLL1CR[CLKCFG] = 00b (PLL1 powered down). The PLL would then be required to be power cycled to regain normal functionality.

Address: 0h base + 2Ch offset = 2Ch

PLLDIG_PLL1FM field descriptions

Field	Description
0 Reserved	This field is reserved.

Table continues on the next page...



PLLDIG_PLL1FM field descriptions (continued)

Field	Description
1 MODEN	Modulation enable. This bit enables the frequency modulation. 0 Frequency modulation disabled. 1 Frequency modulation enabled.
2 MODSEL	Modulation selection. This bit selects whether modulation is centered around the nominal frequency or spread below the nominal frequency. 0 Centre Spread Modulation - Modulation centred around nominal frequency. 1 Down Spread Modulation - Modulation spread below nominal frequency.
3–15 MODPRD	Modulation period. MODPRD is the modulation period variable derived from the formulas shown in Frequency modulation.
16 Reserved	This field is reserved.
17–31 INCSTP	Increment step. This field is the INCSTP variable derived from the formulas shown in Frequency modulation.

23.5.8 PLLDIG PLL1 Fractional Divide Register (PLLDIG_PLL1FD)

The PLL1FD register provides the enable and fractional divide factor for the loop divider. This register should be written when PLL1CR[CLKCFG] = 00b (PLL1 powered down). Changing the values of FDEN once the PLL is running, and has locked, can result in the PLL losing its lock and the device being reset (PLL*n*CR[LOLRE] = 1). The PLL would then require power cycling to regain normal functionality.

Address: 0h base + 30h offset = 30h

PLLDIG_PLL1FD field descriptions

Field	Description
0 Reserved	This field is reserved.
1 FDEN	Fractional Divide Enable This bit enables the fractional divider in the loop divider for PLL1.

Table continues on the next page...

PLLDIG_PLL1FD field descriptions (continued)

Field	Description
	0 Fractional divide disabled. 1 Fractional divide enabled.
2–13 Reserved	This field is reserved.
14–15 Reserved	Reserved. This field is reserved. **Important:** This field must be written 00b.
16–19 Reserved	This field is reserved.
20–31 FRCDIV	Fractional divide input. When the fractional divide is disabled, the VCO clock frequency is the product of the input clock and the loop divide factor (MFD). When fractional divide is enabled, the mean VCO clock frequency is given by the equation in the section Clock configuration.

23.6 Register classification for safety requirements

This module is classified as ViMo (Vital Modules) for functional safety. Hence, the registers of this module have been classified as shown in the Functional Safety chapter.

23.7 Functional description

This section explains the operation and configuration of the Dual PLLDIG module.

23.7.1 Input clock frequency

PLL0 and PLL1 are designed to operate over an input clock frequency range. The operating ranges for the PLLs are discussed in detail in the *Data Sheet*.

23.7.2 Clock configuration

The relationship between input and output frequency is determined by programming the PLL0DV, PLL1DV, and PLL1FD registers, and calculated according to the following equations:

$$f_{pll0_phi} = f_{pll0_ref} \times \left(\frac{PLL0DV[MFD]}{PLL0DV[PREDIV] \times PLL0DV[RFDPHI]} \right)$$

Figure 23-9. PLL0 PHI Output Frequency

$$f_{pll0_phi1} = f_{pll0_ref} \times \left(\frac{PLL0DV[MFD]}{PLL0DV[PREDIV] \times PLL0DV[RFDPHI1]} \right)$$

Figure 23-10. PLL0 PHI1 Output Frequency

$$f_{pll1_phi} = f_{pll1_ref} \times \left(\frac{PLL1DV[MFD] + \frac{PLL1FD[FRCDIV]}{2^{12}} + \frac{1}{2^{13}}}{2 \times PLL1DV[RFDPHI]} \right)$$

Figure 23-11. PLL1 PHI Output Frequency

The relationship between the VCO frequency (f_{VCO}) and the output frequency of the PLLs is determined by the configuration of the PLL1DV, PLL1FD, and PLL0DV registers, according to the following equations:

$$f_{pll0_VCO} = \frac{f_{pll0_ref} \times PLL0DV[MFD] \times 2}{PLL0DV[PREDIV]}$$

Figure 23-12. PLL0 VCO Frequency

$$f_{pll1_VCO} = f_{pll1_ref} \times \left(PLL1DV[MFD] + \frac{PLL1FD[FRCDIV]}{2^{12}} + \frac{1}{2^{13}} \right)$$

Figure 23-13. PLL1 VCO Frequency

NOTE

f_{pll0_phi1} is the reference clock generated by PLL0 for PLL1

When programming the PLLs, user software must not violate the maximum system clock frequency or max/min VCO frequency specification of PLL0 and PLL1. Furthermore, the PLL0DV[PREDIV] value must not be set to any value that causes the input frequency to the phase detector of analog PLL blocks to go below the prescribed ranges.

The lock signal and PLL*n*SR[LOCK] flag are immediately negated if the fields of the PLL*n*DV registers are changed without powering down the analog PLLs.

When any of these events occur, an internal timer is initialized to count 64 cycles of the PLL input clock. During this period (64 cycles and a few extra clock cycles for synchronization, for example, 64 to 72 cycles), the PLL*n*SR[LOCK] flag is held negated. After the timer expires, the PLL*n*SR[LOCK] flag reflects the value coming from the PLL lock detection circuitry. To prevent an immediate reset, the PLL*n*CR[LOLRE] bit of the respective PLLs must be cleared before doing any of the above operations.

Note

The PLL must be powered down and powered up by configuring, then executing, a mode change in the MC_ME_<*mode*>_MC before PLL0DV[PREDIV], PLL0DV[MFD], PLL1DV[MFD], or the input clocks are modified.

The recommended procedure to program the PLLs and engage normal mode is shown in Initialization information.

Coming out of reset, PLL1 and PLL0 are off and in bypass mode. The recommended procedure to program the PLLs and engage normal mode is described in the 'Clocking' chapter.

23.7.3 Frequency modulation

Frequency modulation uses a triangular profile as shown in Figure 23-14. The modulation frequency and depth are controlled using PLL1FM[MODPRD] and PLL1FM[INCSTP].

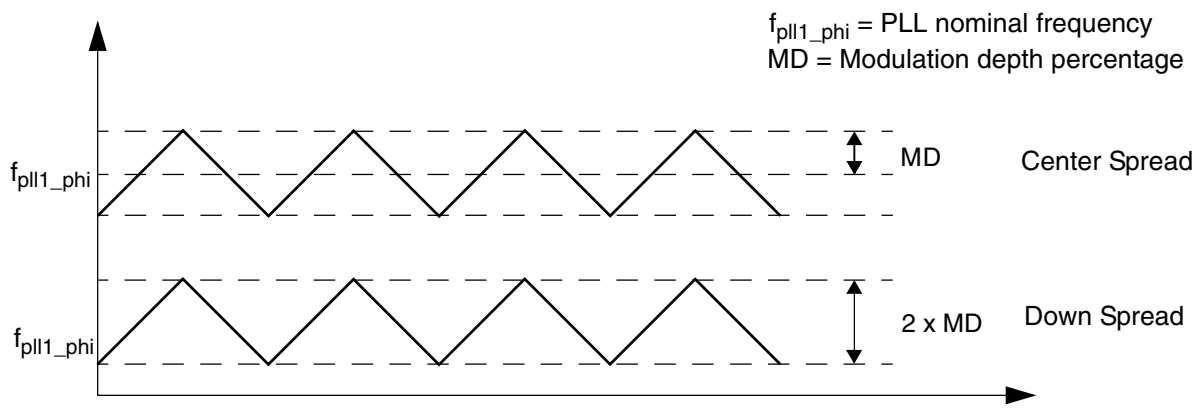


Figure 23-14. Triangular frequency modulation

NOTE

The device maximum operating frequency includes the frequency modulation. If center modulation is used, the f_{sys} must be below f_{max} by MD percentage such that $f_{max} = f_{sys} \times (1 + (MD\% / 100))$.

The following equations define how to calculate PLL1FM[MODPRD] and PLL1FM[INCSTP] based on the output frequency of the feedback divider (f_{ref}), the modulation frequency (f_{mod}) and the modulation depth percentage (MD).

$$PLL1FM[MODPRD] = round\left(\frac{f_{pll1_ref}}{4 \times f_{mod}}\right)$$

Figure 23-15. PLL1FM[MODPRD] Calculation

The equation to determine PLL1FM[INCSTP] is shown in Figure 23-16.

$$PLL1FM[INCSTP] = round\ \left(\frac{(2^{15}-1) \times MD \times PLL1DV[MFD]}{100 \times 5 \times PLL1FM[MODPRD]}\right)$$

Figure 23-16. PLL1FM[INCSTP] Calculation

PLL1FM[MODPRD] and PLL1FM[INCSTP] are subject to the following restriction:

$$(PLL1FM[MODPRD] \times PLL1FM[INCSTP]) < 2^{15}$$

Figure 23-17. PLL1FM[MODPRD] and PLL1FM[INCSTP] Restriction

Because of the above rounding operations, the effective modulation depth applied to the FMPLL is shown in Figure 23-18.

$$ModulationDepth = round\left(\frac{PLL1FM[MODPRD] \times PLLIFM[INCSTP] \times 100 \times 5}{(2^{15} - 1) \times PLL1DV[MFD]}\right)$$

Figure 23-18. Modulation Depth

FM parameters should only be changed, and FM enabled, after PLL0 has obtained lock. The sequence for reprogramming the FM is:

1. Power down PLL1 by writing MC_ME_<*mode*>_MC[PLL1ON] = 0, followed by a mode change.
2. Write a mode change to MC_ME_<*mode*>_MC[PLL1ON].

3. Program the PLL1FM while PLL1 is powered down.
4. Power up the PLL1 by writing MC_ME_<*mode*>_MC[PLL1ON] = 1, followed by a mode change.
5. Write a mode change to MC_ME_<*mode*>_MC[PLL1ON].

23.8 Maximum lock time

This describes the maximum lock time of the PLL across process, supply voltages, and junction temperature. Maximum lock time is for the condition when the operating mode of the PLL has changed from power-down to Normal mode, input control bits are stable, and supplies (analog and digital) have attained levels shown in the *Data Sheet*. It is also the time in which the PLLs regain lock after a loss of lock event, assuming all inputs are stable and supplies are within specifications.

23.9 Initialization information

Coming out of reset PLL0 and PLL1 are disabled per the DRUN mode configuration register, MC_ME_DRUN_MC. The Dual PLLDIG initialization procedure is described in the "Clocking" chapter.

NOTE

See the "Mode Entry Module (MC_ME)" chapter in this *Reference Manual* more details.

Chapter 24
Clock Monitor Unit (CMU)

24.1 Introduction

The Clock Monitor Unit (CMU), also referred to as Clock Quality Checker or Clock Fault Detector, serves three purposes:

- Measures the frequency of clock source CLKMT0_RMN with CLKMN0_RMT as the reference clock
- Monitors CLKMN0_RMT frequency with CLKMT0_RMN as reference clock
- Monitors CLKMN1 frequency with CLKMT0_RMN as reference clock and detects if the monitored clock frequency leaves an upper or lower frequency boundary

NOTE

See the "Clocking" chapter for chip-specific sources used by the CMU.

One of the tasks is to supervise the integrity of the various clock sources on the chip, for example CLKMN0_RMT or CLKMN1. If the monitored clock frequency is less than the reference clock, or it violates an upper or lower frequency boundary, the CMU detects and reports this event. These events signal the FCCU, which can take the necessary corrective actions as its configuration dictates.

The CMU can monitor CLKMN0_RMT, which must have a frequency higher than that of CLKMT0_RMN divided by the factor shown in CMU_CSR[RCDIV], and reports this event. The CMU can also monitor CLKMN1 and generate an event if CLKMN1 is greater than a high frequency boundary or less than a low frequency boundary. The upper and lower frequency boundaries are defined by the CMU High Frequency Reference Register (CMU_HFREFR) and CMU Low Frequency Reference Register (CMU_LFREFR).

The second task of the CMU is to provide a frequency meter, which allows measuring the frequency of a clock source against a reference clock. This is useful to allow the calibration of the metered clocks (such as CLKMT0_RMN), as well as to be able to correct/calculate the time deviation of a counter that is clocked by the metered clocks.

NOTE

See the "Clocking" chapter for the number of CMU instances on this chip.

24.1.1 Main features

- CLKMT0_RMN frequency measurement with CLKMN0_RMT as reference clock.
- CLKMN0_RMT monitoring with respect to CLKMT0_RMN ÷ $2^{CSR[RCDIV]}$ clock.
- Upper or lower frequency boundary monitoring of CLKMN1 with respect to CLKMT0_RMN ÷ 4.
- Event generation for various failures detected inside monitoring unit.

24.2 Block diagram

The block diagram of the CMU module(s) is shown in the “Clocking" chapter of this Reference Manual.

24.3 Signals

The table below describes the signals on the boundary of the CMU (in alphabetical order).

Table 24-1. Signal description

Signal	I/O	Description
CLKMN0_RMT	I	Monitored Clock Signal 0/Metered Clock Signal Reference — Receives a clock signal that the CMU compares to a specified low-limit frequency to determine whether the frequency of the clock signal is greater than the specified limit. Also provides a reference clock signal for all metered clock signals.
CLKMN1	I	Monitored Clock Signal 1 — Receives a clock signal that the CMU compares to specified low-limit and high-limit frequencies to determine whether the frequency of the clock signal is between the specified limits.
CLKMT0_RMN	I	Metered Clock Signal 0/Monitored Clock Signal Reference — Receives a clock signal that the CMU measures against a reference clock frequency. Also provides a reference clock signal for all monitored clock signals.

NOTE

See the "Clocking" chapter for device specific clock sources of each CMU.

24.4 Register description and memory map

This section describes in address order all the CMU registers. Each description includes a standard register diagram with an associated figure number. The CMU memory map is listed in the following table.

NOTE

See "Clocking" chapter for register and field availability details.

CMU memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	CMU Control Status Register (CMU_CSR)	32	R/W	See section	24.4.1/690
4	CMU Frequency Display Register (CMU_FDR)	32	R	0000_0000h	24.4.2/691
8	CMU High Frequency Reference Register CLKMN1 (CMU_HFREFR)	32	R/W	0000_0FFFh	24.4.3/692
C	CMU Low Frequency Reference Register CLKMN1 (CMU_LFREFR)	32	R/W	0000_0000h	24.4.4/692
10	CMU Interrupt Status Register (CMU_ISR)	32	w1c	See section	24.4.5/693
18	CMU Measurement Duration Register (CMU_MDR)	32	R/W	0000_0000h	24.4.6/695

24.4.1 CMU Control Status Register (CMU_CSR)

Address: 0h base + 0h offset = 0h

* Notes:
- RCDIV field: Not all CMU blocks will utilize this feature. See the “Clocking” chapter for CMU implementation details.
- CKSEL1 field: Not all CMU blocks will utilize this feature. See the “Clocking” chapter for CMU implementation details.
- SFM field: Not all CMU blocks will utilize this feature. See the “Clocking” chapter for CMU implementation details.

CMU_CSR field descriptions

Field	Description
0–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8 SFM	Start frequency measure. The software can only set this bit to start a clock frequency measure. It is reset by hardware when the measure is ready in the CMU_FDR. 0 Frequency measurement is completed or not yet started 1 Frequency measurement is not completed
9–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22–23 CKSEL1	Frequency measure clock selection bit. CKSEL1 selects the clock to be measured by the frequency meter. This only affects CMU instances that utilizes clock metering. Not all CMU blocks will utilize this feature. See the “Clocking” chapter for device specific CMU implementation details. 00 CLKMT0_RMN is selected 01 Reserved 10 Reserved 11 CLKMT0_RMN is selected
24–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29–30 RCDIV	CLKMT0_RMN division factor.

Table continues on the next page...

CMU_CSR field descriptions (continued)

Field	Description
	These bits specify the CLKMT0_RMN division factor. The output clock frequency is $f_{CLKMT0_RMN} \div 2^{CMU_CSR[RCDIV]}$. This output clock is used as reference clock to compare with CLKMN0_RMT for crystal clock monitor feature. 00 CLKMT0_RMN ÷ 1 (No division) 01 CLKMT0_RMN ÷ 2 10 CLKMT0_RMN ÷ 4 11 CLKMT0_RMN ÷ 8
31 CME	CLKMN1 monitor enable. 0 CLKMN1 monitor is disabled 1 CLKMN1 monitor is enabled

24.4.2 CMU Frequency Display Register (CMU_FDR)

The CMU_FDR is used to determine the measured frequency of:

- CLKMT0_RMN

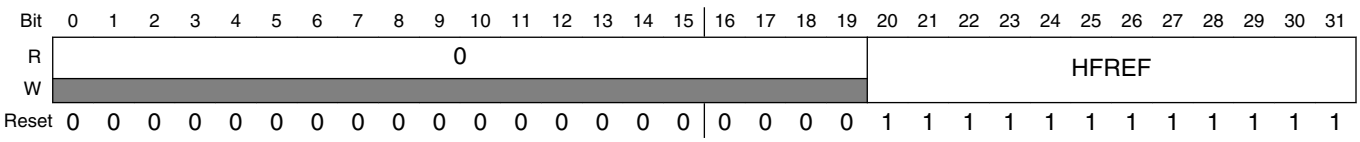
with respect to the reference clock CLKMN0_RMT.

NOTE

The CMU_FDR should be read only when CMU_CSR[SFM] = 0.

Address: 0h base + 4h offset = 4h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0												FD																			
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0



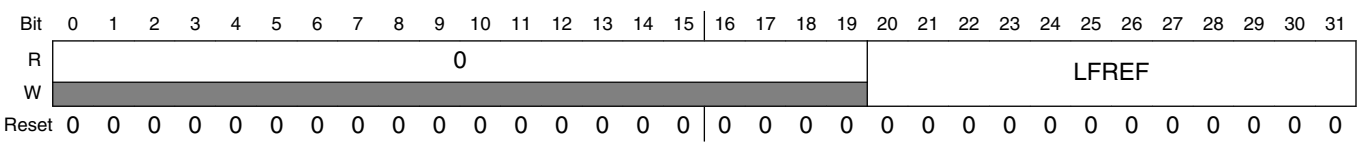
CMU_FDR field descriptions

Field	Description
0–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12–31 FD	Measured frequency bits. This register displays the measured frequency (f_{sel}) with respect to the reference clock (f_{CLKMN0_RMT}). The measured value is given by the following formula: $f_{sel} = (f_{CLKMN0_RMT} \times CMU_MDR[MD]) \div CMU_FDR[FD]$

24.4.3 CMU High Frequency Reference Register CLKMN1 (CMU_HFREFR)

The HFREFR is configured for the high frequency reference that the CMU will use for comparing against the monitored clock. The figure and table below show the CMU_HFREFR register.

Address: 0h base + 8h offset = 8h



CMU_HFREFR field descriptions

Field	Description
0–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20–31 HFREF	High Frequency reference value. These bits determine the high reference value for the CLKMN1 frequency. The reference value is given by: (HFREF ÷ 16) × (f_{CLKMT0_RMN} ÷ 4).

24.4.4 CMU Low Frequency Reference Register CLKMN1 (CMU_LFREFR)

The LFREFR is configured for the low frequency reference that the CMU will use for comparing against the monitored clock. The figure and table below show the CMU_LFREFR register.

Address: 0h base + Ch offset = Ch

CMU_LFREFR field descriptions

Field	Description
0–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

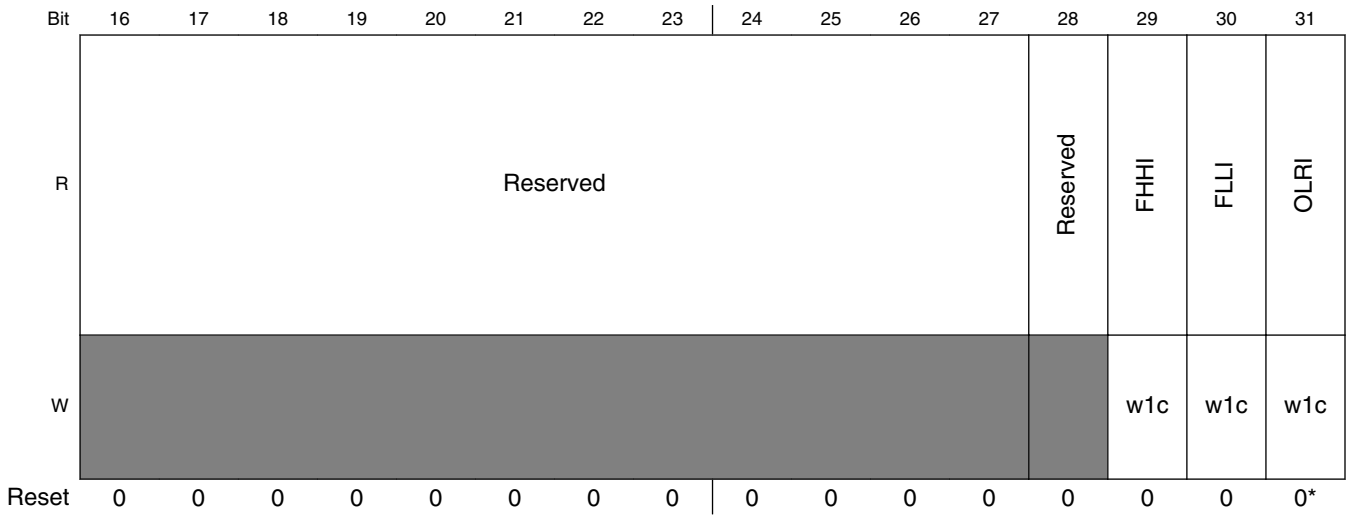
Table continues on the next page...

CMU_LFREFR field descriptions (continued)

Field	Description
20–31 LFREF	Low Frequency reference value. These bits determine the low reference value for the CLKMN1 frequency. The reference value is given by: (LFREF ÷ 16) × (f_{CLKMT0_RMN} ÷ 4).

24.4.5 CMU Interrupt Status Register (CMU_ISR)

NOTE



All flags in the CMU_ISR are set asynchronously. This register must be read only after an interrupt(safe mode entry) is triggered by the CMU. Otherwise, a read access on this register may fetch an incorrect value (see "Clocking" chapter for interrupt operation) .

NOTE

Before entering low-power stop modes, all clock frequency measurements in the CMU should be disabled. Failing to do so may result in spurious interrupts.

Address: 0h base + 10h offset = 10h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	Reserved															
W

* Notes:
- OLRI field: Not all CMU blocks will utilize this feature. See the "Clocking" chapter for specific CMU implementation details.

CMU_ISR field descriptions

Field	Description
0–27 Reserved	This field is reserved.
28 Reserved	This field is reserved.
29 FHHI	CLKMN1 frequency higher than high reference event status. This bit is set by hardware when CLKMN1 frequency becomes higher than the high frequency reference value determined by CMU_HFREFR[HFREF] and CLKMN1 is 'ON' as signaled by the MC_ME. It can be cleared by software by writing '1'. 0 No FHH event 1 FHH event occurred
30 FLLI	CLKMN1 frequency less than low reference event status. This bit is set by hardware when CLKMN1 frequency becomes lower than the low frequency reference value determined by CMU_LFREFR[LFREF], and CLKMN1 is 'ON' as signaled by the MC_ME. Software clears this field by writing a '1'. 0 No FLL event 1 FLL event occurred
31 OLRI	Oscillator frequency less than $f_{CLKMT0_RMN} \div 2^{CMU_CSR[RCDIV]}$event status. This bit is set by hardware when the f_{CLKMN0_RMT} is less than $f_{CLKMT0_RMN} \div 2^{CMU_CSR[RCDIV]}$frequency and CLKMN0_RMT is 'ON' as signaled by the MC_ME. It can be cleared by software by writing '1'. **NOTE:** While entering STOP mode, OLRI may be triggered. To avoid this when the system is running on the PLL, disable the XOSC before entering STOP mode. 0 No OLR event 1 OLR event occurred

24.4.6 CMU Measurement Duration Register (CMU_MDR)

Address: 0h base + 18h offset = 18h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0												MD																			
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

CMU_MDR field descriptions

Field	Description
0–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12–31 MD	Measurement duration bits This field displays the measurement duration in terms of selected clock (CLKMT0_RMN) cycles. This value is loaded in the frequency meter down-counter. The down-counter starts counting when CMU_CSR [SFM] = 1.

24.5 Functional description

24.5.1 Frequency meter

The purpose of the frequency meter is to evaluate the deviation from the nominal metered source (such as CLKMT0_RMN) frequencies. This in turn allows either recalibration of these clocks or other timing corrections. Programming of the CMU_CSR[CKSEL1] field is used to select one of the metered clocks from a multiplexer that drives a simple Frequency Meter (see the CMU Block Diagram in the "Clocking" chapter). The reference clock for the Frequency Meter is the CLKMN0_RMT signal. The measurement starts when CMU_CSR[SFM] = 1. The measurement duration is given by the contents of CMU_MDR[MD] in terms of number of clock cycles of the selected metered clock. The CMU_CSR[SFM] bit is cleared by hardware once the frequency measurement is complete and the count is loaded in CMU_FDR[FD]. The frequency of the selected clock (f_{sel}) can be derived from the value loaded in the CMU_FDR[FD] as shown in the following equation:

$$f_{sel} = f_{CLKMN0_RMT} \times \frac{CMU_MDR[MD]}{CMU_FDR[FD]}$$

24.5.2 CLKMN0_RMT supervisor

If frequency of CLKMN0_RMT is smaller than the frequency of CLKMT0_RMN ÷ $2^{CMU_CSR[RCDIV]}$ and CLKMN0_RMT is 'ON' as signaled by the MC_ME, then:

- The CMU writes 1 to CMU_ISR[OLRI].
- The CMU asserts the OLR signal.

Note

f_{CLKMN0_RMT} must be greater than $f_{CLKMT0_RMN} \div 2^{CMU_CSR[RCDIV]}$ by at least 0.5 MHz in order to guarantee correct f_{CLKMN0_RMT} monitoring.

24.5.3 CLKMN1 supervisor

The frequency of CLKMN1(f_{CLKMN1}) can be monitored by programming CMU_CSR[CME] = 1. CLKMN1 monitoring starts as soon as CMU_CSR[CME] = 1. This monitor can be disabled at any time by programming CMU_CSR[CME] = 0.

If f_{CLKMN1} is greater than the reference value determined by fields CMU_HFREFR[HFREF] and CLKMN1 is 'ON' as signaled by the MC_ME, then:

- The CMU writes 1 to CMU_ISR[FHHI].
- The CMU asserts the FHH signal.

If f_{CLKMN1} is less than a reference value determined by the bits CMU_LFREFR[LFREF] and the CLKMN1 is 'ON' as signaled by the MC_ME, then:

- The CMU writes 1 to CMU_ISR[FLLI].
- The CMU asserts the FLL signal.

Note

An example of determining the $HFREF_{Actual}$ is as follows. Assume a f_{CLKMT0_RMN} = 16 MHz with a accuracy of +/-5%. In order to monitor a f_{CLKMN1} = 200 MHz, the ideal $HFREF_{Ideal}$ = 800. The actual HFREF value will be 842 when the accuracy is taken into consideration ($HFREF_{Actual}$ = ($HFREF_{Ideal}$ ÷ 0.95).

The actual LFREF value will be 762 when accuracy is taken into consideration ($LFREF_{Actual} = LFREF_{Ideal} \div 1.05$).

Chapter 25
Clock Generation Module (MC_CGM)

25.1 Introduction

This chapter describes the Clock Generation Module (MC_CGM).

25.1.1 Overview

The clock generation module (MC_CGM) generates reference clocks for all the chip blocks. The MC_CGM selects one of the system clock sources to supply the system clock. The MC_ME module controls the system clock selection (see the MC_ME chapter for more details). Peripheral clock selection is controlled by MC_CGM control registers. A set of MC_CGM registers controls the clock dividers which are used for divided system and peripheral clock generation. The memory spaces of system and peripheral clock sources which have addressable memory spaces can be accessed through the MC_CGM memory space.

The following figure shows the MC_CGM block diagram.

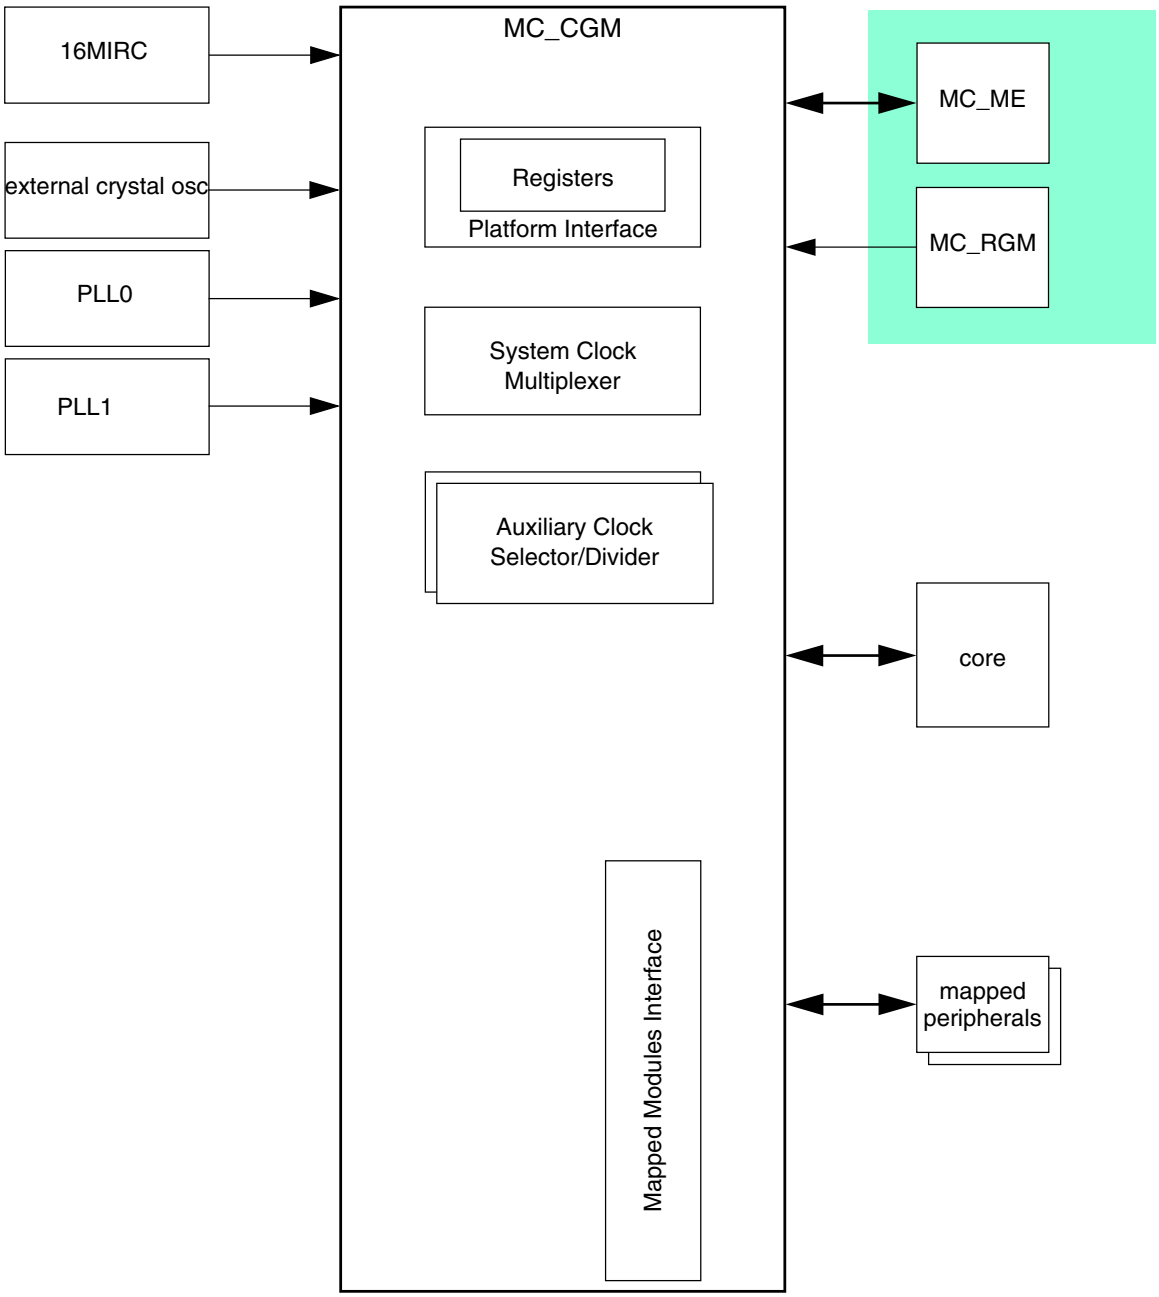

Figure 25-1. MC_CGM Block Diagram

25.1.2 Features

The MC_CGM includes the following features:

- generates system and peripheral clocks
- selects and enables/disables the system clock supply from system clock sources according to MC_ME control

- performs progressive system clock frequency change depending on MC_ME mode configuration
- contains a set of registers to control clock dividers for divided clock generation
- contains a set of registers to control peripheral clock selection
- supports multiple clock sources and maps their address spaces to its memory map
- contains IPS interface for mapped clock source modules
- supports PLL control by PLL-based-scan controller
- supports 8, 16, and 32-bit wide read/write accesses

25.2 External Signal Description

The MC_CGM delivers output clocks to the clkout pins for off-chip use and/or observation.

25.3 MC_CGM Registers

The following subsections show the MC_CGM registers memory map and the detailed definition of each register.

MC_CGM memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	PCS Switch Duration (MC_CGM_PCS_SDUR)	8	R/W	00h	25.3.1/704

25.3.1 PCS Switch Duration (MC_CGM_PCS_SDUR)

This register contains the progressive system clock switching duration for each step. See Section "Progressive System Clock Switching" for details on how to set this value.

Address: 0h base + 0h offset = 0h

Bit	0	1	2	3	4	5	6	7
Read Write	SDUR							
Reset	0	0	0	0	0	0	0	0

MC_CGM_PCS_SDUR field descriptions

Field	Description
0–7 SDUR	Switch Duration - This value defines the duration of one PCS clock switch step in terms of 16 MHz internal RC osc. cycles.

25.3.2 PCS Divider Change for external crystal oscillator (MC_CGM_PCS_DIVC1)

These registers define the rate of frequency change and initial change value on frequency ramp-up for the progressive system clock switching when switching to or from the external crystal oscillator. See Section "Progressive System Clock Switching" for details on how to set these values.

NOTE

Byte write accesses are not allowed for the INIT field of this register. Such an access will not result in an exception, however the value will not be loaded with the new value.

Address: 0h base + 4h offset = 4h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

MC_CGM_PCS_DIVC1 field descriptions

Field	Description
0–15 INIT	Divider Change Initial Value - This is initial change value of the clock divider for the clock ramp-up phase when switching to external crystal oscillator.
16–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–31 RATE	Divider Change Rate - This value controls the change value of the clock divider for the clock ramp-up and ramp-down phase when switching from the external crystal oscillator.

25.3.3 PCS Divider End for external crystal oscillator (MC_CGM_PCS_DIVE1)

These registers define the final division value on frequency ramp-down for the progressive system clock switching when switching from or to external crystal oscillator on ramp up and ramp down. See Section "Progressive System Clock Switching" for details on how to set these values.

NOTE

Byte and half-word write accesses are not allowed for this register. Such an access will not result in an exception, however the value will not be loaded with the new value.

Address: 0h base + 8h offset = 8h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

MC_CGM_PCS_DIVE1 field descriptions

Field	Description
0–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12–31 DIVE	Divider End Value - This is the clock divider end value for the clock ramp-down phase when switching from the external crystal oscillator.

25.3.4 PCS Divider Start for external crystal oscillator (MC_CGM_PCS_DIVS1)

These registers define the initial division value on frequency ramp-up for the progressive system clock switching when switching the system clock from or to the external crystal oscillator on ramp up and ramp down. See Section "Progressive System Clock Switching" for details on how to set these values.

NOTE

Byte and half-word write accesses are not allowed for this register. Such an access will not result in an exception, however the value will not be loaded with the new value.

Address: 0h base + Ch offset = Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

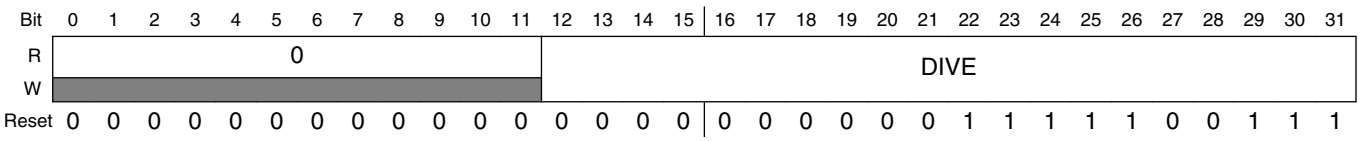
MC_CGM_PCS_DIVC4 field descriptions

Field	Description
0–15 INIT	Divider Change Initial Value - This is initial change value of the clock divider for the clock ramp-up phase when switching to PLL1 PHI.
16–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–31 RATE	Divider Change Rate - This value controls the change value of the clock divider for the clock ramp-up and ramp-down phase when switching from the PLL1 PHI.



25.3.9 PCS Divider End for PLL1 PHI (MC_CGM_PCS_DIVE4)

These registers define the final division value on frequency ramp-down for the progressive system clock switching when switching from or to PLL1 PHI on ramp up and ramp down. See Section "Progressive System Clock Switching" for details on how to set these values.

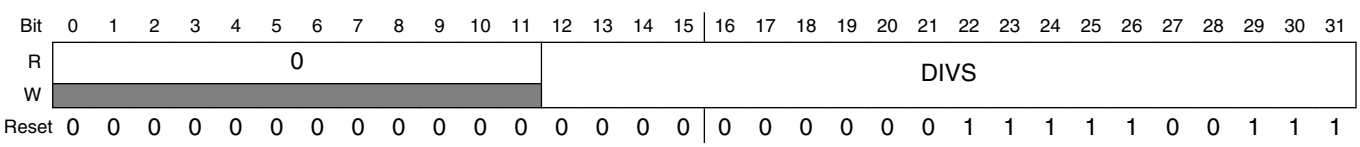
NOTE

Byte and half-word write accesses are not allowed for this register. Such an access will not result in an exception, however the value will not be loaded with the new value.

Address: 0h base + 2Ch offset = 2Ch

MC_CGM_PCS_DIVE4 field descriptions

Field	Description
0–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12–31 DIVE	Divider End Value - This is the clock divider end value for the clock ramp-down phase when switching from the PLL1 PHI.



25.3.10 PCS Divider Start for PLL1 PHI (MC_CGM_PCS_DIVS4)

These registers define the initial division value on frequency ramp-up for the progressive system clock switching when switching the system clock from or to the PLL1 PHI on ramp up and ramp down. See Section "Progressive System Clock Switching" for details on how to set these values.

NOTE

Byte and half-word write accesses are not allowed for this register. Such an access will not result in an exception, however the value will not be loaded with the new value.

Address: 0h base + 30h offset = 30h

MC_CGM_PCS_DIVS4 field descriptions

Field	Description
0–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12–31 DIVS	Divider Start Value - This is the start value of the clock divider for the clock ramp-up phase when switching to the PLL1 PHI.

25.3.11 System Clock Divider Ratio Change Register (MC_CGM_SC_DIV_RC)

This register selects whether the system clock divider ratios will change from the current configuration to the configuration in the next update. If the value of SYS_DIV_RATIO_CHNG is ‘1’ at the time of a write to the CGM_DIV_UPD_TRIG register and a pre-loaded system clock divider update is pending, the crossbar is halted while the system clock divider update takes place. If the value of SYS_DIV_RATIO_CHNG is ‘0’, the crossbar switch is not halted. This register has no effect if the system clock divider update is configured in the CGM_DIV_UPD_TYPE register to be immediate.

An example of a divider ratio not changing is divider 0 changes from divide by 1 to divide by 2, and divider 1 changes from divide by 2 to divide by 4. The ratio is 1:2 in both configurations.

An example of a divider ratio changing is divider 0 changes from divide by 1 to divide by 2, and divider 1 changes from divide by 2 to divide by 6. The ratio changes from 1:2 to 1:3.

The value of SYS_DIV_RATIO_CHNG is returned to ‘1’ automatically on each write to the CGM_DIV_UPD_TRIG register.

For usage information, see Section "Divider Update Triggering".

Address: 0h base + D0h offset = D0h

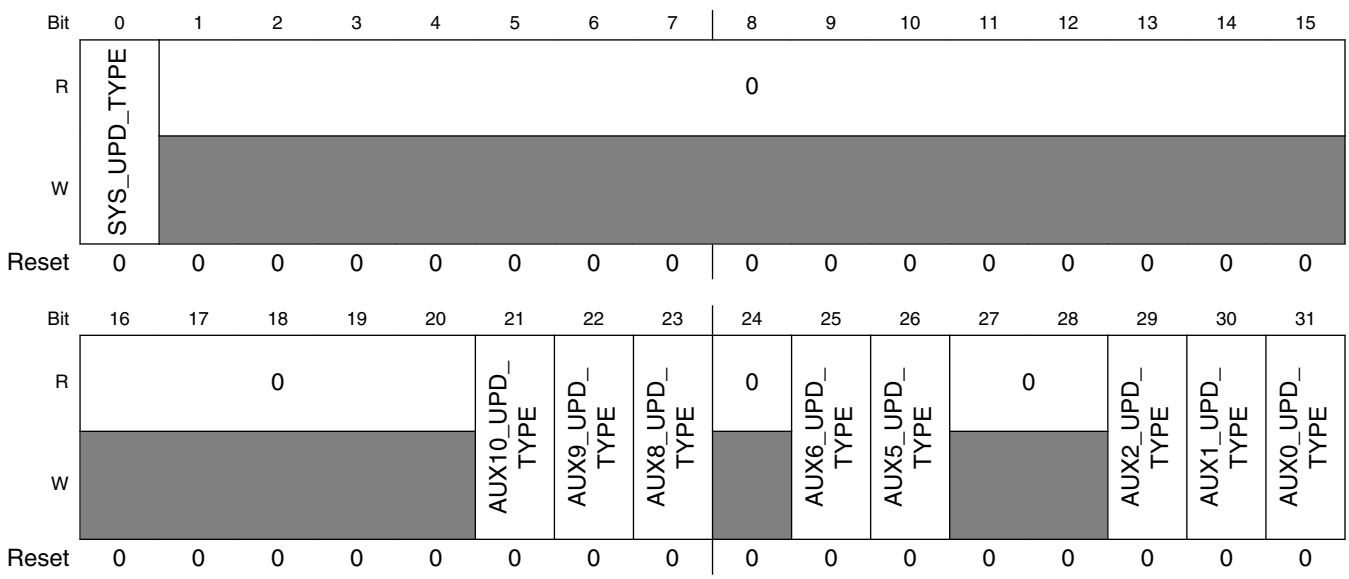
MC_CGM_SC_DIV_RC field descriptions



Field	Description
0–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 SYS_DIV_ RATIO_CHNG	System Clock Divider Ratio Change 0 The system clock divider ratios will not change with the next system clock divider configuration update. 1 The system clock divider ratios will change with the next system clock divider configuration update.

25.3.12 Divider Update Type (MC_CGM_DIV_UPD_TYPE)

This register selects whether the dividers associated with a clock are updated immediately on writing to the corresponding divider configuration register or only on writing to the divider update trigger register CGM_DIV_UPD_TRIG, after which the pre-loaded configuration in the divider configuration registers wil take effect.

For usage information, see Section“Divider Update Triggering”.

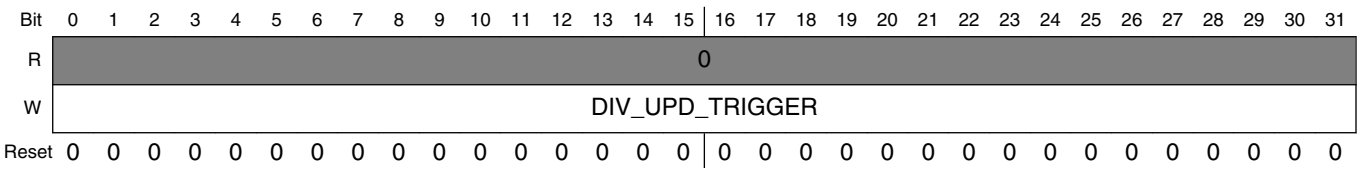
Address: 0h base + D4h offset = D4h

MC_CGM_DIV_UPD_TYPE field descriptions

Field	Description
0 SYS_UPD_TYPE	System Clock Divider Update Type 0 the configuration for each system clock divider is updated immediately on writing to the corresponding CGM_SC_DCi register 1 the configuration for each system clock divider is preloaded on writing to the corresponding CGM_SC_DCi register, and the pre-loaded configurations of all the system clock dividers are updated on writing to the CGM_DIV_UPD_TRIG register

Table continues on the next page...

MC_CGM_DIV_UPD_TYPE field descriptions (continued)



Field	Description
1–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21 AUX10_UPD_TYPE	Auxiliary Clock n Divider Update Type 0 the configuration for each auxiliary clock n divider is updated immediately on writing to the corersponding CGM_ACn_DCi register 1 the configuration for each auxiliary clock n divider is preloaded on writing to the corersponding CGM_ACn_DCi register, and the pre-loaded configurations of all the auxiliary clock n dividers are updated on writing to the CGM_DIV_UPD_TRIG register
22 AUX9_UPD_TYPE	(See the Description for the AUX10_UPD_TYPE bit.)
23 AUX8_UPD_TYPE	(See the Description for the AUX10_UPD_TYPE bit.)
24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25 AUX6_UPD_TYPE	(See the Description for the AUX10_UPD_TYPE bit.)
26 AUX5_UPD_TYPE	(See the Description for the AUX10_UPD_TYPE bit.)
27–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29 AUX2_UPD_TYPE	(See the Description for the AUX10_UPD_TYPE bit.)
30 AUX1_UPD_TYPE	(See the Description for the AUX10_UPD_TYPE bit.)
31 AUX0_UPD_TYPE	(See the Description for the AUX10_UPD_TYPE bit.)

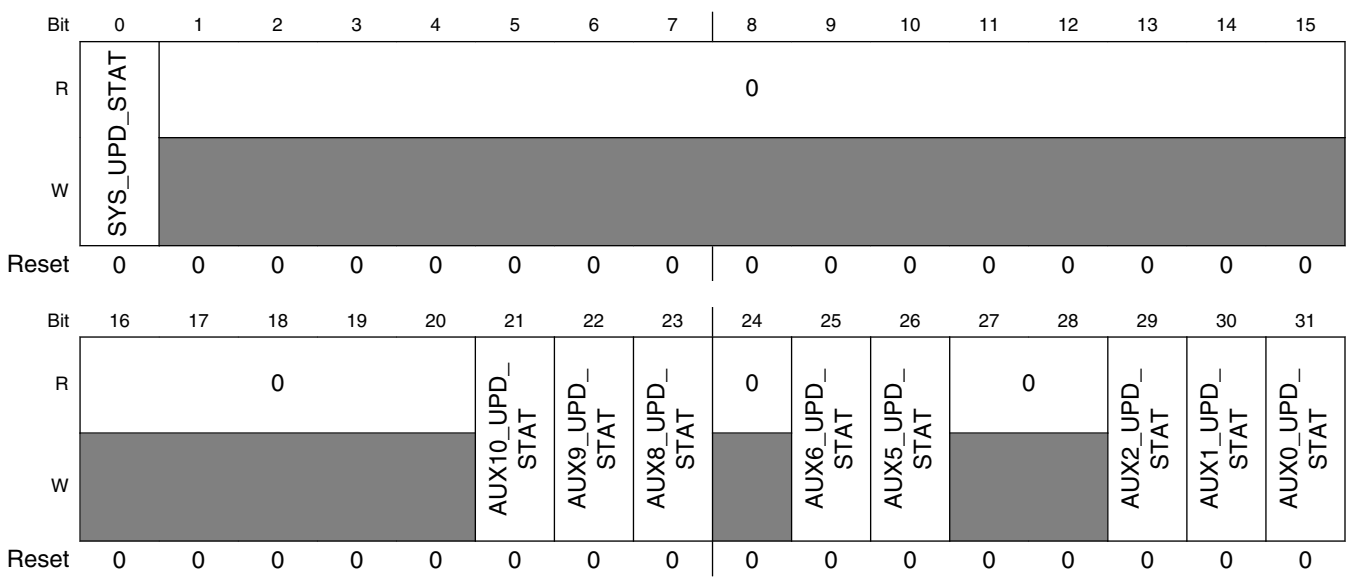
25.3.13 Divider Update Trigger (MC_CGM_DIV_UPD_TRIG)

Writing any value to this register will cause all dividers that have corresponding bits set to "1" in the CGM_DIV_UPD_TYPE register and have pre-loaded configurations to be updated immediately. Reading this register will always return all zeroes.

For usage information, see Section “Divider Update Triggering”.

Address: 0h base + D8h offset = D8h

MC_CGM_DIV_UPD_TRIG field descriptions



Field	Description
0–31 DIV_UPD_ TRIGGER	Writing any value to this register will cause all dividers that have corresponding bits set to "1" in the CGM_DIV_UPD_TYPE register and have pre-loaded configurations to be updated immediately.

25.3.14 Divider Update Status (MC_CGM_DIV_UPD_STAT)

This register indicates whether a divider for each clock is in the process of being updated. If the CGM_DIV_UPD_TYPE[i] is "0", CGM_DIV_UPD_STAT[i] is set to "1" immediately on writing to one of the corresponding divider configuration registers. Otherwise, CGM_DIV_UPD_STAT[i] is set to "1" immediately on writing to the CGM_DIV_UPD_TRIG register if one of the corresponding divider configurations has been pre-loaded. CGM_DIV_UPD_STAT[i] is cleared to "0" as soon as all the corresponding dividers have been updated and the dividers generate the desired frequency.

For usage information, see Section “Divider Update Triggering”.

Address: 0h base + DCh offset = DCh

MC_CGM_DIV_UPD_STAT field descriptions

Field	Description
0 SYS_UPD_STAT	System Clock Divider Update Status 0 the configuration for at least one system clock divider is not being updated 1 the configuration for at least one system clock divider is being updated
1–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21 AUX10_UPD_ STAT	Auxiliary Clock n Divider Update Status 0 the configuration for at least one auxiliary clock n divider is not being updated 1 the configuration for at least one auxiliary clock n divider is being updated
22 AUX9_UPD_ STAT	(See the Description for the AUX10_UPD_STAT bit.)
23 AUX8_UPD_ STAT	(See the Description for the AUX10_UPD_STAT bit.)
24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25 AUX6_UPD_ STAT	(See the Description for the AUX10_UPD_STAT bit.)
26 AUX5_UPD_ STAT	(See the Description for the AUX10_UPD_STAT bit.)
27–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29 AUX2_UPD_ STAT	(See the Description for the AUX10_UPD_STAT bit.)
30 AUX1_UPD_ STAT	(See the Description for the AUX10_UPD_STAT bit.)
31 AUX0_UPD_ STAT	(See the Description for the AUX10_UPD_STAT bit.)

25.3.15 System Clock Select Status (MC_CGM_SC_SS)

This register provides the current system clock source selection.

Address: 0h base + E4h offset = E4h

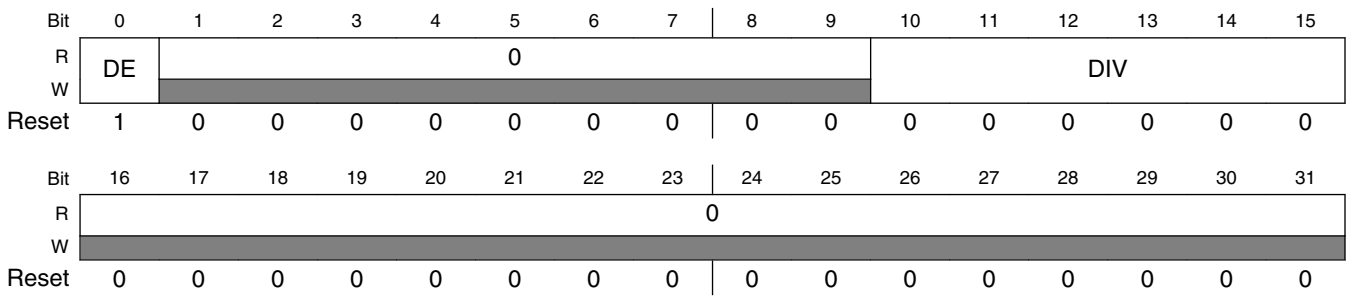
MC_CGM_SC_DC0 field descriptions

Field	Description
0 DE	Divider 0 Enable 0 Disable system clock divider 0 1 Enable system clock divider 0
1–9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
10–15 DIV	Divider i Division Value -0 The resultant FXBAR clock will have a period ‘DIV + 1’ times that of the system clock. If DE is set to ‘0’ (divider 1 is disabled), any write access to the DIV field is ignored and the FXBAR clock remains disabled.
16–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.



25.3.17 System Clock Divider Configuration 1 (MC_CGM_SC_DC1)

This register controls system clock divider 1. See Section "Divider Update Synchronization" for details on division value limitations.

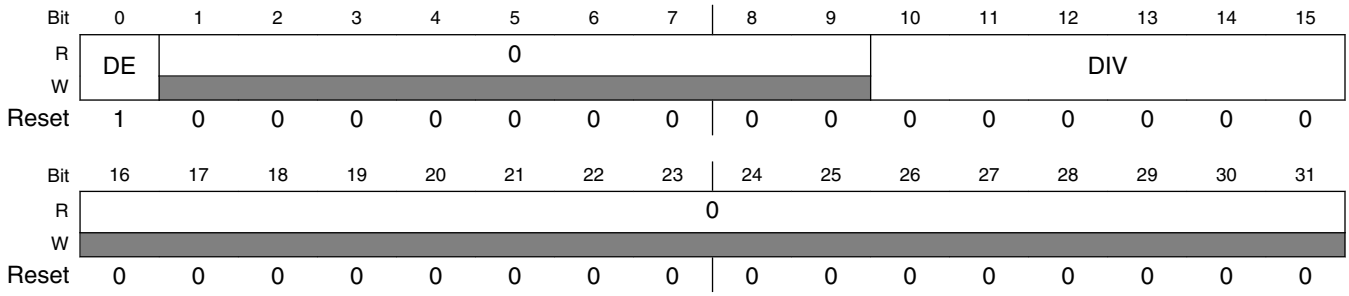
NOTE

Byte and half-word write accesses are not allowed for this register. Such an access will not result in an exception, however the value will not be loaded with the new value.

Address: 0h base + ECh offset = ECh

MC_CGM_SC_DC1 field descriptions

Field	Description
0 DE	Divider 1 Enable 0 Disable system clock divider 1 1 Enable system clock divider 1
1–9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
10–15 DIV	Divider 1 Division Value The resultant SXBAR clock will have a period ‘DIV + 1’ times that of the system clock. If DE is set to ‘0’ (divider 1 is disabled), any write access to the DIV field is ignored and the SXBAR clock remains disabled.
16–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.



25.3.18 System Clock Divider Configuration 2 (MC_CGM_SC_DC2)

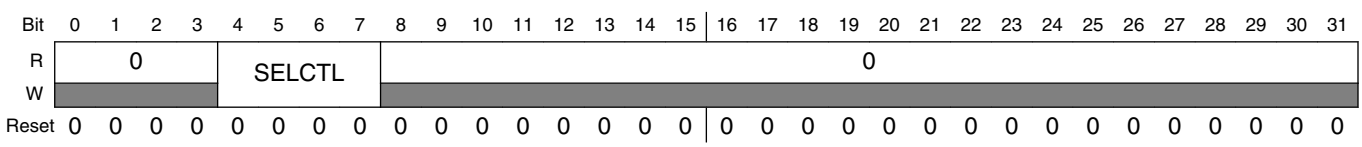
This register controls system clock divider 2. See Section "Divider Update Synchronization" for details on division value limitations.

NOTE

Byte and half-word write accesses are not allowed for this register. Such an access will not result in an exception, however the value will not be loaded with the new value.

Address: 0h base + F0h offset = F0h

MC_CGM_SC_DC2 field descriptions



Field	Description
0 DE	Divider 2 Enable 0 Disable system clock divider 2 1 Enable system clock divider 2
1–9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
10–15 DIV	Divider 2 Division Value The resultant PBRIDGE clock will have a period 'DIV + 1' times that of the system clock. If DE is set to '0' (divider 1 is disabled), any write access to the DIV field is ignored and the PBRIDGE clock remains disabled.
16–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

25.3.19 Aux Clock 0 Select Control (MC_CGM_AC0_SC)

This register is used to select the current clock source for the following clocks:

- undivided: unused
- divided by auxiliary clock 0 divider 0: peripheral clock
- divided by auxiliary clock 0 divider 1: sigma delta ADC clock
- divided by auxiliary clock 0 divider 2: SAR ADC clock
- divided by auxiliary clock 0 divider 3: DSPI clock0
- divided by auxiliary clock 0 divider 4: DSPI clock 1

Address: 0h base + 100h offset = 100h

MC_CGM_AC0_SC field descriptions

Field	Description
0–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4–7 SELCTL	Auxiliary Clock 0 Source Selection Control - This value selects the current source for auxiliary clock 0. 0000 internal RC osc. 0001 external crystal osc. 0010 PLL0 PHI Other values are reserved
8–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

25.3.20 Aux Clock 0 Select Status (MC_CGM_AC0_SS)

This register provides the current auxiliary clock 0 source selection.

MC_CGM_AC10_DC0 field descriptions

Field	Description
0 DE	Divider Enable 0 Disable auxiliary clock 10 divider 0 1 Enable auxiliary clock 10 divider 0
1–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12–15 DIV	Divider Division Value - The resultant Ethernet TXCLK_REF clock will have a period 'DIV + 1' times that of auxiliary clock 10. If DE is set to 0 (divider 0 is disabled), any write access to the DIV field is ignored and the Ethernet TXCLK_REF clock remains disabled.
16–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

25.4 Functional Description

This section describes the functions of the MC_CGM module.

25.4.1 System Clock Generation

The figure below shows the block diagram of the system clock generation logic.The MC_ME provides the system clock select, progressive clock switching control, and switch mask (see MC_ME chapter for more details), and the MC_RGM provides the safe clock request (see MC_RGM chapter for more details). The safe clock request forces the selector to select the clk_sys_src[0] as the system clock and to ignore the system clock select.

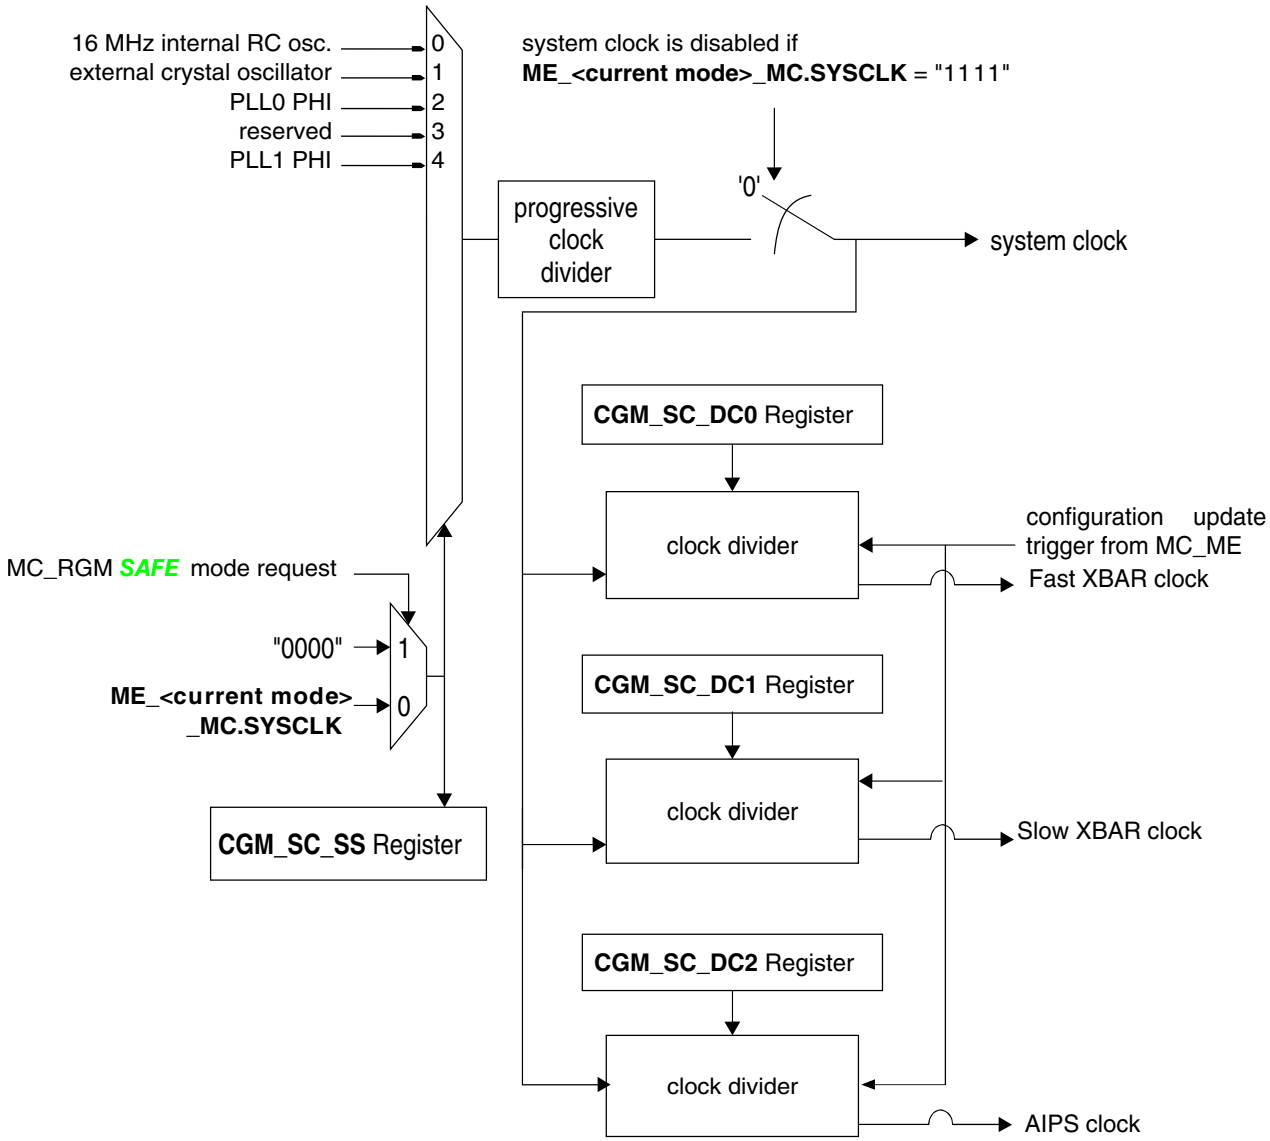

Figure 25-53. MC_CGM System clock generation overview

25.4.1.1 System Clock Source Selection

During normal operation the system clock selection is controlled

- on a ***SAFE*** mode or reset event, by the the MC_RGM
- otherwise, by the MC_ME

25.4.1.2 Progressive System Clock Switching

Based on the power level values of the current and target modes, the MC_ME requests the MC_CGM to ramp the system clock frequency down and/or up. During ramp-down, the rate of the frequency change is based on the **CGM_PCS_SDUR**, **CGM_PCS_DIVC*n***, and **CGM_PCS_DIVE*n*** registers, where *n* corresponds to the current system clock source selection. During ramp-up, the rate of the frequency change is based on the **CGM_PCS_SDUR**, **CGM_PCS_DIVC*n***, and **CGM_PCS_DIVS*n*** registers, where *n* corresponds to the target system clock source selection.

25.4.1.2.1 Generic Clock Change Requirements

For a maximum allowed change of the frequency (f_{chg}) and for a given source clock frequency f_{src} (current or target clock source), the maximum allowed frequency change rate a_{max} is given in the following equation.

$$a_{max} = \frac{f_{chg}}{f_{src}}$$

25.4.1.2.2 Configuration of CGM_PCS_SDUR

The switch duration field **CGM_PCS_SDUR[SDUR]** defines the duration of one system clock switch step in terms of 16 MHz internal RC osc. After the expiration of this time, the module changes the clock divider value which changes the frequency of the system clock.

25.4.1.2.3 Configuration of CGM_PCS_DIVC*n*[RATE]

For a given maximum allowed frequency change rate a_{max} the value d to be programmed into the **PCS_DIVC*n*[RATE]** register is given in the following table.

Table 25-53. MC_CGM CGM_PCS_DIVC*n*[RATE] Values

a_{max}	d = CGM_PCS_DIVC*n*[RATE]	RATE Field Value
0.05	0.012	00001100
0.10	0.048	00110000
0.15	0.112	01110000
0.20	0.184	10111000

25.4.1.2.4 Generic Clock Change Properties

The number *k* of required steps to reach or leave the divided system clock with frequency f_{safe} from the source clock with frequency f_{src} is given in the following equation.

$$k = \left\lceil 0.5 + \sqrt{0.25 - \frac{2\left(1 - \frac{f_{src}}{f_{safe}}\right)}{d}} \right\rceil$$

Where f_{safe} is the frequency of the 16 MHz internal RC osc. clock.

25.4.1.2.5 Clock Ramp-Down

The clock ramp-down starts with the divider value 1 and with the given divider increment value **PCD_DIVC*n*[RATE]** and ends with the given divider value **PCS_DIVE*n*[DIVE]**.

The divider end value for clock ramp-down is given in the following equation.

$$\text{PCS_DIVEn[DIVE]} = \frac{f_{curr}}{f_{safe}} \times 1000 - 1$$

Where f_{curr} is the frequency of the currently selected system clock source.

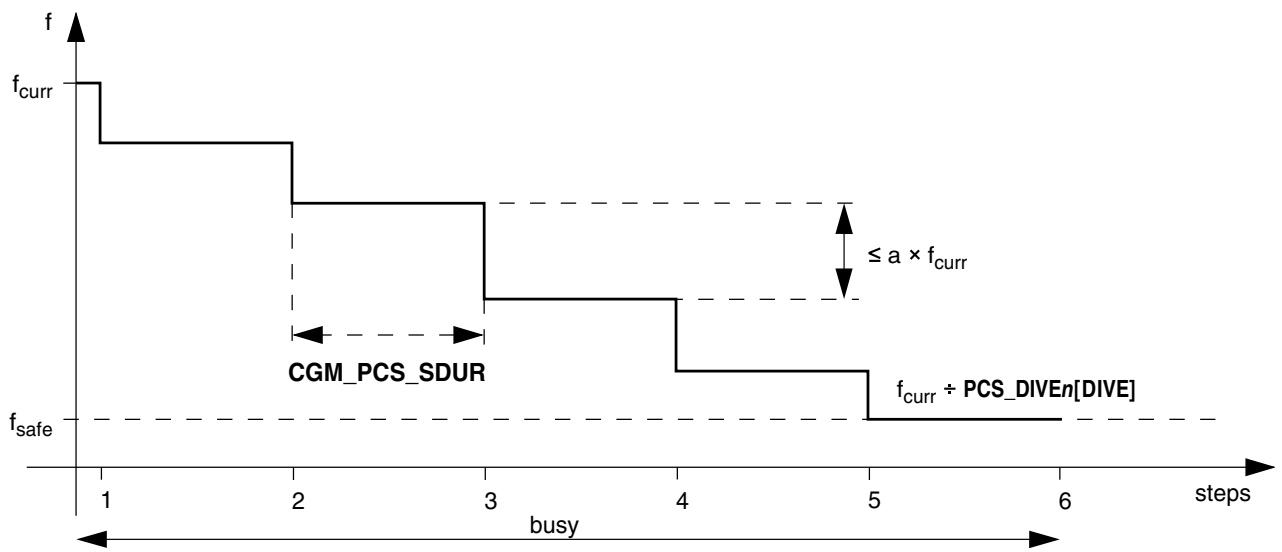

Figure 25-54. MC_CGM System Clock Ramp-Down Timing (k = 6 example)

25.4.1.2.6 Clock Ramp-Up

The clock ramp-up starts with the given divider value **PCS_DIVS*n*[DIVS]** and with the given divider decrement value **PCD_DIVC*n*[INIT]** and ends with the divider value 1.

The initial divider change start value **PCS_DIVC*n*[INIT]** for system clock ramp-up is given in the following equation.

PCS_DIVCn[INIT] = d ×k ×1000

Where k is calculated from the equation in section Generic Clock Change Properties using the target system clock source frequency f_{targ}. The divider start value for clock ramp-up is given in the following equation.

$$PCS_DIVSn[DIVS] = \left(1 + d\frac{k(k+1)}{2}\right) \times 1000 - 1$$

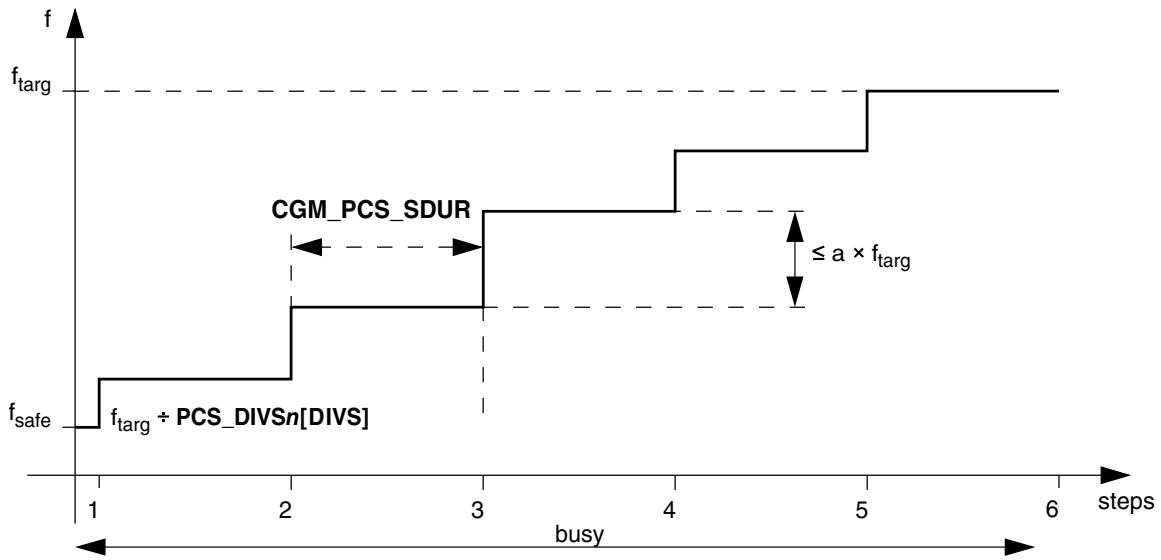

Figure 25-55. MC_CGM System Clock Ramp-Up Timing (k = 6 example)

25.4.1.2.7 PCS code sample

It is highly recommended to use PCS in both directions whenever the system clock frequency changes, while going from one MC_ME mode to another. If system clock frequency changes abruptly, it'll cause sharp current load transition on the voltage supply which may lead to unexpected voltage overshoots and undershoot that may even lead to an LVD / HVD reset.

25.4.1.3 System Clock Disable

During the ***TEST*** mode, the system clock can be disabled by the ME.

25.4.1.4 System Clock Dividers

The MC_CGM generates the following derived clocks from the system clock.

- Fast XBAR clock - controlled by the **CGM_SC_DC0** register
- Slow XBAR clock - controlled by the **CGM_SC_DC1** register
- AIPS clock - controlled by the **CGM_SC_DC2** register

25.4.2 Auxiliary Clock Generation

The figures below show the block diagram of the auxiliary clock generation logic. See the following sections for auxiliary clock selection control:

- "Auxiliary Clock 0 Select Control Register (CGM_AC0_SC)"

- "Auxiliary Clock 1 Select Control Register (CGM_AC1_SC)"
- "Auxiliary Clock 3 Select Control Register (CGM_AC3_SC)"
- "Auxiliary Clock 4 Select Control Register (CGM_AC4_SC)"
- "Auxiliary Clock 6 Select Control Register (CGM_AC6_SC)"
- "Auxiliary Clock 8 Select Control Register (CGM_AC8_SC)"
- "Auxiliary Clock 9 Select Control Register (CGM_AC9_SC)"
- "Auxiliary Clock 10 Select Control Register (CGM_AC10_SC)"

NOTE

All dividers default to the IRC 16MHz clock. The user needs to program the selection register properly to enable the right clock.

25.4.2.1 Auxiliary Clock Dividers

The MC_CGM generates the following derived clocks

- peripheral clock - controlled by the CGM_AC0_DC0 register
- sigma delta ADC clock - controlled by the CGM_AC0_DC1 register
- SAR ADC clock - controlled by the CGM_AC0_DC2 register
- DSPI clock 0 - controlled by the CGM_AC0_DC3 register
- DSPI clock 1 - controlled by the CGM_AC0_DC4 register
- BD LFAST PLL clock - controlled by the CGM_AC1_DC0 register
- SENT clock - controlled by AC2_DC0 register
- eTPU clock - controlled by AC5_DC0 register
- eMIOS clock - controlled by AC5_DC1 register
- CLKOUT - controlled by AC6_DC0 register
- FLEXCAN clock - controlled by AC8_DC0 register
- RTI clock - controlled by AC9_DC0 register
- TXCLK ref clock - controlled by AC10_DC0 register

25.4.3 Dividers Functional Description

Dividers are used for the generation of divided system and peripheral clocks. The MC_CGM has the following control registers for built-in dividers:

- System Clock Divider 0 Configuration Register (CGM_SC_DC0)
- Auxiliary Clock 0 Divider 0 Configuration Register (CGM_AC0_DC0)
- Auxiliary Clock 0 Divider 1 Configuration Registers (CGM_AC0_DC1)
- Auxiliary Clock 0 Divider 2 Configuration Registers (CGM_AC0_DC2)
- Auxiliary Clock 0 Divider 3 Configuration Registers (CGM_AC0_DC3)
- Auxiliary Clock 0 Divider 4 Configuration Registers (CGM_AC0_DC4)
- Auxiliary Clock 1 Divider 0 Configuration Register (CGM_AC1_DC0)
- Auxiliary Clock 1 Divider 1 Configuration Register (CGM_AC1_DC1)
- Auxiliary Clock 2 Divider 0 Configuration Register (CGM_AC2_DC0)
- Auxiliary Clock 5 Divider 0 Configuration Register (CGM_AC5_DC0)
- Auxiliary Clock 5 Divider 1 Configuration Register (CGM_AC5_DC1)
- Auxiliary Clock 6 Divider 0 Configuration Register (CGM_AC6_DC0)
- Auxiliary Clock 8 Divider 0 Configuration Register (CGM_AC8_DC0)
- Auxiliary Clock 9 Divider 0 Configuration Register (CGM_AC9_DC0)
- Auxiliary Clock 10 Divider 0 Configuration Register (CGM_AC10_DC0)

The reset value of all counters is '1'. If a divider has its **DE** bit in the respective configuration register set to '0' (the divider is disabled), any value in its **DIV** field is ignored.

25.4.3.1 Punch-Out Divider Details

All system clock dividers FXBAR, SXBAR, and AIPS are punch-out dividers. Punch-out dividers are integer dividers and are based on a counter/comparator pair. An enable signal generated by this pair is asserted when the counter reaches the value '0' and is deasserted when its value is non-zero. The consequence of this design is that the duty cycle of output clock generated by this pair is not 50%.

A punch-out divided clock can be considered synchronous to other punch-out and 50% duty cycle divided clocks which are sourced by the same clock source selector, but only the system clock dividers are aligned.

Table 25-54. MC_CGM Punch-Out Divider Characteristics

Characteristic	Value
min frequency	$F_{\text{"divider source clock"}} \div$ "division factor"
max frequency	$F_{\text{"divider source clock"}} \div$ "division factor"
duty cycle	"high period of divider source clock" ÷ ("period of divider source clock" × "division factor")

Table continues on the next page...

Table 25-54. MC_CGM Punch-Out Divider Characteristics (continued)

Characteristic	Value
jitter due to divider	0

25.4.3.2 50% Duty Cycle Divider Details

All auxiliary dividers are 50% duty cycle dividers except the one for DSPIM1 and M2. 50% duty cycle dividers generate a real divided clock. The division factor is always an integer but is not restricted to even numbers. The rising edge of the divided clock is always synchronous to the rising edge of the divider source clock, but the falling edge is synchronous to the rising edge or the falling edge depending on whether the division factor is even or odd, respectively.

A 50% duty cycle divided clock can be considered synchronous to other punch-out and 50% duty cycle divided clocks which are sourced by the same clock source selector, but only the system clock dividers are aligned.

Table 25-55. MC_CGM 50% Duty Cycle Divider Characteristics

Characteristic	Value
min frequency	$F_{\text{"divider source clock"}} \div$ "division factor"
max frequency	$F_{\text{"divider source clock"}} \div$ "division factor"
duty cycle	50%[1]
jitter due to divider	0

1. for a division factor of 1, the duty cycle = the duty cycle of the divider source clock

For system clock dividers, $i = 16 \times m$, where m = the divider number. For auxiliary clock dividers, $i = 96 \times n + 16 \times m$, where n = the auxiliary clock number and m = the divider number.

25.4.3.3 Fractional Divider Details

Fractional dividers generate a real divided clock of AUX0_3 (DSPIM0, M2). The division factor is always an integer divided by either 1, 10, 100, or 1,000. Both the rising and the falling edges of the divider source clock are used to generate the rising and falling edges of the divided clock. Therefore, the rising edge of the divided clock may sometimes be synchronous to the rising edge and at other times to the falling edge. The same is true for the divided clock's falling edge.

A fractionally divided clock must be considered asynchronous to all other clocks.

Table 25-56. MC_CGM Fractional Divider Characteristics

Characteristic	Value
min frequency	$F_{\text{"divider source clock"}}$ ÷ "division factor rounded up to the nearest .0 or .5"[1]
max frequency	$F_{\text{"divider source clock"}}$ ÷ "division factor rounded down to the nearest .0 or .5"[1]
duty cycle	50% ± 0.25 × "period of divider source clock" [1]
jitter due to divider	≤ 0.25 × "period of divider source clock"[1]

1. assuming that the duty cycle of the divider source clock = 50%

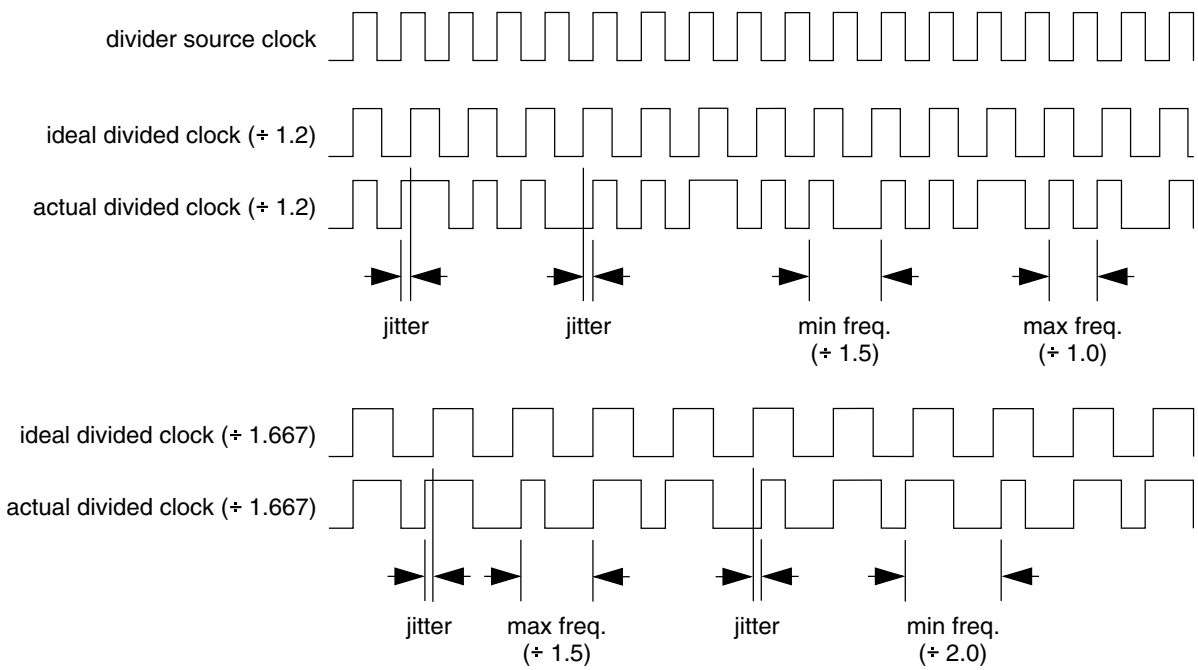

Figure 25-66. MC_CGM Fractional Clock Division Examples

25.4.3.4 Divider Update Synchronization

For the system clock and all the auxiliary clocks, all the associated dividers of the punch-out and 50% duty cycle types are synchronized to each other such that the rising edges of the lower frequency clocks are aligned with those of the higher frequency clocks. This, however, imposes limitations on the division factors which can be used. In order for the synchronization to work properly, each division factor must be selected such that its value is an integer multiple of each division factor that has a lower value.

The following table shows an example of a correct divider configuration.

Table 25-57. MC_CGM Example Clock Division Values Compatible with Divider Synchronization

Divider	Division Factor	Register Value
0	1	**CGM_xC_DC0[DIV]** = 0
1	2	**CGM_xC_DC1[DIV]** = 1
2	6	**CGM_xC_DC2[DIV]** = 5

In this case, clock divider 1 has a division factor greater than that of clock divider 0. Since 2 is an integer multiple of 1, its configuration is correct. Also, clock divider 3 has a division factor that is greater than those of both clock dividers 0 and 1. Since 6 is an integer multiple of 1 and 6 is an integer multiple of 2, its configuration is also correct.

The following table shows an example of an incorrect divider configuration.

Table 25-58. MC_CGM Example Clock Division Values Incompatible with Divider Synchronization

Divider	Division Factor	Register Value
0	1	**CGM_xC_DC0[DIV]** = 0
1	4	**CGM_xC_DC1[DIV]** = 3
2	6	**CGM_xC_DC2[DIV]** = 5

In this case, clock divider 1 has a division factor greater than that of clock divider 0. Since 4 is an integer multiple of 1, its configuration is correct. Also, clock divider 3 has a division factor that is greater than those of both clock dividers 0 and 1. Since 6 is not an integer multiple of 4, its configuration is incorrect.

NOTE

Configuring the clock dividers incorrectly will cause the divided clocks to become unsynchronized. This may lead to lost communication between the clock domains and/or the inability to further change the clock divider division factors without first disabling them or performing a reset.

25.4.3.5 Divider Update Triggering

There are two methods for updating the dividers associated with the system clock and each auxiliary clock: immediate and register triggered. Which method is used for which set of dividers is controlled by the **CGM_UPD_TYPE** register.

Regardless of which method is selected for a given group of dividers, once an update of one of the dividers of that group has been triggered, the associated bit in the **CGM_UPD_STAT** register is set. This bit is then cleared when all the dividers of that group have completed the update process and are running with the current configuration.

25.4.3.5.1 Immediate Divider Update

If a divider group has been configured to be updated immediately (i.e., the corresponding **CGM_UPD_TYPE** register bit = '0'), the configuration of a divider in that group will be applied immediately on the write to that divider's configuration register. The actual update will take some time to actually reach the divider output due to the clock domain crossing and edge alignment mechanisms. Timing examples are shown in the following figures.

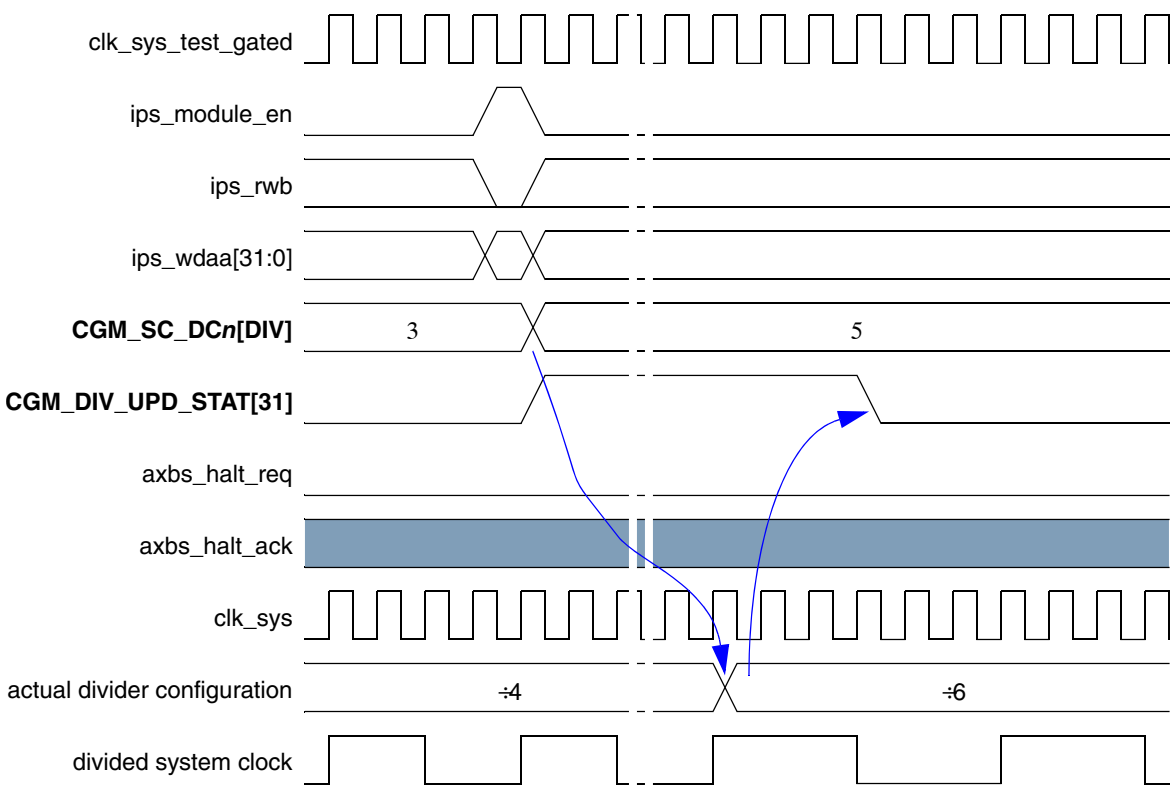

Figure 25-67. MC_CGM Immediate System Clock Divider Update Example

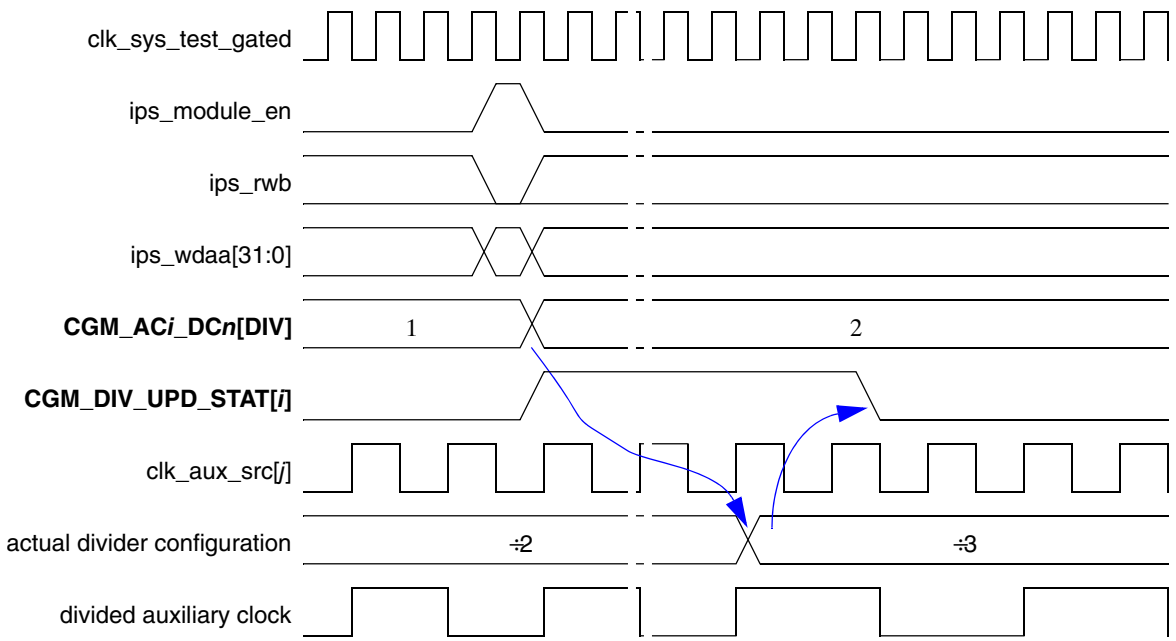

Figure 25-68. MC_CGM Immediate System Clock Divider Update Example

25.4.3.5.2 Software-Triggered Divider Update

If a divider group has been configured to be updated via a software trigger (i.e., the corresponding **CGM_UPD_TYPE** register bit = '1'), the configuration of a divider in that group will not be applied immediately on the write to that divider's configuration register. Instead, the configuratoin in the corresponding configuration register will be applied only when software writes any value to the **CGM_UPD_TRIG** register. The actual update will take some time to actually reach the divider output due to the clock domain crossing and edge alignement mechanisms.

In the case of the system clock dividers, if the SYS_DIV_RATIO_CHNG bit in the CGM_SC_DIV_RC register = `1', the crossbar switch is requested to halt its ongoing transactions, and only after the crossbar switch has acknowledged the request does the update of the system clock dividers take place. Once these updates have completed, the halt request to the crossbar is deasserted.

Timing examples are shown in the following figures.

NOTE

If halting the crossbar can cause a bus master to starve and thus lead to lost data or other problems, it is recommended to vary the system clock divider configurations without changing the ratios and to set CGM_SC_DIV_RC[SYS_DIV_RATIO_CHNG] to `0'.

NOTE

In order to ensure a clean clock divider configuration update, software must check that all ongoing updates have already completed (i.e., all relevant bits in the CGM_DIV_UPD_STAT register are `0') before triggering a new update via the CGM_DIV_UPD_TRIG register.

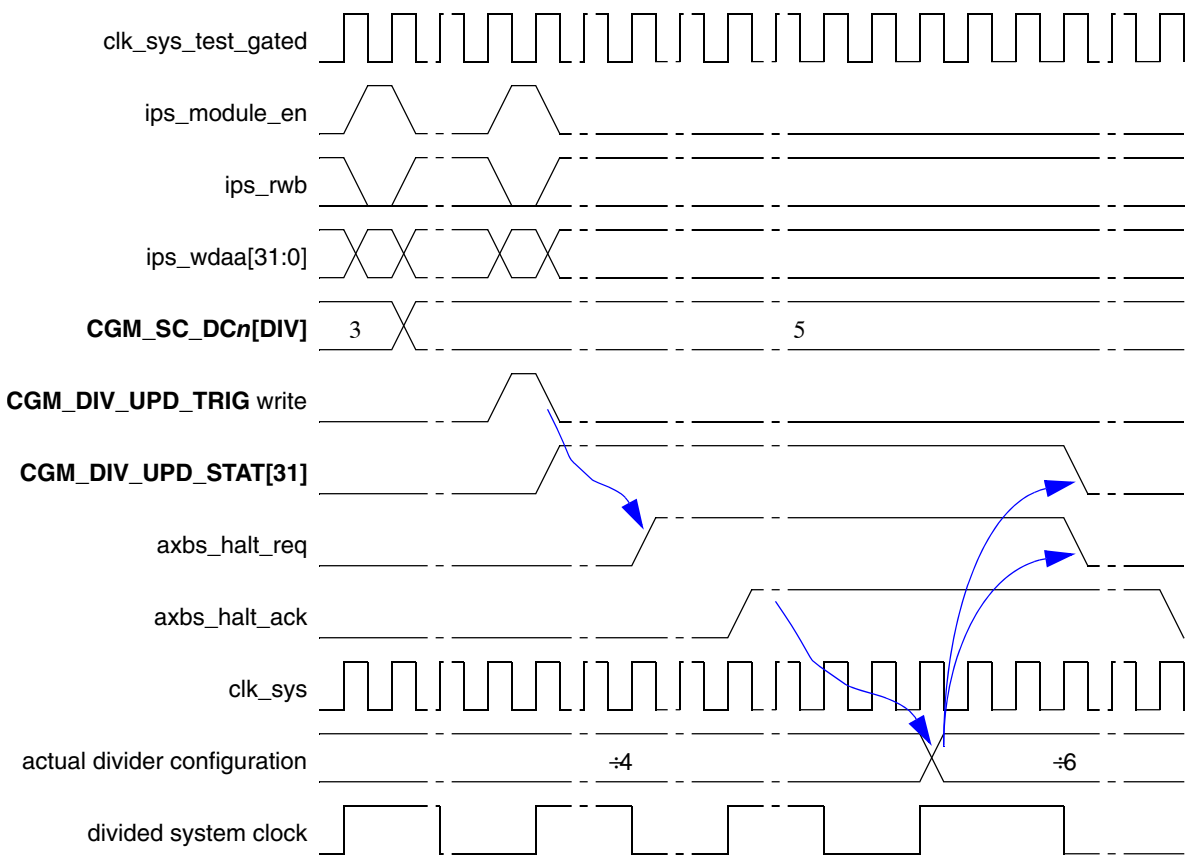

Figure 25-69. MC_CGM Software-Triggered System Clock Divider Update Example (ratio change)

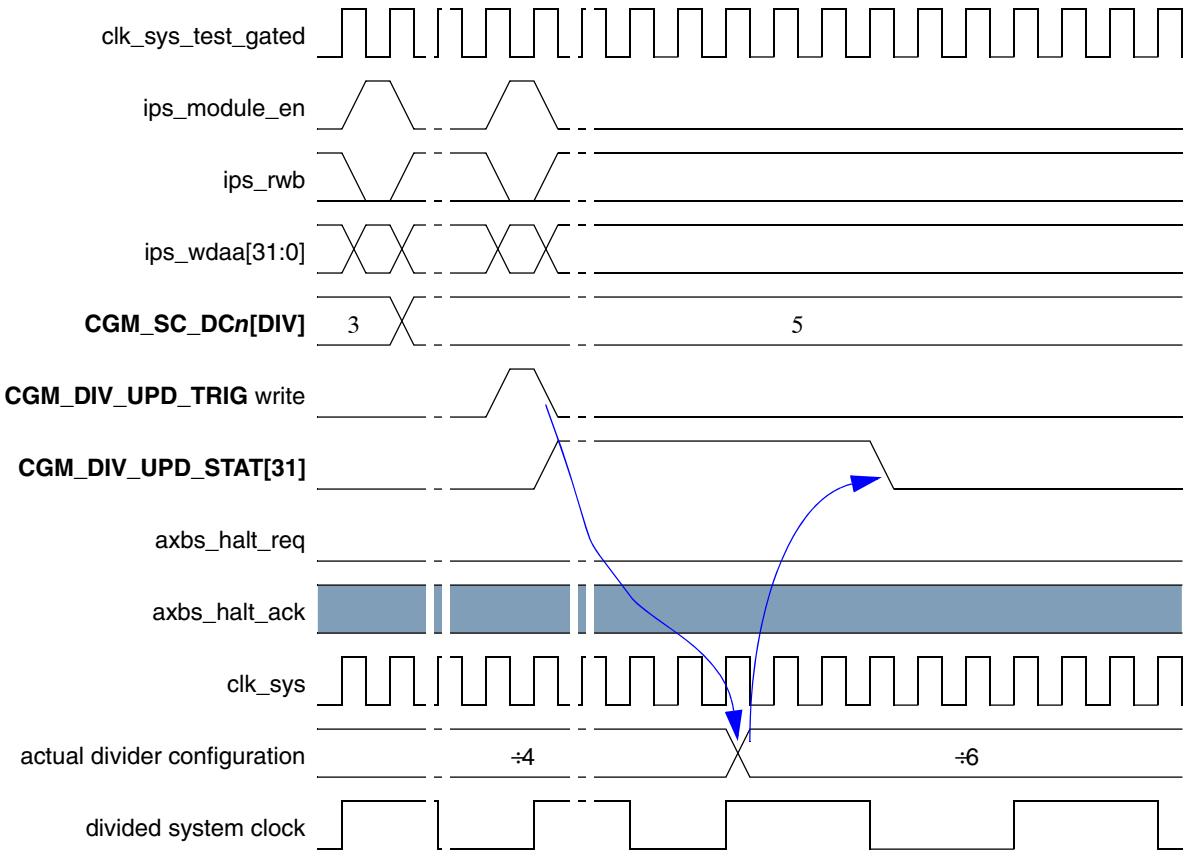

Figure 25-70. MC_CGM Software-Triggered System Clock Divider Update Example (no ratio change)

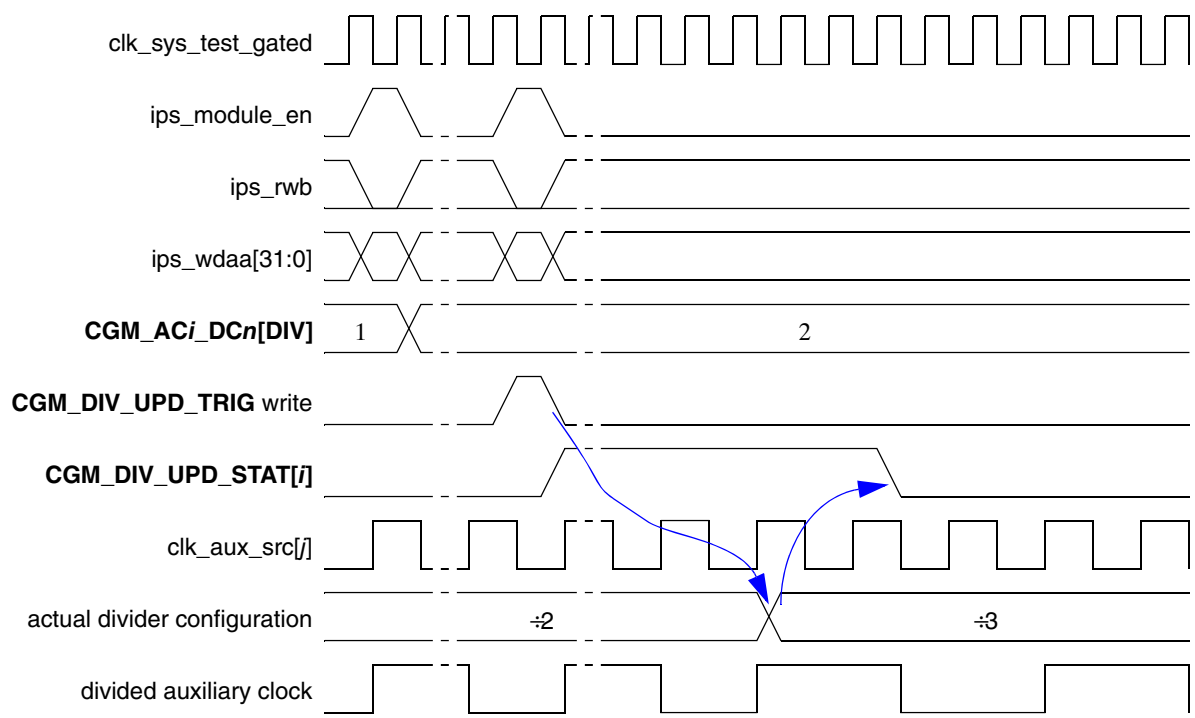

Figure 25-71. MC_CGM Software-Triggered Auxiliary Clock Divider Update Example

25.4.3.5.3 Reset-Triggered Divider Update

When a reset occurs as indicated by the assertion of the ipg_hard_async_reset_b input, all clock dividers are reconfigured to their default values, regardless of any other pending or ongoing divider configuration update.

In the system clock case, in order to prevent frequency overshoot and to allow the highest possible frequency during the device configuration part of the reset sequence, the dividers are updated in three steps as shown in the following figure.

1. safe_clock_busy deassertion edge after ipg_hard_async_reset_b assertion edge causes system clock dividers to switch to division factor = 1
2. sscm_done assertion causes system clock dividers to switch to the default division factor 0 (DIV1)
3. clk_sys_div_def_val_done is asserted when all system clock dividers have completed update to default division factors

The clk_sys_div_def_val_done output is used to indicate to the MC_RGM that the reset sequence can exit reset PHASE3, which ensures that ipg_hard_async_reset_b will not be deasserted until after the system clock dividers have completed updating to their default configurations.

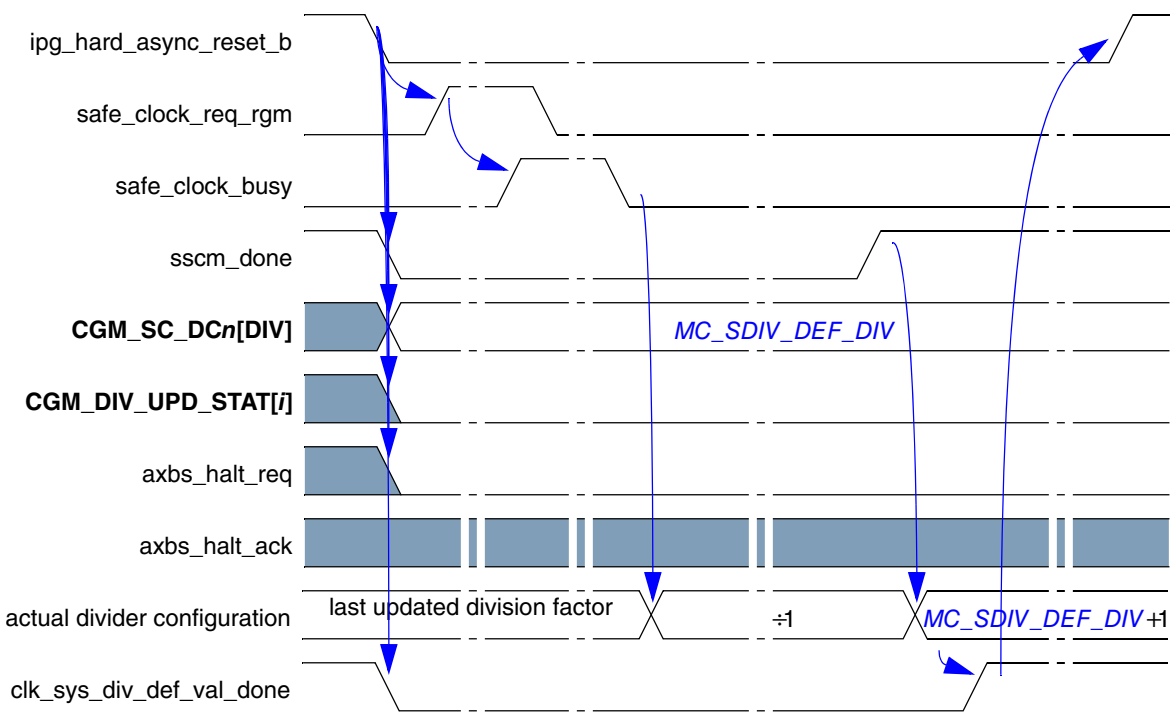

Figure 25-72. MC_CGM Reset-Triggered System Clock Divider Update Example

In the auxiliary clock case, this update takes place immediately on ipg_hard_async_reset_b assertion as shown in the following figure.

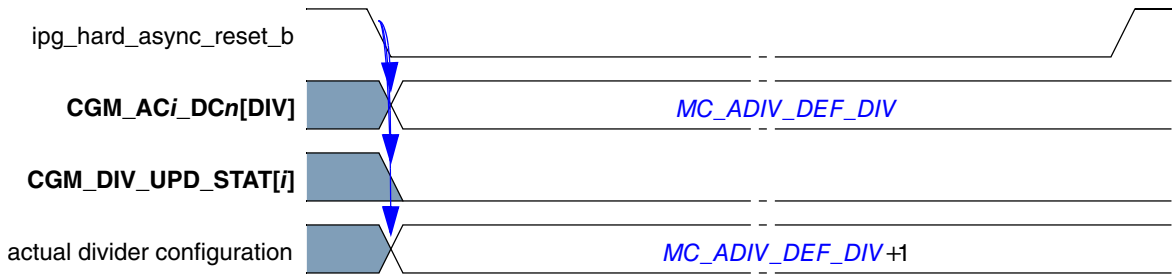

Figure 25-73. MC_CGM Reset-Triggered Auxiliary Clock Divider Update Example

Chapter 26
OSC Digital Interface (XOSC)

26.1 Introduction

The XOSC digital interface is used to control the on-chip oscillator (XOSC) and provide the register interface for the programmable features. Selection of the XOSC as a source clock is controlled by the Clock Generation Module (MC_CGM). The XOSC is enabled and disabled by configuring the Mode Entry Module (MC_ME).

The programmable features of the XOSC digital interface are as follows:

- Oscillator power-down control and status
- Oscillator startup delay
- Oscillator clock available interrupt
- Oscillator bypass mode control

26.2 Functional description

The XOSC digital interface provides control of the on-chip oscillator and the register interface for the mode and startup delay control. The oscillator provides an output clock that is used as an input to the PLL and can be selected as the reference clock for many of the peripherals on the device.

The table below shows the possible configurations of the XOSC.

Table 26-1. XOSC configurations

OSC EN (from MC_ME)	XOSC_CTL[OSCBYP]	XTAL	EXTAL	XOSC Output	XOSC MODE
0	0	Crystal, or left opened	Crystal, or left opened	0	Power down, IDDQ
0	1	x	external clock	Undefined	Reserved, OSC Disabled
1	1	x	external clock	XTALOUT	Bypass, OSC Enabled
1	0	crystal	crystal	XTALOUT	Normal, OSC Enabled

26.2.1 Oscillator power-down control and status

Enabling and disabling of the oscillator is done in the Mode Entry (MC_ME) module (see "Mode Entry Module (MC_ME)" chapter). The ME_<*mode*>_MC[XOSCON] controls the power down of oscillator based on the current device mode (see "MC_ME Memory Map" table for available *modes*). The status of the XOSC is shown in the MC_ME_GS[S_XOSC].

26.2.2 Oscillator startup delay

If enabled, the analog portion of the oscillator is powered-up during Phase3 of the device reset sequence (pre-self-test sequence). In order to allow the oscillator to reach full amplitude before use, the internal counter (OSCCNT) is started when the device exits reset. The counter is driven by the oscillator output clock. When the counter reaches XOSC_CTL[EOCV] × 512, a signal is sent to the MC_ME module, allowing a mode switch to the oscillator (when used as a system clock or an input to the PLL).

The default value for this field after reset depends on implementation and can be found in the XOSC Device Configuration. After reset, software can clear or change the EOCV field in order to shorten or lengthen the delay until the oscillator is ready.

Note

It is advised that if the EOCV value is modified it should be done as early as possible in user code. This will ensure that the new value will be used before OSCCNT reaches the count value.

26.2.3 Oscillator clock available interrupt

An interrupt can be generated when the count value is reached (OSCCNT = XOSC_CTL[EOCV] × 512). The XOSC_CTL[I_OSC] will be set and an interrupt will be generated if the interrupt mask is set (XOSC_CTL[M_OSC] = 1).

26.2.4 Oscillator bypass mode

The oscillator circuit can be bypassed by setting XOSC_CTL[OSCBYP]. This field can only be set by software and is only cleared by a system reset. In bypass mode, the oscillator is disabled and the input clock on the EXTAL pins is level-shifted and driven to the logic on the device. The bypass configuration is independent of the power-down mode of the oscillator.

NOTE

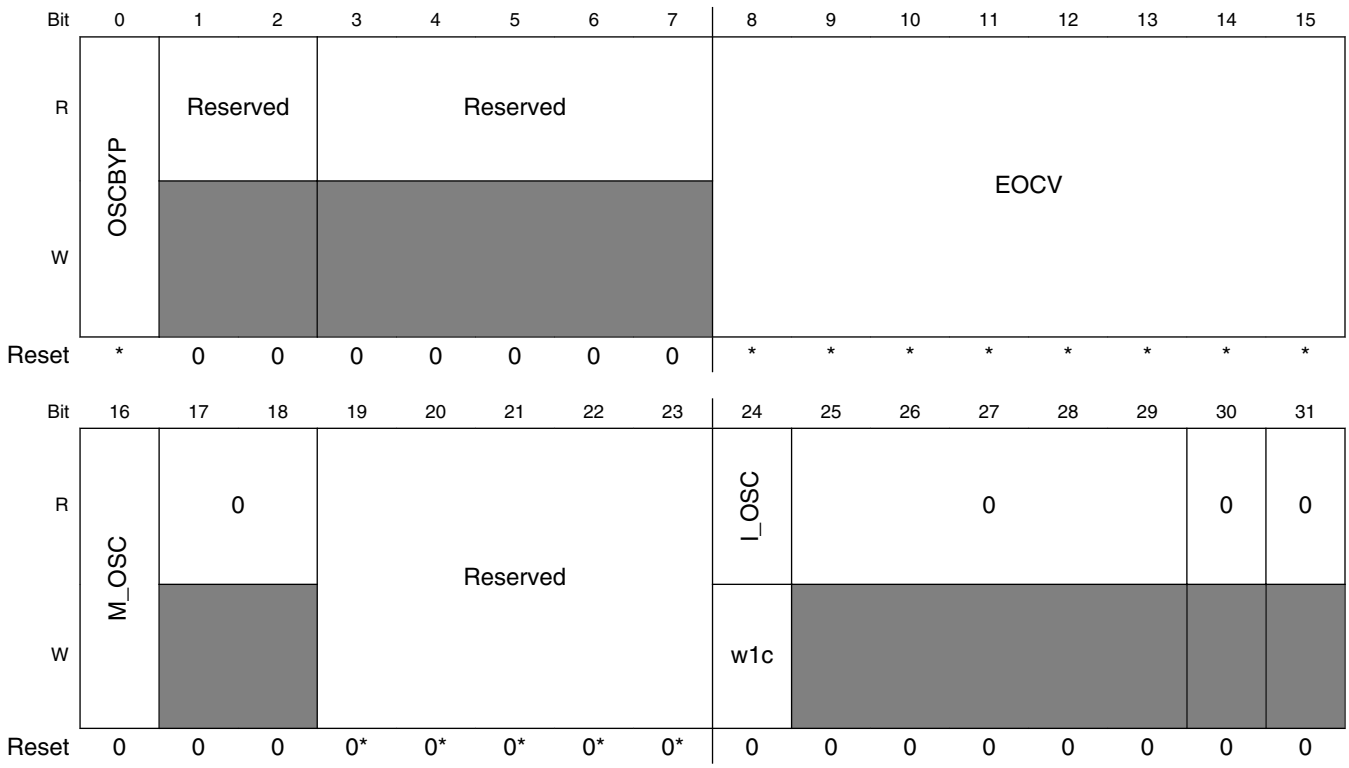
The external oscillator must be running before the XOSC is turned off. If XOSC is being turned on, the status will be updated only after the clock starts toggling.

NOTE

Power down from the MC_ME will have no effect on the oscillator. The bypass clock will continue running in the device. It is ensured that mode transitions from the MC_ME complete successfully by providing bypass information to the MC_ME.

26.3 Memory map and register definition

XOSC memory map



Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	XOSC Control Register (XOSC_CTL)	32	R/W	See section	26.3.1/772

26.3.1 XOSC Control Register (XOSC_CTL)

NOTE

The XOSC_CTL is only writable in supervisor mode.

Address: 0h base + 0h offset = 0h

* Notes:

- Reserved field: This field can be written at any time, but writes have no effect. Reads return the previously written value.
- M_OSC field: See Clocking chapter for reset value.
- EOCV field: See Clocking chapter for reset value.
- OSCBYP field: See Clocking chapter for reset value.

XOSC_CTL field descriptions

Field	Description
0 OSCBYP	Crystal Oscillator bypass This bit specifies whether the oscillator should be bypassed or not. Software can only set this bit. System reset is needed to reset this bit. 0 Oscillator output is used as root clock. 1 EXTAL is used as root clock.
1–2 Reserved	This field is reserved.

Table continues on the next page...

XOSC_CTL field descriptions (continued)

Field	Description
3–7 Reserved	This field is reserved.
8–15 EOCV	End of Count Value These bits specify the end of count value to be used for comparison by the oscillator stabilization counter OSCCNT after reset or whenever it is switched on from the off state. This counting period ensures that external oscillator clock signal is stable before it can be selected by the system. When oscillator counter reaches the value EOCV × 512, oscillator available interrupt request is generated. The OSCCNT counter is kept under reset if oscillator bypass mode is selected.
16 M_OSC	Crystal oscillator clock interrupt mask This bit masks the I_OSC interrupt bit. 0 Crystal oscillator clock interrupt is masked. 1 Crystal oscillator clock interrupt is enabled.
17–18 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
19–23 Reserved	This field is reserved. This field can be written at any time, but writes have no effect. Reads return the previously written value.
24 I_OSC	Crystal oscillator clock interrupt This bit is set by hardware when OSCCNT counter reaches the count value EOCV x 512. It is cleared by software by writing 1. 0 No oscillator clock interrupt occurred. 1 Oscillator clock interrupt pending.
25–29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Chapter 27
IRCOSC Digital Interface

27.1 Introduction

The Internal RC Oscillator Digital Interface (IRCOSC) controls the internal 16 MHz RC oscillator system. This oscillator system includes the main internal RC oscillator (MRC), as well as an internal temperature sensor and an internal voltage regulator used to compensate external variations in temperature and voltage. It also provides access to trimming information used for safety implementations.

27.2 Functional description

The IRCOSC provides a high frequency (f_{MRC}) clock with a nominal frequency of 16 MHz. After deassertion of reset, the output clock is available after a short time (see the Data Sheet for timing details) which is required for stabilization. The IRCOSC status is updated in the MC_ME_GS[S_IRC] field (see the "Mode Entry Module MC_ME" chapter).

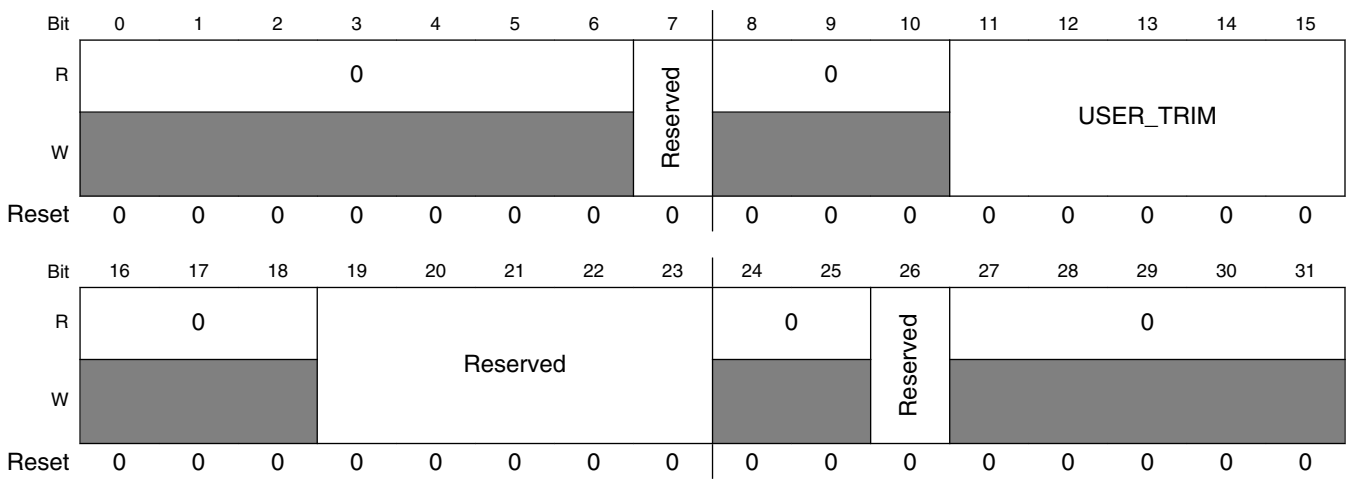
During a power on reset sequence the following are initialized from TEST flash memory:

- Native trimming bits
- Fine trimming bits
- TSENS code bits

The IRCOSC output frequency can be trimmed by configuring IRCOSC_CTL[USER_TRIM[4:0]]. The USER_TRIM bits can be programmed to modify internal capacitor/resistor values to match output clock frequency with δf_{var_SW}, as defined in the Data Sheet.

27.3 Memory map and register definition

IRCOSC memory map



Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	IRCOSC Control Register (IRCOSC_CTL)	32	R/W	See section	27.3.1/776

27.3.1 IRCOSC Control Register (IRCOSC_CTL)

The IRCOSC_CTL contains user programmable parameters.

IRCOSC_CTL is writable only in supervisor mode.

Address: 0h base + 0h offset = 0h

IRCOSC_CTL field descriptions

Field	Description
0–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 Reserved	This field is reserved. This bit can be written with any value, but writes are ignored. A read returns last written value.
8–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11–15 USER_TRIM	User trimming bits with respect to nominal factory frequency The MSB of the USER_TRIM bits is used to determine whether the frequency will be increased or decreased. If MSB = 0 then a change in USER_TRIM[3:0] will decrease the frequency, and likewise, if MSB = 1 then a change in USER_TRIM[3:0] will increase the frequency. Frequency trimming calculation shows how RCOSC_CTL[USER_TRIM] field is used to trim the IRCOSC frequency.
16–18 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

IRCOSC_CTL field descriptions (continued)

Field	Description
19–23 Reserved	This field is reserved. This field can be written at any time, but writes have no effect. Reads return the previously written value.
24–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26 Reserved	This field is reserved. This field may sometimes have the value of 1, and can be cleared by writing a 1 to this bit. However, this field has no effect on the IRCOSC or chip behavior.
27–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

27.3.2 Frequency trimming calculation

Table 27-3. IRCOSC_CTL[USER_TRIM] frequency trimming calculation

USER_TRIM[4:0] value	Frequency
....	....
10011	$f + (3 \cdot \delta f_{TRIM})$
10010	$f + (2 \cdot \delta f_{TRIM})$
10001	$f + \delta f_{TRIM}$
10000	f
00000	f
00001	$f - \delta f_{TRIM}$
00010	$f - (2 \cdot \delta f_{TRIM})$
00011	$f - (3 \cdot \delta f_{TRIM})$
....	....

NOTE

See the data sheet for δf_{TRIM} value and min/max frequency variations.

Chapter 28
RAM Controller (PRAMC)

28.1 Introduction

This section provides an overview of the Platform RAM Controller. The RAM controller acts as an interface between the system bus (AHB-Lite 2.v6) and the integrated system RAM. It converts the protocols between the system bus and the dedicated RAM array interface.

The RAM controller supports two 64-bit AHB interfaces and a 64-bit RAM array interface. The primary AHB port provides a connection to the platform crossbar for direct RAM access from the various crossbar masters. The backdoor AHB port provides a connection from the flash controller to facilitate calibration overlay access. Shown below in Figure 28-1 is a simplified block diagram depicting the position of the RAM controller within a typical platform architecture.

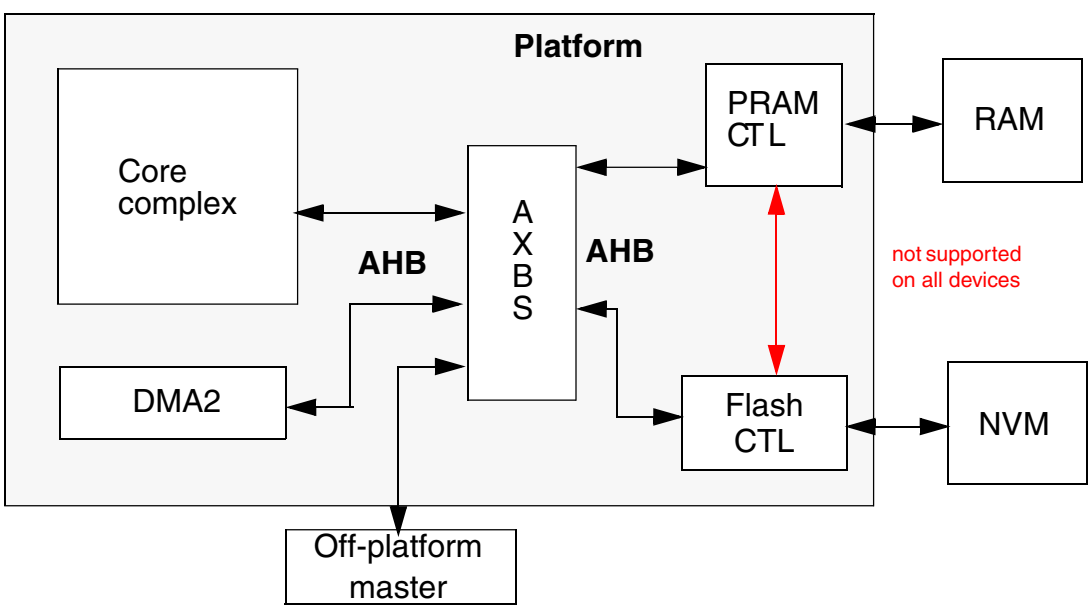


Figure 28-1. Simplified platform block diagram

The following list summarizes the key features of the RAM controller:

- System bus supports 64-bit data + 8-bit ECC AHB interfaces
- Array interface supports a 64-bit data + 8-bit ECC interface
- Late-write support via 64-bit data + 8-bit ECC storage buffer to support single-cycle write accesses
- Configurable read access timing (zero or one wait-state programmable) allowing use in large range of frequency targets
- Read-modify-write operation to support array write size less than a doubleword

The address path of the RAM controller contains a mux that chooses among the addresses presented on the system bus for a read request, either the address from the temporary holding register or the address from the late-write buffer. The temporary holding register contains the address which was presented during the AHB address phase of the write request. The request is stalled from being presented to the RAM by one cycle in order to present simultaneously the address and associated write data, which is not valid until the AHB dataphase. The late-write buffer holds write requests which are delayed to facilitate single-cycle response on the system bus.

The read datapath contains a mux that chooses the source of the read data to be presented on the system bus on a read request. In the event that a read request matches the contents of the late-write buffer, a RAM access is not required and the late-write buffer contents are selected onto the read databus. Otherwise, the read data is a result of a RAM access. Along with the read and write data, the corresponding ECC codewords traverse the entire datapath of the RAM controller, including the late-write storage buffer, to support end-to-end ECC (e2eECC) coverage.

The write datapath contains the mux that chooses the source of the write data as well as the control logic for generating read-modify-write operations on writes that are less than 64 bits in size. A write operation can be performed to empty the contents of the late-write buffer. In the case of back-to-back writes, the write may be forced to bypass the late-write buffer and instead be stored directly, precisely in the RAM.

28.2 SRAM controller memory map and register definition

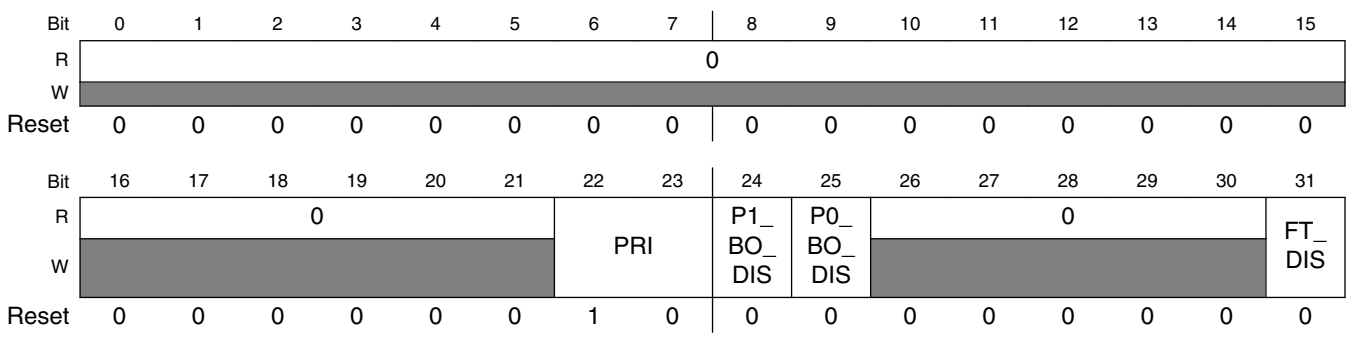
The RAM controller module provides an IPS programming model mapped to a standard on-platform peripheral slot. The programming model can only be referenced using a 32-bit (word) access. Attempted references using different access sizes or to undefined (reserved) addresses generate an IPS error termination.

NOTE

Attempted updates to the PRAMC programming model while a PRAMC operation is in progress will result in non-deterministic behavior. Software must be architected to avoid this scenario by ensuring that PRAMC configuration changes are made only during system boot or when only one master is enabled. In multi-core devices, update the PRAMC configuration only when one core is active and no other masters, e.g., DMA or communications modules, are enabled. Move any instruction execution or memory references outside the system RAM while updating the PRAMC configuration, e.g., to the core local memory space.

PRAMC memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	Platform RAM Configuration Register 1 (PRAMC_PRCR1)	32	R/W	0000_0200h	28.2.1/781



28.2.1 Platform RAM Configuration Register 1 (PRAMC_PRCR1)

The Platform RAM Configuration Register 1 (PRCR1) is used to specify operation of the RAM controller.

NOTE

This register is accessible only in supervisor mode. Accesses in user mode return a transfer error.

Address: 0h base + 0h offset = 0h

PRAMC_PRCR1 field descriptions

Field	Description
0–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

PRAMC_PRCR1 field descriptions (continued)

Field	Description

24 P1_BO_DIS	Port p1 read burst optimization disable. **NOTE:** The number of cycles taken for a RAM access can vary ±1 clock cycle depending on the RAM speed relative to the PRAMC controller clock frequency. If system RAM is running at the same frequency as the PRAMC controller, a random initial access takes 2 clock cycles. If system RAM is running at a slower frequency, a random initial access may take 3 clock cycles. Subsequent burst beats take either 1 or 2 cycles depending on RAM speed relative to the PRAMC controller clock frequency. 0 64-bit WRP4 read bursts are optimized such that the controller returns a 2-1-1-1 response when PRCR1[FT_DIS]=1 1 64-bit WRP4 read bursts are not optimized; the controller returns a 2-2-2-2 response when PRCR1[FT_DIS]=1
25 P0_BO_DIS	Port p0 read burst optimization disable. **NOTE:** The number of cycles taken for a RAM access can vary ±1 clock cycle depending on the RAM speed relative to the PRAMC controller clock frequency. If system RAM is running at the same frequency as the PRAMC controller, a random initial access takes 2 clock cycles. If system RAM is running at a slower frequency, a random initial access may take 3 clock cycles. Subsequent burst beats take either 1 or 2 cycles depending on RAM speed relative to the PRAMC controller clock frequency. 0 64-bit WRP4 read bursts are optimized such that the controller returns a 2-1-1-1 response when PRCR1[FT_DIS]=1 1 64-bit WRP4 read bursts are not optimized; the controller returns a 2-2-2-2 response when PRCR1[FT_DIS]=1
26–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 FT_DIS	Flow through disabled. This field defines the AHB response on reads. The state of this field has no impact on the response latency on writes. This bit is cleared by hardware reset. **NOTE:** Do not change the FT_DIS bit value while accessing system RAM. Relocate code programming the FT_DIS bit to another memory area, e.g., local core memory. 0 RAM read data is passed directly to the system bus, incurring no additional latency 1 RAM read data is registered prior to returning on the system bus, incurring 1 extra cycle of latency

28.3 Functional description

This section describes the functions of the RAM controller.

28.3.1 Read and Write operations

The RAM controller processes read and write requests to on-chip RAM and provides a register interface for access to performance tuning functions.

NOTE

The RAM controller register interface is accessible only in supervisor mode. Accesses in user mode return a transfer error.

28.3.1.1 Reads

Read transfers, of any size, can be configured to complete with a zero or one additional wait state response on the system bus.

28.3.1.2 Optional read wait-state

The RAM controller can be optionally programmed to register RAM read data prior to returning it on the system bus. Setting the PRCRx[FT_DIS] field inserts a register in the read data path for use when operating the controller at high frequencies. The state of PRCRx[FT_DIS] field has no effect on writes.

A random, initial access will take 2 clock cycles (2T) to complete if PRCRx[FT_DIS]=0, and a WRAP4 burst will have an access time of 2-2-2-2. A random, initial access will take 3 clock cycles (3T) to complete if PRCRx[FT_DIS]=1, and a WRAP4 burst will have an access time of 3-2-2-2.

NOTE

The number of cycles taken for a RAM access can vary ±1 clock cycle depending on the RAM speed relative to the PRAMC controller clock frequency. If system RAM is running at the same frequency as the PRAMC controller, a random initial access takes 2 clock cycles. If system RAM is running at a slower frequency, a random initial access may take 3 clock cycles. Subsequent burst beats take either 1 or 2 cycles

depending on RAM speed relative to the PRAMC controller clock frequency.

28.3.2 Writes

This section discusses various write operations of the RAM controller.

28.3.2.1 64-bit writes

Aligned 64-bit writes execute in a single AHB data phase cycle, allowing for zero wait states on back-to-back writes of these sizes. If, during the data phase of a write, a read is requested on the AHB, the write is registered in the late-write buffer, allowing the read to take place without a wait state. The valid buffered or late-write data is stored on the next available array address phase.

Back to back 64-bit writes execute slightly differently whereby the first write bypasses the late-write buffer. Rather, the write data is stored directly to the array in the same cycle in which it is valid on the AHB.

28.3.2.2 Less than 64-bit writes

Writes of size less than 64 bits incur a read-modify-write action as a consequence of the ECC coding scheme's 64-bit granularity. In the case of a read-modify-write action, the RAM controller performs SEC/DED on the read data. The write data is merged into the appropriate byte lanes along with the potentially corrected read data. A new codeword is generated based on the newly formed doubleword. The newly formed doubleword and its associated checkbits are subsequently written to the RAM. Figure 28-3 provides details on the read-modify-write datapath. For details on the ECC coding scheme, refer to Reliability considerations.

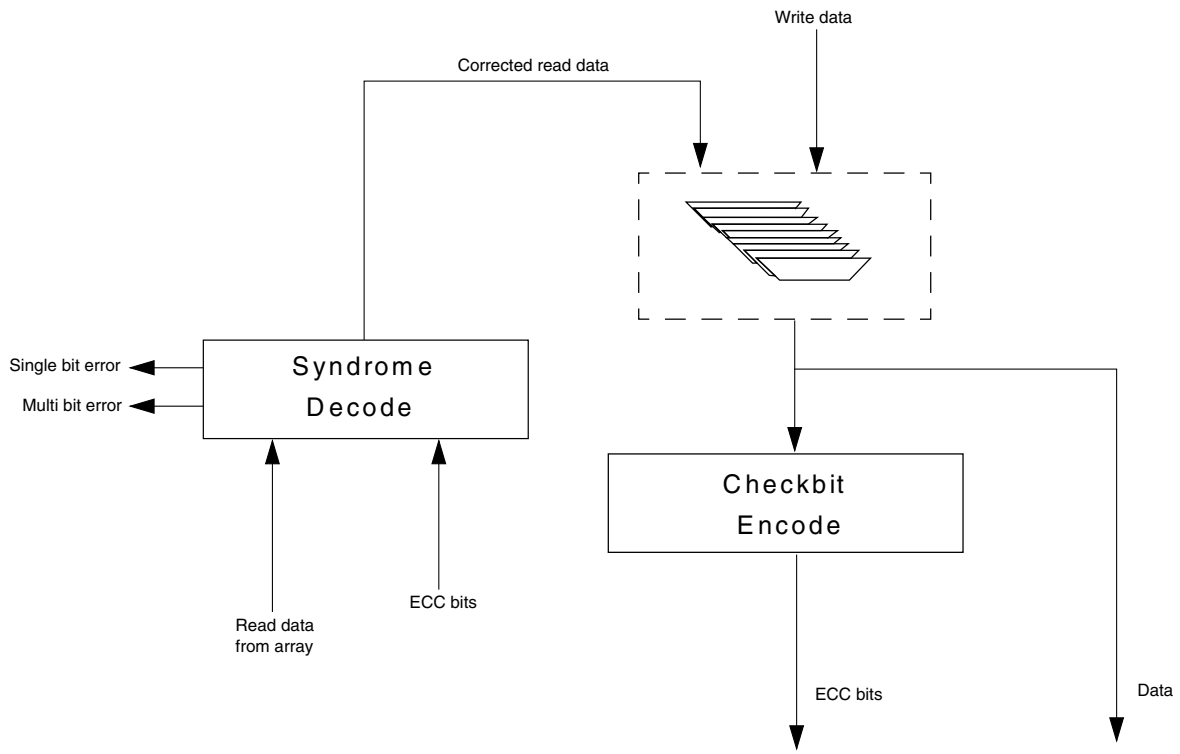

Figure 28-3. Read-modify-write datapath

On a read-modify-write operation, the array read data is registered after it is decoded and before it is merged with the AHB write data. Therefore, writes of size less than 64 bits require the insertion of one wait state before the data phase can be completed.

28.3.2.3 Unaligned writes

The RAM controller is compliant with the AMBA-AHB2.v6 Extensions specification with regard to byte strobes. The size of the transfer is sufficient to cover all bytes being written and covers more bytes in the case of an unaligned transfer. The address of the transfer is rounded down to the nearest boundary of the size of the transaction.

NOTE

Unaligned writes always generate read-modify-write operations in the RAM controller in order to preserve the validity of the ECC codeword.

28.4 Initialization/application information

It is essential that each memory address be written to a known value before it is read, to initialize the ECC. This includes reads generated from the read-modify-write operation which occurs when a write transfer of less than 64 bits or an unaligned write is requested. Without writing an address to a known value first, a read from this address will most likely generate an uncorrectable ECC event.

One possibility for initializing PRAMC memory space is to use a stored 64-bit word instruction such as Store Multiple Word (e_stmw) in Power Architecture VLE.

28.5 Reliability considerations

This section discusses reliability considerations of the RAM controller.

28.5.1 Hsiao ECC algorithm

The e2eECC scheme implements a single-error correction, double-error detection (SECDED) code using the so-called Hsiao odd-weight column criteria. These codes are named for M.Y. Hsiao, an IBM researcher who published extensively in the early 1970s on SECDED codes better suited for implementation in protecting (mainframe) computer memories than traditional Hamming codes.

The Hsiao codes are Hamming distance 4 implementations which provide the SECDED capabilities. The minimum odd-weight constraints defined by Hsiao are relatively simple in the resulting implementation of the parity check H matrix which defines the association between the data (and address) bits and the checkbits. They are:

1. There are no all-zeroes columns.
2. Every column is distinct.
3. Every column contains an odd number of ones, and hence is "odd weight".

In defining the H-matrix for this family of devices, these requirements from Hsiao were applied. Additionally, there are a variety of ECC codeword requirements associated with specific functional requirements associated with the system RAM that further dictated the specific column definitions. In any case, the resulting ECC is organized based on 64 data bits plus 29 address bits (the upper bits of the 32-bit address field minus the 3 bits which select the byte within the 64-bit (8-byte) data field.

The basic H-matrix for this (101, 93) code (93 is the total number of data bits, 101 is the total number of data bits (93) plus 8 checkbits) is shown in the following table. A '*' in the table indicates the corresponding data or address bit is XOR'ed to form the final checkbit value on the left. For 64-bit data writes, the table sections corresponding to D[63:32], D[31:0], and A[31:3] are logically summed (output of each table section is XOR'ed) together to the final value driven on the hwchkbit[7:0] outputs. Note that this table uses *the AHB bit numbering convention where bit[0] is the least significant bit*.

Table 28-3. RAM controller basic H-matrix definition

		XOR sum	Data Bit[1, 1]																																					
			Byte 7								Byte 6								Byte 5								Byte 4

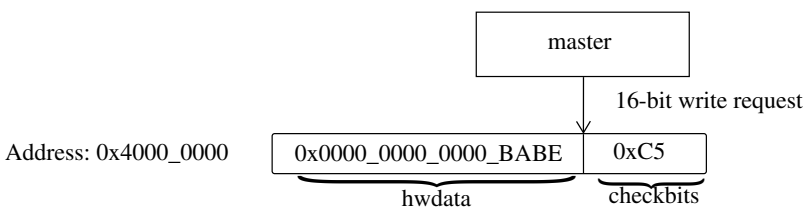
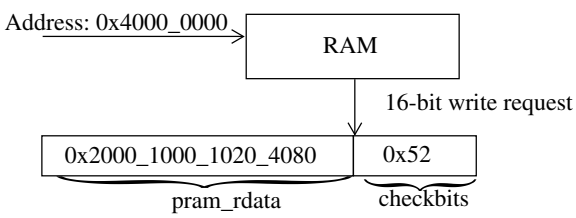
1. Bit numbering is AHB convention: bit 0 is LSB. D[7:0] corresponds to byte at address 0. D[63:56] corresponds to byte at address 7.



2. Bit numbering is AHB convention: bit 0 is LSB. D[7:0] corresponds to byte at address 0. D[63:56] corresponds to byte at address 7.

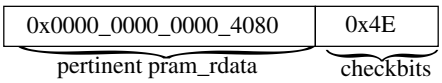
28.5.1.1 e2eECC considerations on less-than-64-bit write transactions

Recall writes of size less than 64-bit incur a read-modify-write action as a consequence of the ECC coding scheme 64-bit granularity. In the case of a read-modify-write action, the RAM controller performs SEC/DED on the read data. The RAM controller uses the following checkbit manipulation technique to ensure any faults in the PRAMC control logic associated with performing the read-modify-write action will ultimately be detectable by e2eECC:



- On an 8-, 16-, or 32-bit write request, the write data is presented by the master on the AHB bus in the correct byte lanes, with the non-pertinent byte lanes zeroed out, and the associated checkbit is based on this "zero-padded" write data.

  Consider the following example whereby the master presents a 16-bit write request at address 0x40000000:



- The RAM controller detects that the request is a less-than-64-bit write request and initiates a read to address 0x40000000. An ECC check and potential single-bit correction is performed on the data returned from the RAM. In addition, the ECC event is reported to the Memory Error Management Unit (MEMU).

  If a non-correctable ECC event is detected, the AHB request is terminated with error on the system bus. In addition, the ECC event is reported to the MEMU.

- The RAM controller isolates the pertinent byte lanes of the read data by zero-padding the non-pertinent byte lanes and calculating the checkbit contribution associated with the read data in the byte lanes to be updated as a result of the write request.

- Merge the non-pertinent read data bytes with the write data in the appropriate byte lanes. Take the checkbit value that was stored in the RAM and remove the checkbit contribution associated with the read data in the byte lanes to be updated. Then introduce the checkbits associated with the write data. The result is ultimately a checkbit value associated with the complete 64-bit data to be written to the array.

This technique calculates the ultimate checkbit value on a read-modify-write transaction through a series of data manipulations, taking care to avoid discarding the original checkbits provided by the requesting master, such that faults in the crossbar (XBAR) and RAM controller datapath and control logic are covered by e2eECC.

Malfunction of the ECC logic described above may result in the corruption of the SEC/DED event reporting. The RAM controller performs EDC after ECC check on all read-modify-write transactions. If a mismatch is detected, indicating a failure in the ECC logic, the event is reported to the FCCU module.

Chapter 29
Flash memory controller

29.1 Flash memory controller (PFLASH) chip-specific module information

29.1.1 PFCR1[RWSC]

Although the PFLASH_PFCR1[RWSC] field is 5 bits wide, the MSB of this field has no effect on this chip.

29.2 Introduction

The flash memory controller has these functions:

- It acts as an interface between the system bus (AHB-Lite 2.v6) and the flash memory array.
- It serves as the interface to the on-chip overlay RAM.
- It serves as the interface to on-chip System RAM that can be used as overlay RAM.
- It serves as the interface to the off-chip buddy device.[1]

The flash memory controller supports two 64-bit AHB buses and a 256-bit read data interface from each flash memory array. Each AHB port contains a 4-entry, 2-way set-associative mini-cache as well as an associated controller that prefetches sequential lines of data from the flash arrays into the mini-cache. This buffer mechanism serves to deliver flash read data with zero-wait state response on lines that reside in the cache. AHB requests that miss the cache generate the needed flash array access and are forwarded to the AHB upon completion. Each mini-cache entry is 256 bits in size, matching the flash array page size and providing 256 bytes of total buffered storage. Along with the read and

1. The term "buddy device" refers to an optional companion chip with additional memory and debug features that is paired with a production chip during system development. It is not used in production devices.

write data, the corresponding ECC codewords traverse the entire datapath of the flash memory controller, including the mini-cache, to support end-to-end ECC (e2eECC) coverage.

29.3 Features

The following list summarizes the key features of the flash memory controller:

- Two 64-bit AHB interface ports (p0, p1) allowing simultaneous access to dedicated prefetch mini-cache per slave port.
- 256-bit read data bus + 64-bit write data bus
- Configurable read buffering and line prefetching support via 4-entry, 2-way set-associative mini-cache plus prefetch controller per AHB port to provide single-cycle "buffer hit" read response.
- Configurable access control based on read/write and AHB master ID attributes.
- Configurable access timing (wait-state programmable) allowing use in a wide range of frequency targets.
- Optional address pipelining capability to maximize throughput.
- Support for reporting of single- and multi-bit flash ECC events on a 64-bit doubleword boundary.
- Configurable overlay remapping of logical flash accesses to on-chip calibration RAM, extended off-chip calibration RAM, on-chip system RAM
- Nexus trace stream interface supports message dumping to the on-chip overlay RAM

29.4 Block diagrams

Figure 29-1 provides a block diagram showing the flash memory controller and the attached flash array.

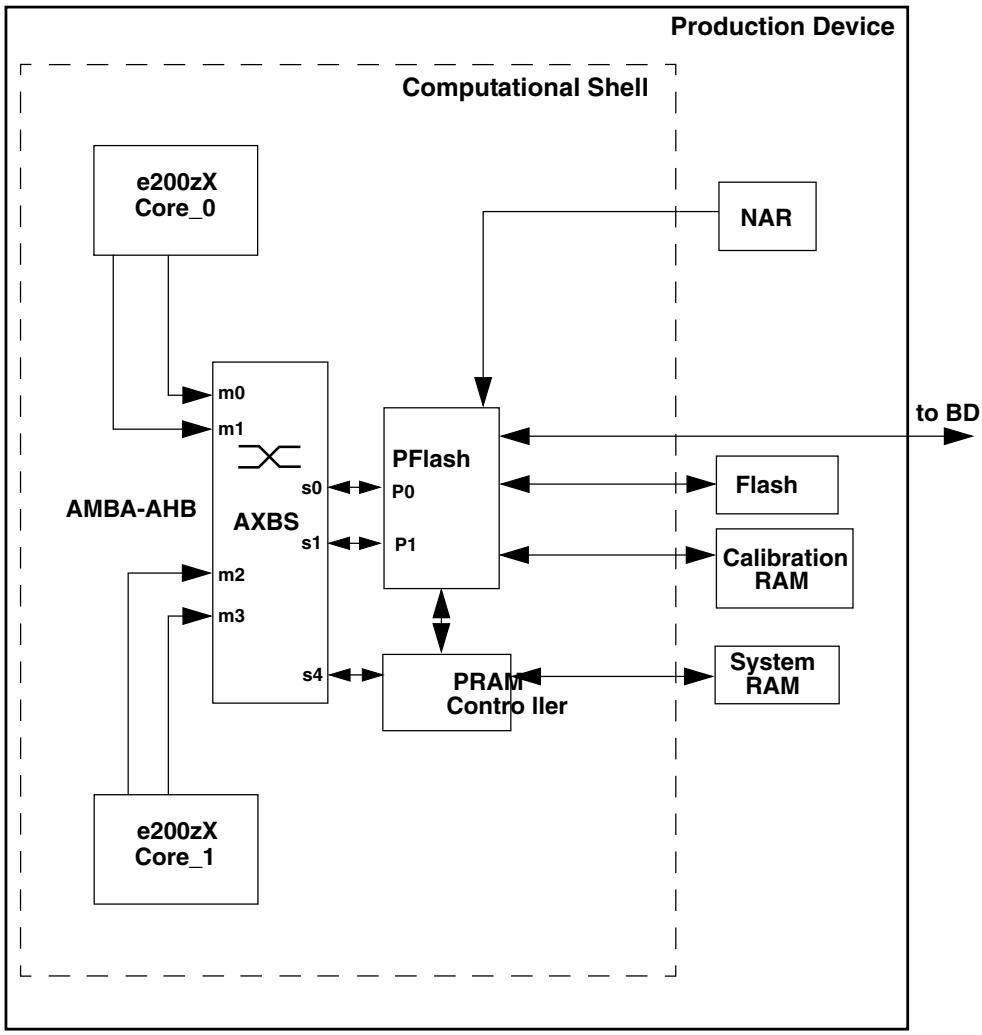


Figure 29-1. Platform-centric simple block diagram with flash memory ontroller

29.5 Flash memory controller memory map

The flash memory controller module provides an IPS programming model mapped to a standard 16 KB on-platform peripheral slot. The programming model consists of flash memory access configurationand overlay remapping configuration.

The programming model can only be referenced using a 32-bit (word) access. Attempted references using different access sizes or to undefined (reserved) addresses or in user mode generates an IPS error termination. The flash controller allows access to the programming model by all system bus masters.

The programming model can only be accessed in supervisor mode.

Attempted updates to the programming model while the flash memory controller module is in the midst of an operation will result in non-deterministic behavior. Software must be architected to avoid this scenario. There is no idle indicator for the flash controller. The recommended flow for multi-core devices is to start only one core and execute initialization code to completion before starting the remaining cores. If the user needs to reconfigure the flash, code execution must be temporarily moved to system RAM.

29.5.1 Platform Flash Configuration Register 1 (PFLASH_PFCR1)

The PFlash Configuration Register 1 (PFCR1) controls the operation of Port p0 of the PFLASH_C55FM flash memory controller.

NOTE

See the chip-specific platform flash controller information for information on the masters.

PFLASH_PFCR1 field descriptions

Field	Description
0 P0_M15PFE	Port0 Master 15 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 15. This bit is cleared by hardware reset. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
1 P0_M14PFE	Port0 Master 14 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 14. This bit is cleared by hardware reset. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
2 P0_M13PFE	Port0 Master 13 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 13. This bit is cleared by hardware reset. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
3 P0_M12PFE	Port0 Master 12 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 12. This bit is cleared by hardware reset. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
4 P0_M11PFE	Port0 Master 11 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 11. This bit is cleared by hardware reset. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
5 P0_M10PFE	Port0 Master 10 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 10. This bit is cleared by hardware reset. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
6 P0_M9PFE	Port0 Master 9 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 9. This bit is cleared by hardware reset.

Table continues on the next page...

PFLASH_PFCR1 field descriptions (continued)

Field	Description
	0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
7 P0_M8PFE	Port0 Master 8 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 8. This bit is cleared by hardware reset. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
8 P0_M7PFE	Port0 Master 7 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 7. This bit is cleared by hardware reset. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
9 P0_M6PFE	Port0 Master 6 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 6. This bit is cleared by hardware reset. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
10 P0_M5PFE	Port0 Master 5 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 5. This bit is cleared by hardware reset. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
11 P0_M4PFE	Port0 Master 4 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 4. This bit is cleared by hardware reset. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
12 P0_M3PFE	Port0 Master 3 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 3. This bit is cleared by hardware reset. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
13 P0_M2PFE	Port0 Master 2 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 2. This bit is cleared by hardware reset. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
14 P0_M1PFE	Port0 Master 1 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 1. This bit is cleared by hardware reset. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
15 P0_M0PFE	Port0 Master 0 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 0. This bit is cleared by hardware reset. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
16–18 APC	Address Pipeline Control. This field controls the number of cycles that a subsequent flash read from the opposite AHB port can be initiated prior to the previous read data being valid. This field applies to the configuration of Port0 and Port1.

Table continues on the next page...

PFLASH_PFCR1 field descriptions (continued)

Field	Description
	For valid RWSC and APC combinations please refer to the device data sheet. **NOTE:** 1. A value of '1' in the most significant bit causes the flash controller to function in retrograde/ legacy mode, in which there is no pipelining between the sampling of flash read data and the presentation of the next address for flash lookup. 2. Flash operation is not guaranteed for RWSC/APC combinations other than those specified in the data sheet. 000 Pipelined access to the flash disabled. 001 A pipelined access can be initiated 1 cycle before the previous data is valid 010 A pipelined access can be initiated 2 cycles before the previous data is valid 011 A pipelined access can be initiated 3 cycles before the previous data is valid 1xx Pipelined access to the flash is disabled and one wait state is inserted before a subsequent access can be initiated
19–23 RWSC	Read Wait State Control. This field controls the number of wait-states to be added to the best-case flash array access time for reads. The best-case flash array access time for reads is one cycle. This field must be set to a value corresponding to the operating frequency of the flash memory controller and the actual read access time of the flash memory controller. For valid RWSC and APC combinations please refer to the device data sheet. **NOTE:** 1. Higher operating frequencies require non-zero settings for this field for proper flash operation. 2. Flash operation is not guaranteed for RWSC/APC combinations other than those specified in the device data sheet. This field applies to the configuration of Port0 and Port1. 00000 No additional wait-states are added 00001 One additional wait-state is added ... 11111 Thirty-one additional wait-states are added
24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25 P0_DPFEN	Port0 Data Prefetch Enable. This field enables or disables prefetching initiated by a data read access. This field is cleared by hardware reset. 0 No prefetching is triggered by a data read access 1 Prefetching may be triggered by any data read access
26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 P0_IPFEN	Port0 Instruction Prefetch Enable. This bit enables or disables prefetching initiated by an instruction read access. This field is cleared by hardware reset. 0 No prefetching is triggered by an instruction read access 1 Prefetching may be triggered by any instruction read access
28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29–30 P0_PFLIM	Port0 PFlash Prefetch Limit. This field controls the prefetch algorithm used by the prefetch controller. This field defines a limit on the maximum number of sequential prefetches which will be attempted between buffer misses. In all situations when enabled, only a single prefetch is initiated on each buffer miss or hit.

Table continues on the next page...

PFLASH_PFCR1 field descriptions (continued)

Field	Description
	This field is cleared by hardware reset. 00 No prefetching or buffering is performed. 01 The referenced line is prefetched on a buffer miss, that is, prefetch on miss. 10 The referenced line is prefetched on a buffer miss, or the next sequential line is prefetched on a buffer hit (if not already present), that is, prefetch on miss or hit. 11 The referenced line is prefetched on a buffer miss, or the next sequential line is prefetched on a buffer hit (if not already present), that is, prefetch on miss or hit.
31 P0_BFEN	Port0 PFlash Line Read Buffers Enable. This bit enables or disables line read buffer hits. It is also used to invalidate the buffers. This bit can only be updated while PFCR3[BAF_DIS]=0. After execution of the boot code, as indicated by PFCR3[BAF_DIS]=1, this bit becomes read-only until the next hardware reset. 0 The line read buffers are disabled from satisfying read requests, and all buffer valid bits are cleared. 1 The line read buffers are enabled to satisfy read requests on hits. Buffer valid bits may be set when the buffers are successfully filled.

29.5.2 Platform Flash Configuration Register 2 (PFLASH_PFCR2)

The PFlash Configuration Register 2 (PFCR2) controls the operation of Port1 of the PFLASH_C55FM flash memory controller.

NOTE

See the chip-specific platform flash controller information for details about the masters.

PFLASH_PFCR2 field descriptions (continued)

Field	Description
10 P1_M5PFE	Port1 Master 5 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 5. This bit is cleared by hardware reset. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
11 P1_M4PFE	Port1 Master 4 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 4. This bit is cleared by hardware reset. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
12 P1_M3PFE	Port1 Master 3 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 3. This bit is cleared by hardware reset. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
13 P1_M2PFE	Port1 Master 2 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 2. This bit is cleared by hardware reset. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
14 P1_M1PFE	Port1 Master 1 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 1. This bit is cleared by hardware reset. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
15 P1_M0PFE	Port1 Master 0 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 0. This bit is cleared by hardware reset. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
16–24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25 P1_DPFEN	Port1 Data Prefetch Enable. This field enables or disables prefetching initiated by a data read access. This field is cleared by hardware reset. 0 No prefetching is triggered by a data read access 1 Prefetching may be triggered by any data read access
26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 P1_IPFEN	Port1 Instruction Prefetch Enable. This bit enables or disables prefetching initiated by an instruction read access. This field is cleared by hardware reset. 0 No prefetching is triggered by an instruction read access 1 Prefetching may be triggered by any instruction read access
28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29–30 P1_PFLIM	Port1 PFlash Prefetch Limit. This field controls the prefetch algorithm used by the prefetch controller. This field defines a limit on the maximum number of sequential prefetches which will be attempted between buffer misses. In all situations when enabled, only a single prefetch is initiated on each buffer miss or hit. This field is cleared by hardware reset.

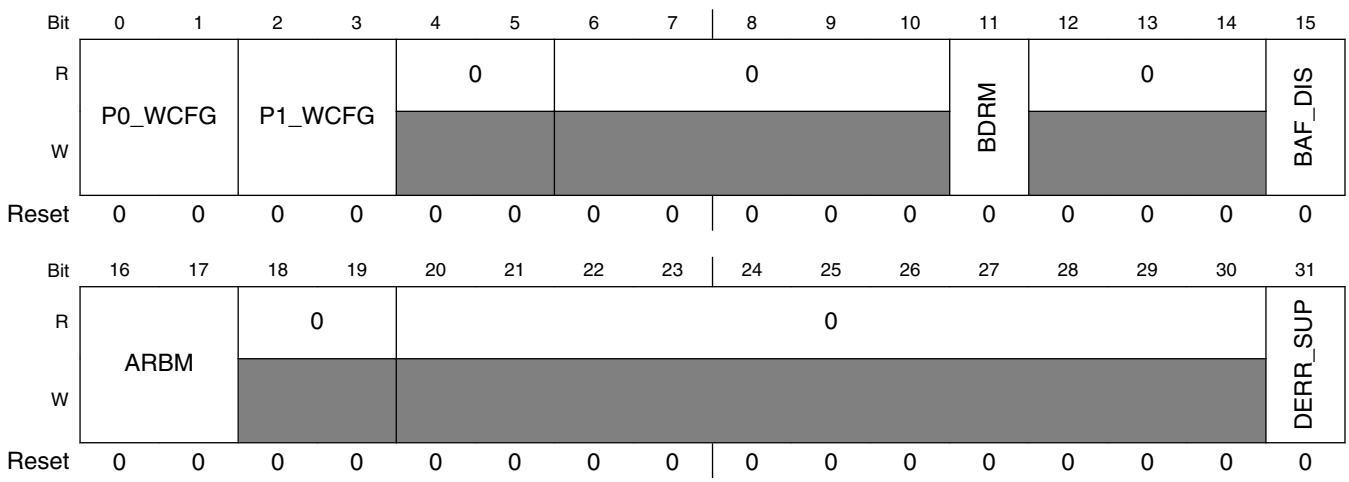

Table continues on the next page...

PFLASH_PFCR2 field descriptions (continued)

Field	Description
	00 No prefetching or buffering is performed. 01 The referenced line is prefetched on a buffer miss, that is, prefetch on miss. 10 The referenced line is prefetched on a buffer miss, or the next sequential line is prefetched on a buffer hit (if not already present), that is, prefetch on miss or hit. 11 The referenced line is prefetched on a buffer miss, or the next sequential line is prefetched on a buffer hit (if not already present), that is, prefetch on miss or hit
31 P1_BFEN	Port1 PFlash Line Read Buffers Enable. This bit enables or disables line read buffer hits. It is also used to invalidate the buffers. This bit can only be updated while PFCR3[BAF_DIS]=0. After execution of the boot code, as indicated by PFCR3[BAF_DIS] = 1, this bit becomes read-only until the next hardware reset. 0 The line read buffers are disabled from satisfying read requests, and all buffer valid bits are cleared. 1 The line read buffers are enabled to satisfy read requests on hits. Buffer valid bits may be set when the buffers are successfully filled.

29.5.3 Platform Flash Configuration Register 3 (PFLASH_PFCR3)

Address: 0h base + 8h offset = 8h

PFLASH_PFCR3 field descriptions

Field	Description
0–1 P0_WCFG	Port0 Way Configuration. This field controls the configuration of the line buffers for a given set acrosstwo ways in the controller cache. The indexed set can be organized as a "pool" of available resources, or with a fixed partition between instruction and data buffers. In all cases, when a buffer miss occurs, the flash page is assigned a location within the controller cache. Within the indexed set, the way is selected using a least-recently-used replacement policy, and the entry is then marked as most-recently-used for that set. If the flash access is for the next-sequential line (prefetch), the buffer is not marked as most-recently-used until the given address produces a buffer hit. This field is initialized by hardware reset. 00 Both buffers in an indexed set are available for any flash access, that is, there is no partitioning of the buffers based on the access type. 01 Reserved

Table continues on the next page...

PFLASH_PFCR3 field descriptions (continued)

Field	Description
	10 The buffers in an indexed set are partitioned into two groups with way 0 allocated for instruction fetches and way 1 for data accesses. 11 Reserved
2–3 P1_WCFG	Port1 Way Configuration. This field controls the configuration of the line buffers for a given set across two ways in the controller cache. The indexed set can be organized as a "pool" of available resources, or with a fixed partition between instruction and data buffers. In all cases, when a buffer miss occurs, the flash page is assigned a location within the controller cache. Within the indexed set, the way is selected using a least-recently-used replacement policy, and the entry is then marked as most-recently-used for that set. If the flash access is for the next-sequential line (prefetch), the buffer is not marked as most-recently-used until the given address produces a buffer hit. This field is initialized by hardware reset. 00 Both buffers are available for any flash access, that is, there is no partitioning of the buffers based on the access type. 01 Reserved 10 The buffers are partitioned into two groups with way 0 allocated for instruction fetches and way 1 for data accesses. 11 Reserved
4–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11 BDRM	Buddy Device Read Mode - This field controls the PFLASH_C55FM bus response when the master presents a read request targeting the extended overlay RAM on the Buddy Device(BD) using the direct, non-remapped address. This field is ignored on production ECUs where the Buddy Device is not present. On production ECUs, this memory map region is provided for the "OLDA" (on-line data acquisition) function. Read requests on production ECUs targeting the non-existent extended overlay RAM using the direct, non-remapped address are terminated with error on the system bus. This field is ignored on write requests targeting the extended overlay RAM using the direct, non-remapped address. Write requests on production ECUs targeting the non-existent extended overlay RAM using the direct, non-remapped address are ignored and terminate cleanly on the system bus. Write requests on engineering ECUs targeting the extended overlay RAM using the direct, non-remapped address are executed. This field is initialized by hardware reset. 0 Read requests targeting the extended overlay RAM on the Buddy Device(BD) using the direct, non-remapped address are aborted, and the request is terminated with error on the system bus. 1 Read requests targeting the extended overlay RAM on the Buddy Device(BD) using the direct, non-remapped address are allowed. The PFLASH_C55FM returns the requested data from the extended overlay RAM, which resides on the BD. Any system bus errors returned by the BD are passed onto the master.
12–14 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15 BAF_DIS	BAF Disable. This field controls executable access to the BAF (Boot Assist Flash) region of the flash. Once this field is set, attempted instruction accesses targeting the BAF region are aborted and terminated with a system bus error. The affect of this field applies to system bus transfers through both, Port0 and Port1. Data-type accesses to the BAF region are not affected by this field.

Table continues on the next page...

PFLASH_PFCR3 field descriptions (continued)

Field	Description
	Once this field is set, it becomes a read-only field and can only be cleared by hardware reset. Once this field is set, any subsequent write attempts to modify this field are ignored with an error-free data transfer termination. This field is initialized by hardware reset. 0 Executable access to the BAF flash region is allowed. 1 Executable access to the BAF flash region is prohibited.
16–17 ARBM	Arbitration Mode. This 2-bit field controls the arbitration of concurrent flash access requests from the two AHB ports of the flash memory controller. In both fixed priority or round-robin modes, write requests are prioritized higher than read requests, and read requests are prioritized higher than speculative prefetch requests whenever both ports issue concurrent requests. This field is initialized by hardware reset. 00 Fixed priority arbitration with AHB p0>p1 01 Fixed priority arbitration with AHB p1>p0 10 Round-robin arbitration 11 Round-robin arbitration
18–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 DERR_SUP	Data Error Suppression. Refer to the Embedded Flash Memory configuration information for which Flash blocks are affected by this field. 0 ECC events on data flash accesses are reported. 1 ECC events on data flash accesses are suppressed. Single-bit and multi-bit ECC errors are not reported. On multibit ECC events, the corrupted read data is replaced with a fixed, ECC-clean illegal opcode value of 0x15551555.

29.5.4 Platform Flash Access Protection Register (PFLASH_PFAPR)

The PFlash Access Protection Register (PFAPR) is used to control read and write accesses to the flash array.

NOTE

See the chip-specific platform flash controller information for details about the actual masters available on the device.

PFLASH_PFAPR field descriptions

Field	Description
0–1 M0AP	Master 0 Access Protection. This field controls whether read and write accesses to the flash are allowed based on the master ID of a requesting master. These fields are initialized by hardware reset. 00 No accesses may be performed by this master 01 Only read accesses may be performed by this master 10 Only write accesses may be performed by this master 11 Both read and write accesses may be performed by this master
2–3 M1AP	Master 1 Access Protection. This field controls whether read and write accesses to the flash are allowed based on the master ID of a requesting master. These fields are initialized by hardware reset. 00 No accesses may be performed by this master 01 Only read accesses may be performed by this master 10 Only write accesses may be performed by this master 11 Both read and write accesses may be performed by this master
4–5 M2AP	Master 2 Access Protection. This field controls whether read and write accesses to the flash are allowed based on the master ID of a requesting master. These fields are initialized by hardware reset. 00 No accesses may be performed by this master 01 Only read accesses may be performed by this master 10 Only write accesses may be performed by this master 11 Both read and write accesses may be performed by this master
6–7 M3AP	Master 3 Access Protection. This field controls whether read and write accesses to the flash are allowed based on the master ID of a requesting master. These fields are initialized by hardware reset. 00 No accesses may be performed by this master 01 Only read accesses may be performed by this master 10 Only write accesses may be performed by this master 11 Both read and write accesses may be performed by this master
8–9 M4AP	Master 4 Access Protection. This field controls whether read and write accesses to the flash are allowed based on the master ID of a requesting master. These fields are initialized by hardware reset. 00 No accesses may be performed by this master 01 Only read accesses may be performed by this master 10 Only write accesses may be performed by this master 11 Both read and write accesses may be performed by this master
10–11 M5AP	Master 5 Access Protection. This field controls whether read and write accesses to the flash are allowed based on the master ID of a requesting master. These fields are initialized by hardware reset. 00 No accesses may be performed by this master 01 Only read accesses may be performed by this master 10 Only write accesses may be performed by this master 11 Both read and write accesses may be performed by this master
12–13 M6AP	Master 6 Access Protection. This field controls whether read and write accesses to the flash are allowed based on the master ID of a requesting master. These fields are initialized by hardware reset. 00 No accesses may be performed by this master 01 Only read accesses may be performed by this master 10 Only write accesses may be performed by this master 11 Both read and write accesses may be performed by this master

Table continues on the next page...

PFLASH_PFAPR field descriptions (continued)

Field	Description
14–15 M7AP	Master 7 Access Protection. This field controls whether read and write accesses to the flash are allowed based on the master ID of a requesting master. These fields are initialized by hardware reset. 00 No accesses may be performed by this master 01 Only read accesses may be performed by this master 10 Only write accesses may be performed by this master 11 Both read and write accesses may be performed by this master
16–17 M8AP	Master 8 Access Protection. This field controls whether read and write accesses to the flash are allowed based on the master ID of a requesting master. These fields are initialized by hardware reset. 00 No accesses may be performed by this master 01 Only read accesses may be performed by this master 10 Only write accesses may be performed by this master 11 Both read and write accesses may be performed by this master
18–19 M9AP	Master 9 Access Protection. This field controls whether read and write accesses to the flash are allowed based on the master ID of a requesting master. These fields are initialized by hardware reset. 00 No accesses may be performed by this master 01 Only read accesses may be performed by this master 10 Only write accesses may be performed by this master 11 Both read and write accesses may be performed by this master
20–21 M10AP	Master 10 Access Protection. This field controls whether read and write accesses to the flash are allowed based on the master ID of a requesting master. These fields are initialized by hardware reset. 00 No accesses may be performed by this master 01 Only read accesses may be performed by this master 10 Only write accesses may be performed by this master 11 Both read and write accesses may be performed by this master
22–23 M11AP	Master 11 Access Protection. This field controls whether read and write accesses to the flash are allowed based on the master ID of a requesting master. These fields are initialized by hardware reset. 00 No accesses may be performed by this master 01 Only read accesses may be performed by this master 10 Only write accesses may be performed by this master 11 Both read and write accesses may be performed by this master
24–25 M12AP	Master 12 Access Protection. This field controls whether read and write accesses to the flash are allowed based on the master ID of a requesting master. These fields are initialized by hardware reset. 00 No accesses may be performed by this master 01 Only read accesses may be performed by this master 10 Only write accesses may be performed by this master 11 Both read and write accesses may be performed by this master
26–27 M13AP	Master 13 Access Protection. This field controls whether read and write accesses to the flash are allowed based on the master ID of a requesting master. These fields are initialized by hardware reset. 00 No accesses may be performed by this master 01 Only read accesses may be performed by this master 10 Only write accesses may be performed by this master 11 Both read and write accesses may be performed by this master

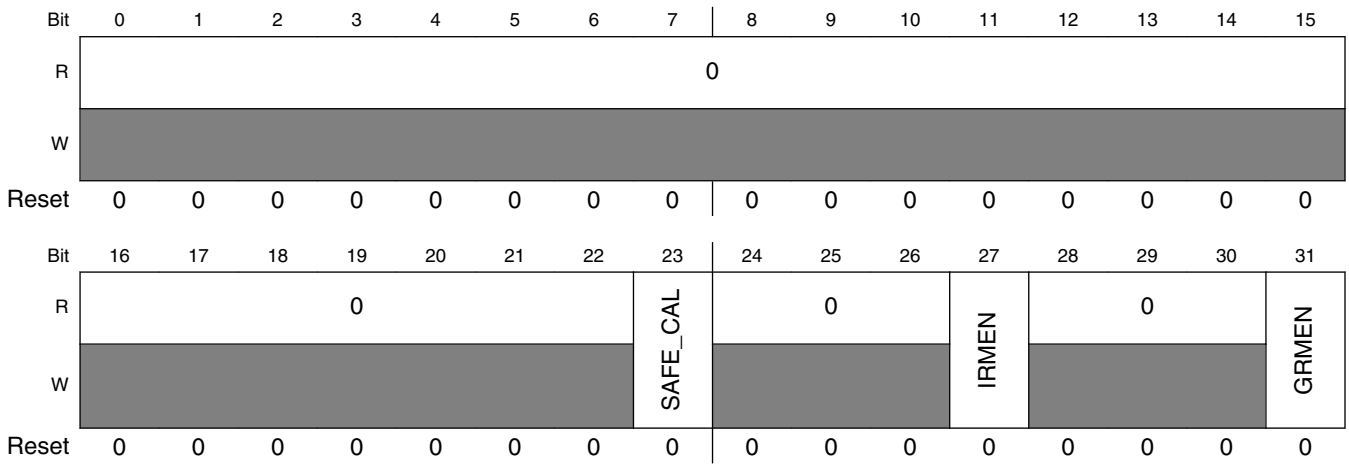
Table continues on the next page...

PFLASH_PFAPR field descriptions (continued)

Field	Description
28–29 M14AP	Master 14 Access Protection. This field controls whether read and write accesses to the flash are allowed based on the master ID of a requesting master. These fields are initialized by hardware reset. 00 No accesses may be performed by this master 01 Only read accesses may be performed by this master 10 Only write accesses may be performed by this master 11 Both read and write accesses may be performed by this master
30–31 M15AP	Master 15 Access Protection. This field controls whether read and write accesses to the flash are allowed based on the master ID of a requesting master. These fields are initialized by hardware reset. 00 No accesses may be performed by this master 01 Only read accesses may be performed by this master 10 Only write accesses may be performed by this master 11 Both read and write accesses may be performed by this master

29.5.5 Platform Flash Remap Control Register (PFLASH_PFCRCR)

The PFCRCR is used to globally enable/disable the calibration remap function.



CAUTION

Overlay remap functions, when used with line read buffers enabled (PFLASH_PFCRx[BFy_EN] field(s)='1') have a potential to cause data coherency issues, i.e., prefetched data in a line read buffer can become out-of-sync with data contained at the associated flash address range. To prevent this issue, always clear the flash controller line read buffers prior to enabling any remap region.

To clear the flash controller line read buffers, issue an interlock write command to a valid flash memory address. There will not be an actual flash program operation performed, but the flash controller mini-cache will be cleared as a side effect of executing the command. The interlock write must be issued from a core having appropriate access to flash. The sequence is as follows:

1. Set the C55FMC_MCR[PGM] field to '1'
2. Issue a 64-bit write to a valid flash address on a 64-bit boundary, i.e., the least significant 5 bits of the address are '0'
3. Clear C55FMC_MCR[PGM]

Address: 0h base + 10h offset = 10h

PFLASH_PFCRCR field descriptions

Field	Description
0–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23 SAFE_CAL	Safe Calibration. This bit facilitates the use of safety-critical calibration data. When this bit is enabled, the flash memory controller is configured to perform redundancy checking on the calibration remap function and reduce the total number of potential calibration regions from 32 to 16. This field is initialized by hardware reset. 1 Established calibration overlay regions are considered safety-critical. 0 Established calibration overlay regions are not considered safety-critical.
24–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 IRMEN	Instruction Remap. This bit enables calibration remapping evaluation on instruction fetches. When PFCRCR[GRMEN] is disabled, this bit is ignored. This field is initialized by hardware reset. 0 Calibration remap evaluation is performed on any incoming data fetch requests only. 1 Calibration remap evaluation is performed on all incoming flash access requests - data and instruction fetches.
28–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 GRMEN	Global Remap Enable. This bit globally enables or disables the calibration remapping evaluation on system flash accesses. This field is initialized by hardware reset. 0 Calibration remap evaluation is not performed on any incoming system flash access requests. 1 Calibration remap evaluation is performed on all incoming system flash access requests.

29.5.6 Platform Flash Remap Descriptor Enable Register (PFLASH_PFCRDE)

The PFlash Calibration Remap Descriptor Enable Register (PFCRDE) is used to enable or disable up to 32 calibration remap descriptors. Note there is also a global remap enable (PFCRCR[GRMEN]) that also must be asserted in conjunction with the individual CRDnEN flags to enable a given remap descriptor.

Address: 0h base + 14h offset = 14h

29.5.7 Platform Flash Calibration Region Descriptor n Word0 (PFLASH_PFCRD*n*_Word0)

Each 96-bit (12-byte) region descriptor specifies an overlay region where a flash access can be remapped during calibration and debug. The calibration remap descriptors are organized sequentially as 128-bit (16-byte) structures in the Platform Flash Controller's programming model. Each of the three 32-bit words that define a single calibration region are detailed in the subsequent sections; the fourth word is unused.

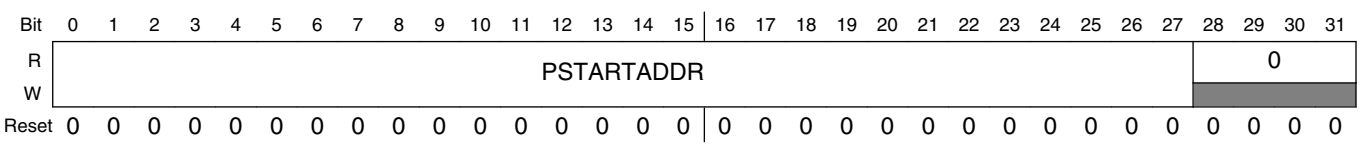
The first word of the flash memory controller overlay region descriptor defines the 0-modulo-size logical start (byte) address of the calibration remap region. It is software's responsibility to guarantee the low-order bits of the address, as defined by the remap descriptor size, are zeroed to enable the remap descriptor hit logic to function correctly.

The hardware performs basic checks on the validity of the logical start address when this word is written; if a non-supported logical start address is defined, the register write is terminated with an error and the register left unchanged and the valid bit cleared. Successful writes to this word also clear the calibration remap descriptor's valid bit.

Address: 0h base + 100h offset + (16d × i), where i=0d to 31d

PFLASH_PFCRD*n*_Word0 field descriptions

Field	Description
0–27 LSTARTADDR	Logical Start Address. This field defines the most significant bits of the 0-modulo-size logical start address of the overlay remap region. It corresponds to the logical system address which maps to the flash memory space. Any write to PFCRDn.Word{0,1,2} clears the corresponding PFCRDE[CRDnEN] bit, leaving the calibration remap descriptor invalid.
28–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.



29.5.8 Platform Flash Calibration Region Descriptor n Word1 (PFLASH_PFCRD*n*_Word1)

The second word of the flash memory controller calibration region descriptor defines the 0-modulo-size byte physical start (byte) address of the calibration remap region.

The contents of this word define the targeted destination overlay memory. It is software's responsibility to guarantee the low-order bits of the address, as defined by the remap descriptor size, are zeroed to enable the remap descriptor hit logic to function correctly.

Attempted writes to this register with illegal values, as defined by the sizes and locations of the overlay memories, are terminated with an error and clear the valid bit. Successful writes to this word also clear the calibration remap descriptor's valid bit.

Address: 0h base + 104h offset + (16d × i), where i=0d to 31d

PFLASH_PFCRD*n*_Word1 field descriptions

Field	Description
0–27 PSTARTADDR	Calibration Remap Descriptor *n* Physical Start Address - This field defines the most significant bits of the 0-modulo-size physical start byte address of the calibration remap descriptor. This address corresponds to

Field	Description
	the physical address which maps to the destination calibration overlay memory. Any write to PFCRDn.Word{0,1,2} clears the corresponding PFCRDE[CRDnEN] bit, leaving the calibration remap descriptor invalid.
28–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

29.5.9 Platform Flash Calibration Region Descriptor n Word2 (PFLASH_PFCRD*n*_Word2)

The third word of the calibration region descriptor defines a per-master calibration remap enable and the remap region size. For cacheable spaces being remapped, the minimum region size is 32 bytes to match the flash page and cache line sizes. Writes to this word clear the calibration remap descriptor's valid bit.

Address: 0h base + 108h offset + (16d × i), where i=0d to 31d

29.6 Functional description

The flash memory controller interfaces between:

- The AHB system bus ports
- Nexus trace
- Flash memory array
- Overlay RAM
- Off-chip Buddy Device
- System RAM

For accesses targeting the flash array, the flash memory controller generates read and write enables, block selects, array address, write size and write data as inputs to the flash array. The flash memory controller captures read data from the flash array and drives it onto the AHB system bus. Up to four pages of data (256-bit page size) may be buffered

in each of two ways of the flash memory controller mini-cache. Lines may be prefetched in advance of being requested, allowing single-cycle (zero AHB wait-states) read data responses on buffer hits.

Several prefetch control algorithms are available for controlling line read buffer fills. Prefetch triggering may be restricted to instruction accesses only, data accesses only, or may be unrestricted. Prefetch triggering may also be controlled on a per-master basis.

Buffers may also be selectively enabled or disabled for allocation by instruction and data prefetch.

Access protections may be applied on a per-master basis for both reads and writes to support security and privilege mechanisms.

29.6.1 Basic interface protocol

Read accesses are terminated under control of the appropriate wait state settings. Thus, the access time of the operation is determined by the setting of the PFCR1[RWSC] field. Access timing can be varied to account for the operating conditions of the SoC (frequency, voltage, temp) by appropriately setting the PFCR1[RWSC] field.

29.6.2 Access protections

On-chip Flash memory accesses are subject to restrictions based on chip security implementation and/or requirements based on functional restrictions of the flash memory, e.g., a read access to a flash block while it is currently being written is not allowed. When a prohibited access is attempted, a system bus error termination results.

The flash memory controller may invoke a system bus error termination in the following scenarios:

- Attempted access by an AHB master whose corresponding read access control or write access control settings do not allow the access, thus causing a protection violation. See Platform Flash Access Protection Register (PFLASH_PFAPR) for more detail. In this case the flash memory controller does not initiate the requested flash array access.
- Attempted instruction fetch by an AHB master to the BAF flash region when the PFCR3[BAF_DISABLE] field in Platform Flash Configuration Register 3 (PFCR3) is set. The assertion of PFCR3[BAF_DISABLE] indicates that code stored in the BAF region should not be executed. See Platform Flash Configuration Register 3

(PFLASH_PFCR3) for more detail. In this case, the flash memory controller does not initiate a flash array access.
- Attempted access by an AHB master to a flash region where the corresponding censorship control is asserted.
- The flash or overlay RAM returns an error response on an attempted access to a partition that is unavailable. (see Flash error response operation or Embedded Flash Memory).
- Attempted access by an AHB master to a reserved region in the flash memory map.

The flash array may also signal an error response to terminate a requested access due to improper sequencing during program/erase operations, improper sequencing during array integrity testing. When an error response is received the flash memory controller does not update or validate a page read buffer. An error response may be signaled on a read or interlock write operation. For more information on the specifics related to signaling of flash errors, including flash ECC events, array integrity testing and read-while-write events, refer to the flash memory chapter.

29.6.2.1 Censorship

The flash space is defined by regions:

- Code flash (instruction and constant data)
- Data flash (data for EEPROM emulation)
- UTEST flash

Each section can be independently censored, and the flash memory controller provides independent censorship control inputs for each region on a read vs. write basis.

29.6.2.2 PFAPR - Platform Flash Access Protection Register (PFAPR)

The flash memory controller provides programmable, configurable access protections for both read and write cycles on a per-master basis via the PFlash Access Protection Register (PFAPR). It allows restriction of read and write requests on a per-master basis. This functionality is described in Platform Flash Access Protection Register (PFLASH_PFAPR). Detection of a protection violation results in an error response from the flash memory controller on the AHB transfer.

29.6.2.3 BAF execution disable

The flash memory controller provides a mechanism to disable instruction execution of the BAF (Boot Assist Flash) code. Setting the BAF Disable field (BAF_DIS) in the PFlash Configuration Register 3 (PFCR3) prevents execution of the BAF instructions. When this field is set, all incoming requests from the system bus on Port0 or Port1 are evaluated. If the flash memory controller detects an attempted instruction fetch access to the BAF region of the flash, the flash memory controller aborts the access and returns a system bus error. Data accesses to the BAF region are not affected by the state of PFCR3[BAF_DIS].

29.6.3 Access pipelining

Accesses to the flash array may be pipelined by driving a subsequent access address and control signals while waiting for the current access to complete. Pipelined access requests are always run to completion and are not aborted by the flash memory controller. Flash access pipelining allows for improved performance by reducing the access latency seen by the AHB master. Access pipelining may be applied only to read cycles targeting the flash array. Address pipelining is enabled by setting the PFCR1[APC] field.

Access pipelining is only supported for normal flash access and is not supported for calibration overlay RAM fetches. On calibration reads, the setting of PFCR1[APC] is ignored.

NOTE

Not all combinations of PFCR1[APC] (Address Pipeline Control) and PFCR1[RWSC] (Read Wait State Control) settings are recommended or supported. Please refer to the device data sheet for guidance.

29.6.4 Line read buffers and prefetch operation

The AHB ports of the flash memory controller each contain a two-way set-associative mini cache, where each way contains four page buffers which are used to hold data read from the flash arrays. Each 256-bit buffer operates independently, and is filled using a single array access. The buffers are used for both prefetch and normal demand fetches.

Prefetch triggering is controllable on a per-master and access-type basis (see Platform Flash Configuration Register 1 (PFLASH_PFCR1)). Bus masters may be enabled or disabled from triggering prefetches, and triggering may be further restricted based on whether a read access is for instruction or data. A read access by the flash memory controller may trigger a prefetch to the next sequential line of array data on the cycle

following the request. The access address is incremented by 32-bytes, and a subsequent flash access is initiated. A flash array prefetch is initiated if the data is not already resident in a line read buffer. Prefetched data is always loaded into the least-recently-used buffer.

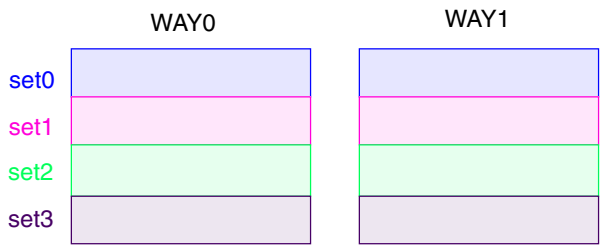

Figure 29-107. Flash memory controller 4-entry, 2-way mini-cache organization

Once the candidate line buffer has been selected, the flash array is accessed and read data loaded into the buffer. If the buffer load was in response to a miss, the buffer which was loaded is immediately marked as most-recently-used. If the buffer load was in response to a speculative fetch to the next-sequential line address after a buffer hit, *the recently-used status is not changed*. Rather, it is marked as most-recently-used only after a subsequent buffer hit.

This policy maximizes performance based on reference patterns of flash accesses and allows for prefetched data to remain valid when non-prefetch enabled bus masters are granted flash access.

Several algorithms are available for prefetch control which trade off performance for power. They are described in Platform Flash Configuration Register 1 (PFLASH_PFCR1). More aggressive prefetching may increase power due to the number of potentially discarded prefetches, but may increase performance by lowering average read latency.

For prefetching to occur, all of the following must apply:

1. PFCR{1,2}[P{0,1}_BFEN] must be set to ‘1’,
2. PFCR{1,2}[P{0,1}_PFLIM] must be non-zero, and
3. Either PFCR{1,2}[P{0,1}_IPFEN] or PFCR{1,2}[P{0,1}_DPFEN] must be asserted.

Refer to Platform Flash Configuration Register 1 (PFLASH_PFCR1) for a description of these controls.

29.6.5 Instruction/Data prefetch triggering

Port0 prefetch triggering may be enabled for instruction reads via the PFCR1[IPFEN] control field, while Port0 prefetching for data reads is enabled via the PFCR1[DPFEN] control field. Additionally, the PFCR1[PFLIM] must also be set to enable prefetching on Port0. Refer to Platform Flash Configuration Register 1 (PFLASH_PFCR1) for a description of these controls. Prefetches are never triggered by write cycles.

Port1 prefetch triggering may be enabled for instruction reads via the PFCR2[IPFEN] control field, while Port1 prefetching for data reads is enabled via the PFCR2[DPFEN] control field. Additionally, the PFCR2[PFLIM] must also be set to enable prefetching on Port1. Refer to Platform Flash Configuration Register 2 (PFLASH_PFCR2) for a description of these controls. Prefetches are never triggered by write cycles.

29.6.6 Per-Master prefetch triggering

Prefetch triggering may be controlled for individual bus masters. Refer to Platform Flash Configuration Register 1 (PFLASH_PFCR1) for a description of these controls.

29.6.7 Buffer allocation

Allocation of the line read buffers is controlled via the PFCR3 control register, specifically the line buffer configuration ({P0,P1}_WCFG) field. Refer to Platform Flash Configuration Register 3 (PFLASH_PFCR3). The buffers can be organized as a "pool" of available resources (with both ways within a given set) or with a fixed partition between ways allocated to instruction or data accesses. For the fixed partitions, way 0 is allocated for instruction fetches and way 1 for data accesses.

29.6.8 PFlash calibration remap support

The flash memory controller supports calibration development by providing a remapping function to route flash accesses to overlay RAM and on-chip System RAM that can be used as overlay RAM.

Recall this family of devices includes a comprehensive set of features including dedicated overlay RAM arrays to aid calibration and debug. The overlay function supports the following features:

- Can be mapped over internal flash memory

    - Allows calibration of constant data without requirement for additional external RAMs and calibration memory interfaces
- Can be used to hold device debug trace stream
    - Allows limited trace based debug without requirement for complex debug tool hardware and access to high speed trace port
- Protected with error detection and correction mechanism
- Accesses to all overlay RAMs can achieve the same timing as accesses to internal flash
    - Timing for calibration accesses to a particular overlay RAM is only guaranteed if it is not being used as a destination for trace streaming at the same time
    - Timing for calibration accesses to overlay RAM is only guaranteed if RWSC is set sufficiently high to cover the intrinsic burst access incurred when fetching a full page of calibration data
- Support for up to 32 distinct calibration remap regions.
- Protection against accidental enable and reconfiguration of calibration remap function :
    - Two stage mechanism to enable remap, using both global and individual calibration region descriptor enable bits
    - Optional configuration of calibration region descriptors as redundant pairs, allowing detection of accidental region reconfiguration.
- Support for overlay remapping to unique calibration regions on a per-master basis.

The calibration remap function supports the following overlay targets:

- An internal overlay RAM is included on all standard production devices.
- An extended overlay RAM is an additional memory that is only available on special ED devices.
- A portion of the system RAM can be used for overlay.

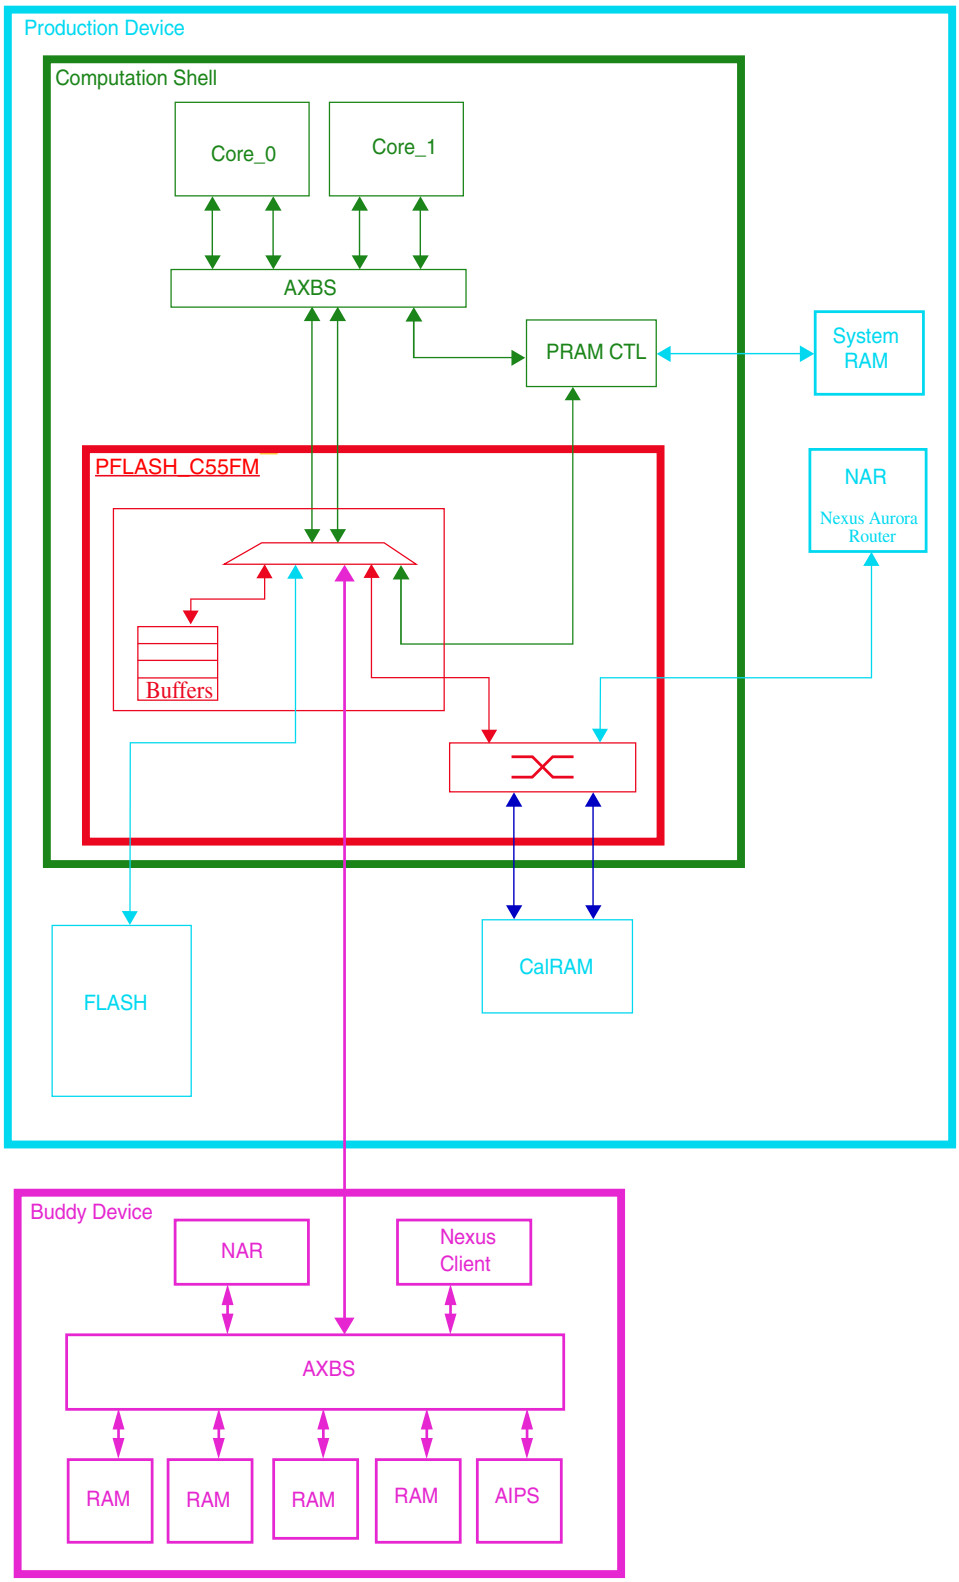

Figure 29-108. Flash memory controller and associated calibration remap targets

29.6.8.1 PFlash calibration remap to RAM

The overlay RAM is selected based on the translated physical address.

To better understand the functionality of the calibration remap, consider more detailed block diagrams, one showing the overall structure of the calibration remap function and another showing more detail on the actual remap logic. Recall the flash memory controller implements a hardware interconnection matrix connecting the three input ports and four destination memories. See Figure 29-109.

The following figure illustrates the calibration remap connection matrix.

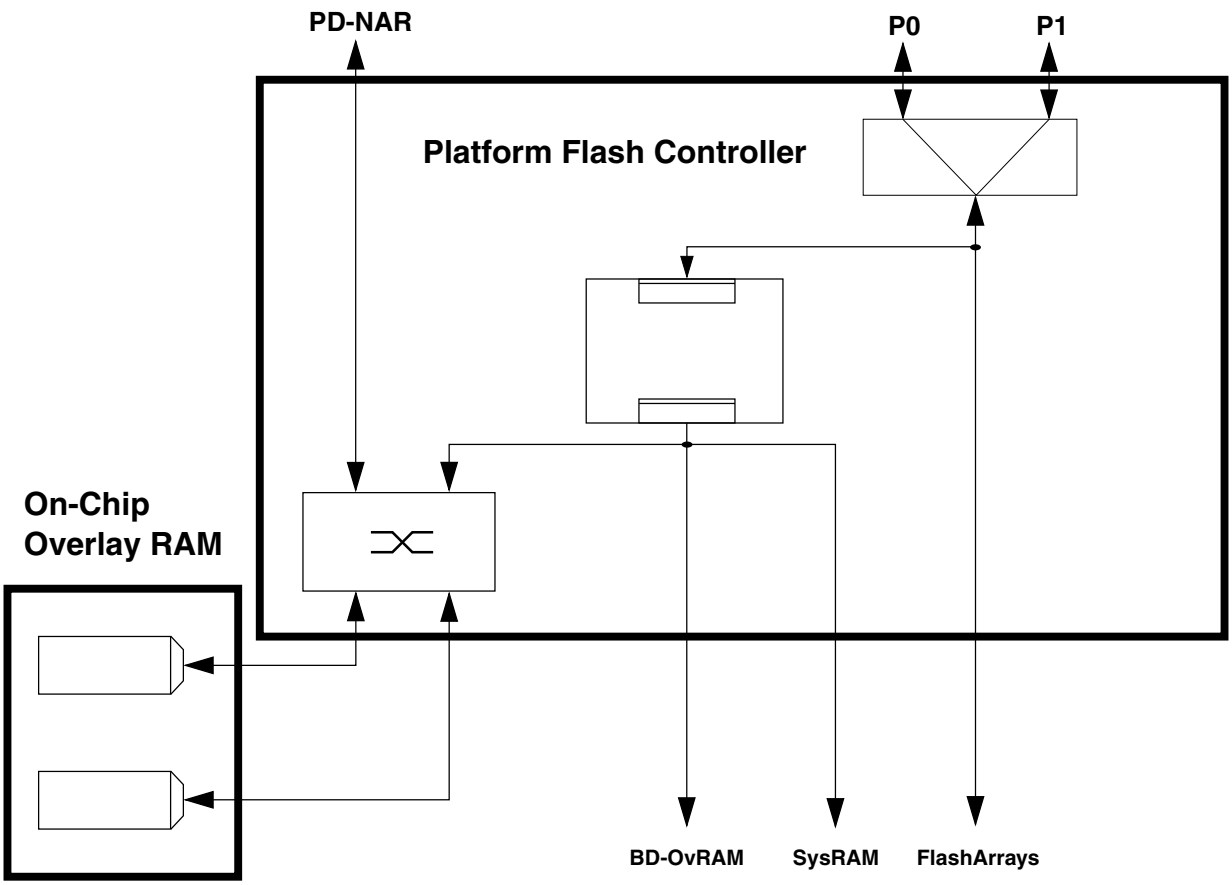

Figure 29-109. PFlash calibration remap connection matrix

Note the 64-bit on-chip overlay RAM is split into 2 equal-sized memories to allow concurrent accesses for calibration data from the P0, P1 (where these are the crossbar slave input ports) plus trace data writes from the Production Device Nexus Aurora Router (PD-NAR).

The translated physical address defines the destination memory. Table 29-107 shows the base addresses for the calibration data memories as defined by the system memory map.

Table 29-107. Calibration data memory base addresses

Calibration Memory	Base Address	Possible Access Sources
Flash Arrays	0x0{8,9,A}--_----	P0, P1
System RAM	0x40{0,1}-_----	P0, P1
On-chip Overlay RAM	0x0D00_----	P0, P1, PD-NAR
Buddy Device (Extended) Overlay RAM	0x0C{0,1}-_----	P0, P1

Note the trace data from the Nexus Aurora Router (PD-NAR) can only be routed to the on-chip overlay RAM; there is a different connection path in the Buddy Device from the BD-NAR into the extended overlay RAM.

The system RAM connection from the calibration remap logic is implemented via a private 64-bit connection to the platform RAM controller.

Accesses to the flash arrays always use the logical, non-remapped system address. Calibration data store references to the system RAM, on-chip or buddy device (extended) overlay RAM always use the physical, non-remapped system address. Conversely, calibration data load references can be accessed using a translated physical address or, if provided by the requesting master, the physical, non-remapped system address. Byte-, halfword-, word-, and doubleword-sized data store references to the on-chip overlay RAM are supported. Byte-, halfword-, word-, and doubleword-sized store references to the buddy device (extended) overlay RAM are supported.

The read data interface of system RAM, on-chip overlay RAM, and buddy (extended) device is 64 bits wide for each, whereas the flash read data interface is 256 bits wide. As a result, a remapped calibration load access initiates a four-beat burst sequence to mimic the throughput of a single flash access. There is a direct relationship between the operating frequency range and the required number of wait states to correctly sample flash read data. By contrast, a remapped calibration load access has a fixed, intrinsic 4-beat latency, where the access time of each individual beat depends on the overlay target - system RAM, on-chip overlay RAM or buddy device. The access time when fetching data from the buddy device presents the longest latency. Therefore, in order for an initial, random calibration load access to mimic the flash access time, PFCR1[RWSC] read wait state setting must be programmed to a value which sufficiently covers the intrinsic access time to complete a four-beat burst sequence from the slowest available overlay target at the specified device operating frequency. Expressed mathematically:

$$(\mathrm{RWSC}+2) \geq \left(\frac{\mathrm{IntrinsicFlashAccessTime}}{\mathrm{OperatingFrequencyClockPeriod}}+2\right) \geq (\mathrm{OverlayRAMTransferBurstLatency})$$

Figure 29-110. Access time

Notice the overall latency on a random, initial flash access that does not hit in the prefetch mini-buffer incurs an additional cycle latency beyond the intrinsic flash access time. This cycle accounts for pipeline stalls incurred by the flash controller state machine. The formula above is based on specified intrinsic flash access times of the C55FMC array at 150 °C. Calibration data that is loaded in the flash controller's mini-cache is returned with single-cycle latency.

The memory-mapped calibration remap (region) descriptor (CRD*n*) registers define the required address translation. Each calibration remap descriptor includes the logical base address, the translated physical base address and a region size (plus other control bits). The calibration remap evaluation is initiated when the flash controller is presented with a flash access request from any system bus master to a location in the mirrored flash address space. Conversely, references using the associated non-mirrored flash system address are not evaluated for calibration remapping. Generally, not all areas of the flash memory map are available for calibration remapping. EEPROM, BAF and UTEST are usually not available for calibration remapping. Flash access requests which present an address targeting EEPROM, BAF or UTEST will bypass calibration remap evaluation and return flash data.

The address translation mechanism requires the logical and physical base addresses of the region be aligned on 0-modulo-size boundaries. See Figure 29-111.

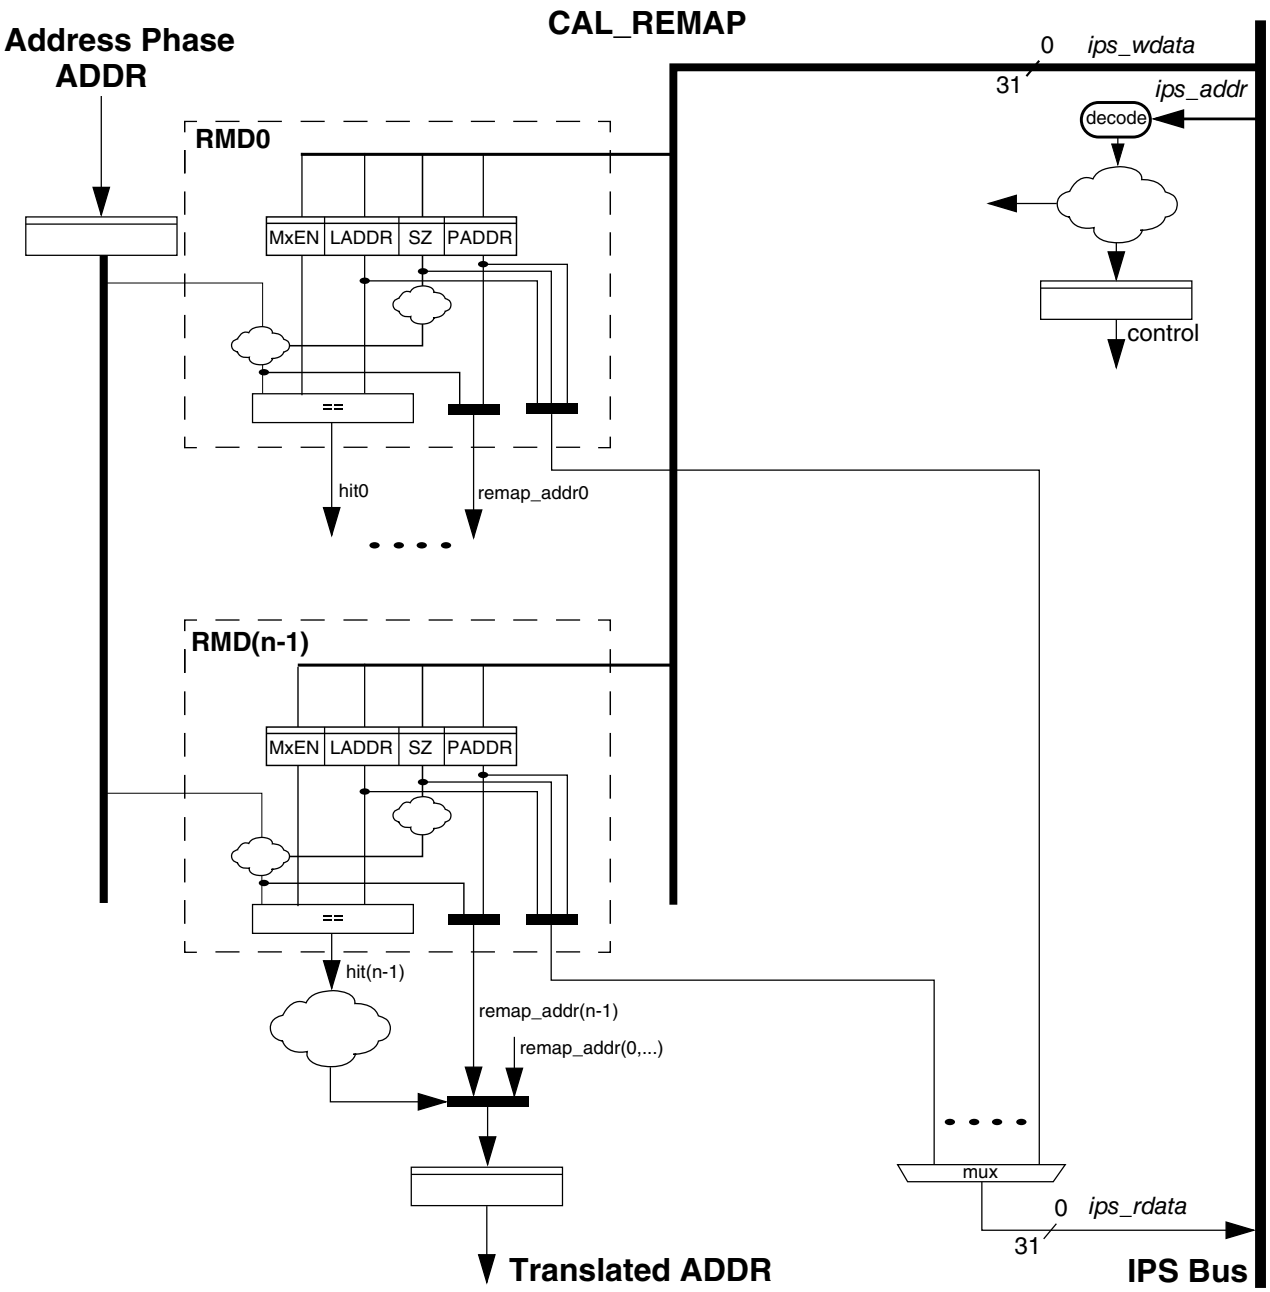

Figure 29-111. PFlash calibration remap logic detail

Each instantiation of the basic calibration remap function {RMD0,…, RMD(*n*-1)} in Figure 29-111 includes the three descriptor registers containing the logical start address (LADDR in the figure), the physical start address (PADDR), region size (SZ), and per-master enable bits (MxEN). The region size is decoded to create the appropriate address bit enables which are then applied to the registered logical flash address. An equality comparator then compares the adjusted logical flash address against the logical address from the calibration remap descriptor to determine the region "hit". The hit determination is further qualified based on the bus master number that initiated the flash access. At the same time, the logical flash address and the physical address defined in the calibration

remap descriptor are merged to form the translated address to be used in the event of a calibration region hit. Aside from the individual instantiations of the calibration remap descriptors, this logic examines all the descriptor hit indicators to select the appropriate translated address.

In the absence of a region "hit" data is returned from the flash at the provided logical address.

It should be noted in the event of *overlapping remap regions*, the calibration remap descriptor with the largest number is used for the address translation, that is, if a logical flash address hits in multiple descriptors, say CRDx and CRDy, the translated address from CRDy is used, given y > x.

In general, the calibration remap logic operates only on flash *data* accesses. However, flash instruction references can optionally remapped while in debug modes of operation to support the use of software breakpoints when PFCRC[IRMEN] is set.

29.6.9 Reliability considerations

This section summarizes mechanism to enhance the reliability of flash by correcting and detecting faults.

29.6.9.1 e2eECC End-to-End ECC

29.6.9.1.1 e2eECC and flash accesses

There are multiple complications associated with the use of the standard e2eECC algorithm with flash memory. The basic issues involve: the default state of a flash block that is erased (all ones) and the fact that programming an erased flash involves changing the state of memory bit from a logical 1 to a logical 0. These factors require that the system level e2eECC must be modified on references to the flash memory in three ways.

First, the all-ones codeword, since it reflects the state of an erased flash location, is treated as a valid error free encoding; in particular, it is required that the checkbits associated with the all all-ones value and the all zeroes data value are required to be the same with a checkbit value of 0xFF. Second, since an erased flash block generates an all-ones data for all locations, the address field cannot be included in the ECC code used by the flash. The flash array implements special address re-encoding logic based on the decoded array address to protect against address faults. Third, there are additional ECC implications associated with the flash memory and its support for EEPROM emulation. Lastly, there are ECC implications associated with the storage and retrieval of overlaid calibration data.

In summary, the basic operation of an NVM bit cell impacts the e2eECC algorithm used in the flash memory in multiple ways. The required ECC adjustments are handled by the platform flash controller before data is written to the flash array(s) or applied to read data accessed from the array(s). These adjustments are two-fold. Consider a flash write during a programming event:

1. Remove the address field from the ECC codeword by XOR'ing the address calculation of the H-matrix from the checkbits.
2. Invert the resulting 8-bit ECC checkbit vector. This step is required to support the all-ones erased state.

On a flash read operation, a similar but "reversed" set of steps are performed as the data is driven into the system bus interconnect:

1. Invert the 8-bit ECC checkbit vector read from the flash.
2. Factor the address field into the ECC checkbits by XOR'ing the address calculation of the H-matrix.

Consider the following flash ECC example. Let the flash block containing address 0x00345678 be erased. The following is the sequence of operations:

1. Read address 0x00345678. Flash array returns fl_rdata = 0xFFFFFFFF_FFFFFFFF, fl_cdata = 0xFF. The flash memory controller calculates the addr_chkbit = 0xC4 using the H-matrix; it inverts the fl_cdata vector to 0x00 and factors in the addr_chkbit = 0xC4 to produce the following valid e2eECC codeword:

   addr = 0x00345678, rdata = 0xFFFFFFFF_FFFFFFFF, rchkbit = 0xC4 (0x00 ^ 0xC4)

2. Program address 0x00345678 with data = 0xBABEFACE_DEADBEEF. The initiating bus master calculates the e2eECC codeword as:

   addr = 0x00345678, wdata = 0xBABEFACE_DEADBEEF, wchkbit = 0xE3

   Before performing the interlock write to the flash array, the flash memory controller adjusts the chkbit value as fl_wchkbit = 0xD8 (0xE3 ^ 0xff ^ 0xC4) by toggling the original write checkbits and then factoring in the addr_ecc. Accordingly, the codeword stored in the flash array is:

   fl_data = 0xBABEFACE_DEADBEEF, fl_checkbit = 0xD8

3. Read address 0x00345678. The flash array returns the stored codeword, fl_rdata = 0xBABEFACE_DEADBEEF, fl_rchkbit = 0xD8. The flash memory controller inverts the checkbit vector and factors in the address checkbits (0xD8 ^ 0xFF ^ 0xC4) to produce:

   addr = 0x00345678, rdata = 0xBABEFACE_DEADBEEF, rchkbit = 0xE3

This read codeword matches the original e2eECC codeword generated by the write.

Malfunction of the ECC logic described above may result in the corruption of the SEC/DED event reporting. The flash memory controller performs EDC after ECC check on all flash transactions. If a mismatch is detected, indicating a failure in the ECC logic, the event is reported to the device fault collection module.

29.6.9.2 Flash address generation check

Fault detection coverage of the address and data are handled by ECC performed within the flash and e2eECC performed at the master. Fault detection coverage of the address path and control within the flash memory controller rely on a feedback path between the flash controller and flash. Recall on a requested access to flash, the flash memory controller must decode the system AHB bus signals to generate the corresponding flash interface signals to invoke a flash lookup. In addition to providing the requested read data, the flash also provides output sidebands reflecting the encoded address and block selects used to perform the actual row lookup.

This sideband information is used by the flash memory controller to verify the expected transaction. If a mismatch is detected, indicating a failure in the address generation or control logic within the flash memory controller or the transmission path between the flash memory controller and flash array, the event is forwarded to the device fault collection module and the corresponding buffer is invalidated.

29.6.9.2.1 On-Chip Overlay RAM feedback check

The integrity of the address and data on an overlay RAM transaction is covered by e2eECC check performed by the requesting master. Fault detection coverage of the address path and control within the flash memory controller is handled by a transaction monitor which verifies the integrity of the transactions between the flash memory controller and the on-chip overlay RAM. The function of the transaction monitor relies on a feedback path between the flash memory controller and the on-chip overlay RAM, wherein the RAM provides latched address and control feedback outputs as an indication of received inputs when a RAM access is initiated. This feedback information is used by the flash memory controller transaction monitor to verify the expected transaction. If a mismatch is detected, indicating a failure in the address generation or control logic within the flash memory controller or the transmission path between the flash memory controller and on-chip overlay RAM array, the event is forwarded to the Fault Collection and Control Unit (FCCU).

29.6.9.2.2 Reliability considerations on overlay accesses

Because calibration write accesses are always presented with the physical, non-remapped system address, the write data checkbits presented by the master are calculated based on the physical overlay RAM system address. On a subsequent overlay read, the ECC checkbits must be manipulated to replace the physical overlay RAM address contribution with the logical flash address contribution. This is required to satisfy the e2eECC check at the originating master.

In addition, the flash memory controller can be configured to treat calibration RAM space as a safety-critical component. By programming PFCRCR[SAFE_CAL]=1, the flash memory controller treats the set of available calibration region descriptors as a replicated pair, with each set containing half the total number of available calibration region descriptors.

If there are 32 calibration region descriptors, CRD0 – CRD31, and PFCRCR[SAFE_CAL]=1, the flash memory controller treats CRD0 – CRD15 and CRD16 – 32 as replicated sets of 16 calibration region descriptors, where:

- CRD0 and CRD16 are configured identically
- CRD1 and CRD17 are configured identically
- CRD2 and CRD18 are configured identically
- ...
- and CRD15 and CRD31 are configured identically

Expressed more generally, the contents of CRD[n] must be identical to the contents of CRD[(N/2) + n], where N is the total number of region descriptors and $0 \le n \le (N/2) - 1$.

Note

It is the user's responsibility to establish redundant calibration region descriptors by programming the associated pairs of CRDs.

Incoming flash read requests are compared simultaneously against the calibration regions defined in CRD0 to CRD[(N/2) – 1] and the calibration regions defined in CRD[N/2] to CRD[N – 1]. Due to the enabled redundancy, the parallel overlay remap hardware structures should evaluate to symmetric results. If a mismatch is detected, the event is reported to the FCCU and calibration remapping is not performed. Instead, data is returned from the flash.

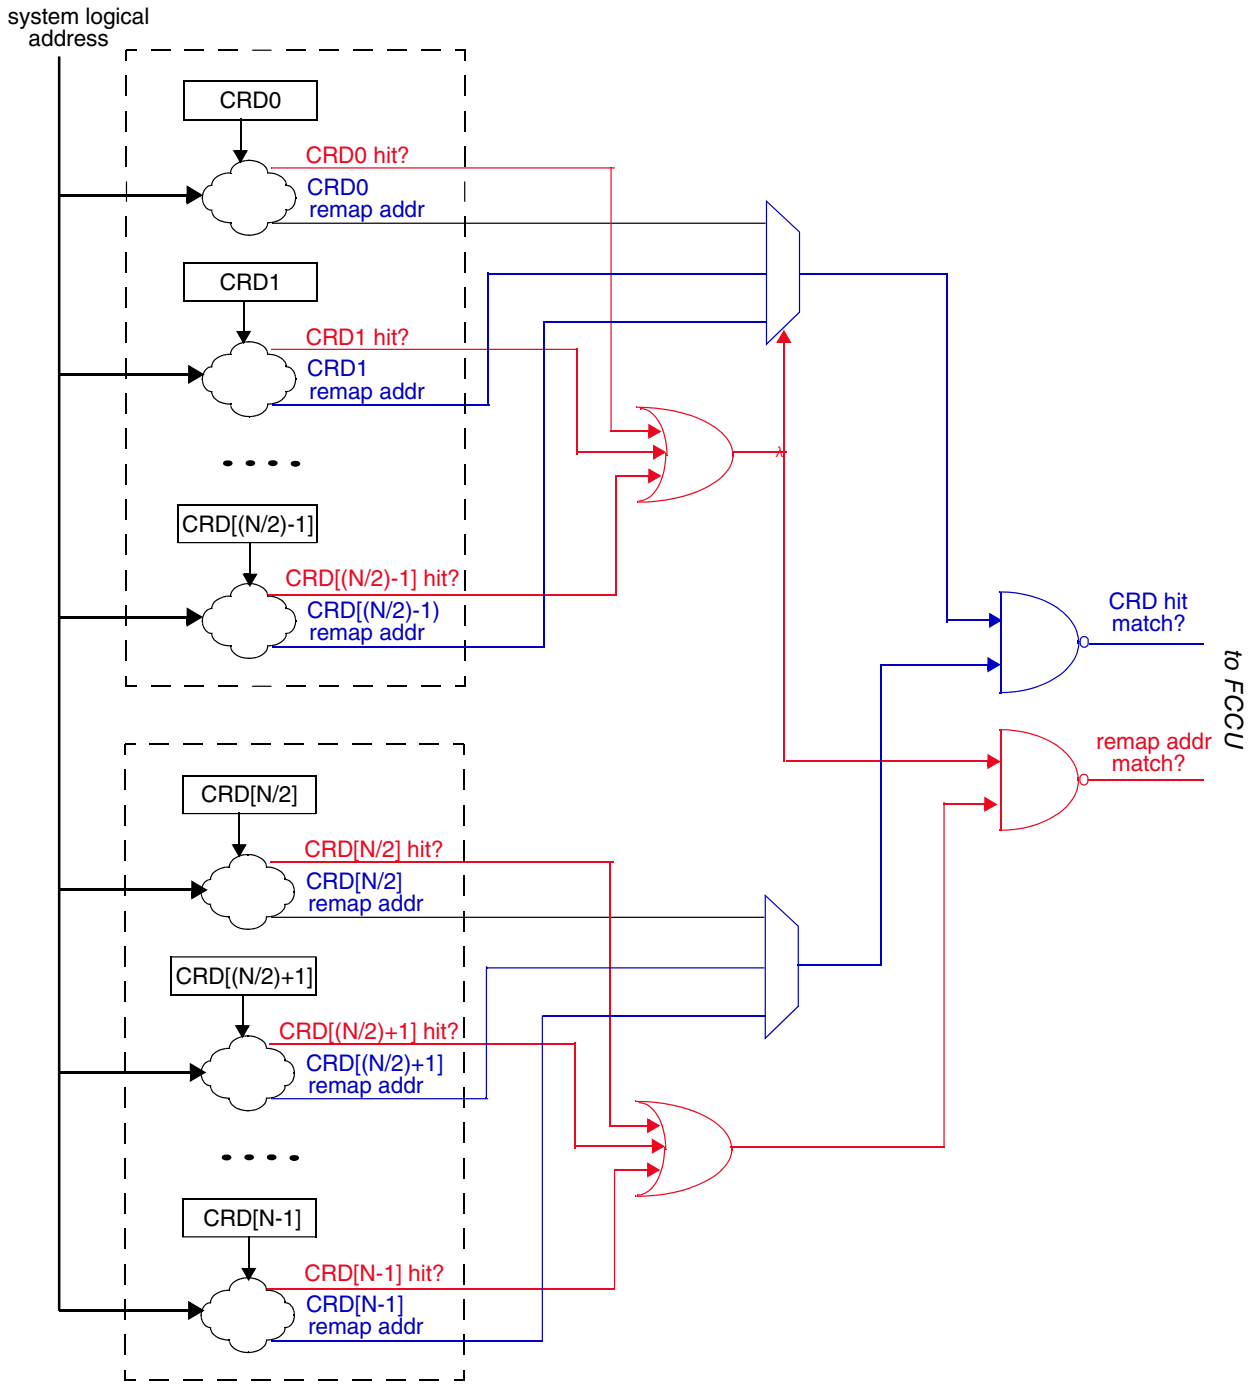

Figure 29-112. Safety-critical calibration remap datapath with redundancy

29.6.10 ECC on data flash accesses

When PFCR3[DERR_SUP] is enabled, ECC errors on data flash blocks are handled specially.

ECC events detected on accesses to data flash blocks are suppressed from being reported to the Memory Error Management Unit (MEMU).

In the event of a single-bit correction, the corrected data and checkbits are returned to the requesting master, and the single-bit correction event is suppressed from being reported to the MEMU.

In the event of a non-correctable error detection, a fixed, illegal opcode value is returned to the requesting master along with the associated ECC checkbits as determined by the requesting address, and the non-correctable error event is suppressed from being reported to the MEMU. For non-correctable error detection, the flash memory controller returns a value of 1555_1555h to the requesting master.

NOTE

EEPROM should be avoided for storage of executable code.

29.6.11 Array integrity considerations

During an array integrity sequence, the flash memory array ignores any incoming read requests. When a flash array integrity check is in progress, the flash memory controller terminates all flash access requests with an error. More specifically, it aborts the incoming flash access requests and terminates the system bus transfer with an error.

Chapter 30
Embedded Flash Memory (c55fmc)

30.1 Embedded Flash Memory (c55fmc) chip-specific module information

This section describes the configuration of this module specific to the MPC5746R.

30.2 C55FMC_LOCK*n* register bit mapping

See the attached Flash Block Assignment spreadsheet for the C55FMC_LOCK*n* register bit mapping.

30.3 C55FMC_SEL*n* register bit mapping

See the attached Flash Block Assignment spreadsheet for the C55FMC_SEL*n* register bit mapping..

30.4 Embedded Flash Memory (c55fmc) register reset values

Table 30-1 lists chip-specific register reset values specific to the MPC5746R. Any registers not listed have the reset values shown in their respective sections of this chapter.

Table 30-1. Chip specific c55fmc flash memory reset values for the MPC5746R

Register	Reset Value
Module Configuration Register (C55FMC_MCR)	0000_0600b
Extended Module Configuration Register (C55FMC_MCRE)	0700_244Bb

Table continues on the next page...

Table 30-1. Chip specific c55fmc flash memory reset values for the MPC5746R (continued)

Register	Reset Value
Over-Program Protection 0 register (C55FMC_OPP0)	Dependent on customer settings[1, 1]
Over-Program Protection 1 register (C55FMC_OPP1)	Dependent on customer settings[1]
Over-Program Protection 2 register (C55FMC_OPP2)	Dependent on customer settings[1]
Over-Program Protection 3 register (C55FMC_OPP3)	Dependent on customer settings[1]

1. The reset value of the C55FMC_OPP*n* registers, for each flash memory block mapped to a bit within each register, reflects whether the block has been marked as One Time Programmable (OTP). The C55FMC_OPP*n* registers have the same bit-to-block mapping as the C55FMC_LOCK*n* registers. A 1 indicates a block has been marked as OTP. The reset values of the C55FMC_OPP*n* are similar to the reset values of the TDM_OTPEN*n* registers in the Tamper Detection Module (TDM).

30.5 Introduction

The primary function of the embedded flash memory is to serve as electrically programmable and erasable non-volatile memory (NVM) that may be used for instruction or data storage.

The following figure shows the top-level diagram and functional organization of the flash memory unit.

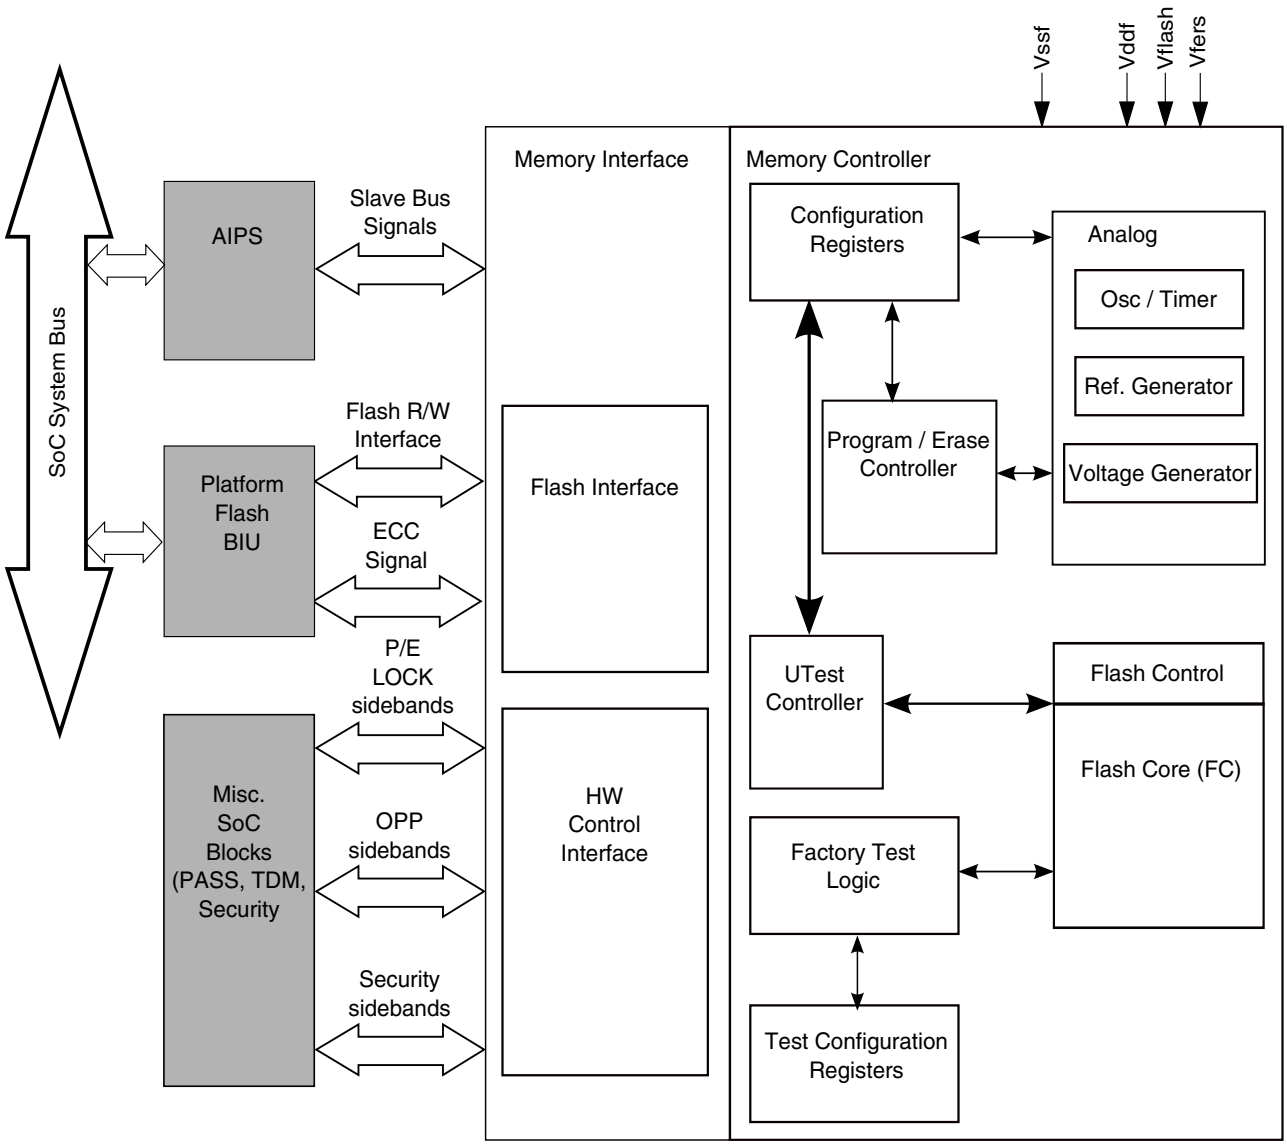

Figure 30-1. c55fmc block diagram

30.5.1 Overview

The embedded flash memory is addressable by word (32 bits) or double word (64 bits) for program operation, and page (256 bits) for read operation. Multiple word or double-word writes may be done to the flash memory to fill up the program page buffer (256 bits), enabling page programming (256 bits, requiring 4 double-word writes) and quad-page programming (1024 bits, requiring 16 double-word writes). Flash memory reads always return 256 bits, although read page buffering may be performed by the Bus Interface Unit (BIU).

For more details on the embedded flash memory architecture and features, see Functional Description.

30.5.2 Features

The embedded flash memory includes these distinct features:

- Test information stored in a dedicated nonvolatile block (referred to as the UTest block)
- OTP space made available in the UTest block
- Read page size of 256 bits (8 words)
- ECC with single-bit correction, double-bit detection (all 1's valid)
- Quad Page programming (64-bit granularity)
- Software programmable block program/erase restriction control
- Erasing of selected block(s)
- Independent programming of the UTest NVM block
- Embedded hardware program and erase algorithms
- Support for reading while writing when the accesses are to different partitions
- Erase suspend, program suspend, and erase-suspended program
- UTest mode (user-accessible test modes) including Array Integrity and Margin Read
- Triple Voted Flops for flash functions requiring high reliability, e.g., internal trimming, redundancy, and mode control

30.5.3 Modes of operation

Following is a brief description of the embedded flash memory operating modes.

- *User mode* is the default operating mode of the embedded flash memory. In this mode, it is possible to read and write registers, read and interlock write the memory array, program the memory array, and erase the memory array. In this mode program and erase operations are initiated by doing array and register writes, and are controlled by an internal state machine.
- *UTest mode* is a tiered test mode strategy in which a portion of the factory test modes are made available. This mode is protected but accessible.

30.6 UTest NVM block

The UTest NVM block may be enabled by the BIU. When the UTest NVM space is enabled, all operations are mapped to the UTest NVM block. User-mode programming of the UTest NVM block is enabled only when MCR[PEAS] is high. The UTest NVM block is an OTP block (assuming Test Mode Disable Seal is written) - thus erase is not allowed.

The UTest NVM block supports RWW, and is grouped with the blocks in partition 0.

The UTest NVM block may be locked against program by using the lock registers.

Programming of the UTest NVM space has restrictions that are similar to those of the main space in terms of how ECC is calculated. Only one program operation is allowed per 64-bit ECC segment.

The UTest NVM block contains specified data that is needed for embedded flash memory or SoC features.

30.7 Test mode disable seal

Also included in the UTest NVM block is a mechanism to disable factory entry into Test mode. Extreme care must be taken when using this feature, as blocks that are selected to be protected in this method will not be able to have possible failures analyzed by factory failure analysts. Once sealed, the UTest block becomes OTP (Erase Locked, and Over Program Protection enabled). The UTest Block also is not accessible in Test mode.

Protection of this sort prevents all high-voltage operations to the flash executed by the internal state-machine, as well as reads through this state machine, and reads through the Array Integrity state machine when using Test mode interfaces.

UTest operations Margin Read and Array Integrity are also protected by preventing MISR updates on blocks selected for protection, although reads will still be done and single bit corrections and double bit detections will be logged. Protection through other interfaces is protected by normal User mode protection mechanisms, and are device-specific.

The method to disable factory entry into Test mode is to first program the Test Mode Disable Seal location to be 0x2D3C_4B5A. Once the next reset is asserted, Test mode will be disabled.

It is possible to create a password to enable factory entry into test mode. This can be programmed into the Test Mode Disable Override Passcode. The passcode may not be 0x0000_0000, 0xFFFF_FFFF, or 0x5555_5555. These are all invalid passcodes and will not be accepted to override. If it is desired by the customer that override never be possible, one of the three invalid passcodes should be put into this location. Passcode may be entered to authenticate entry (if enabled) by doing a 32-bit register write to register address 0x90. The UTest NVM block is always protected even if the Test Mode Disable Seal password is written. UTest operations Margin Read and Array Integrity are always protected even if the Test Mode Disable Seal password is written.

Only blocks selected in the Test Mode Disable Block Select field(s) are controlled by the Test Mode Disable feature. Thus it is possible for customers to selectively pick blocks that have this type of protection, and will not be eligible for factory failure analysis. Bits programmed to 0 in the Test Mode Disable Block Select field(s) will designate blocks that are controlled by the Test Mode Disable feature. If either Test Mode Disable Block Select - 0 or Test Mode Disable Block Select - 1 have a 0 programmed, that block will be protected. In order to provide two opportunities to select blocks for the Test Mode Disable, two regions are available, Test Mode Disable Block Select - 0 and Test Mode Disable Block Select - 1. The bit of these two regions are logically ANDed, to define which blocks are effectively selected for the Test Mode Disable feature. The Block Select field is organized as follows, and aligns with how blocks are defined in the LOCK registers.

Table 30-2. Test mode disable block select

Block	Bits used to select blocks
Low Block Disable	Data[13:0]
Unused	Data[15:14]
Mid Block Disable	Data[31:16]
High Block Disable	Data[47:32]
256K Block Disable	Data[95:48]

30.8 Memory map and register definition

The embedded flash memory map consists of a flash memory array (which includes main array space and UTest NVM space) and a region of registers associated with the programming model that enable flash memory array operation and modification.

The address space consists of 16 KB, 32 KB, 64 KB, and 256 KB blocks..

30.8.1 Module Configuration Register (C55FMC_MCR)

NOTE

1. A number of Module Configuration Register (MCR) bits are locked against write by other bits. These locks are discussed in relationship to each bit in this section. Simultaneously writing bits which lock each other out is also discussed in Functional Description.
2. See Functional Description for information about simultaneous MCR writes, and priority levels.

Address: 0h base + 0h offset = 0h

C55FMC_MCR field descriptions

Field	Description
0 RVE	Read Voltage Error RVE provides information on previous reads monitoring the read pump voltage. If the read voltage is detected to be out of range, this bit is set to indicate that previous reads requested may have been

Table continues on the next page...

C55FMC_MCR field descriptions (continued)

Field	Description
	corrupted. Since this bit is a status flag, it must be cleared to a 0 by writing a 1 to the register location. A write of 0 has no effect. 0 Reads are occurring without voltage issues 1 A previous read may have been corrupted due to read voltage being out of range
1 RRE	Read Reference Error RRE provides information on previous reads monitoring the read reference. If the read reference is detected to be out of range, this bit is set to indicate that previous reads requested may have been corrupted. Since this bit is a status flag, it must be cleared to a 0 by writing a 1 to the register location. A write of 0 has no effect. 0 Reads are occurring without reference issues 1 A previous read may have been corrupted due to read reference being out of range
2 AEE	Address Encode Error AEE provides information on previous reads monitoring the address encode feature. On every read request to the flash, the incoming address is compared to an encoded address (row, column, and block) coming back from the memory array using the read data sense amplifier timing. If these two values do not match (zero selected, multiple selected, wrong selected), or the timing is incorrect, an address encode error will be recorded. If an address encode mismatch is detected, this bit is set to indicate that previous reads requested may have been corrupted. Since this bit is a status flag, it must be cleared to a 0 by writing a 1 to the register location. A write of 0 has no effect. 0 Reads are occurring without address encode mismatches 1 A previous read may be corrupted based on address encode mismatch
3 EEE	ECC after ECC Error EEE provides information on previous reads monitoring the ECC after ECC feature. On every read request to the flash, ECC is recalculated serially, and if there is a mismatch between the ECC calculations (taking into account corrections or detections) a late error will be reported. If an ECC after ECC mismatch is detected, this bit is set to indicate that previous reads requested may have been corrupted. Since this bit is a status flag, it must be cleared to a 0 by writing a 1 to the register location. A write of 0 has no effect. 0 Reads are occurring without ECC after ECC mismatches 1 A previous read may be corrupted based on ECC calculation errors
4–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 EER	ECC Event Error This bit provides information on previous reads. If a double bit detection occurred, the EER bit is set to a '1'. This bit must then be cleared, or a reset must occur before it returns to a 0 state. This bit may not be set by software. In the event of a single bit detection and correction, this bit is not set. If EER is not set, or remains 0, this indicates that all previous reads (from the last reset, or clearing of EER) are correct. Since this bit is an error flag, it must be cleared to a 0 by writing a 1 to the register location. A write of 0 has no effect. 0 Reads are occurring normally. 1 An ECC Error occurred during a previous read.
17 RWE	Read-While-Write Event Error This bit provides information on previous read-while-write (RWW) reads. If an RWW error occurs, this bit is set to 1. The bit must then be cleared, or a reset must occur before it returns to a 0 state. This bit may not be written to a 1. If RWE is not set, or remains 0, this indicates that all previous RWW reads (from the last

Table continues on the next page...

C55FMC_MCR field descriptions (continued)

Field	Description
	reset, or clearing of RWE) are correct. Since this bit is an error flag, it must be cleared to a 0 by writing a 1 to the register location. A write of 0 has no effect. 0 Reads are occurring normally. 1 A read-while-write error occurred during a previous read.
18 SBC	Single Bit Correction SBC provides information on previous reads, if the SBCE is set. If a single bit correction occurred, the SBC bit is set to a 1. This bit must then be cleared, or a reset must occur before this bit returns to a 0 state. If SBC is not set, or remains 0, this indicates that all previous reads (from the last reset, or clearing of SBC) did not require a correction. Since this bit is a status flag, it must be cleared to a 0 by writing a 1 to the register location. A write of 0 has no effect. 0 Reads are occurring without corrections. 1 A Single Bit Correction occurred during a previous read.
19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20 PEAS	Program Access Space PEAS indicates which space is valid for program or erase operations — either main array space or UTest NVM space. It should be noted that if the flash is sealed, and the Test Mode Disable Seal is programmed, erase is not allowed on the UTest NVM space. PEAS = 0 indicates the main address space is active for all program or erase operations. PEAS = 1 indicates the UTest NVM address space is active for program or erase (if applicable) operations. The value in PEAS is captured and held when the UTest NVM block is enabled with the first interlock write done for program operations(and erase operations if the flash is unsealed). The value of PEAS is retained between sampling events (in other words, subsequent first interlock writes). The value in PEAS may be changed during erase-suspended program, and reverts back to its original state once the erase-suspended program is completed. PEAS is read only. 0 UTest NVM address space is disabled for program/erase and main address space enabled. 1 UTest NVM address space is enabled for program/erase and main address space disabled.
21 DONE	State Machine Status DONE indicates whether the embedded flash memory is performing a high voltage operation. DONE is set to a 1 on termination of the embedded flash memory reset. DONE is read only. DONE is set to a 1 at the end of program and erase high voltage sequences. **NOTE:** This bit transitions from a 0 to 1 during reset and remains at 1 after reset. 0 Flash memory is executing a high voltage operation. 1 Flash memory is not executing a high voltage operation.
22 PEG	Program/Erase Good The PEG bit indicates the completion status of the last flash memory program or erase sequence for which high voltage operations were initiated. The value of PEG is updated automatically during the program and erase high voltage operations. Aborting a program/erase high voltage operation causes PEG to be cleared, indicating the sequence failed. PEG is set to a 1 when the embedded flash memory is reset. PEG is read only. The value of PEG is valid only when PGM = 1 or ERS = 1 and after DONE transitions from 0 to 1 due to an abort or the completion of a program/erase operation. PEG is valid until PGM/ERS makes a 1 to 0 transition or EHV makes a 0 to 1 transition. The value in PEG is not valid after a 0 to 1 transition of DONE caused by PSUS or ESUS being set to logic 1. If PGM and ERS are both 1 when DONE makes a qualifying 0 to 1 transition the value of PEG indicates the completion status of the PGM sequence. This happens in an erase-suspended program operation.

Table continues on the next page...

C55FMC_MCR field descriptions (continued)

Field	Description
	PEG will be 0 if an Erase-Suspended Program is attempted to a block that has been selected for Erase. PEG will also be 0 in the event of an error in the interlock write for program only. An error in the interlock write occurs when the ECC value provided to the flash memory does not match the ECC calculated within the flash memory. In the event of this, high voltage will not be applied to the array, and PEG will indicate a failed program. **NOTE:** 1. If program or erase operations are attempted on blocks that are locked, the response from embedded flash memory is PEG = 1, indicating that the operation was successful, and the contents of the block are properly protected from the program or erase operation. PEG = 1 is also true if an abort occurs during an HV request to a locked block. 2. If a program operation is attempted to a location marked as OTP, the response from the embedded flash memory is PEG = 0, indicating that the operation was not allowed, and the value interlocked was not programmed, since the desired doubleword was already programmed with a previous program operation. 0 Program or erase operation failed. 1 Program or erase operation successful.
23 PECIE	Program/Erase Complete Interrupt Enable PECIE provides a mechanism to trigger an interrupt request upon the assertion of the DONE flag due to a high voltage event (program or erase) finishing (normal, abort, suspend). If PECIE is written while not in a high voltage event, the interrupt will not immediately trigger, but will trigger after the next high voltage event is completed. 0 An interrupt request will not be generated when the DONE flag is set. 1 An interrupt request will be generated when the DONE flag is set.
24–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 PGM	Program PGM is used to set up embedded flash memory for a program operation. A 0 to 1 transition of PGM initiates a program sequence. A 1 to 0 transition of PGM ends the program sequence. PGM can be set only under one of the following conditions: • User mode read (ERS is low and UTE is low) • Erase suspend (ERS and ESUS are 1) with EHV low PGM can be cleared only when PSUS and EHV are low and DONE is high. PGM is cleared on reset. 0 Flash memory is not executing a program sequence. 1 Flash memory is executing a program sequence.
28 PSUS	Program Suspend PSUS is used to indicate the embedded flash memory is in program suspend or in the process of entering a suspend state. The embedded flash memory is in program suspend when PSUS = 1 and DONE = 1. PSUS can be set high only when PGM and EHV are high. A 0 to 1 transition of PSUS starts the sequence which sets DONE and places the embedded flash memory in program suspend. The embedded flash memory enters suspend within Tpsus of this transition. PSUS can be cleared only when DONE and EHV are high. A 1 to 0 transition of PSUS with EHV = 1 starts the sequence which clears DONE and returns the embedded flash memory to program. The embedded flash memory cannot exit program suspend and clear DONE while EHV is low. PSUS is cleared on reset. 0 Program sequence is not suspended. 1 Program sequence is suspended.

Table continues on the next page...

C55FMC_MCR field descriptions (continued)

Field	Description
29 ERS	Erase ERS is used to set up embedded flash memory for an erase operation. A 0 to 1 transition of ERS initiates an erase sequence. A 1 to 0 transition of ERS ends the erase sequence. ERS can only be set in user mode read (PGM is low and UTE is low). ERS can be cleared only when ESUS and EHV are low and DONE is high. ERS is cleared on reset. 0 Flash memory is not executing an erase sequence. 1 Flash memory is executing an erase sequence.
30 ESUS	Erase Suspend ESUS is used to indicate that the embedded flash memory is in erase suspend or in the process of entering a suspend state. The embedded flash memory is in erase suspend when ESUS = 1 and DONE = 1. ESUS can be set high only when ERS and EHV are high and PGM is low. A 0 to 1 transition of ESUS starts the sequence which sets DONE and places the flash memory in erase suspend. The embedded flash memory enters suspend within Tesus of this transition. ESUS can be cleared only when DONE and EHV are high and PGM is low. A 1 to 0 transition of ESUS with EHV = 1 starts the sequence which clears DONE and returns the embedded flash memory to erase. The embedded flash memory cannot exit erase suspend and clear DONE while EHV is low. ESUS is cleared on reset. 0 Erase sequence is not suspended. 1 Erase sequence is suspended.
31 EHV	Enable High Voltage The EHV bit enables the embedded flash memory for a high voltage program/erase operation. EHV is cleared on reset. EHV must be set after an interlock write to start a program/erase sequence. EHV may be set, initiating a program/erase, after an interlock under one of the following conditions: • Erase (ERS = 1, ESUS = 0) • Program (ERS = 0, ESUS = 0, PGM = 1, PSUS = 0) • Erase-suspended program (ERS = 1, ESUS = 1, PGM = 1, PSUS = 0) If a program operation is to be initiated while an erase is suspended, EHV must be cleared while in erase suspend before setting PGM. In normal operation, a 1 to 0 transition of EHV with DONE high, PSUS low, and ESUS low terminates the current program/erase high-voltage operation. In an erase-suspended program operation, a 1 to 0 transition of EHV with DONE high, ESUS high, PGM high, ERS high, and PSUS low terminates the program that is the current high voltage operation. When an operation is aborted, there is a 1 to 0 transition of EHV with DONE low and the suspend bit for the current program/erase sequence low. An abort causes the value of PEG to be cleared, indicating a failed program/erase; address locations being operated on by the aborted operation contain indeterminate data after an abort. EHV may not be written to a 1 after an abort is requested (EHV being cleared) and before DONE transitions high. A suspended operation cannot be aborted. EHV may be written during suspend. EHV must be high for the embedded flash memory to exit suspend. EHV may not be written after a suspend bit is set high and before DONE transitions high. EHV may not be set low after the current suspend bit is set low and before DONE transitions low. **NOTE:** Aborting a high voltage operation leaves FC addresses in an indeterminate data state. This may be recovered by executing an erase on the affected blocks. 0 Flash memory is not enabled to perform a high voltage operation. 1 Flash memory is enabled to perform a high voltage operation.

30.8.2 Extended Module Configuration Register (C55FMC_MCRE)

NOTE

The reset value of this register is set at the factory and varies among devices. See the chip-specific C55FMC information for details.

Address: 0h base + 8h offset = 8h

C55FMC_MCRE field descriptions

Field	Description
0 HT	High Temperature Enabled. HT provides configuration information of the module. If the flash is tuned for high temperature operation (165 °C) at reduced performance (slower read at 165 °C and less and slower program and erase at 150 °C or less), and limited features at this temperature (no margin reads), the HT status bit will be a 1. Default is 150 °C as maximum operating temperature, and the HT status bit will be a 0. HT is read only. 0 150 °C maximum operating temperature. **NOTE:** 165 °C operating temperature maximum is not supported on this device. 1 Reserved
1–2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3–7 n256K	Number of 256 KB blocks. The value of this field is dependent upon the size of the embedded flash memory. This field is read only. 00000 Zero 256 KB blocks. 00001 Two 256 KB blocks (512 KB total). 00010 Four 256 KB blocks (1 MB total). 00011 Six 256 KB blocks (1.5 MB total). 00100 Eight 256 KB blocks (2 MB total).

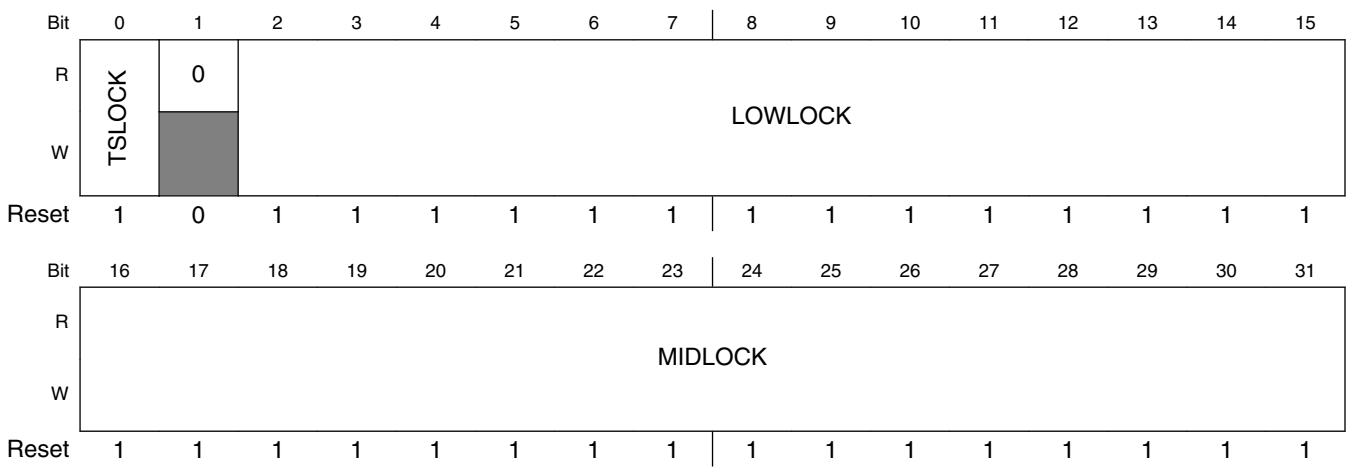
21–23 n16Km	Number of 16 KB blocks in partitions 2 and 3. This field is read only. 000 Zero 16 KB blocks. 001 Two 16 KB blocks. 010 Four 16 KB blocks. 011 Six 16 KB blocks. 100 Eight 16 KB blocks. 101 Reserved. 110 Reserved. 111 Reserved.
24–26 n64Kl	Number of 64 KB blocks in partitions 0 and 1. This field is read only. 000 Zero 64 KB blocks. 001 Two 64 KB blocks. 010 Four 64 KB blocks. 011 Six 64 KB blocks. 100 Eight 64 KB blocks. 101 Reserved. 110 Reserved. 111 Reserved.
27–28 n32Kl	Number of 32 KB blocks in partitions 0 and 1. This field is read only. 00 Zero 32 KB blocks. 01 Two 32 KB blocks. 10 Four 32 KB blocks. 11 Reserved.

Table continues on the next page...



C55FMC_MCRE field descriptions (continued)

Field	Description
29–31 n16Kl	Number of 16 KB blocks in partitions 0 and 1. This field is read only. 000 Zero 16 KB blocks. 001 Two 16 KB blocks. 010 Four 16 KB blocks. 011 Six 16 KB blocks. 100 Reserved. 101 Reserved. 110 Reserved. 111 Reserved.

30.8.3 Lock 0 register (C55FMC_LOCK0)

The Lock 0 (LOCK0) register provides a means to protect blocks from being modified.

Address: 0h base + 10h offset = 10h

C55FMC_LOCK0 field descriptions

Field	Description
0 TSLOCK	UTest NVM Lock. This bit is used to lock the UTest NVM block from programs (erase protection not needed since UTest NVM is OTP and not erasable). A value of 1 in the TSLOCK register signifies that the UTest NVM block is locked for program. A value of 0 in the TSLOCK register signifies that the UTest NVM block is available to receive program pulses. The TSLOCK register is not writable once an interlock write is completed until DONE is set at the completion of the requested operation. Likewise, TSLOCK register is not writable if a high voltage operation is suspended.

Table continues on the next page...

C55FMC_LOCK0 field descriptions (continued)

Field	Description
	0 UTest NVM block is available to be programmed. 1 UTest NVM block is locked and cannot be programmed.
1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2–15 LOWLOCK	Low Block Lock A value of 1 in a bit of the lock register signifies that the corresponding block is locked for program and erase. A value of 0 in the lock register signifies that the corresponding block is available to receive program and erase pulses. The block numbering for the Low Blocks starts at LOWLOCK[0] with 16 KB block region (if available), then the 32 KB block region (if available), and lastly the 64 KB block region (if available). This continues until all blocks are accounted. Low Blocks exist in partitions 0 and 1. The lock register is not writable once an interlock write is completed until DONE is set at the completion of the requested operation. Likewise, the lock register is not writable if a high voltage operation is suspended. The default value of the LOCK bits is locked. In the event that blocks are not present (due to configuration or total memory size), the LOCK bits default to be locked, and are not writable. The reset value is always 1, and register writes have no effect. 0 Block is available for program and erase operations. 1 Block is locked and unavailable for program and erase operations
16–31 MIDLOCK	Mid Block Lock A value of 1 in a bit of the lock register signifies that the corresponding block is locked for program and erase. A value of 0 in the lock register signifies that the corresponding block is available to receive program and erase pulses. The block numbering for the Mid Blocks starts at MIDLOCK[0] with 16 KB block region (if available), then the 32 KB block region (if available), and lastly the 64 KB block region (if available). This continues until all blocks are accounted. Mid Blocks exist in partitions 2 and 3. The lock register is not writable once an interlock write is completed until DONE is set at the completion of the requested operation. Likewise, the lock register is not writable if a high-voltage operation is suspended. The default value of the LOCK bits is locked. In the event that blocks are not present (due to configuration or total memory size), the LOCK bits default to be locked, and are not writable. The reset value is always 1, and register writes have no effect. 0 Block is available for program and erase operations. 1 Block is locked and unavailable for program and erase operations

30.8.4 Lock 1 register (C55FMC_LOCK1)

The Lock 1 (LOCK1) register provides a means to protect blocks from being modified.

Address: 0h base + 14h offset = 14h

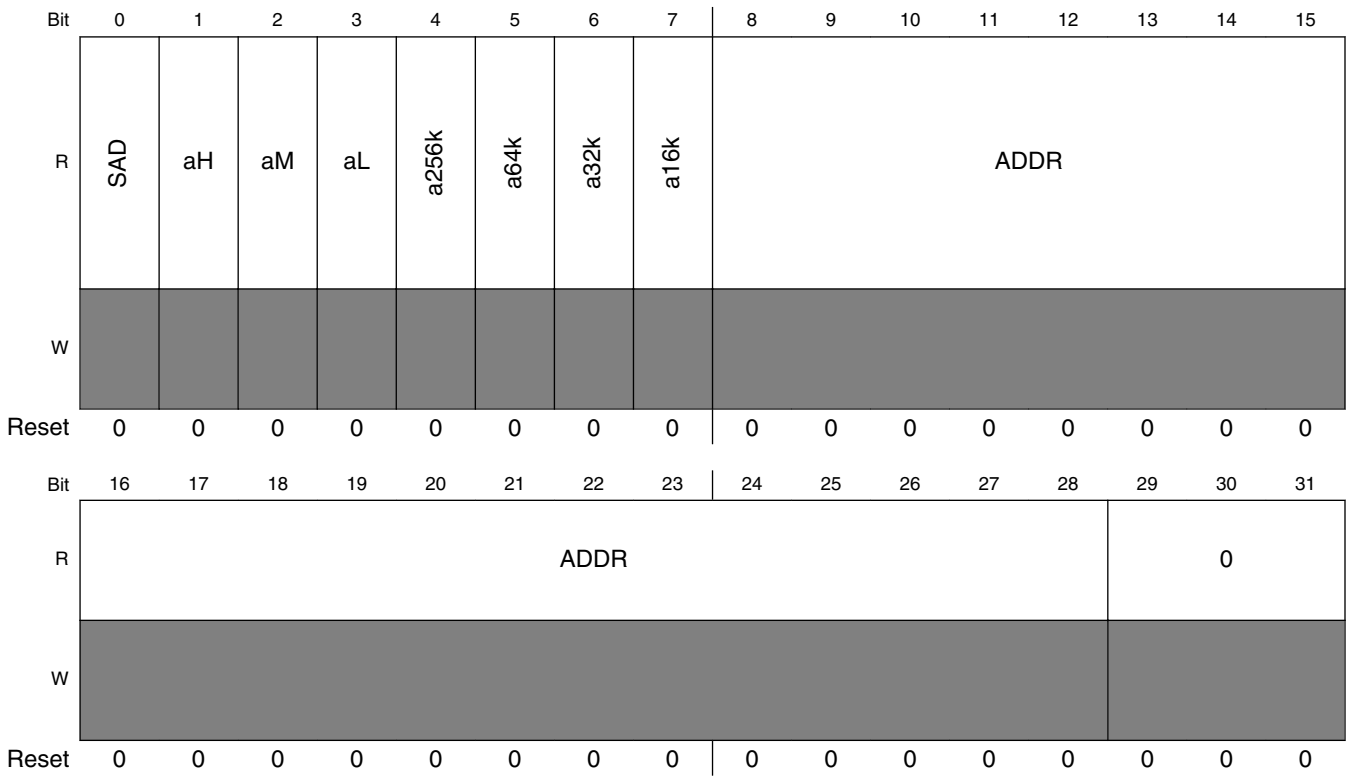
C55FMC_SEL2 field descriptions

Field	Description
0–31 A256KSEL	256 KB Block Select. A value of 1 in the select register signifies that the block is selected for erase. A value of 0 in the select register signifies that the block is not selected. The reset value for the select registers is 0, or unselected. The block numbering for the 256 KB blocks starts with 256KSEL[0] and continues until all blocks are accounted. The blocks must be selected (or unselected) before doing an erase interlock write as part of the erase sequence. The select register is not writable once an interlock write is completed until DONE is set at the completion of the requested operation, or if a high-voltage operation is suspended. 256KSEL is also not writeable during UTest operations, when AIE is high. In the event that blocks are not present (due to configuration or total memory size), the corresponding select bits default to unselected, and are not writable. The reset value is always 0, and register writes have no effect. 0 The block is not selected 1 The block is selected for erase

30.8.10 Select 3 register (C55FMC_SEL3)

The Select 3 (SEL3) register provides a means to select blocks to be operated on during erase.

Address: 0h base + 44h offset = 44h



C55FMC_SEL3 field descriptions

Field	Description
0–15 Reserved	This field is reserved. Reserved, reset to 0.
16–31 A256KSEL	256 KB Block Select. A value of 1 in the select register signifies that the block is selected for erase. A value of 0 in the select register signifies that the block is not selected. The reset value for the select registers is 0, or unselected. The block numbering for the 256 KB blocks starts with 256KSEL[0] and continues until all blocks are accounted. The blocks must be selected (or unselected) before doing an erase interlock write as part of the erase sequence. The select register is not writable once an interlock write is completed until DONE is set at the completion of the requested operation, or if a high-voltage operation is suspended. 256KSEL is also not writeable during UTest operations, when AIE is high. In the event that blocks are not present (due to configuration or total memory size), the corresponding select bits default to unselected, and are not writable. The reset value is always 0, and register writes have no effect. 1 The block is selected for erase. 0 The block is not selected.

30.8.11 Address register (C55FMC_ADR)

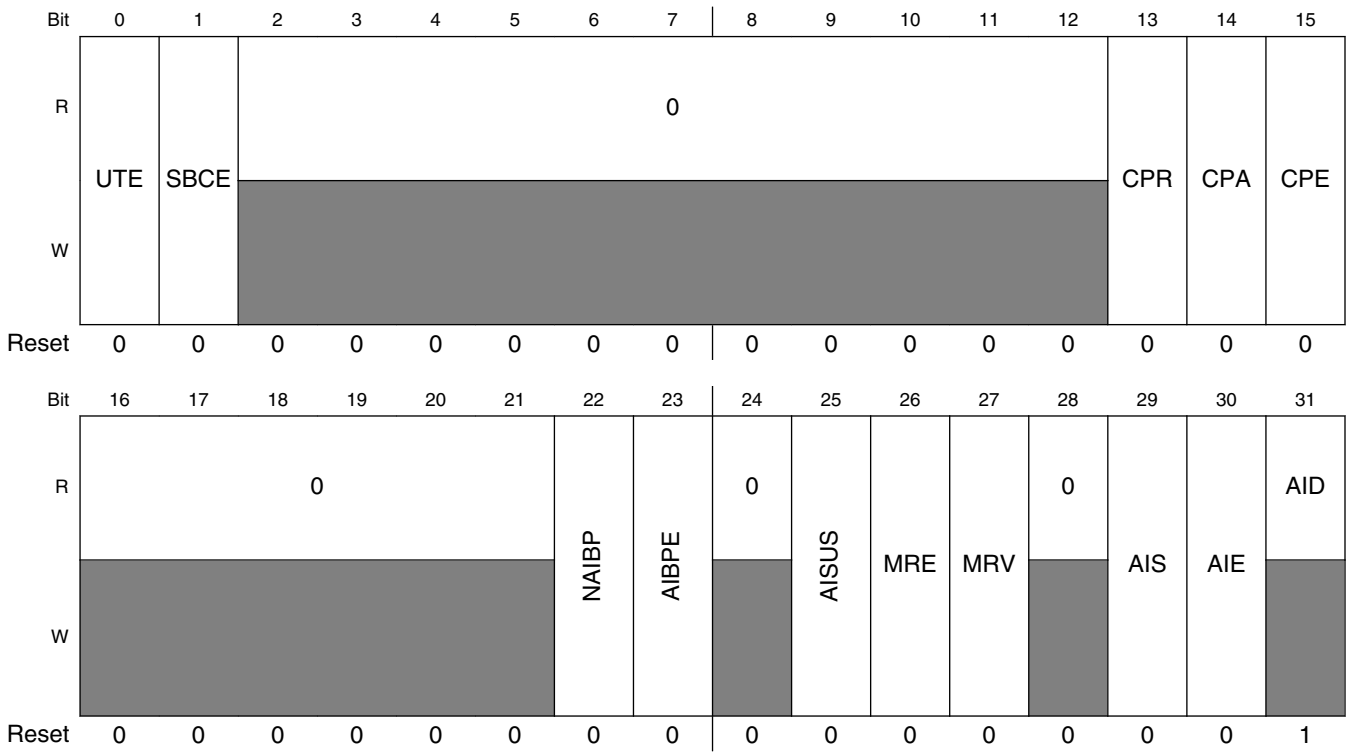
The Address register (ADR) provides the first failing address in the event of a failure (ECC or PGM/Erase state machine), as well as single bit correction information.

Address: 0h base + 50h offset = 50h

C55FMC_ADR field descriptions

Field	Description
0 SAD	UTest NVM Address. The SAD bit qualifies the address captured during an ECC Event Error, Single Bit Correction, or State Machine operation. SAD has the same characteristics as ADDR related to capturing of addresses. The SAD field is not writable. 0 Address captured is from main array Space. 1 Address captured is from UTest NVM array space.
1 aH	Address High region. The aH bit qualifies the address field (ADDR) to the region of a16K, a32K and a64k. If aH is set, then the ADDR field maps to that region. See ADDR description for more information. 0 Address captured or to be accessed is not from high address region. 1 Address captured or to be accessed is from high address region.
2 aM	Address Mid region. The aM bit qualifies the address field (ADDR) to the region of a16K, a32K and a64k. If aM is set, then the ADDR field maps to that region. See ADDR description for more information.

Table continues on the next page...



C55FMC_ADR field descriptions (continued)

Field	Description
	0 Address captured or to be accessed is not from mid address region. 1 Address captured or to be accessed is from mid address region.
3 aL	Address Low region. The aL bit qualifies the address field (ADDR) to the region of a16K, a32K and a64k. If aL is set, then the ADDR field maps to that region. See ADDR description for more information. 0 Address captured or to be accessed is not from low address region. 1 Address captured or to be accessed is from low address region.
4 a256k	Address 256 KB region. The a256k bit qualifies the address field (ADDR) to the region. If a256k is set, then the ADDR field maps to that region. See ADDR description for more information. The a256k register is writable. 0 Address captured or to be accessed is not from 256 KB region. 1 Address captured or to be accessed is from 256 KB region.
5 a64k	Address 64 KB region. The a64k bit qualifies the address field (ADDR) to the region. If a64k is set, then the ADDR field maps to that region. See ADDR description for more information. 0 Address captured or to be accessed is not from 64 KB region. 1 Address captured or to be accessed is from 64 KB region.
6 a32k	Address 32 KB region. The a32k bit qualifies the address field (ADDR) to the region. If a32k is set, then the ADDR field maps to that region. See ADDR description for more information. 0 Address captured or to be accessed is not from 32 KB region. 1 Address captured or to be accessed is from 32 KB region.
7 a16k	Address 16 KB region. The a16k bit qualifies the address field (ADDR) to the region. If a16k is set, then the ADDR field maps to that region. See ADDR description for more information. 0 Address captured or to be accessed is not from 16 KB region. 1 Address captured or to be accessed is from 16 KB region.
8–28 ADDR	Address. The ADR provides the first failing address in the event of ECC event error (EER set), Single Bit Correction (SBC set), as well as providing the address of a failure that may have occurred in a state machine operation (PEG cleared). ECC event errors take priority over Single Bit Corrections, which take priority over state machine errors. This is especially valuable in the event of an RWW operation, where the read senses an ECC error or Single Bit correction, and the state machine fails simultaneously. The failing address for ECC event error is held until EER is cleared. The failing address for Single Bit Correction is held until an ECC event error, or until SBC is cleared. State machine address is held until an ECC event error or Single Bit Correction event occurs, or until the next state machine event (PEG cleared) occurs. This address is always a doubleword address that selects 64 bits. ADDR[23:3] is an offset from a base address of 0x0 for each block size region. The aH, aM, aL, a16k, a32k, a64k, and a256k qualify the block size region the ADDR field.
29–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

30.8.12 UTest 0 register (C55FMC_UT0)

The User Test 0 (UT0) register provides a means to control UTest. UTest mode gives the ability to perform test features on the flash memory. This register is only writable when the flash memory is put into UTest mode by writing a passcode.

Address: 0h base + 54h offset = 54h

C55FMC_UT0 field descriptions

Field	Description
0 UTE	U-Test Enable. This status bit gives indication when U-Test is enabled. All bits in UT0, UM0, UM1, UM2, UM3, UM4, UM5, UM6, UM7, UM8 and UM9 are locked when this bit is 0. This bit is not writeable to a 1, but may be cleared. The reset value is 0. The method to set this bit is to provide a password, and if the password matches, the UTE bit is set to reflect the status of enabled, and is enabled until it is cleared by a register write. The UTE password will only be accepted if PGM = 0 and ERS = 0 (program and erase are not being requested). UTE can only be cleared if AID = 1, MRE and AIE = 0. While clearing UTE, writes to set AIE or MRE will be ignored. For UTE, the password 0xF9F9_9999 must be written to the UT0 register. 0 All bits in the UT0, UM0, UM1, UM2, UM3, UM4, UM5, UM6, UM7, UM8 and UM9 registers are locked 1 Bits in the UT0, UM0, UM1, UM2, UM3, UM4, UM5, UM6, UM7, UM8 and UM9 registers are unlocked
1 SBCE	Single Bit Correction Enable. SBCE enables Single Bit Correction results to be observed in SBC. ECC corrections that occur when SBCE is cleared will not be logged.

Table continues on the next page...

C55FMC_UT0 field descriptions (continued)

Field	Description
	0 Single Bit Corrections observation is disabled. 1 Single Bit Correction observation is enabled.
2–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13 CPR	Customer Programmable Read Voltage and Reference Detection. This bit is used to control the error generation for the Customer Programmable Detection area in the UTest block. If this bit is set, and the Customer Programmable Detection location in UTest is read, a Read Voltage and Reference Error detection will be noted. This bit may not be set while CPE and CPA are set. If CPE or CPA are high, this bit will be locked. If attempts are made to write CPR, CPA or CPE simultaneously, none of them will be written. 0 Customer Programmable Read Voltage and Reference Detection Error is not enabled 1 Customer Programmable Read Voltage and Reference Detection Error is enabled
14 CPA	Customer Programmable Address Encode Detection. This bit is used to control the error generation for the Customer Programmable Detection area in the UTest block. If this bit is set, and the Customer Programmable Detection location in UTest is read, a Address Encode Error detection will be noted. This bit may not be set while CPE and CPR are set. If CPE or CPR are high, this bit will be locked. If attempts are made to write CPR, CPA or CPE simultaneously, none of them will be written. 0 Customer Programmable Address Encode Detection Error is not enabled 1 Customer Programmable Address Encode Detection Error is enabled
15 CPE	Customer Programmable EDC after ECC Detection. This bit is used to control the error generation for the Customer Programmable Detection area in the UTest block. If this bit is set, and the Customer Programmable Detection location in UTest is read, a EDC after ECC Error detection will be noted. This bit may not be set while CPR and CPA are set. If CPR or CPA are high, this bit will be locked. If attempts are made o write CPR, CPA or CPE simultaneously, none of them will be written. 0 Customer Programmable EDC after ECC Detection Error is not enabled 1 Customer Programmable EDC after ECC Detection Error is enabled
16–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22 NAIBP	Next Array Integrity Break Point. If AIBPE is set, NAIBP will be set once a single bit correction (if enabled) or double bit detection is noted during the Array Integrity test. NAIBP is not writable to 1, but may be cleared to 0. Clearing NAIBP to 0, will enable the Array Integrity operation to be re-started after a breakpoint is encountered. If the Array Integrity operation completes without encountering another correction or detection, AID will be set with NAIBP remaining 0. 1 Array Integrity state machine is at a break point. 0 Array Integrity state machine is not currently at a break point.
23 AIBPE	Array Integrity Break Point Enable. If you want to enable breakpoints during an array integrity test, AIBPE may be set. See NAIBP description for more information about array integrity breakpoints. 1 Array Integrity breakpoints are enabled during Array Integrity Checks. 0 Array Integrity breakpoints are not enabled.
24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25 AISUS	Array Integrity Suspend. AISUS enables a suspend of an Array Integrity Operation. Array Integrity may be suspend by Setting AISUS, and resumed by clearing AISUS. AISUS is writeable only when AID is low. AISUS is clearable only when AID is high. Attempting to write AISUS and AIE on the same clock cycle will result in only AIE getting written.

Table continues on the next page...

C55FMC_UT0 field descriptions (continued)

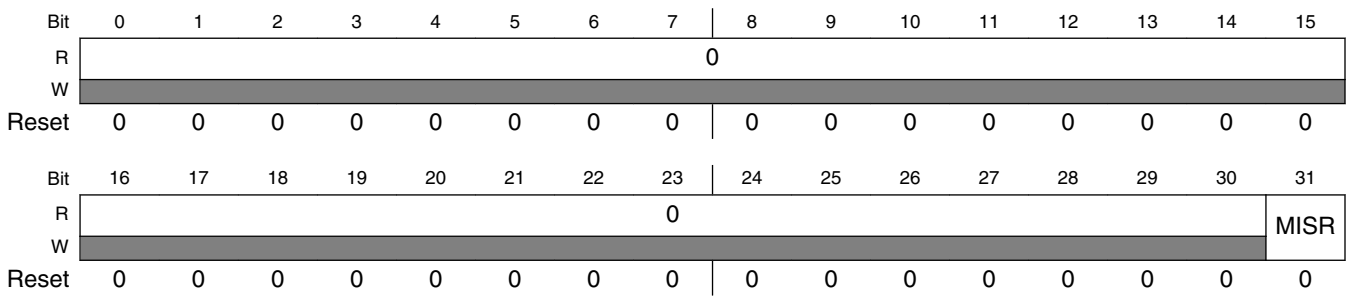
Field	Description
	1 Array integrity sequence is suspended. 0 Array integrity sequence not suspended.
26 MRE	Margin Read Enable. MRE combined with MRV enables user margin reads to be done. Normal user reads are not affected by MRE, although user reads while the margin read operation is ongoing are not supported. MRE is not writable if AID is low, or if AISUS is high, or if NAIBP is high. 1 Margin reads are enabled. 0 Margin reads are not enabled.
27 MRV	Margin Read Value. MRV selects the margin level that is being checked. Margin can be checked to an erased level (MRV=1) or to a programmed level (MRV=0). In order for this value to be valid, MRE must also be set. MRV is not writable if AID is low, or if AISUS is high, or if NAIBP is high. 1 One's margin reads are requested. 0 Zero's margin reads are requested.
28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29 AIS	Array Integrity Sequence. AIS determines the address sequence to be used during array integrity checks. The default sequence (AIS = 0) is meant to replicate sequences that normal user code follows, and thoroughly checks the read propagation paths. This sequence is proprietary. The alternative sequence (AIS = 1) is logically sequential. It should be noted that the time to run a sequential sequence is shorter than the time to run the proprietary sequence. AIS is not writeable if AIE is high. 1 Array integrity sequence is sequential. 0 Array integrity sequence is proprietary sequence.
30 AIE	Array Integrity Enable. AIE set to one starts the array integrity check done on all selected blocks. The address sequence is determined by AIS, and the MISR (UM0 through UM9) can be checked after the operation is complete, to determine if a correct signature has been obtained. Once an array integrity operation is requested (AIE=1), it may be terminated by clearing AIE if the operation has finished (AID = 1) or aborted by clearing AIE if the operation is ongoing (AID = 0). AIE is not simultaneously writable to a 1 as UTE is being cleared to a 0. 0 Array integrity checks are not enabled. 1 Array integrity checks are enabled.
31 AID	Array Integrity Done. AID is cleared upon an array integrity check being enabled (to signify the operation is ongoing). Once completed, AID is set to indicate that the array integrity check is complete. At this time the MISR (UMR registers) can be checked. AID may also assert if breakpoints are enabled (AIBPE is set), an abort is requested or a suspend is requested. AID cannot be written, and is status only. 0 Array integrity check is ongoing. 1 Array integrity check is done.

30.8.13 UMISR register (C55FMC_UM*n*)

The Multiple Input Signature registers provide a means to evaluate array integrity.

Address: 0h base + 58h offset + (4d × i), where i=0d to 8d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	MISR																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0



C55FMC_UM*n* field descriptions

Field	Description
0–31 MISR	MISR[31:0]. The MISR registers accumulate a signature from an array integrity event. The MISR captures all data fields, as well as ECC fields, and the ECC error signal. Data (read and ECC) captured in the MISR is after the ECC logic, and represents corrected data (if required). The MISR can be seeded to any value by writing the MISR registers. **NOTE:** Writing the MISR register during an array integrity operation (including suspend or breakpoint) although possible, is not recommended. A write of the MISR registers at this point may alter the final signature in an unpredictable way. The MISR register provides a means to calculate a MISR during array integrity operations. The MISR can be represented by the following polynomial: $x^{289} + x^{7} + x^{6} + x^{5} + x^{4} + x^{2} + 1$ The MISR is calculated by taking the previous MISR value and then "exclusive ORing" the new data. In addition the most significant bit (in this case it is MISR[288]), is then "exclusive ORed" into input of MISR[7], MISR[6], MISR[5], MISR[4], MISR[2] and MISR[0]. The result of the "exclusive OR" is shifted left on each read. The MISR register is used in array integrity operations. If during address sequencing, reads extend into an invalid address location (in other words, greater than the maximum address for a given array size) then reads are still executed to the array, but the results from the array read are not deterministic. In this instance, the MISR registers is not recalculated, and the previous value is retained.

30.8.14 UMISR register (C55FMC_UM9)

The Multiple Input Signature registers provide a means to evaluate array integrity.

Address: 0h base + 7Ch offset = 7Ch

C55FMC_UM9 field descriptions

30.8.19 Test Mode Disable Password Check register (C55FMC_TMD)

The Test Mode Disable Password Check (TMD) register provides a means to provide a challenge password to disable the Test Mode Disable Seal block select.

Writes to the register have no effect except for a password challenge. Reads to this register always return 0.

Address: 0h base + 90h offset = 90h

C55FMC_TMD field descriptions

Field	Description
0–31 PWD	Password challenge

30.9 Functional Description

The embedded flash memory consists of address spaces in four groupings:

- Low address space
- Mid address space
- High address space
- 256 KB address space

The main address space is divided into partitions. Each address space mentioned above consists of a partition pair. Partitions are used to determine locations for valid read-while-write (RWW) operations. While the embedded flash memory is performing a write (program or erase) to a given partition, it can simultaneously perform a read from any other partition. For program operations, only the address specified by an interlock write determines the partition being written (block locking and block select registers do not determine the RWW partitions being written). For erase operations, only blocks that are selected and unlocked determine the RWW partitions being written.

The main address space is also divided into blocks to implement independent erase and program protection. The UTest NVM block also exists as a block, and has independent program protection. The UTest NVM block is included to support systems that require nonvolatile memory (NVM) for security or to store system initialization information.

A number of MCR bits are protected against write when another bit, or set of bits, is in a specific state. These write locks are covered on a bit-by-bit basis in Module Configuration Register (C55FMC_MCR). The write locks do not consider the effects of trying to write two or more bits simultaneously. The embedded flash memory does not allow bits to be written simultaneously which put the device into an illegal state. This is implemented through a priority mechanism among the bits. The bit changing priorities are detailed in the following table.

Table 30-32. MCR bit set/clear priority levels

Priority level	MCR Bit(s)
1	ERS
2	PGM
3	EHV
4	ESUS, PSUS

If two or more MCR bits are written simultaneously only the bit with the lowest priority number is accepted for modification. Setting two bits with the same priority number is prevented by existing write locks or do not put the flash memory in an illegal state.

For example, setting ERS and PGM simultaneously results in only ERS being set. Attempting to clear EHV while setting PSUS results in EHV being cleared, while PSUS is unaffected.

Each read of the embedded flash memory retrieves a page, or eight consecutive words (256 bits), of information. The address for each word retrieved within a page differs from the other addresses in the page only by address bits [4:2]. The flash memory page read architecture easily supports both cache and burst mode at the BIU level for high-speed read applications.

The embedded flash memory supports fault tolerance through error correction code (ECC) and error detection. ECC implemented within the embedded flash memory corrects single-bit failures and detects double-bit failures.

A software mechanism is provided to independently lock and unlock each block.

Program and erase of the embedded flash memory requires multiple system clock cycles to complete. The program and erase sequence may be suspended or aborted.

The embedded flash memory may reside in various modes. The modes that are available include:

- User mode
- UTest mode

Each of these modes is discussed in detail in the following sections.

30.9.1 User Mode

In user mode the embedded flash memory may be read and written (register writes and interlock writes), programmed or erased. The following sub-sections define all actions that may be performed in user mode.

30.9.1.1 Read and write

The default state of the embedded flash memory is read. The main and UTest NVM address space can be read only in the read state. The MCR is always available for read. The embedded flash memory enters the read state on reset. The embedded flash memory is in the read state under four sets of conditions:

- The read state is active when the embedded flash memory is enabled (User Mode Read).
- The read state is active when MCR[PGM] or MCR[ERS] are high and high-voltage operation is ongoing (read-while-write).

NOTE

Reads done to the partition(s) being operated on (either erased or programmed) result in an error and the MCR[RWE] bit is set.

- The read state is active when MCR[PGM] and MCR[PSUS] are high (program suspend).
- The read state is active when MCR[ERS] and MCR[ESUS] are high and MCR[PGM] is low (erase suspend).

In embedded flash memory, flash core reads return 256 bits (1 page). Register reads return 32 bits of data.

NOTE

Flash core reads are done through the BIU. In many cases the BIU does read page buffering to allow sequential reads to be done with higher performance. This could provide a data coherency issue that must be handled with software. Data coherency may be an issue after a program or erase operation, as well as UTest NVM block operations.

In user mode, registers may be written. Array may be written to do interlock writes.

Register reads to unmapped register address space return all zeroes.

Register writes to unmapped register address space have no effect.

Interlock writes that are attempted during a high-voltage operation (MCR[EHV] = 1 or MCR[DONE] =0) will result in the interlock write being ignored, and address and data will not be updated.

NOTE

Care must be taken when doing 32-bit interlock writes. Performing two 32-bit interlock writes to the same word location is not supported. In addition, mixing 32-bit interlock writes with 64-bit interlock writes to the same double-word location is not supported. If these combinations are done, and a program operation is executed, the result will be MCR[PEG] = 0. See the Module Configuration Register (MCR) section for more information.

30.9.1.2 Program

A flash memory program sequence operates on any page within the flash core. Within a page, up to eight words may be altered in a single program operation. Also, up to four pages can be altered in a single program operation. Whenever the array is programmed, the ECC bits also get programmed. ECC is handled on a 64-bit boundary. Thus, if only one word in any given 64-bit ECC segment is programmed, the adjoining word (in that segment) should not be programmed, since ECC calculation has already completed for that 64-bit segment. Attempts to program the adjoining word will probably result in an operation failure. It is recommended that all programming operations be from 64 bits to 1024 bits, and be 64-bit aligned. The programming operation should completely fill selected ECC segments within the page. Only one program is allowed per 64-bit ECC segment between erases.

Warning

In rare cases over-programming of a 64-bit ECC segment may be done (EEPROM emulation).

Programming changes the value stored in an array bit from logic 1 to logic 0 only. Programming cannot change a stored logic 0 to a logic 1.

NOTE

If a logic 0 is attempted to be over-programmed by a logic 1, the resulting operation will fail (MCR[PEG] = 0), and the 0's that are interlocked will be merged (ORed) with 0's that are already present in the 64-bit ECC segment, unless the block is designated as an Over-Program Protected block.

Addresses in locked/disabled blocks cannot be programmed. Values may be programmed in any or all of eight words, within a page, with a single program sequence. Page-bound words have addresses which differ only in address bits [4:2]. Up to four pages can be programmed at once on a quad-page boundary, which differ only in address bits [6:5]. The program operation consists of the following sequence of events:

1. Change the value in the MCR[PGM] bit from a 0 to a 1.

   NOTE

   Ensure the block that contains the address to be programmed is unlocked.

2. Write the first address to be programmed with the program data. The embedded flash memory latches address bits [22:7] and SoC-specific UTest NVM enable at this time. The embedded flash memory latches data written as well. This write is referred to as

a program data interlock write. An interlock write may be done as a 64-bit transaction or a 32-bit transaction. Refer to the Flash Memory Controller chapter for information on the size of writes that are allowed.

3. If more than one word or doubleword is to be programmed, write each additional address in the page with data to be programmed. This is referred to as a program data write. The embedded flash memory ignores address bits [22:7] and SoC-specific UTest NVM enable for program data writes. All unwritten data words default to 0xFFFF_FFFF.
4. Write a logic 1 to the MCR[EHV] bit to start the internal program sequence or skip to step 9 to terminate.
5. Wait until the MCR[DONE] bit goes high.

NOTE

Since MCR[DONE] clears with MCR[EHV] being set, it may not be possible for software to read MCR[DONE] as a 0 prior to this step, depending on the operation selected.

6. Confirm MCR[PEG] = 1.
7. Write a logic 0 to the MCR[EHV] bit.
8. If more addresses are to be programmed, return to step 2.
9. Write a logic 0 to the MCR[PGM] bit to terminate the program sequence.

The first write after a program is initiated determines the quad-page address to be programmed. Program may be initiated with the 0 to 1 transition of the MCR[PGM] bit or by clearing the MCR[EHV] bit at the end of a previous program. This first write is referred to as an interlock write. The interlock write determines if the UTest NVM or normal array space is to be programmed by sampling SoC-specific UTest NVM enable and causing MCR[PEAS] to be set/cleared.

In the case of an erase-suspended program, the values in MCR[PEAS] may be modified via the program interlock write, enabling erase-suspended programs to and from UTest NVM space.

An interlock write must be performed before setting MCR[EHV]. A program sequence may be terminated by clearing MCR[PGM] prior to setting MCR[EHV].

After the interlock write, additional writes affect the data to be programmed at the word location determined by address bits [4:2], as well as the page location within a 1024-bit segment (determined by address bits [6:5]). Unwritten locations default to a data value of 0xFFFF_FFFF. If multiple writes are done to the same location, the data for the last write is used in programming.

While DONE is low, EHV is high, and PSUS is low, then EHV may be cleared, resulting in a program abort. A program abort forces the embedded flash memory to step 8 of the program sequence. An aborted program results in PEG being set low, indicating a failed operation. The data space being operated on before the abort contains indeterminate data. A program sequence may not be aborted while in program suspend.

Warning

Aborting a program operation leaves the flash core addresses being programmed in an indeterminate data state. This may be recovered by executing an erase on the affected blocks.

30.9.1.2.1 Program software locking

A software mechanism is provided to independently lock/unlock blocks against program and erase.

Software locking is done through the LOCK0, LOCK1, LOCK2, and LOCK3 registers. These may be written through register writes, and may be read through register reads.

30.9.1.2.2 Program hardware locking

Hardware locking which only affects the program operation is also available for UTest, 16 KB, 32 KB, 64 KB, and 256 KB blocks.

30.9.1.2.3 Program suspend/resume

The program sequence may be suspended to allow read access to the flash core. It is not possible to erase during a program suspend, or to program during a program suspend. These operations are prevented by register locking described in the Module Configuration Register (MCR) section. Read-while-write operation may also be used to read the array during a program sequence, providing the read is to a different partition.

A program suspend can be initiated by changing the value of the MCR[PSUS] bit from a 0 to a 1. MCR[PSUS] can be set high at any time when MCR[PGM] and MCR[EHV] are high. A 0 to 1 transition of MCR[PSUS] causes the embedded flash memory to start the sequence to enter program suspend, which is a read state. MCR[DONE] must become a logic level 1 before the embedded flash memory is suspended. At this time flash core reads may be attempted. Once suspended, the flash core may only be read. During suspend, all reads to flash core locations targeted for program, and blocks targeted for erase, return indeterminate data.

The program sequence is resumed by writing a logic 0 to MCR[PSUS]. MCR[EHV] must be set to a 1 before clearing MCR[PSUS] to resume operation. When the operation resumes, the embedded flash memory continues the program sequence from one of a set of predefined points. This may extend the time required for the program operation.

NOTE

Repeated suspends at a high frequency may result in the operation timing out, and the embedded flash memory will respond by completing the operation with a fail code (MCR[PEG] = 0). Although suspend frequency in not limited, enabling at least 20uS between suspend resume and future suspend requests improve the opportunity for the flash to complete the operation.

30.9.1.2.4 Over-program protection enable

One-time programming can be enabled on a block basis. In an over-program protection enabled block, any doubleword which has already been programmed cannot be programmed again. The over-program protection enable does not affect erase operation. Attempts to over-program will result in MCR[PEG] being cleared. If any doubleword within the quad-page has an over-program protection violation, MCR[PEG] will be cleared, and no doublewords will be programmed.

One-time programming can be enabled for 16 KB, 32 KB, 64 KB, or 256 KB blocks.

Over-program protection is enabled by sideband signals, and if enabled, the program operation will be modified to check for programmed bits prior to doing a high-voltage program event.

30.9.1.2.5 Successful program address

To enable the SoC to create logic to authenticate operations with a program (such as in a diary operation), the flash module provides the last successful address programmed as a sideband signal. This value will be held until the next successful program. A successful program is defined as a program operation of data that is not all 1's to an unlocked block, and the operation results in MCR[PEG] returning a 1. If any doubleword within the pages being programmed is interlocked with all 1's, the sideband signal will not be updated. An address of all 1's, and each of the block size selects selected, is the default (and invalid) address after reset.

30.9.1.3 Erase

Erase changes the value stored in all bits of the selected block(s) to logic 1. An erase sequence operates on any combination of blocks in the main address space. The erase sequence is fully automated within the flash memory. Blocks to be erased must be selected prior to initiating the erase sequence. Locked/disabled blocks cannot be erased. If multiple blocks are selected for erase during an erase sequence, the blocks are erased sequentially starting with the lowest numbered block and terminating with the highest (low first, mid second, high last, 16 KB first, 32 KB second, 64 KB third, last blocks are 256 KB). The erase sequence consists of the following events:

1. Change the value in the MCR[ERS] bit from 0 to 1.
2. Select the block or blocks to be erased by writing ones to the appropriate registers in SEL0, SEL1, SEL2, or SEL3 registers.

NOTE

Lock and Select are independent. If a block is selected and locked, no erase occurs.

3. Write to any address in flash memory. This is referred to as an erase interlock write. An erase interlock write to UTest NVM space is not allowed if sealed (since erase is not allowed in the UTest NVM space when sealed).
4. Write a logic 1 to the MCR[EHV] bit to start an internal erase sequence or skip to step 9 to terminate.
5. Wait until the MCR[DONE] bit goes high.

NOTE

Since MCR[DONE] clears with MCR[EHV] being set, it may not be possible for software to read MCR[DONE] as a 0 prior to this step, depending on the operation selected.

6. Confirm MCR[PEG] = 1.
7. Write a logic 0 to the MCR[EHV] bit.
8. If more blocks are to be erased, return to step 2.
9. Write a logic 0 to the MCR[ERS] bit to terminate the erase.

After setting ERS, one write, referred to as an interlock write, must be performed before EHV can be set to a 1. Data words written during erase sequence interlock writes are ignored. The erase sequence may be terminated by clearing ERS before setting EHV.

An erase operation may be aborted by clearing EHV, assuming DONE is low, EHV is high, and ESUS is low. An erase abort forces the embedded flash memory to step eight of the erase sequence. An aborted erase results in PEG being set low, indicating a failed operation. The block(s) being operated on before the abort contain indeterminate data. An erase sequence may not be aborted while in erase suspend.

30.9.1.3.1 Erase software locking

Software Locking affect erase operation. For details on this see Program software locking.

30.9.1.3.2 Erase hardware locking

Hardware locking which only affects the erase operation is also available for UTest, 16 KB, 32 KB, 64 KB, and 256 KB blocks.

30.9.1.3.3 Erase suspend/resume

The erase sequence may be suspended to allow read access to the flash core. The erase sequence may also be suspended to program (Erase-Suspended Program) the flash core. A program started during erase suspend can in turn be suspended. Only one erase suspend and one program suspend are allowed at a time during an operation. It is not possible to erase during an erase suspend, or program during a program suspend. During suspend, all reads to flash core locations targeted for program and blocks targeted for erase return indeterminate data.

Read-while-write operation may also be used to read the array during an erase sequence, provided the read is to a partition not selected for erase.

An erase suspend can be initiated by changing the value of the MCR[ESUS] bit from a 0 to a 1. MCR[ESUS] can be set to a 1 at any time when MCR[ERS] and MCR[EHV] are high and MCR[PGM] is low. A 0 to 1 transition of MCR[ESUS] causes the embedded flash memory to start the sequence which places it in erase suspend. MCR[DONE] must become a logic level 1 before the embedded flash memory is suspended and further actions are attempted. Once suspended, the array may be read or a program sequence may be initiated (erase-suspended program). Before initiating a program sequence, MCR[EHV] must first be cleared. If a program sequence is initiated, the values of SoC-specific UTest NVM enable is recaptured. Once the erase-suspended program is completed, the value of PEAS is returned to its erase value. Flash core reads that occur while MCR[ESUS] = 1 from the block(s) being erased will return indeterminate data.

The erase sequence is resumed by writing a logic 0 to MCR[ESUS]. MCR[EHV] must be set to a 1 and MCR[PGM] must be cleared (in the event of an erase-suspended program) before MCR[ESUS] can be cleared to resume the operation. The embedded flash memory continues the erase sequence from one of a set of predefined points. This may extend the time required for the erase operation.

Warning

In an erase-suspended program, programming flash core locations in blocks which were being operated on will respond by completing the operation with a fail code (MCR[PEG] = 0). Programming voltages will not be applied to the memory array in this case.

Warning

Repeated suspends at a high frequency may result in the operation timing out, and the embedded flash memory will respond by completing the operation with a fail code (MCR[PEG] = 0). Although suspend frequency is not limited, enabling at least 5mS between suspend resume and future suspend requests improve the opportunity for the flash to complete the operation.

30.9.2 UTest mode

UTest mode is a mode into which customers can put the embedded flash memory so as to do specific tests that check the integrity of the embedded flash memory.

30.9.2.1 Array integrity self check

Array integrity is checked using a predefined address sequence (based on UT0[AIS]), and this operation is executed on selected blocks. The data to be read is customer-specific - user code may be programmed into the flash memory and the correct MISR signature is calculated based on that code. Any random or nonrandom code is valid. Once the operation is completed, the results of the reads can be checked by reading the MISR value, to determine if an incorrect read or ECC detection was noted. Array integrity MISR value is calculated after ECC detection and correction. Array integrity requires that the Read Wait States and Address Pipelined control registers in the BIU be set to match the system frequency being used. The array integrity check consists of the following sequence of events:

1. Enable UTest mode.
2. Select the block or blocks to be receive the array integrity check by writing 1's to the appropriate registers in SEL0, SEL1, SEL2, or SEL3 registers. Blocks selected for array integrity check do not need to be unlocked.

NOTE

Unselected blocks are still read as part of the array integrity sequence, to enable full transition coverage. The result read on unselected blocks will not be captured in the MISR. Selecting fewer blocks may not result in a faster array integrity execution time, depending on the combinations of blocks selected and the sequence.

NOTE

Blocks protected with the Test Mode Disable Seal are still read as part of the array integrity sequence. The resulting read on sealed blocks will not be captured in the MISR, but the Single Bit Correction, Double Bit Detection and breakpoints will still be honored.

NOTE

It is not possible to do array integrity operations on the UTest NVM block.

3. If desired, set the UT0[AIS] bit to 1 for sequential addressing only.

NOTE

For normal integrity checks of the flash memory, sequential addressing is recommended. If it is required to more fully check the read path (in a diagnostic mode), it is recommended that AIS be left at 0, to use the address sequence that checks the read path more fully, and examine read transitions. This sequence takes more time.

4. Seed the MISR registers (UM0 — UM9) with desired values.
5. If breakpoints are desired, set UT0[AIBPE] to 1, and ensure that MCR[EER] and MCR[SBC] are cleared. If it is desired to break on single-bit correction, ensure that UT0[SBCE] is set.
6. Set the UT0[AIE] bit.
   a. If desired, the array integrity operation may be aborted prior to UT0[AID] going high. This may be done by clearing the UT0[AIE] bit and then continuing to the next step. It should be noted that in the event of an aborted array integrity check the MISR registers will contain a signature for the portion of the operation that was completed prior to the abort, and will not be deterministic. Prior to doing another array integrity operation, the UM0, UM1, UM2, UM3, UM4, UM5, UM6, UM7, UM8, and UM9 registers may need to be initialized to the desired seed value by doing register writes.
   b. If desired, the array integrity operation may be suspended prior to UT0[AID] going high. UT0[AISUS] may be set to request an array integrity suspend. After

the UT0[AISUS] bit is set, the user should wait for UT0[AID] bit to go high, which indicates the flash has entered the suspend state, and normal reads to the flash may be done. Once [AID] goes high, UT0[AISUS] may be cleared to resume the array integrity sequence.

NOTE

User mode array reads requested during the array integrity test will be ignored, to ensure that the array integrity operation is not corrupted. The memory array will not respond to array read requests during this time. User mode array reads may be executed if suspended or at a breakpoint.

7. Wait until the UT0[AID] bit goes high.
8. If breakpoints were enabled, check UT0[NAIBP], and if this is set to 1, the MCR[EER], MCR[SBC], and ADDR registers may be checked to determine the cause of the break and the address of the break. Prior to resuming the operation, clear MCR[SBC] or MCR[EER] bits. Then the operation may be resumed by clearing UT0[NAIBP]. Continue to wait until the UT0[AID] bit goes high. If breakpoints were not enabled, or if UT0[NAIBP] is low when UT0[AID] goes high, then the operation is complete. Continue to the next step.
9. Read values in the MISR registers (UM0 — UM9) to ensure correct signature.

NOTE

Array integrity reads may be done to unselected (or non-present) locations. Reads done to these locations do not update the MISR, and do not update the MCR[EER] and MCR[SBC] error bits.

10. Write a logic 0 to the UT0[AIE] bit.

30.9.2.2 User margin read

User margin read may be done using the array integrity interface, and has all the associated features of the array integrity interface (MISR and Breakpoints). User margin reads are done at a read margin level checking for erased bits or programmed bits encroaching on the nominal read level. User margin read is a self-timed event, and is independent of system clocks or wait states selected. Margin ECC corrections and detections are noted during the user margin read test. Margin read MISR value is calculated after ECC detection and correction.

The data to be read is customer-specific, and user code may be programmed into the flash memory. Any random or non-random code is valid. Once the operation is completed, the margin read results can be checked by reading the MCR[EER] bit and the MCR[SBC] bits to determine if zero, one, or two bits are being detected by the margin read, as well as checking the MISR.

The use model for margin read is in the event of a user-detected single bit correction (through user reads). A margin read may be done to check for a possible second bit falling within the selected margin levels.

The procedure for doing margin reads is:

1. Enable UTest mode.
2. Select the block or blocks to receive margin read check by writing 1's to the appropriate registers in SEL0, SEL1, SEL2, or SEL3 registers. Blocks selected for margin read do not need to be unlocked.

NOTE

Unselected blocks are still read as part of the margin read sequence, to enable full transition coverage. The result read on unselected blocks will not be captured in the MISR. Selecting fewer blocks will not result in a faster margin read execution time.

NOTE

Blocks protected with the Test Mode Disable Seal are still read as part of the margin read sequence. The resulting read on sealed blocks will not be captured in the MISR, but the Single Bit Correction, Double Bit Detection and breakpoints will still be honored.

NOTE

It is not possible to do margin read operations on the UTest NVM block.

3. Set the UT0[AIS] bit to 1 for sequential addressing only.

NOTE

For margin read checks of the flash memory, sequential addressing is recommended. Setting AIS to 0 is possible for Margin Reads, but using the sequence takes more time, and is not recommended.

4. Seed the MISR registers (UM0 — UM9) with desired values.
5. Ensure that the MCR[EER] and MCR[SBC] bits are cleared.
6. If you want to detect single bits during margin read, set UT0[SBCE] to 1.

7. Set the UTO[MRE] bit.
8. Set the UT0[MRV] bit to the desired value depending on if it is desired to do one's margin or zero's margin.
9. Set the UT0[AIE] bit.

NOTE

User mode array reads requested during the margin read test will be ignored, to ensure that the margin read operation is not corrupted. The memory array will not respond to array read requests during this time. User mode array reads may be executed if suspended or at a breakpoint.

NOTE

During Margin Read operations, with AID low, it is not recommended to attempt write operations to the MCR[SBC] and MCR[EER] bits. It is recommended that these bits only be written during suspend, breakpoints, or at completion of the Margin Read operation.

10. Wait until the UT0[AID] bit goes high.
    a. If breakpoints were enabled or a suspend was requested during margin read, the operation may be at a breakpoint or a suspend state. See Array integrity self check for more information.
11. Read values in the MISR registers (UM0 — UM9) to ensure correct signature.

NOTE

Margin reads may be done to unselected (or non-present) locations. Reads done to these locations do not update the MISR, and do not update the MCR[EER] and MCR[SBC] error bits.

12. Write a logic 0 to the UT0[AIE] bit.

30.10 Initialization information

A reset is the highest priority operation for the embedded flash memory and terminates all other operations.

The embedded flash memory uses reset to initialize register and status bits to their default reset values. If the embedded flash memory is executing a program or erase operation (PGM or ERS = 1) and a reset is issued, the operation is aborted and the embedded flash

memory disables the high-voltage logic without damage to the high-voltage circuits. Reset aborts all operations and forces the embedded flash memory into user mode ready to receive accesses.

After reset is requested, MCR[DONE] goes low, and remains low during reset and reset recovery. At the end of reset recovery, MCR[DONE] transitions from a 0 to a 1.

After reset is completed, register reads may be done, although it should be noted that registers that require updating from UTest NVM information, or other inputs, may not read updated values until MCR[DONE] transitions high.

During reset recovery, register writes are not allowed until the MCR[DONE] bit transitions high to indicate reset recovery is completed.

Warning

Resetting during a program or erase operation leaves the flash core blocks being programmed or erased in an indeterminate data state. This may be recovered by executing an erase on the affected blocks.

Chapter 31
Decorated Storage Memory Controller (DSMC)

31.1 Decorated Storage Memory Controller (DSMC) chip-specific module information

The DSMC supports five store and three load operations, including:

- Bit field inserts
- Compare-and-store
- Bitwise AND, OR, and XOR operators
- Simple memory load
- Swap
- Load-and-set-1(bit)

As the DSMC generates the atomic read-modify-write bus transactions to the attached slave memory controller, the two transactions (read, write) are fully pipelined with no idle cycles introduced. During these transactions, the AHB hlock control signal is asserted to the slave during the entire read-modify-write.

The module includes error checking logic that validates the decoration field, making sure that it is properly defined (all illegal commands are rejected and the transfer error terminated). Additionally, the decorated storage memory controller only operates on aligned, single data transfers (misalignment and/or bursts are not supported and error terminated if attempted).

The DSMC is instantiated multiple times within the core platform and physically resides between the slave ports of the crossbar and the targeted memory controllers.

For the this device, the DSMC is instantiated five times, three times in the computational platform shell and two times in the peripheral platform shell. The access size is forced to 64-bit for system RAM, 32-bit for the core xMEMs and PBRIDGE.

Table 31-1. DSMC instantiations

DSMC and memory controller association	
Computational shell	System RAM
	Core 0 xMEM (Backdoor Port to the core local Instruction and Data Memories)
	Core 1 xMEM (Backdoor Port to the core local Instruction and Data Memories)
Peripheral shell	PBRIDGE_0 (Bridge to peripheral subsystem)
	PBRIDGE_1 (Bridge to peripheral subsystem)

31.2 Introduction

This section details the hardware support for atomic read-modify-write memory operations. In the Power Architecture, these capabilities are called "*decorated storage*". It is supported by capabilities in the processor cores plus instantiations of a Decorated Storage Memory Controller (DSMC).

The Decorated Storage APU defines instructions for providing load and store operations to memory addresses that require *additional semantics* beyond just the reading and writing of data values to the addressed memory locations. Decorated storage operations are intended to be used for specific devices or memory targets that require these additional semantics. A "decoration" is the additional semantic information to be applied to the decorated storage operation by the DSMC.

Consider the basic mnemonics, syntax and formats for the decorated load instructions.

For loads, the syntax is `l[b,h,w]d{cb}x rT,rB,rA` where the data size specifier is defined as 8-bit (`b` = byte), 16-bit (`h` = halfword) or 32-bit (`w` = word), and the three register specifiers include `rT` as the destination target register, `rB` as the effective address and `rA` as the decoration. The optional `{cb}` specifier defines a version of the instruction which is treated as a cache bypass operation.

The syntax for store instruction is `st[b,h,w]d{cb}x rS,rB,rA` where the same data size specifiers are used, and the three register specifiers are `rS` as the source data register, `rB` as the effective address and `rA` as the decoration. The cache bypass attribute is again specified with the use of the optional `{cb}` in the instruction mnemonic.

For all decorated loads and stores, the memory effective address is simply defined by the rB register (hence the "x" mnemonic suffix, signaling an "indexed" addressing mode) and the decoration is specified by the rA register. The core transmits the contents of the rA register as the decoration value along with the access address (register rB) to the DSMC.

The decorated load and store instruction formats are shown in the following figure.

Table 31-2. Power Architecture decorated load and store instruction formats

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
lbdx	0	1	1	1	1	1	rT						rA				rB				1	0	0		0	0	0	0	0	1	1	/
lhdx	0	1	1	1	1	1	rT						rA				rB				1	0	0		0	1	0	0	0	1	1	/
lwdx	0	1	1	1	1	1	rT						rA				rB				1	0	0		1	0	0	0	0	1	1	/
lbdcbx	0	1	1	1	1	1	rT						rA				rB				1	0	0		0	0	0	0	0	1	0	/
lhdcbx	0	1	1	1	1	1	rT						rA				rB				1	0	0		0	1	0	0	0	1	0	/
lwdcbx	0	1	1	1	1	1	rT						rA				rB				1	0	0		1	0	0	0	0	1	0	/
	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
stbdx	0	1	1	1	1	1	**r**S						**r**A				**r**B				1	0	1		0	0	0	0	0	1	1	/
sthdx	0	1	1	1	1	1	**r**S						**r**A				**r**B				1	0	1		0	1	0	0	0	1	1	/
stwdx	0	1	1	1	1	1	**r**S						**r**A				**r**B				1	0	1		1	0	0	0	0	1	1	/
stbdcbx	0	1	1	1	1	1	**r**S						**r**A				**r**B				1	0	1		0	0	0	0	0	1	0	/
sthdcbx	0	1	1	1	1	1	**r**S						**r**A				**r**B				1	0	1		0	1	0	0	0	1	0	/
stwdcbx	0	1	1	1	1	1	**r**S						**r**A				**r**B				1	0	1		1	0	0	0	0	1	0	/

The basic decorated load or store memory reference supplements the access address and attribute information with a 32-bit "decoration". The DSMC decoration defines the special memory operation to be performed and optionally includes bit specifiers and/or operand data for the command.

The default format for the 32-bit decoration field defines a 4-bit command in the most significant bits (decoration[0:3]).

The cache bypass decoration load (`l[b,h,w]dcbx`) and store (`st[b,h,w]dcbx`) instructions do not distinguish between cacheable and cache-inhibited storage attributes, and instead have semantics to effectively emulate a cache-inhibited operation to storage regardless of the actual storage attributes. This is desired in order to allow a small portion of an otherwise cacheable storage area to be treated as non-cacheable using instruction supplied semantics, regardless of storage attributes provided by a memory management, protection or other memory control scheme. This allows decoration or other accesses to be applied to a portion of memory that is normally treated as cacheable according to its storage attributes, as well as to ensure that any stale copies of storage locations present in the cache are not used.

The combination of the decorated load and store instruction support in the e200zX cores plus the decorated storage memory controller in the core platform adds a robust atomic read-modify-write capability to the Power Architecture. The architecture capability defined by these core and platform functions is targeted at manipulation of *n*-bit fields in peripheral registers (and is consistent with I/O hardware addressing in the Embedded C standard) as well as software synchronization data structures needed in multi-core systems (mutexes, semaphores, test-and-set and compare-and-swap structures).

For additional information on the decorated load and store instructions from the core's perspective, refer to the appropriate e200zX core reference manual.

31.3 Decorated stores: st[b,h,w]d{cb}x rS,rA,rB

The next sections present descriptions of the specific operations, based on the 4-bit command field defined in decoration[0:3]. These descriptions include the bit pattern definitions for the 32-bit decoration value and include pseudo-code detailing the sequence of operations. The decoration formats are defined using a <command>.<size> syntax where the operand size specifier is b (byte, 8-bit), h (halfword, 16-bit) or w (word, 32-bit). The operand size is specified directly in the decorated instruction executed in the core, and this attribute is driven to the system bus as part of the decorated data transfer. Additionally, the write data is taken from the right-justified 8, 16 or 32 bits of the rS register, that is:

```
 8-bit wdata = rS[24:31]
16-bit wdata = rS[16:31]
32-bit wdata = rS[ 0:31]
```

Likewise, read data is loaded into the right-justified 8, 16 or 32 bits of the rT register:

```
 8-bit rdata = rT[24:31]
16-bit rdata = rT[16:31]
32-bit rdata = rT[ 0:31]
```

For the byte and halfword decorated load instructions, the upper bits of the rT register are zero filled.

The starting bit (SRTBIT) position follows the Power Architecture convention where the MSB is bit 0 and the LSB is bit 31. The bit field width (BFW) value defines the width and BFW = 0 specifies the maximum width, that is, the container size.

The basic decorated store includes three data transfer fields sourced from the core: the access address (rB), the decoration (rA) and the write data (wdata) operand (rS). There are five operations defined and most of these transactions convert a single core AHB write bus cycle into an atomic read-modify-write, that is, an indivisible read followed by

write sequence. Support for three basic boolean logic functions (AND, OR, XOR) is provided along with a compare-and-store operation plus a bit field insert operation. These operations do not support any type of bit field wrapping.

In the next sections detailing the decorated store operations, the following associations between the pseudocode variables and the core registers apply.

- decoration = rA
- accessAddress = rB
- wdata = rS

31.3.1 Bit Field Insert (BFINS) into an 8, 16 or 32-bit memory container

Table 31-3. Decoration format: BFINS

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
bfins.b	0	0	0	0	0	0	0	SRTBIT			0	0	0	BFW			-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
bfins.h	0	0	0	0	0	0	SRTBIT				0	0	BFW				-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
bfins.w	0	0	0	0	0	SRTBIT					0	BFW					-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

This command inserts a bit field defined by SRTBIT and BFW into the memory "container" defined by the access size associated with the decorated store instruction using an atomic read-modify-write sequence.

```
tmp = mem[accessAddress, size] // memory read
if bfw == 0
         then bfw = container

if ((srtbit + bfw) <= container) // generate bit mask
    mask = ((1 << bfw) - 1) << (container - (srtbit + bfw))
else
    mask = ((1 << bfw) - 1) >> ((srtbit + bfw) - container)

tmp = tmp  & ~mask// modify
    | wdata &  mask

mem[accessAddress, size] = tmp // memory write
```

The write data operand (wdata) associated with the decorated store instruction contains the bit field to be inserted. *It must be properly aligned within a right-justified container in the source register (rS)*, that is, within the lower 8 bits for a byte operation, the lower 16 bits for a halfword or the entire 32 bits for a word operation.

To illustrate, consider the following example of the insertion of the 3-bit field "xyz" into an 8-bit memory container, initially set to "abcd_efgh". For all cases, the bit field width (BFW) is 3.

```
if SRTBIT = 0 and the decorated store rS register[24:31] = xyz-_----,
   then destination is "xyzd_efgh"
if SRTBIT = 1 and the decorated store rS register[24:31] = -xyz_----,
   then destination is "axyz_efgh"
if SRTBIT = 2 and the decorated store rS register[24:31] = --xy_z---,
   then destination is "abxy_zfgh"
if SRTBIT = 3 and the decorated store rS register[24:31] = ---x_yz--,
   then destination is "abcx_yzgh"
if SRTBIT = 4 and the decorated store rS register[24:31] = ---_xyz-,
   then destination is "abcd_xyzh"
if SRTBIT = 5 and the decorated store rS register[24:31] = ---_-xyz,
   then destination is "abcd_exyz"
if SRTBIT = 6 and the decorated store rS register[24:31] = ---_--xy,
   then destination is "abcd_efxy"
if SRTBIT = 7 and the decorated store rS register[24:31] = ---_---x,
   then destination is "abcd_efgx"
```

If the bit field insert operation specifies SRTBIT as 0 and BFW as 0 (indicating the width matches the container width), then the operation is logically equivalent to a simple register store operation.

31.3.1.1 Compare-and-Store (CAST)

Table 31-4. Decoration format: CAST

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
cast.b	1	0	0	1	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	CD8							
cast.h	1	0	0	1	-	-	-	-	-	-	-	-	-	-	-	-	CD16															
cast.w	1	0	0	1	CD28																											

This command begins by performing a read of the referenced memory address and comparing that data with the operand included in the decoration word. If the read data is equal to the compare operand, the write data associated with the decorated store instruction is placed into the memory location, else the original read data is rewritten into the memory location. The write operand is selected from the appropriate data byte lanes in the same manner as any memory store operation; this implies the write data operand is right justified in the rS source register.

```
tmp = mem[accessAddress, size]  // memory read

if (size == 8)             // define compare_operand
    compare_operand = CD8
else if (size == 16)
          compare_operand = CD16
     else compare_operand = {0x0, CD28}// zero-filled data

if (tmp == compare_operand) // compare - "modify"
```

```
     mem[accessAddress, size] = wdata// memory write
else mem[accessAddress, size] = tmp
```

Note for the word size operation (cast.w), the data value specified in the low-order 28 bits of the decoration is zero filled in the most significant bits to create the required 32 bit compare operand.

31.3.1.1.1 Logical AND (AND)

Table 31-5. Decoration format: AND

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
and.{b,h,w}	1	0	1	0	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

This command performs an atomic read-modify-write of the referenced memory location. First, the location is read; it is then modified by performing a logical AND operation using the write operand defined by the rS register; finally, the result of the AND operation is written back into the referenced memory location.

```
tmp = mem[accessAddress, size] // memory read
tmp = tmp & wdata      // modify
mem[accessAddress, size] = tmp// memory write
```

31.3.1.1.2 Logical OR (OR)

Table 31-6. Decoration format: OR

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
or.{b,h,w}	1	1	0	0	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

This command performs an atomic read-modify-write of the referenced memory location. First, the location is read; it is then modified by performing a logical OR operation using the write operand defined by the rS register; finally, the result of the OR operation is written back into the referenced memory location.

```
tmp = mem[accessAddress, size] // memory read
tmp = tmp | wdata         // modify
mem[accessAddress, size] = tmp// memory write
```

31.3.1.1.3 Logical Exclusive-OR (XOR)

Table 31-7. Decoration format: XOR

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
xor.{b,h,w}	1	1	1	1	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

This command performs an atomic read-modify-write of the referenced memory location. First, the location is read; it is then modified by performing a logical XOR operation using the write operand defined by the rS register; finally, the result of the XOR operation is written back into the referenced memory location.

```
tmp = mem[accessAddress, size] // memory read
tmp = tmp ^ wdata          // modify
mem[accessAddress, size] = tmp// memory write
```

31.3.1.2 Decorated Loads: `l[b,h,w]d{cb}x rT,rA,rB`

The basic decorated load includes two data transfer fields sourced from the core: the access address (rB), the decoration (rA) plus the read data (rdata) operand returned from DSMC to the core and loaded into the destination register (rT). There are 3 operations defined and two of these transactions convert a single core AHB read bus cycle into an atomic read-modify-write. Support for a swap function, a load-and-set-1-bit functions are provided along with a simple load (aka an "extract") operation.

In the next sections detailing the decorated load operations, the following associations between the pseudocode variables and the core registers apply.

- decoration = rA
- accessAddress = rB
- rdata = rT

31.3.1.2.1 Simple Load (SLD)

Table 31-8. Decoration format: SLD

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
sld. {b,h,w}	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

This command performs a simple memory load of the reference size from the access address. For this operation, the 12-bit field defined in decoration[4:15] must be zeroes else the transfer is not performed and error terminated.

```
rdata = mem[accessAddress, size] // memory read
```

Support for generic bit field extract operations is best handled using existing core and compiler capabilities involving standard load instructions followed by left and right shift operations to emulate these functions.

31.3.1.2.2 Registers-and-memory exchange (SWAP)

Table 31-9. Decoration format: SWAP

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
swap.b	0	1	0	1	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	WD8							
swap.h	0	1	0	1	-	-	-	-	-	-	-	-	-	-	-	-	**WD16**															
swap.w	0	1	0	1	WD28																											

This command loads the contents of the referenced memory location into the core's rT register and stores the source operand from the core's rA register (the decoration) into the memory location.

```
tmp   = mem[accessAddress, size] // memory read
rdata = tmp// rT = rdata = tmp

if (size == 8)             // store_operand - "modify"
    store_operand = WD8
else if (size == 16)
           store_operand = WD16
    else store_operand = {0x0, WD28} // zero-filled write data

mem[accessAddress, size] = store_operand// memory write
```

Note for the word size operation (swap.w), the data value specified in the low-order 28 bits of the decoration is zero filled in the most significant bits to create the required 32 bit store operand.

31.3.1.2.3 Load-and-Set-1(Bit) (LAS1)

Table 31-10. Decoration format: LAS1

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
las1.b	0	1	1	0	0	0	0	BIT			-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
las1.h	0	1	1	0	0	0	BIT				-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
las1.w	0	1	1	0	0	BIT					-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

This command first reads the referenced memory location; it then modifies the read operand by setting the single bit position defined in the decoration (BIT); the modified data is then written back to the referenced memory location and the original read data returned to the initiating processor core.

```
tmp   = mem[accessAddress, size] // memory read
rdata = tmp // rT = rdata = tmp
mask  = 1 << (container - bit - 1) // generate bit mask
tmp   = tmp | mask// modify
mem[accessAddress, size] = tmp// memory write
```

31.4 DSMC instantiations

The decorated storage memory controller which performs these operations is instantiated multiple times within the core platform and physically resides between the slave ports of the crossbar and the targeted memory controllers.

The module includes error checking logic that validates the decoration field is properly defined (all illegal commands are rejected and the transfer error terminated). Additionally, the decorated memory controller only operates on aligned, single data transfers (misalignment and/or bursts are not supported and error terminated if attempted).

As the DSMC generates the atomic read-modify-write bus transactions to the attached slave memory controller, the two transactions (read, write) are fully pipelined with no idle cycles introduced. During these transactions, the AHB hlock control signal is asserted to the slave during the entire read-modify-write.

Chapter 32
Flash Memory Programming and Configuration

32.1 Introduction

This chapter provides basic guidance on activities related to configuring and programming the embedded flash memory in the MPC5746R microcontroller.

Multiple layers of protection are available to prevent unintended updates to flash contents and unauthorized reads and writes to flash contents. The protection mechanisms range from simple write-protect bits for individual flash blocks to four levels of 256-bit password read and/or write protection and configuration of flash memory blocks as One Time Programmable (OTP).

Additionally, the MPC5746R microcontroller includes a tamper detection feature and debug port enable/disable.

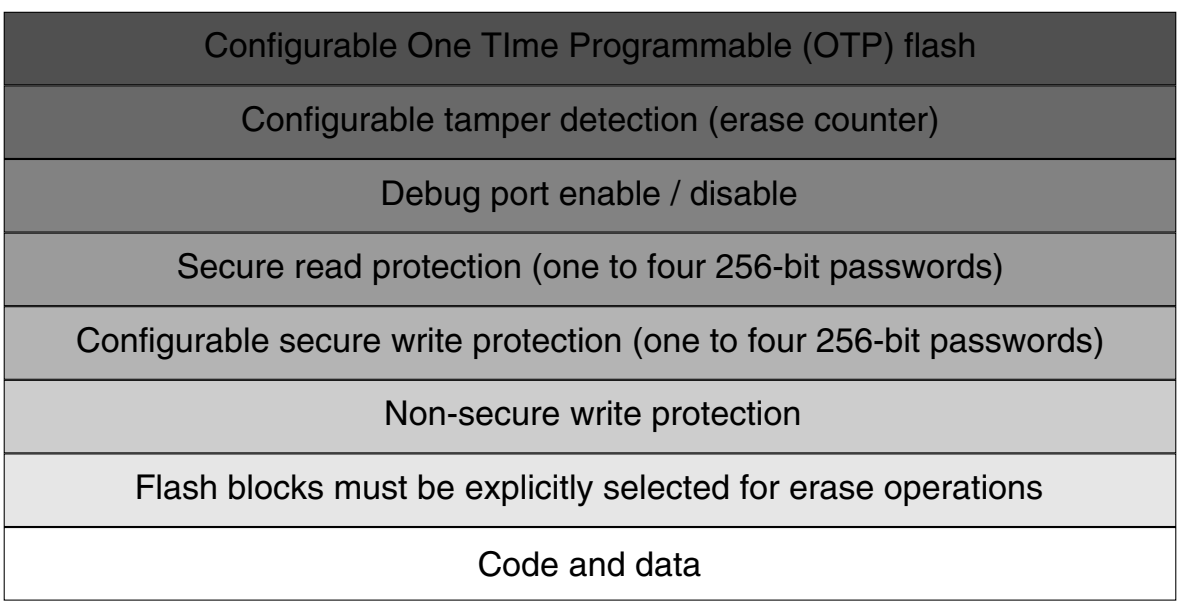

Figure 32-1. Flash memory protection layers

At the lowest layer of protection, all flash erase operations require the explicit selection of one or more blocks of flash memory before the operation is performed. When executed, the operation is only performed on the selected block(s).

The next layer is the chip's ability to lock individual flash blocks against unintended programming and erase operations. This level of protection does not offer any password protection and is intended to provide protection against *accidental* changes to code and data.

The first layer of *secure* protection is the microcontroller's ability to support up to four levels of 256-bit password-secured write protection for individual flash blocks.

Similarly, up to four levels of password-secured read protection can be implemented. Unlike the password-secured *write* protection, which is implemented on a per-block basis, password-secured read protection applies to three pre-defined (at the factory) groups of flash blocks. The read protection applied to a group applies to each block within the group. In contrast, secure write protection is defined at the individual block level.

Secure password protection can also be implemented for the debug port.

The MPC5746R microcontroller also includes a tamper detection feature. In its most basic implementation, tamper detection acts as an erase counter. If tamper detection is implemented, a DCF record in the tamper detection *diary* must be written by software before a protected flash block can be erased. Multiple tamper detection regions can be defined by the customer, with each region containing one or more blocks. A block can be included in more than one tamper detection regions if desired.

Another protection feature, related to tamper detection, is the ability to configure any flash block as one-time programmable (OTP).

The remainder of the chapter provides details on these protection mechanisms and gives a brief overview of security configuration planning.

NOTE

Most of the topics in this chapter build on information presented in previous topics. To get a clear overview of how the flash protection features work and relate to each other, please read the chapter in sequence, from beginning to end.

Access protection configuration is applied on a per-block basis (except read protection and tamper detection applied to groups of flash memory blocks), i.e., a custom level of access protection can be provided for each flash memory block. This is accomplished through the use of registers containing bits that are mapped to individual flash blocks. Understanding the mapping is key to understanding the implementation and use of the MPC5746R microcontroller's flash protection features.

Depending on the type of protection to be applied, different sets of registers (or even DCF records) are used, but the mapping scheme is consistent. This mapping scheme is first presented in Selection of flash memory blocks for erase. It is important to understand the topic before proceeding to other sections.

32.2 Selection of flash memory blocks for erase

The registers used for selecting flash blocks for erase operations are the flash control registers named C55FMC_SEL0 and C55FMC_SEL2.

NOTE

There are also a SEL1 and SEL3 registers, but no flash blocks are mapped to them.

The SEL0 and SEL2 registers are 32-bit registers containing fields associated with low, mid, and 256 KB address spaces. Each non-reserved bit in the fields is mapped to a specific flash block.

For example, the following figure shows the C55FMC_SEL0 register. This register provides a way of selecting blocks in the low and mid address spaces for erase operations. (See the Embedded Flash Memory chapter for details of the SEL0 register.)

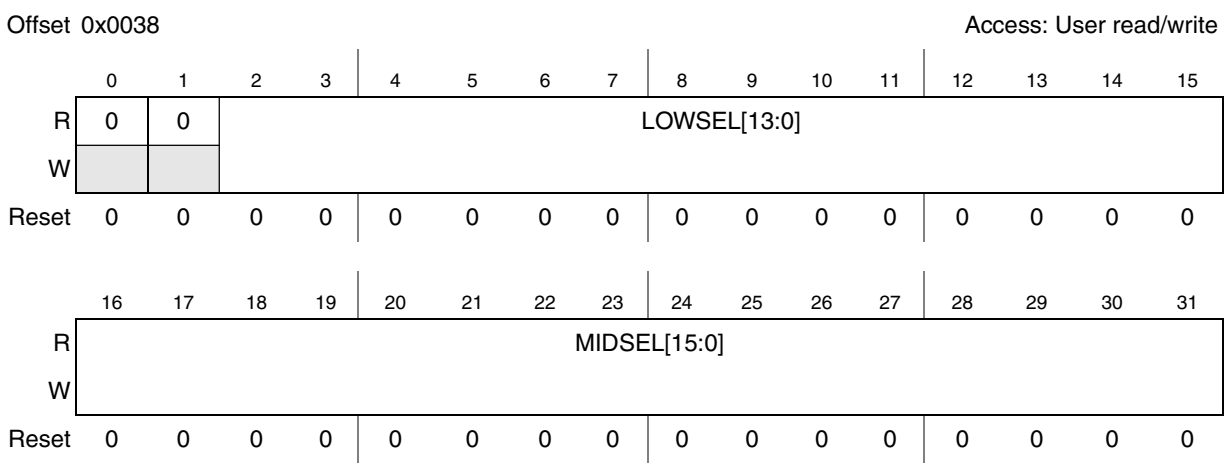

Figure 32-2. SEL0 flash control register

The mapping of the register bits to flash blocks is shown in C55FMC_SEL0 register bit mapping. Note that not all bits of the LOWSEL and MIDSEL fields are mapped; only LOWSEL bits 0-11 and MIDSEL bits 0-9 are mapped.

The following table shows the mapping of SEL0 register's LOWSEL and MIDSEL field bits to individual flash blocks with start and end addresses. Before any mapped block can be erased, it must be selected by writing a '1' to its corresponding bit in one of the SEL*n* registers.

NOTE

Values written to the SEL registers do not persist through device reset. As indicated by the reset values shown in the figure above, all bits are reset to '0'. As a result, after a device reset all blocks mapped to the register are, by default, not selected for erase.

Table 32-1. SEL0 to low and mid address space flash block bit mapping

Start Address	End Address	Size (KB)	Partition	SEL*n* Register	SEL*n* Register Field Bit	Block No.	Description
0x00404000	0x00407FFF	16	0	SEL0	LOWSEL[0]	0	16KB BAF block0[1]
0x00FA0000 0x08FA0000	0x00FA3FFF 0x08FA3FFF	16	0	SEL0	LOWSEL[1]	1	Code Flash block1
0x00FA4000 0x08FA4000	0x00FA7FFF 0x08FA7FFF	16	0	SEL0	LOWSEL[2]	2	Code Flash block2

0x00FE0000 0x08FE0000	0x00FEFFFF 0x08FEFFFF	64	1	SEL0	LOWSEL[10]	2	Code Flash block2
0x00FF0000 0x08FF0000	0x00FFFFFF 0x08FFFFFF	64	1	SEL0	LOWSEL[11]	3	Code Flash block3
0x00800000	0x00803FFF	16	2	SEL0	MIDSEL[0]	0	FMC EEPROM Block0
0x00804000	0x00807FFF	16	2	SEL0	MIDSEL[1]	1	FMC EEPROM Block1
0x00808000	0x0080BFFF	16	2	SEL0	MIDSEL[2]	2	FMC EEPROM Block2
0x0080C000	0x0080FFFF	16	2	SEL0	MIDSEL[3]	3	FMC EEPROM Block3
0x00810000	0x00813FFF	16	3	SEL0	MIDSEL[4]	4	FMC EEPROM Block4
0x00814000	0x00817FFF	16	3	SEL0	MIDSEL[5]	5	FMC EEPROM Block5
0x00818000	0x0081BFFF	16	3	SEL0	MIDSEL[6]	6	FMC EEPROM Block6

Table continues on the next page...

Table 32-1. SEL0 to low and mid address space flash block bit mapping (continued)

Start Address	End Address	Size (KB)	Partition	SEL*n* Register	SEL*n* Register Field Bit	Block No.	Description
0x0081C000	0x0081FFFF	16	3	SEL0	MIDSEL[7]	7	FMC EEPROM Block7
0x00820000	0x0082FFFF	64	2	SEL0	MIDSEL[8]	0	FMC EEPROM Block0
0x00830000	0x0083FFFF	64	3	SEL0	MIDSEL[9]	1	FMC EEPROM Block1

1. The Boot Assist Flash (BAF) is one time programmable and the majority of it is programmed in the factory. The BAF handles the initial start up of the device.

Example 1. Selecting blocks for erase

Referring to the table above, writing the value 0x0030_0000 to the SEL0 register results in the SEL_LOWSEL[4] and SEL_LOWSEL[5] bits being set to '1', selecting the following blocks for erase:

Table 32-2. Selecting blocks for erase

Start Address	End Address	Size (KB)	Partition	SEL*n* Register	SEL*n* Register Field Bit	Block No.	Description
0x00FAC000 0x08FAC000	0x00FAFFFF 0x08FAFFFF	16	1	SEL0	LOWSEL[4]	4	Code Flash block4
0x00F9C000 0x08F9C000	0x00F9FFFF 0x08F9FFFF	16	1	SEL0	LOWSEL[5]	5	Code Flash block5

32.3 Non-secure write protection

Non-secure write protection refers to the chip's ability to lock individual flash blocks against programming and erase operations. This level of protection is intended to provide protection against *accidental* changes to code and data. Although similar in function, this is not associated with the built-in register protection (REG_PROT) feature included with many of the chip's modules. The non-secure write protection feature detailed here applies only to embedded flash memory.

Implementing non-secure write protection is almost identical to selecting specific flash blocks for an erase operation. The only difference is the register used. To provide non-secure write protection for a block, write a '1' to the corresponding mapped bit found in one of the C55FMC_LOCK0 or LOCK2 flash control registers.

NOTE

As indicated by the reset values shown in the following figure, after reset all blocks mapped to the register are, by default locked against programming and erase. Values written to the LOCK and SEL registers do not persist through device reset.

The following figure shows the C55FMC_LOCK0 register.

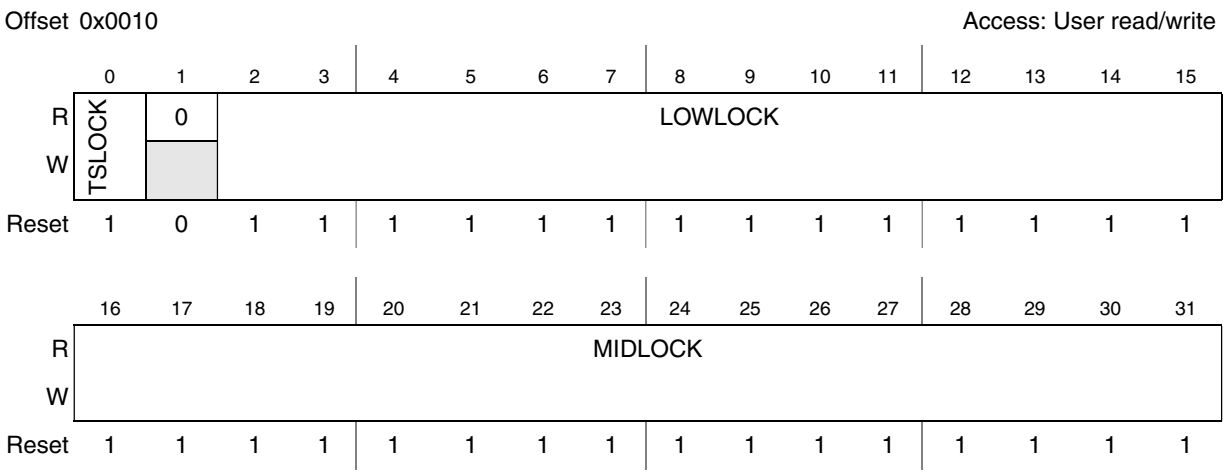

Figure 32-3. LOCK0 flash control register

The same bit mapping that applies to the SEL0 and SEL2 registers also applies to the LOCK0 and LOCK2 registers.

Example 2. Selecting blocks for lock

Referring to Table 32-1 (since bits in the SEL0 and LOCK0 registers map to the same flash blocks), writing the value 0x0030_0000 (same value used in Example 1) to the LOCK0 register (figure above) locks the following blocks (same blocks selected in Example 1) so they cannot be programmed or erased, even if selected for erase:

Table 32-3. Selecting blocks for lock

Start Address	End Address	Size (KB)	Partition	LOCK*n* Register	LOCK*n* Register Field Bit	Block No.	Description
0x00FAC000 0x08FAC000	0x00FAFFFF 0x08FAFFFF	16	1	LOCK0	LOWLOCK[4]	4	Code Flash block4
0x00F9C000 0x08F9C000	0x00F9FFFF 0x08F9FFFF	16	1	LOCK0	LOWLOCK[5]	5	Code Flash block5

As long as the LOCK0[LOWLOCK] bits are unchanged, the above blocks cannot be modified unless the protection is overridden (discussed in Secure write protection). All other blocks mapped to bits in the LOCK0 can be programmed because their corresponding bits have been set to '0'.

32.4 Security configuration planning

Designing the flash security framework consists of selecting the security features to be implemented and determining the scope of implementation for each selected feature.

The security features available in the MPC5746R microcontroller include:

- Secure write protection
- Secure read protection
- Debug port enable/disable
- One-time-programmable (OTP) flash memory block assignment

32.4.1 Creating password groups

Most basic security features in the MPC5746R microcontroller are password-based. Therefore, one of the early tasks that must be performed is the creation of four 256-bit passwords. They are programmed by the customer into the locations identified in the UTest memory map in the Memory Map chapter.

The UTest memory map fields to be written are:

- PASS Password Group 0
- PASS Password Group 1
- PASS Password Group 2
- PASS Password Group 3

Passwords must not be one of the following, which are considered insecure and therefore invalid:

- 0x0000_0000
- 0xFFFF_FFFF
- 0x5555_5555

NOTE

The password fields are in OTP UTest flash, so they can only be written once.

32.5 Secure write protection

Secure write protection refers to the chip's ability to implement up to four levels of 256-bit password-secured write protection for individual flash blocks. Use of this feature is optional but the default behavior of the MPC5746R microcontroller is to apply secure write protection. If there is a need to not write-protect specific blocks, that needs to be configured by creating the appropriate DCF records.

Note that the secure write protection settings override the non-secure write protection detailed in Non-secure write protection.

Implementing a custom secure write protection scheme requires creating DCF records that define the level of write protection to be applied to each flash block. The DCF records use a bit mapping scheme identical to the mapping in the flash module's SEL*n* and LOCK*n* registers. The write protection scheme becomes a permanent part of the device but blocks can be temporarily unlocked. Depending on the specific implementation, temporarily unlocking the write protection requires matching up to four 256-bit passwords.

The easiest way to understand the secure write protection functionality is to examine the role played by the PASS_LOCK0_PG*n*-PASS_LOCK3_PG*n* registers.

The PASS_LOCK0_PG*n*-PASS_LOCK3_PG*n* registers are four identical sets of registers contained in the PASS module. They are distinguished by the PG*n* suffix. The PG*n* (Password Group n) suffix indicates the password required to unlock that set of registers. Password 0 unlocks PASS_LOCK0_PG0, PASS_LOCK1_PG0, PASS_LOCK2_PG0, and PASS_LOCK3_PG0. Similarly, the registers suffixed with PG1 are unlocked by matching password 1, and so on.

The PASS_LOCK0_PG*n*-PASS_LOCK3_PG*n* register sets have two functions related to secure write protection:

- Reading the registers provides the secure write lock status for each flash block.
- Changing the value of a mapped bit in a register changes the secure write protect status of the corresponding flash block.

Each set of registers contains the same mapping of bits to flash blocks as the flash module's SEL*n* and LOCK*n* registers. In any of the four PASS_LOCK*x*_PG*n* register sets, if a mapped bit is set to '1', locking a flash block, that value can only be changed by successfully supplying the password value for that set of registers to gain write access to the register, and setting the bit to '0'. If the same bit is set to '1' in more than one

PASS_LOCK*x*_PG*n* register set, each must be unlocked using the corresponding password and the bit must be set to '0' before the flash block is available for programming or erase.

The following figure shows how the registers interact. Note that secure write protection is only affected by the settings in PASS_LOCK0_PG*n*-PASS_LOCK2_PG*n*. The PASS_LOCK3_PG*n* registers have additional security functions, discussed in later topics.

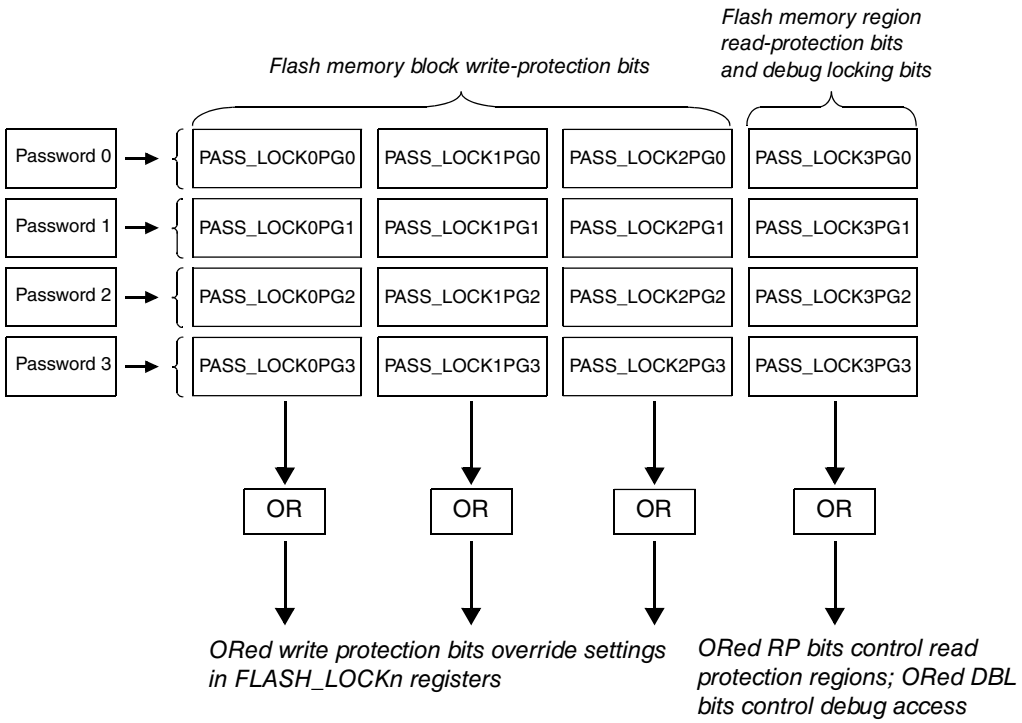

Figure 32-4. Secure write protection

The next sections discuss implementing secure write protection and overriding secure write protection.

32.5.1 Implementing secure write protection

Implementing secure write protection is a one-time task performed either at the factory or by the customer during chip configuration activities. It normally requires creating a DCF record for each of the PASS_LOCK0_PG*n*-PASS_LOCK2_PG*n* registers[1]. The DCF records have a structure that includes the same mapping of bits to flash memory blocks as

1. The default behavior for secure write protection in the case where passwords are created but no secure write protection DCF records are created, is for all blocks to have four levels of password-secured write protection. To vary the protection among all blocks, a DCF record for each password group must be created.

the flash module's SEL*n* and LOCK*n* registers. The values assigned become the permanent register reset values for the PASS_LOCK0_PG*n*-PASS_LOCK2_PG*n* registers.

See the Device Configuration Format (DCF) Records chapter for complete details on DCF records. This section summarizes the contents of a DCF record as required to implement secure write protection.

Even though the mapping of bits to flash memory blocks is identical to the mapping used for selecting flash blocks for erase of non-secure write locking, there are two significant differences:

1. Configuring flash blocks for secure write protection is done only during device configuration to customer specifications, either at the factory or by the customer during OEM production activities. The selection becomes a permanent part of the device configuration.
2. Configuration of blocks for secure write protection is done by writing *DCF records*, which is why the selection becomes a permanent part of the device.

NOTE

Careful planning is required before writing DCF records. They are created in a write-once area of flash. Multiple instances of any DCF record can be created, but in some cases only the record created first is used and with others only the most-recently written record is used. Be sure to understand the characteristics of a DCF record before creating it.

The DCF records required for implementing a secure write protection scheme are detailed in the PASS section of Table 6-5. Table entries provide the CS and Address value combinations that correspond to PASS_LOCK0_PG*n*-PASS_LOCK3_PG*n* registers.

The format of a secure write protection record is summarized here for convenience.

DCF records appear as contiguous double-word (64-bit) entries programmed in a reserved area of OTP UTest flash memory. The structure of a DCF Record is shown in the following figure.

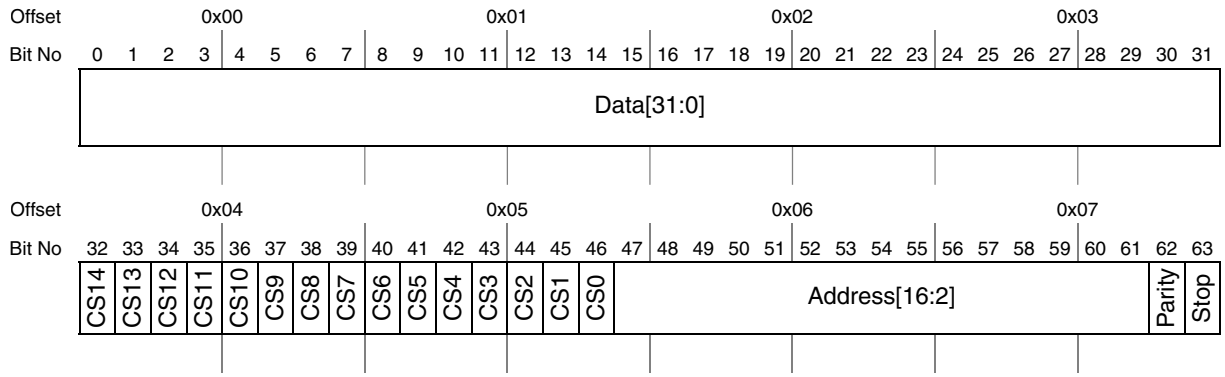

Figure 32-5. DCF record structure

NOTE

1. The values in the PASS_LOCK*x*PG*n* registers override the settings in the flash module's LOCK0-3 registers.
2. Values written to the PASS_LOCK*x*PG*n* registers do not persist through device reset. The reset value is determined by DCF record or, if no relevant DCF record has been created, each mapped bit has a reset value of '1', which causes the associated flash block to be locked against programming or erase.
3. The PASS_LOCK*x*PG*n* bits take effect when the life cycle is matured to "OEM Production" or older.

Example 3. Implementing secure write protection

Implementation of secure write protection is done during initial flash setup as follows:

1. Four 256-bit passwords (passwords 0-3) must be stored in a protected OTP area of device flash called UTest flash. Each password secures a set of registers in the PASS module (PASS_LOCK0_PG*n*-PASS_LOCK3_PG*n*) that have the same mapping of register bits to flash blocks as the flash module's SEL0-3 registers and LOCK0-3 registers.
2. DCF records must be created to define which flash memory blocks are to be locked and which blocks are not locked.

The records defined in step 2, determine the reset values of the PASS_LOCK0_PG*n*-PASS_LOCK3_PG*n* registers and therefore the write protection settings that take effect each time the microcontroller is reset.

Assume four passwords have been previously implemented and the following blocks are to be locked in the password 0 group:

Table 32-4. Flash blocks to implement secure write protection

Start Address	End Address	Size (KB)	Partition	LOCK*n* Register	LOCK*n* Register Field Bit	LOCK*n* DCF Record DATA Bit	Block No.	Description
0x00FAC000 0x08FAC000	0x00FAFFFF 0x08FAFFFF	16	1	LOCK0	LOWLOCK[4]	20	4	Code Flash block4
0x00F9C000 0x08F9C000	0x00F9FFFF 0x08F9FFFF	16	1	LOCK0	LOWLOCK[5]	20	5	Code Flash block5

From the PASS section of Table 6-5 :

DCF CS[14:0]	DCF address [16:2] (binary)	DCF client description
000_0000_0000_1000	000_0000_0100_0000	LOCK0_PG0

Referring to the Figure 32-5, the values for the DCF record are:

- Data[31:0] is 0xFFFF_FFFF (bits 0-31) (same value used in previous examples)
- CS[14:0] is 0b000_0000_0000_1000 (bits 32-46)
- Address[16:2] is 0b000_0000_0100_0000 (bits 47-61)
- Parity value is irrelevant because it is not used in PASS DCF records (bit 62)
- Recommended stop value is 0 for programming subsequent DCF records (see footnotes in the figure below).

The following DCF record provides secure write protection for the blocks in Table 32-1 by setting the reset values PASS_LOCK0_PG0 to the appropriate value to lock the blocks.

Bit No	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
	0	0	0	0	0	0	0	0	0	0	1	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit No	32	33	34	35	36	37	38	39	40	41	42	43	44	45	46	47	48	49	50	51	52	53	54	55	56	57	58	59	60	61	62	63
	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0	x[1]	x[2]

NOTES:
1 Bit 62 indicates parity strategy, which is not used in the PASS DCF records so it is a “don’t care”.
2 Bit 63 indicates whether the current record is the last DCF. Generally, this should be written as ‘0’ so the first unprogrammed (all 1’s) DCF record acts as the stop record.

Figure 32-6. Sample DCF record for secure write protection

The remaining blocks mapped to the PASS_LOCK0_PG*n* registers do *not* have secure write protection provided by the password 0 register set because the DATA field of DCF record has only the bits mapped to flash blocks 4 and 5 set to '1'.

NOTE

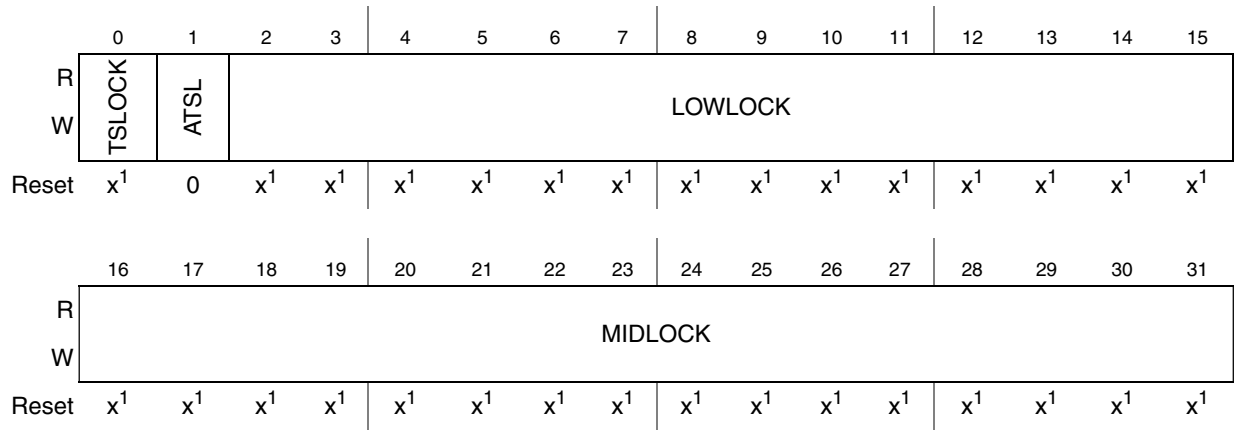
The above example is intended to highlight the need to carefully understand how DCF records work. The protected blocks are secured by password 0 but by default they are also secured by passwords 1, 2, and 3. In contrast the blocks *not* secured by password 0 in this example *are* secured by passwords 1, 2, and 3.

See the PASS section of Table 6-5 for details on the DCF records.

32.5.2 Overriding secure write protection

The "PG*n*" (Password Group *n*) suffix on each the register names indicates the password each set of registers is associated with. For example, password 0, is used to unlock PASS_LOCK0_PG0, PASS_LOCK1_PG0, PASS_LOCK2_PG0, and PASS_LOCK3_PG0. The bits in the first three registers (PASS_LOCK0_PG0, PASS_LOCK1_PG0, and PASS_LOCK2_PG0) are mapped exactly the same as the bits in the flash module's SEL0-2 registers and LOCK0-2 registers.

Like the SEL0 and LOCK0 registers, the PASS_LOCK0_PG*n* registers all contain bits mapped to the low and mid address spaces, and the mapping scheme is the same. A mapped bit set to '1' in any of the registers causes the corresponding block to be locked against program or erase. A mapped bit set to '0' in any of the registers makes the corresponding block available for programming or erase.



If a bit is set to '1', locking a flash block, that value can only be changed by successfully supplying the password value for that set of registers to gain write access, and setting the bit to '0'. If the same bit is set to '1' in more than one of the PASS_LOCKxPG*n* register sets, each must be unlocked using the corresponding password and the bit must be set to '0' before the flash block is available for programming or erase.

The following figure shows the PASS_LOCK0_PG*n* register. As you can see, it has the same structure as the flash module's LOCK0 register. In addition to the main difference of being among a group of four parallel sets of locking registers, the other difference between the PASS_LOCKx_PG*n* registers and the flash LOCK*n* registers is how the reset values are determined.

By default, all mapped bits are set to '1', locking their corresponding flash blocks from programming and erase. The reset value is user-configurable, though, by writing a DCF record. This is discussed in a later section.

Offset 0x0100 LOCK0_PG0
0x0110 LOCK0_PG1
0x0120 LOCK0_PG2
0x0130 LOCK0_PG3

Access: Read/Write

NOTES:
1 If no DCF records have been written to change the lock state, the bit will reset to '1'

Figure 32-7. LOCK0_PG*n* register

NOTE

1. The values in the PASS_LOCK*x*PG*n* registers override the settings in the flash module's LOCK0-3 registers.
2. Values written to the PASS_LOCK*x*PG*n* registers do not persist through device reset. The reset value is determined by DCF record or, if no relevant DCF record has been created, each mapped bit has a reset value of '1', which causes the associated flash block to be locked against programming or erase. The purpose of the registers is to indicate secure write protection status and to provide a way to temporarily override secure write protection.
3. The PASS_LOCK*x*PG*n* bits take effect after the life cycle is matured to "OEM Production" or older.

Example 4. Overriding secure write protection

Assume four passwords have been created but no DCF records have been written to set the reset values of the PASS_LOCK*x*_PG*n* registers, so the reset value for each mapped bit defaults to '1', causing all mapped blocks to have four levels of 256-bit password-secured write protection.

Since the settings in the PASS_LOCK*x*_PG*n* registers override the settings in the flash module's LOCK0-3 registers, the settings in those registers are irrelevant. Each of the four sets of the PASS module's LOCK registers must be unlocked by supplying the correct password for each set and then the appropriate bits must be set to '0' to make the desired flash blocks available for program or erase.

1. First write 0b00 to the PASS_CHSEL[GRP] register field to indicate registers controlled by password 0 are to be unlocked.
2. Write the 256-bit value for password 0 to the set of eight 32-bit password challenge input registers (PASS_CIN*n*) beginning with PASS_CIN0. The password must be written as a sequence of eight 32-bit writes, with the most significant bits of the password written to PASS CIN0.
3. Write 0xFFCF_FFFF to the PASS_LOCK0_PG0 register and verify a successful write.
4. Repeat the above steps for passwords 1-3.

Just as in previous examples, the result is the blocks are available for program and erase operations but at a much higher level of security.

32.6 Secure read protection

Read Protection is ability of the flash controller to block read accesses to the flash memory from all bus masters. This includes the blocking of:

- Instruction fetches and load instructions from the CPU
- Debug reads from an outside tool
- DMA reads
- SIPI reads
- Ethernet reads
- All other types of bus master reads

When secure read protection is active, the affected flash blocks are readable by any bus master until a debugger is attached to the JTAG port and debug is enabled. If a debugger is attached and debug is enabled while an application is running, the next access to a flash read protected region terminates with a bus error.

Not all instances of flash memory read protection in the MPC5746R microcontroller are configurable by the customer. An example of this is the 256-bit passwords stored in UTest flash memory. Password-based read protection is customer-configurable[2] and is similar to the password-based write protection mechanism detailed in Secure write protection.

There are two significant differences between password-based read protection and password-based write protection in the MPC5746R microcontroller.

1. Read protection can only be applied to pre-defined groups of flash memory blocks. These groups, called "Read Lock groups", cannot be re-defined, meaning the blocks assigned to those groups are permanently assigned and cannot be assigned to other groups and no new groups can be created.
2. Read protection is only active either when a debugger is attached to the JTAG port and debug is enabled; or the lifecycle has been advanced to "Failure Analysis".

Another difference is that only the PASS_LOCK3_PG*n* register for each password group is used:

- PASS_LOCK3_PG0
- PASS_LOCK3_PG1
- PASS_LOCK3_PG2
- PASS_LOCK3_PG3

See PASS_LOCK3_PGn register bit mapping for mappings of PASS_LOCK3_PG*n* register bits to flash blocks.

The next sections discuss implementing secure read protection and overriding secure write protection.

32.6.1 Implementing secure read protection

Implementation of secure read protection is done during initial flash setup as follows:

1. Four 256-bit passwords (passwords 0-3) are stored in a protected OTP area of device flash named UTest flash. Each password secures a set of registers in the PASS module (PASS_LOCK0_PG*n*-PASS_LOCK3_PG*n*) that have the same mapping of register bits to flash blocks as the flash module's LOCK0-3 registers and LOCK0-3 registers. These are the same passwords used by secure write protection and other secure functions. The passwords are only created once.

2. Secure read protection is user-configurable in that the default lock/unlock state for each mapped block at reset is controlled by user-created DCF records, giving the user the ability to determine the number of levels of password protection implemented. The read protection is applied to groups of blocks instead of individual blocks and the groups are not user-definable.

2. DCF records must be created to define which flash memory blocks are to be locked. Those records determine the reset values of the PASS_LOCK3_PG*n* registers. Like the other PASS_LOCK*x*_PG*n* registers, the PASS_LOCK3_PG*n* registers have two functions.
   - Reading the registers provides a lock status for each Read Locking group.
   - Changing the value of a mapped bit in a register changes the read protect status of the corresponding Read Locking group.

The layout of the PASS_LOCK3_PG*n* registers is shown in the following figure. The fields relevant to implementing secure read protection are RL4-RL0.

Offset 0x010C LOCK3_PG0
0x011C LOCK3_PG1
0x012C LOCK3_PG2
0x013C LOCK3_PG3

Access: Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

W																
Reset	x[1]	x[2]	x[2]	0	1	1	1	1	0	0	0	x[2]	x[2]	x[2]	x[2]	x[2]

	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	256LCK_U															
W																
Reset	x[2]	x[2]	x[2]	x[2]	x[2]	x[2]	x[2]	x[2]	x[2]	x[2]	x[2]	x[2]	x[2]	x[2]	x[2]	x[2]

NOTES:
1 Reset value depends on life cycle. If life cycle is Customer delivery or earlier, the value will be 0, otherwise 1.
2 If no DCF records have been written to change the lock state, the bit will reset to '1'.

Figure 32-8. PASS_LOCK3_PG*n* Register

Example 5. Implementing secure read protection

Assume four passwords have been previously implemented.

The following table shows the mapping of flash blocks to Read Locking groups.

Table 32-6. Low and mid address space flash block to Read Locking group mapping

Start Address	End Address	Size (KB)	Partition	SEL*n* Register	SEL*n* Register Field Bit	Read Lock Group	Block No.	Description
0x00404000	0x00407FFF	16	0	SEL0	LOWSEL[0]	--	0	16KB BAF block0[1]

Table continues on the next page...

Table 32-6. Low and mid address space flash block to Read Locking group mapping (continued)

Start Address	End Address	Size (KB)	Partition	SEL*n* Register	SEL*n* Register Field Bit	Read Lock Group	Block No.	Description

0x00818000	0x0081BFFF	16	3	SEL0	MIDSEL[6]	2	6	FMC EEPROM Block6

Table continues on the next page...

Table 32-6. Low and mid address space flash block to Read Locking group mapping (continued)

Start Address	End Address	Size (KB)	Partition	SEL*n* Register	SEL*n* Register Field Bit	Read Lock Group	Block No.	Description
0x0081C000	0x0081FFFF	16	3	SEL0	MIDSEL[7]	2	7	FMC EEPROM Block7
0x00820000	0x0082FFFF	64	2	SEL0	MIDSEL[8]	2	0	FMC EEPROM Block0
0x00830000	0x0083FFFF	64	3	SEL0	MIDSEL[9]	2	1	FMC EEPROM Block1

1. The Boot Assist Flash (BAF) is one time programmable and the majority of it is programmed in the factory. The BAF handles the initial start up of the device.

To provide two level of password protection for only Read Lock group 2 and leave all other groups unlocked, the RL2 bit can be set in any two of the four PASS_LOCK3_PG*n* registers. For this example, we will choose password groups 0 and 1.

We need to create DCF records that define the reset values for all RLn bits as 0, with the exception of PASS_LOCK3_PG0 and PASS_LOCK3_PG1. The information required is from the PASS section of the Table 6-5.

Table 32-7. Inplementing secure read protection

DCF CS[14:0]	DCF address [16:2] (binary)	DCF client description
000_0000_0000_1000	000_0000_0100_0011	LOCK3_PG0
000_0000_0000_1000	000_0000_0100_0111	LOCK3_PG1
000_0000_0000_1000	000_0000_0100_1011	LOCK3_PG2
000_0000_0000_1000	000_0000_0100_1111	LOCK3_PG3

Referring to Figure 32-5, the values for the DCF record are:

- For LOCK3_PG0
  - Data[31:0] is 0xFFFF_FFFF (bits 0-31)
  - CS[14:0] is 0b000_0000_0000_1000 (bits 32-46)
  - Address[16:2] is 0b000_0000_0100_0011 (bits 47-61)
  - Parity value is irrelevant because it is not used in PASS DCF records (bit 62)
  - Preferred Stop value is 0.
- For LOCK3_PG1
  - Data[31:0] is 0xFFFF_FFFF (bits 0-31)
  - CS[14:0] is 0b000_0000_0000_1000 (bits 32-46)
  - Address[16:2] is 0b000_0000_0100_0111 (bits 47-61)

    - Parity value is irrelevant because it is not used in PASS DCF records (bit 62)
    - Preferred Stop value is 0.
- For LOCK3_PG2
    - Data[31:0] is 0xFFFF_FFFF (bits 0-31)
    - CS[14:0] is 0b000_0000_0000_1000 (bits 32-46)
    - Address[16:2] is 0b000_0000_0100_1011 (bits 47-61)
    - Parity value is irrelevant because it is not used in PASS DCF records (bit 62)
    - Preferred Stop value is 0.
- For LOCK3_PG3
    - Data[31:0] is 0xFFFF_FFFF (bits 0-31)
    - CS[14:0] is 0b000_0000_0000_1000 (bits 32-46)
    - Address[16:2] is 0b000_0000_0100_1111 (bits 47-61)
    - Parity value is irrelevant because it is not used in PASS DCF records (bit 62)
    - Preferred Stop value is 0.

32.6.2 Overriding secure read protection

As noted previously, the PASS_LOCK3_PGn registers contain five read protection fields, RP0-RP2, that correspond to pre-defined Read Lock groups. To temporarily unlock a Read Lock group, the appropriate PASS_LOCK3_PG*n*[RL*n*] bits must be set to 0.

Like the register bits controlling secure write protection, the reset value of bits controlling secure read protection is determined by DCF record or, in the absence of a relevant DCF record, each bit resets to '1', causing the blocks associated with each read group to be read locked.

Example 6. Overriding secure read protection

Building on Example 5, where Read Lock group 2 was protected by passwords 0 and 1, temporarily overriding secure read protection for that group is accomplished by first unlocking the PASS_LOCK3_PG0 and PASS_LOCK3_PG1 registers and then setting the RL2 bit to '0' in both.

1. First write 0b00 to the PASS_CHSEL[GRP] register field to indicate registers controlled by password 0 are to be unlocked.
2. Write the 256-bit value for password 0 to the set of eight 32-bit password challenge input registers (PASS_CIN*n*) beginning with PASS_CIN0. The password must be written as a sequence of eight 32-bit writes, with the most significant bits of the password written to PASS CIN0.
3. Write a 0 to PASS_LOCK3_PG0[RL2] bit and verify a successful write.
4. Repeat the above steps for password 1.

The result of a successful sequence is that the blocks associated with the unlocked read lock group can be read by a debugger.

32.7 Debug port enable/disable

The mechanism for temporarily enabling the MPC5746R debug port after it has been locked by its life cycle state is similar to the flash memory read protection mechanism detailed in Secure read protection. The difference is that the PASS_LOCK3_PG*n*[DBL] field is used instead of the RP0-RP2 fields.

32.8 Tamper detection

The Tamper Detection Module (TDM) provides a type of flash memory write protection mechanism that forces software to write a record associated with one or more blocks in a Tamper Detection Region (TDR) before the block(s) can be erased. An additional feature is provided to enable customers to override the protection mechanism for any TDR so that no record is required to be written before a block within the TDR can be erased.

This section provides details on the mapping between DCF record bits and individual flash memory blocks to be selected for tamper detection.

See the Tamper Detection Module (TDM) chapter for details on tamper detection, including the DCF clients and two additional memory-mapped registers.

There are two significant differences between selecting blocks for tamper detection and selecting blocks for other activities, e.g., a flash erase operation:

1. Selection of blocks for tamper detection protection is done only during device configuration to customer specifications, either at the factory or by the customer during OEM production activities. The selection becomes a permanent part of the device configuration.
2. The selection of blocks for tamper detection is done by writing *DCF records*, which is why the selection becomes a permanent part of the device.

The Tamper Detect section of Table 6-5 gives the CS and Address value combinations that correspond to groups of LOCK0-LOCK3 registers, similar to the flash module's LOCK0-LOCK3 registers.

The mapping of individual flash blocks to TDM DCF record data field bits is shown in included in the detailed flash block map in the OTPENn DCF clients.

32.8.1 Implementing tamper detection

Implementing tamper detection requires:

1. Creating the tamper detect diary
2. Assigning blocks to Tamper Detection Regions (TDRs)

The tasks are detailed in the following sections

32.8.2 Creating the tamper detect diary

Tamper detection in the MPC5746R microcontroller is user-defined. The basic functionality provided is an erase counter, or diary, for 6 user-defined regions, called "tamper detect regions", or TDRs, within the flash memory. Each TDR is defined using a set of DCF records that is similar in function and layout to the flash module's SEL*n* and LOCK*n* registers, which contain bits matched to specific flash blocks.

For a program or erase operation to be performed on a block included in a TDR, a record must be written to a "diary" that tracks flash modification operations. The format and size of records is customer-defined. The only hardware constraints are that each diary has a maximum size of 2 KB and the minimum size of any programming operation is 8 bytes.

NOTE

The limiting factor for tamper detection records is the diary size. The total diary size is given by the number of TDRs (6 for MPC5746R) multiplied by 2 KB, the portion of the diary allotted to records associated with each TDR.

Since the minimum flash programming operation size is 8 bytes, the maximum number of tamper detect records for a given TDR is 256 8-byte entries.

The diary can be placed within any flash block in the flash array but to maintain the security of the TDR, there are two constraints:

- The block where the diary is placed must be assigned as OTP within the OTP registers (covered in the next section)
- The diary base address must be on a 4 KB boundary, therefore the least significant 12 bits of the base address must all be '0'

NOTE

The tamper detect diary base address DCF record is a "write once" record. All subsequent tamper detect diary base address DCF records created are ignored.

Example 7. Creating the tamper detect diary

If the total space required for a diary is 12 KB (as in the case of 6 TDRs), any flash block can be used because the smallest flash blocks in the MPC5746R microcontroller are 16 KB. Since the diary base address must be on a 4 KB, boundary, though, if the diary base address is within a 16 KB flash block, it can only be assigned to the base address of the block or the address given by the base address plus 4 KB.

If the base address of the 16 KB block is 0x00FC4000, the base address of the diary is given by:

- 0b0000_0000_1111_1100_0000_0000_0000_0000 (16 KB base address), or
- 0b0000_0000_1111_1100_0001_0000_0000_0000 (16 KB base address + 4 KB)

The base address of each TDR's section of the diary is:

- TDR0 = Diary_Base_Address + 0b00_0000_0000_0000
- TDR1 = Diary_Base_Address + 0b00_1000_0000_0000
- TDR2 = Diary_Base_Address + 0b01_0000_0000_0000
- TDR3 = Diary_Base_Address + 0b01_1000_0000_0000
- TDR4 = Diary_Base_Address + 0b10_0000_0000_0000
- TDR5 = Diary_Base_Address + 0b10_1000_0000_0000
- End of the diary = Diary_Base_Address + 0b11_0000_0000_0000

We need to create one DCF record that defines the base address for the diary. The information required is from the Tamper Detect section of Table 6-5.

Table 32-8. Creating the tamper detect diary

DCF CS[14:0]	DCF address [16:2] (binary)	DCF client description
000_0000_0001_0000	000_0000_0000_0000	Diary Base Address

Referring to Figure 32-5, the values for the DCF record are:

- For LOCK3_PG0
  - Data[31:0] is 0x00FC4000 (the base address)
  - CS[14:0] is 0b000_0000_0001_0000 (bits 32-46)
  - Address[16:2] is 0b000_0000_0000_0000 (bits 47-61)
  - Parity value is irrelevant because it is not used in Tamper Detect DCF records (bit 62)
  - Preferred Stop value is 0.

See the Tamper Detect section of Table 6-5 for details.

NOTE

User software must check whether the diary is full. If the diary area for a TDR is full, user software must program a DCF record to override blocking of erase from TDR, disabling tamper detect, so that erases can be done to that TDR without any diary entry. This is detailed in Overriding tamper detection.

32.8.3 Assigning blocks to Tamper Detection Regions (TDRs)

Tamper detection regions are defined by creating TDR*x*_LOCK*n* DCF records. For example, in a microcontroller with six tamper detection regions, the following records define the TDRs:

- TDR0_LOCK0, TDR0_LOCK1, TDR0_LOCK2, TDR0_LOCK3
- TDR1_LOCK0, TDR1_LOCK1, TDR1_LOCK2, TDR1_LOCK3
- TDR2_LOCK0, TDR2_LOCK1, TDR2_LOCK2, TDR2_LOCK3
- TDR3_LOCK0, TDR3_LOCK1, TDR3_LOCK2, TDR3_LOCK3
- TDR4_LOCK0, TDR4_LOCK1, TDR4_LOCK2, TDR4_LOCK3
- TDR5_LOCK0, TDR5_LOCK1, TDR5_LOCK2, TDR5_LOCK3

Each set of TDR*x*LOCK*n* DCF records mapped in exactly the same way as the flash module's SEL*n* and LOCK*n* registers (see the detailed flash block map in TDRx_LOCKn DCF clients for the mapping).

In the TDR*x*LOCK*n* DCF records:

- A bit set to '1' means the corresponding flash block is assigned to this TDR
- A bit set to '0' means the corresponding flash block is NOT assigned to this TDR

The default state (no TDRs defined) is defined as 'Block NOT assigned to the TDR'.

32.8.4 Overriding tamper detection

When a TDR's diary section is full, a Tamper Override (TO) record must be created before a block assigned to the TDR can be programmed or erased.

The details of the data section of the DCF record used to override tamper detection is shown in the following figure.

NOTE

Bits in this DCF record is writable from 0 to 1only. Attempted writes of bits from 1 to 0 are ignored.

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
W	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
W	0	0	0	0	0	0	0	0	0	0	TOE5	TOE4	TOE3	TOE2	TOE1	TOE0

Figure 32-9. Data portion of Tamper Region Override (TO) DCF record

Example 8. Implementing secure write protection

Assume the diary Tamper Detection Region 3 is full

We need to create one DCF record that defines that overrides tamper detection for the tamper detection region whose diary is full. The information required is from the Tamper Detect section of Table 6-5.

Table 32-9. Implementing secrure write protection

DCF CS[14:0]	DCF address [16:2] (binary)	DCF client description
000_0000_0001_0000	000_0000_0000_0001	Tamper Region Override

Referring to Figure 32-5, the values for the DCF record are:

- Data[31:0] is 0x0000_0008 (TOE3)
- CS[14:0] is 0b000_0000_0001_0000 (bits 32-46)
- Address[16:2] is 0b000_0000_0000_0001 (bits 47-61)
- Parity value is irrelevant because it is not used in Tamper Detect DCF records (bit 62)
- Preferred Stop value is 0.

See the Tamper Detect section of Table 6-5 for details.

32.9 Implementing OTP

Any flash block within the flash array can be assigned, at any time, to be OTP. OTP means that flash erase of the entire block is disabled and only 64-bit double words that are already erased (i.e., flash content is 0xFFFF_FFFF_FFFF_FFFF) can be programmed. Over-programming is not possible.

Flash blocks are assigned as OTP by writing a DCF record. The block becomes OTP after the next reset.

NOTE

After a flash block is configured as OTP, it cannot be changed back.

This capability resides within the Tamper Detection Module (TDM). The records are detailed in Table 6-5. See the entries for the OTP_EN0, OTP_EN1, OTP_EN2, and OTP_EN3 DCF records in the Tamper Detect section of the table.

Chapter 33
Analog Peripheral Modules

33.1 Analog sub-system overview

The MPC5746R analog sub-system contains a total of four independent 12-bit SAR ADCs, three independent 16-bit Sigma-Delta ADCs, two Decimation Filter blocks, an ADC Cross-Triggering Unit (BCTU), two customer readable temperature sensors, and bandgap voltage reference.

Each ADC instance has an independent dedicated programming interface. The Decimation filter blocks are used for digital signal processing on the ADC conversion results. The BCTU is used to trigger SAR conversions, and to channel conversion results to the Reaction Module block on the device. The SAR ADCs are used for general purpose A/D conversions, and to read internal nodes on the device (temperature sensors, bandgap voltage reference, device supply voltages, LVD/HVD Comparator references, and SAR ADC references).

33.1.1 Block diagram

The analog sub-system block diagram for the MPC5746R is given in Figure 33-1.

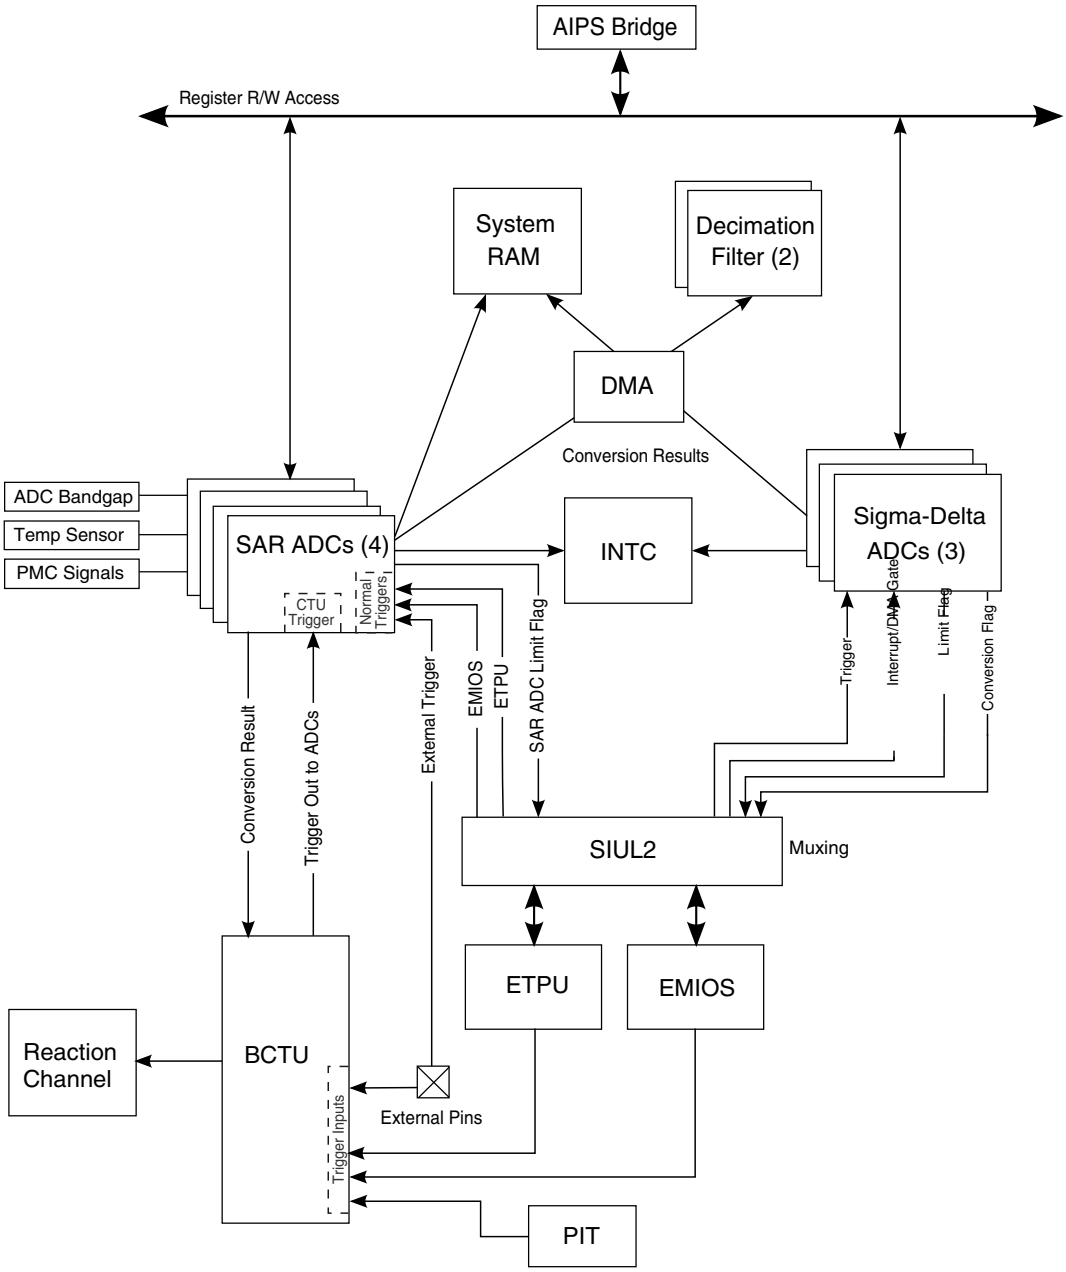

Figure 33-1. Analog sub-system

Chapter 34
Sigma Delta Analog-to-Digital Converter (SDADC) Digital Interface

34.1 Sigma Delta Analog-to-Digital Converter (SDADC) digital interface chip-specific information

34.1.1 Introduction

The following sections contain the chip-specific information for the on-chip SDADC modules. See Sigma Delta Analog-to-Digital Converter (SDADC) digital interface reference for a detailed description of the SDADC modules.

34.1.2 Sigma-Delta ADC features

There are three Sigma Delta ADCs on the MPC5746R. Each Sigma-Delta ADC has the following features:

- 16-bit resolution
- Single-ended or differential input
- Pass band 10 Hz - 100 kHz
- Output sample rate 30 kHz - 333 KHz (full performance)
- Programmable gain (1, 2, 4, 8, 16)
- Biasing of unused single-ended input to VREF/2 or ground
- Biasing of differential inputs to VREF/2 via 100 kΩ
- Optional high pass filter
- Interrupt and DMA support
- Synchronous start of all converters
- Conversion limit watchdog
- Hardware start trigger and mux advance/wrap-around

See the *MPC5746R Microcontroller Data Sheet* for electrical specifications.

34.1.3 Sigma-Delta ADC block diagram

Figure 34-1 gives the block diagram of the Sigma-Delta ADC and the integration into the MPC5746R. The SDADC block is comprised of three pieces: the converter, the bias generator, and the digital interface (shown inside the dotted-line box). All three Sigma Delta ADCs have the same features and integration on the MPC5746R.

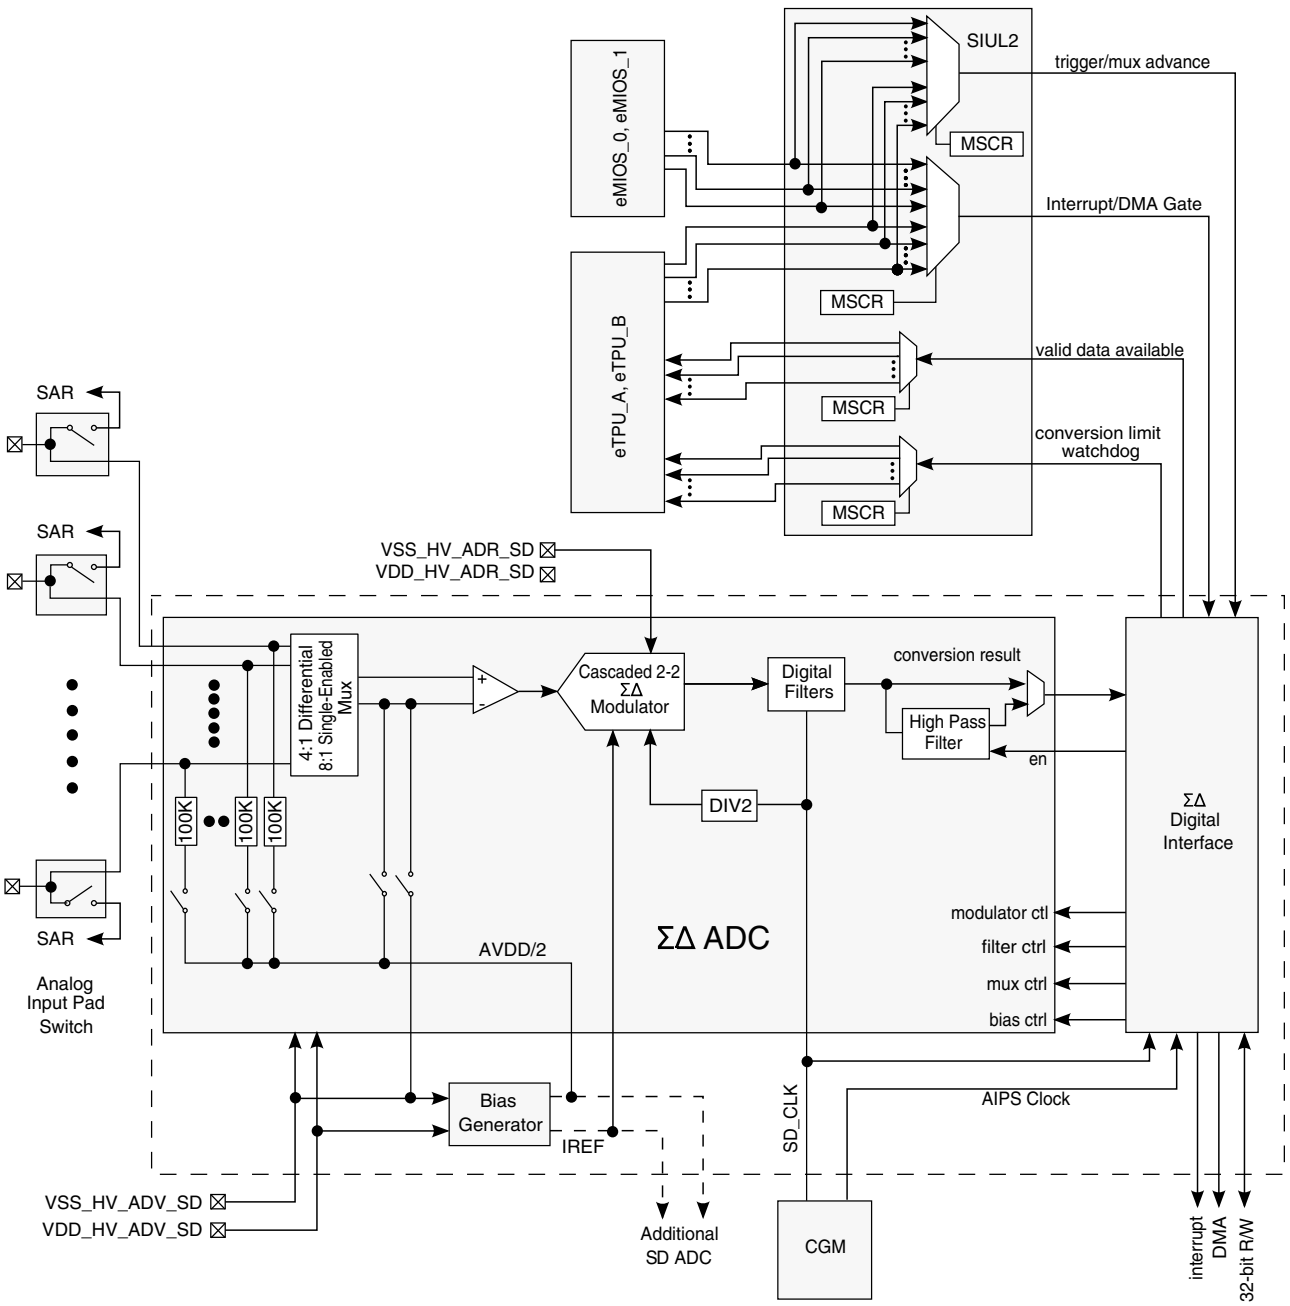

Figure 34-1. MPC5746R Sigma Delta ADC

34.1.4 Sigma-Delta ADC external signal description

The Sigma-Delta ADC external package pins are defined in Table 34-1 and the following sections.

Please refer to the *MPC5746R Microcontroller Data Sheet* for voltage level on signals.

Table 34-1. Sigma-Delta ADC external signal description

Signal Name	Signal Type	Description
PZ[n],PY[n]	Analog Input	Single-Ended or Differential Analog Input
VDD_HV_ADV_SD	Analog Supply	Sigma-Delta ADC Analog Power Supply
VSS_HV_ADV_SD	Analog Ground	Sigma-Delta ADC Analog Ground
VDD_HV_ADR_SD	Analog Supply	Sigma-Delta ADC Reference
VSS_HV_ADR_SD	Analog Ground	Sigma-Delta ADC Ground Reference

34.1.4.1 VDD_HV_ADV_SD/VSS_HV_ADV_SD

The Sigma-Delta ADCs on the MPC5746R share a single supply/ground pair in the packages. The VDD_HV_ADV_SD/VSS_HV_ADV_SD pins are dedicated to the Sigma-Delta ADCs, and are not shared with the SAR ADCs on the device.

See the *MPC5746R Microcontroller Data Sheet* for electrical characteristics.

34.1.4.2 VDD_HV_ADR_SD/VSS_HV_ADR_SD

The Sigma-Delta ADCs on the MPC5746R share a single reference pair in the packages, that is dedicated and not shared with the SAR ADCs.

34.1.5 Sigma-Delta ADC analog input multiplexing

The I/O Signal Description and Input Multiplexing Tables are included in a Microsoft Excel file attached to this document. Locate the paperclip symbol on the left side of the PDF window, and click it. Double-click on the Excel file to open it and select the I/O Signal Description Table tab. Search for "SAR ADC" or "Sigma-Delta ADC" in the I/O Signal Table worksheet to locate the analog input pins.

NOTE

The only configuration option for an analog input is to shut off the digital input buffer to reduce leakage. See the SIUL2 chapter for details.

34.1.6 Sigma-Delta digital interface

Each SDADC has a dedicated digital interface comprised of a set of registers and control functions. All features in the digital interface apply to and are available for each Sigma-Delta with the following exceptions:

- The mapping of input channels is not the same for each ADC and is defined in Table 34-1
- The mapping of the DMA/interrupt gating input and end of conversion signal output to the ETPU is not the same for each ADC and is defined in the SIUL2 chapter of this document.
- External modulator clock and bitstream support is not included on the MPC5746R

34.1.7 Sigma-Delta ADC clock architecture

SDADC clock architecture is discussed in the following sections.

34.1.7.1 Clock source

Each Sigma-Delta ADC digital interface on the MPC5746R has a register clock input, which is separate from the module clock input. The register interface is clocked by the AIPS_CLK. The module clock is sourced by the modulator clock (SD_CLK). See the Clocking chapter for more detail on the clock sources. The input clock for the Sigma-Delta modulator is the SD_CLK. Figure 34-2 gives a block diagram of the required Sigma-Delta ADC clock architecture for the MPC5746R. The frequency range for the SD_CLK is 4 - 16 MHz.

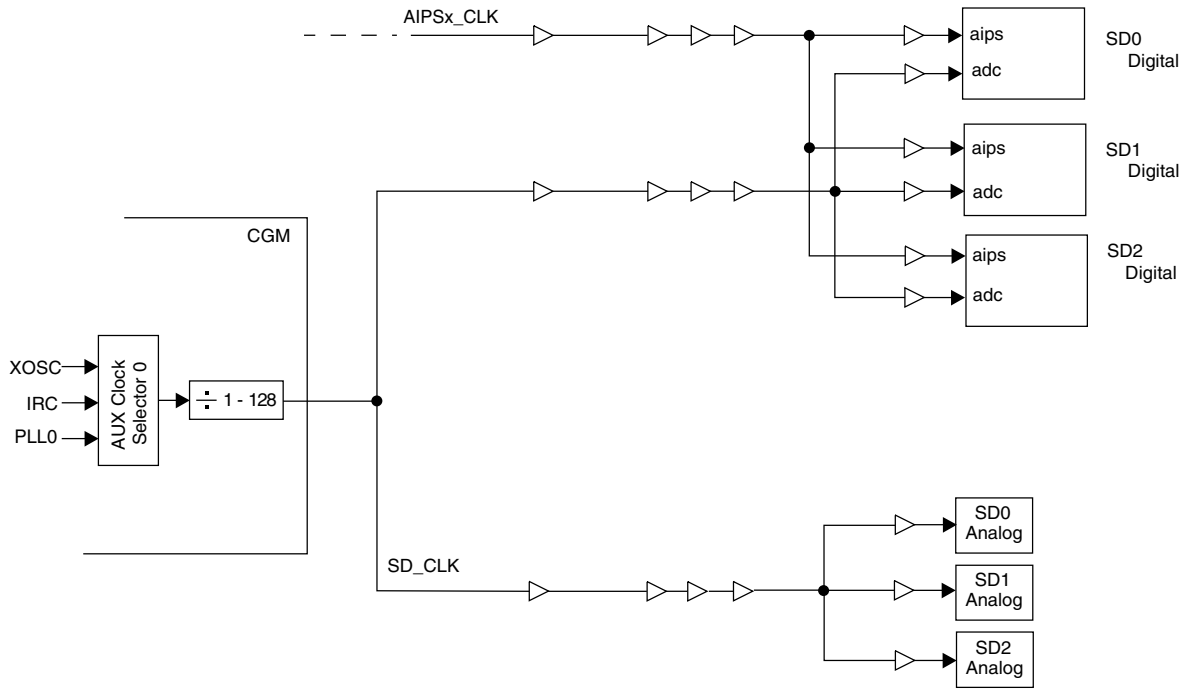

Figure 34-2. MPC5746R Sigma Delta ADC clock diagram

34.1.8 Sigma-Delta ADC starting and triggering

Each Sigma Delta ADC can be started by software or ETPU or EMIOS channel outputs. The external trigger input of the Sigma Delta ADC allows starting of the converter and advancing the channel mux. Mapping of ETPU and EMIOS channels to the Sigma Delta trigger inputs is done in the SIUL2 input multiplexing registers, and defined in the I/O spreadsheet for the device.

NOTE

A minimum startup time of 100 µs needs to be given to SDADC after enabling.

34.1.8.1 Simultaneous start of multiple Sigma-Delta converters

Each Sigma-Delta ADC on the device supports starting the converter with a software write to the start register in the digital interface. The trigger outputs of each Sigma-Delta ADC are connected to the trigger input of each other Sigma-Delta ADC and its own to allow simultaneous starting of all ADCs. Simultaneously is defined as all selected converters start sampling and provide results on the same SD_CLK clock edge.

The user controls which ADCs are simultaneously started by selecting the trigger input from the ADC that will initiate the simultaneous start and enabling the ADC. Then a software or hardware trigger start of the initiating ADC will cause all linked ADCs to start also.

Trigger selection is specified using the SDADC_MCR[TRIGSEL] field (see TRIGSEL)

NOTE

The possible SDADC_MCR[TRIGSEL] field values are specified generically. Use the following values for selecting triggers for the MPC5746R SD ADC:

- 0000 – SDADC_0 output trigger
- 0001 – SDADC_1 output trigger
- 0010 – SDADC_2 output trigger
- 0011 – SDADC START_TRIGGER MSCR
- 0100 – 1111 Reserved

The connections for the simultaneous start of the converters is given in Figure 34-3.

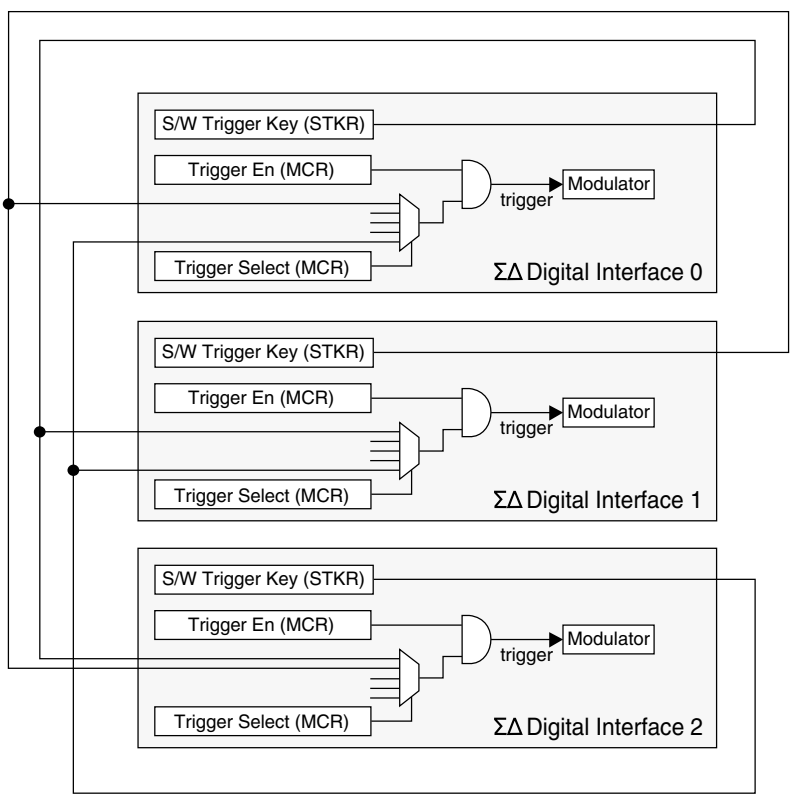

Figure 34-3. Sigma-Delta ADC simultaneous start connectivity

34.1.8.2 Sigma Delta mux input advance and wrap around

The Sigma Delta input mux advance and wrap around feature is enabled and controlled in the digital interface of the Sigma Delta ADC. The advancing of the mux can be controlled in the interface by software or by external ETPU and EMIOS channels. The mapping of ETPU and EMIOS output channels to the mux advance input for each Sigma Delta ADC is controlled in the SIUL2 MSCR registers, and the detailed mapping is given in the input muxing table of the device I/O definition spreadsheet for the device.

34.1.9 Sigma-Delta ADC input biasing

The Sigma Delta ADC inputs can be biased internally on the device. The differential inputs can be biased to half-scale through a 100 KΩ resistor. The unused single-ended input can be biased to half-scale or ground. This is controlled in the SDADC_MCR and SDADC_CSR registers.

34.1.10 Sigma-Delta ADC conversion result processing

Upon start of input sampling, a valid conversion value is available in the result register after twice the group delay of the Sigma Delta ADC. In the case of a switch of the input mux, an additional 100 µs is required for the mux settling time. Each Sigma Delta ADC has an independent 16-bit result register.

The Sigma Delta ADC always returns a 16-bit signed result with a result FIFO depth of 16.

NOTE

The Sigma-Deltas on the MPC5746R have a fixed FIFO depth of 16. The FIFO depth is set at the factory and is not programmable but the amount of available FIFO space used in an application is programmable using the SDADC_FCR[FTHLD] field.

An option for an interrupt/DMA is available for FIFO full. Optional interrupt requests are available for FIFO empty and FIFO overrun conditions.

34.1.10.1 Optional high-pass filter of conversion result

There is an optional high-pass filter that the output conversion result can be fed through before being captured in the result register in the digital interface. The filter is enabled/ disabled in the digital interface. The -3 db point of the filter is defined in the *MPC5746R Microcontroller Data Sheet*.

34.1.10.2 Interrupt support

Each Sigma-Delta ADC has an independent interrupt vector. The interrupt vectors for the Sigma-Delta ADC are defined in the interrupt chapter of this document.

Each ADC combines all interrupt sources into a single interrupt request output signal. Each interrupt source is cleared with an independent register flag bit.

34.1.10.3 DMA support

Each Sigma-Delta ADC is able to generate an independent DMA request for a result FIFO full request. The DMA channel assignments for the Sigma-Delta ADCs are defined in the DMA chapter of this document.

34.1.11 Sigma-Delta interface to ETPU module

Interfacing of SDADC to the ETPU module is discussed in the following sections.

34.1.11.1 Valid data available output to ETPU

The Sigma-Delta digital interface outputs a logic level 1 pulse on the end-of-conversion signal to the ETPU with each update to the data register. The actual operation is such that the valid data available signal is asserted on the rising edge of the SD_CLK. This aligns to the actual end-of-conversion. The converted value is written to the data register on the next falling edge of clock, introducing a half SD_CLK delay until the value can be read.

The mapping of Sigma-Delta valid data available signals to ETPU inputs is controlled in the SIUL2 MSCR registers, and the detailed mapping is given in the input muxing table of the device I/O definition spreadsheet for the device.

34.1.11.2 DMA/interrupt gating input from ETPU

The Sigma-Delta ADC digital interface has an input signal that is used to disable interrupt and DMA requests for conversion results. The input gating signal is connected to ETPU channel outputs. The digital interface has a register bit for enabling and disabling the interrupt/DMA gating feature.

When the gating signal from the ETPU is asserted, no interrupt or DMA request is generated. The polarity of the gating signal is such that when the signal is high, interrupt and DMA requests are passed. When the gating signal is low, interrupt and DMA requests are blocked.

When the ETPU gating signal is asserted, the Sigma-Delta FIFO cannot overflow.

The gating signal for each ADC is driven by several ETPU output channels. The mapping of ETPU outputs to Sigma-Delta DMA/IRQ gating inputs is controlled in the SIUL2 MSCR registers, and the detailed mapping is given in the input muxing table of the device I/O definition spreadsheet for the device.

34.1.11.3 Conversion limit watchdog output to ETPU

Each Sigma-Delta ADC provides an optional conversion limit check for upper and lower bounds. The enable bit and the two 16-bit limit registers for the feature are included in the Sigma-Delta ADC digital interface. If a conversion result exceeds one of the limits, a flag bit is asserted in a status register. The flag bit is output to the ETPU for each ADC. The mapping of Sigma-Delta conversion limit watchdog outputs to ETPU inputs is controlled in the SIUL2 MSCR registers, and the detailed mapping is given in the input muxing table of the I/O definition spreadsheet for the device.

34.1.12 Sigma-Delta interface to eMIOS module

Interfacing of SDADC to the eMIOS module is discussed in the following sections.

34.1.12.1 DMA/interrupt gating input from eMIOS

The Sigma-Delta ADC digital interface has an input signal that is used to disable interrupt and DMA requests for conversion results. The input gating signal is connected to eMIOS channel outputs. The digital interface has a register bit for enabling and disabling the interrupt/DMA gating feature.

When the gating signal from the eMIOS is asserted, no interrupt or DMA request is generated. The polarity of the gating signal is such that when the signal is high, interrupt and DMA requests are passed. When the gating signal is low, interrupt and DMA requests are blocked.

When the eMIOS gating signal is asserted, the Sigma-Delta FIFO cannot overflow.

The gating signal for each ADC is driven by several eMIOS output channels. The mapping of eMIOS outputs to Sigma-Delta DMA/IRQ gating inputs is controlled in the SIUL2 MSCR registers, and the detailed mapping is given in the input muxing table of the device I/O definition spreadsheet for the device.

34.1.13 Sigma-Delta interface to decimation filter modules

There is no dedicated hardware interface from the Sigma Delta ADCs to the Decimation Filter blocks on the device. Transfer of ADC conversion results to the decimation filters for application processing must be done by software or DMA on the MPC5746R.

NOTE

The Decimation Filter blocks on the MPC5746R should not be confused with the internal decimation filter of the Sigma Delta ADC.

34.1.14 Sigma-Delta interface to reaction channels

There is no dedicated hardware interface from the Sigma Delta ADCs to the reaction channels on the MPC5746R.

34.1.15 Sigma-Delta Interface to the Cross Triggering Unit (CTU)

There is no dedicated hardware interface from the Sigma Delta ADCs to the BCTU on the MPC5746R.

34.2 Sigma Delta Analog-to-Digital Converter (SDADC) digital interface reference

34.2.1 Introduction

The Sigma-Delta Analog-to-Digital Converter (SDADC) digital interface block controls the on-chip SDADC and holds control and status registers accessible for application. It provides accurate conversion data for a wide range of applications.

34.2.2 Overview

The SDADC digital interface block provides all control information for operating mode selection (single-ended or differential), analog input gain, decimation rate, high-pass filter enable, etc. It also generates the bias controls for common mode voltage selection, to bias the positive and negative terminals to different voltage levels (for example, half scale bias, reference ground, reference supply) for diagnostics. It generates the analog multiplexer control signals for the selected channels. To assist synchronous operation across multiple ADC blocks, hardware trigger support is implemented to start data conversion.

34.2.3 Features

The features of the SDADC are as follows:

- 16-bit data resolution output
- Single-ended input or differential input mode of operation
- Programmable wraparound mechanism for both modes of operation
    - Configurable trigger sources: hardware or software
    - Configurable initial entry and wraparound values for the loop
- Configurable biasing for negative input terminal in single-ended mode
- Gain and offset calibration support using fixed bias for input terminals
- Programmable decimation rate
- Programmable gain for analog inputs
- Optional high-pass filter for pure AC application
- Hardware trigger support for synchronous operation of multiple SDADC blocks
- Trigger event output generation by software
- Programmable FIFO structure for storing up to 16 datawords of 16-bit converted data
- Interrupt/DMA request generation based on various conditions:

  - Data buffer above threshold
  - Data buffer overrun
  - Watchdog (WDG) crossover event
- Programmable threshold range watchdog support
- Low consumption mode
- Optional conversion process halt mechanism on SoC debug request

34.2.4 Modes of operation

This section describes the different operation modes of the SDADC. When exiting reset, the mode of operation is determined by the Module Configuration Register (MCR).

34.2.4.1 Differential input mode

This mode is entered by negating the MCR[MODE] bit. In this mode, a pair of analog inputs are connected to positive and negative terminals of ADC modulator. In order to support gain and offset calibration for diagnostics, it is possible in this mode to select fixed bias voltages to both input terminals.

34.2.4.2 Single-ended input mode

This mode is entered by asserting the MCR[MODE] bit. In this mode, the negative input terminal is biased with a fixed voltage based on selection information in MCR, and the other analog input is connected to the selected external analog channel.

34.2.5 External signal description

The following table shows the list of signals driven by external pins. See the chip-specific details about SDADC signals and package pinouts for information about signal muxing and availability external to the chip.

Table 34-2. Signal properties

Name	Function	I/O	Reset	Pull-up
AN[0:7]	Single-ended analog inputs or Differential pairs of analog inputs	I	—	—
VREFP	Voltage reference for SDADC	I	—	—
VREFN	Ground reference for SDADC	I	—	—
AVDD	Analog voltage supply for SDADC	I	—	—

Table continues on the next page...

Table 34-2. Signal properties (continued)

Name	Function	I/O	Reset	Pull-up
AVSS	Analog ground supply for SDADC	I	—	—
DVDD	Digital voltage supply for SDADC	I	—	—
DVSS	Digital ground supply for SDADC	I	—	—

34.2.6 Memory map and register definition

This section provides the memory map for the SDADC block.

SDADC memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page

14 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15 HPFEN	High Pass Filter Enable 0 High-pass (DC removal) filter is disabled 1 High-pass (DC removal) filter is enabled
16 WDGEN	Watchdog Enable This bit enables the WDG monitor. 0 WDG is disabled 1 WDG is enabled
17–18 TRIGEDSEL	Trigger Edge Selection 00 Falling edge of trigger input is selected 01 Rising edge of trigger input is selected 10 Both edges of trigger input are selected 11 Both edges of trigger input are selected

Table continues on the next page...

SDADC_MCR field descriptions (continued)

Field	Description
19 TRIGEN	Trigger Enable This field enables the hardware trigger input to initiate a fresh conversion. Upon receiving a trigger event, SDADC reset input is asserted and deasserted synchronously with respect to the peripheral clock. The reset pulse width is fixed to four peripheral clock cycles. The trigger event is ignored if the SDADC internal modulator is not enabled (MCR[EN] = 0). 0 Trigger input is disabled 1 Trigger input is enabled
20–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22–23 TRIGSEL	Trigger Input Selection This field selects which input will be used for hardware triggered conversions. 00 SDADC_0 output trigger is selected. 01 >SDADC_1 output trigger is selected. 10 SDADC_2 output trigger is selected. 11 SDADC START_TRIGGER MSCR is selected.
24 FRZ	Freeze This field enables stopping the SDADC conversions at the end of the current channel conversion when the chip enters debug mode. When the chip enters debug mode, further conversions by the SDADC analog block will be stopped, and converted data output from the SDADC analog block are ignored. The ongoing channel conversion will be completed and the converted data is stored. When the chip exits debug mode, SDADC resumes the job that was left before halting the conversions. 0 Conversions are not stopped 1 Conversions are stopped
25–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 VCOMSEL	Common Voltage Bias Selection This field selects the common voltage bias for the negative input terminal of the SDADC during single-ended mode (MODE = 1). 0 Negative input terminal is biased with VREFN 1 Negative input terminal is biased with VREFP/2 (half-scale bias)
28 WRMODE	Wrap-Around Mode This bit selects the wraparound mechanism for conversion of programmed sequence of channels. 0 Wraparound mechanism disabled (in this case the default software control mechanism will be enabled) 1 Wraparound mechanism enabled
29 GECEN	Accurate Gain Error Mode Enable This bit selects the accurate gain error mode, and must be set during gain error calibration as well as during conversions requiring accurate gain error mode. It can be kept '0' if gain error calibration mode is not needed. 0 Gain error calibration mode disabled 1 Gain error calibration mode enabled

Table continues on the next page...

SDADC_CSR field descriptions

Field	Description
0–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8–15 BIASEN	Bias enable If BIASEN[i] = 1, analog input AN[i] (could be single-ended input or differential analog input) is connected to half-scale bias through a 100 kOhm resistor.
16–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21–23 ANCHSEL_ WRAP	Analog Channel Selection Wraparound Value (ANCHSEL_WRAP) When in wraparound mode, this field indicates the maximum value of the wraparound counter, after which it will wrap around back to initial value 000. This value should be programmed before enabling wraparound mechanism (MCR[WRMODE] = 1).
24–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

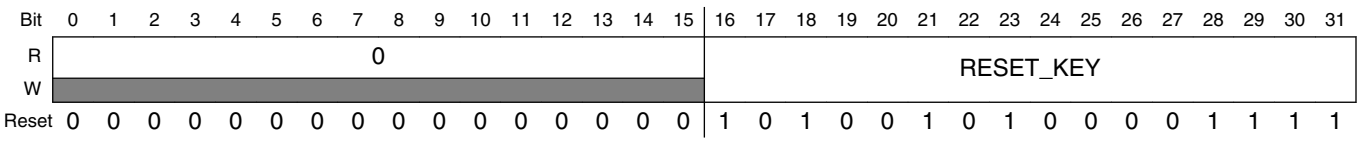
<tr><th>Field</th><th>Description</th></tr>
<tr><td>29–31
ANCHSEL</td><td>
Analog Channel Selection(ANCHSEL)

Based on single-ended or differential mode of operation (MCR[MODE]), common mode voltage selection (MCR[VCOMSEL]), this field defines the connectivity of analog inputs to either positive or negative polarity terminals of the SDADC according to the following table.



Wraparound Mode:
• This field also indicates the initial entry value for the first loop of the wraparound sequence from where the wraparound counter will start incrementing when wraparound mode is entered (when wraparound mechanism enabled (MCR[WRMODE] = 1)).
• If this field is written any time during wraparound mode (when MCR[WRMODE] = 1), the present value of the wraparound counter will be updated with the value of ANCHSEL - the next trigger will act on the updated channel, and the next increment will be on the updated channel. Here, the value of ANCHSEL chosen should be < ANCHSEL_WRAP; otherwise it will be ignored by hardware.
• Wraparound will always be from initial counter value 000.

34.26.3 Reset Key Register (SDADC_RKR)

The Reset Key Register (RKR) is the target for a predefined key write operation used to reset the SDADC to start a fresh conversion.

Address: 0h base + 8h offset = 8h

SDADC_RKR field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 RESET_KEY	Reset Key This field, when written with 5AF0h, is used to generate the reset for the SDADC block and to reload the internal counterwith the start value programmed in OSDR. Any write access to this register which is different from the predefined key is ignored. Read access will always return the inverted key.

34.26.4 Status Flag Register (SDADC_SFR)

The Status Flag Register (SFR) contains status and flag bits. These bits are set by hardware and reflect the status of the SDADC and indicate the occurrence of events that may generate an interrupt or a DMA request. Software can clear some flags by writing '1' to those bits. Writing a '0' to a flag has no effect.

Address: 0h base + Ch offset = Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0													ANCHSEL_CNT		
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0							DFEF	0			WTHH	WTHL	CDVF	DFORF	DFFF
W												w1c	w1c		w1c	w1c
Reset	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0

SDADC_SFR field descriptions

Field	Description
0–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13–15 ANCHSEL_CNT	Analog Channel Selection Counter(ANCHSEL_CNT) This field reflects the current value of the internal Analog Channel Selection Counter. It indicates the present number of the channel selected through the analog multiplexer.
16–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23 DFEF	Data FIFO Empty Flag This field is asserted when there is no dataword in the FIFO.

Table continues on the next page...

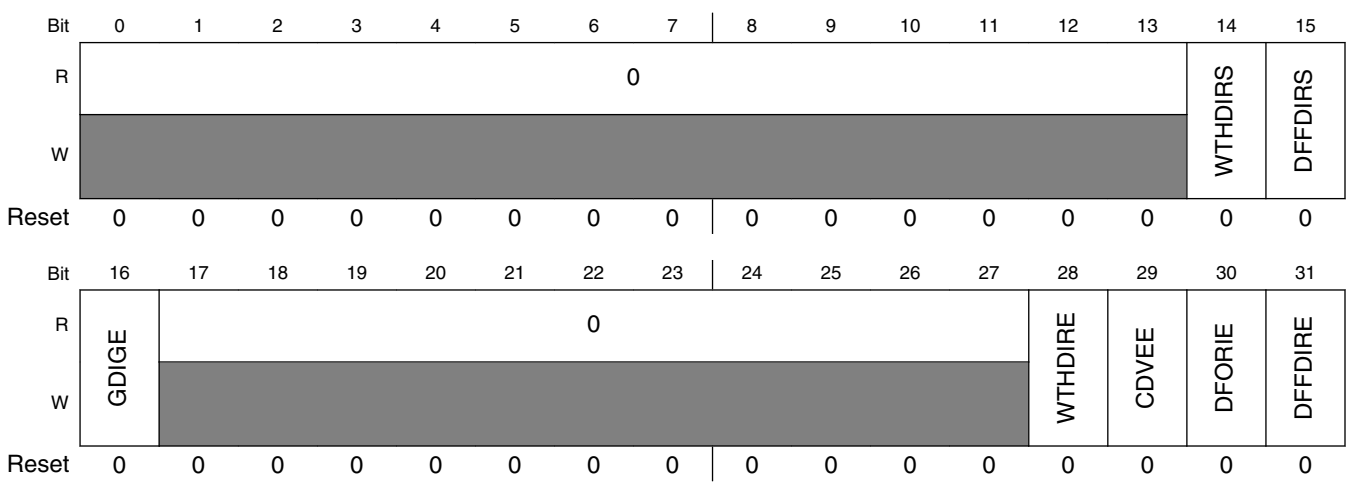
SDADC_SFR field descriptions (continued)

Field	Description
	0 Data FIFO is not empty 1 Data FIFO is empty
24–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 WTHH	Watchdog Upper Threshold Cross Over Event This field is set when Converted Data crosses Upper Threshold of WDG. It can be cleared by software writing '1' to clear. **NOTE:** This bit is also cleared by an acknowledgement from the DMA module when all of the following conditions are met: • SDADC_RSER[WTHDIRE]=1 (When this field is set by the occurrence of a watchdog upper threshold cross over event, a request is generated) • SDADC_SFR[WTHDIRS]=1 (The request generated when this field is set is a DMA request) • SDADC_RSER[GDIGE]=0 OR, if SDADC_RSER[GDIGE]=1, the external gating signal is asserted 0 Watchdog Upper Threshold Cross Over Event did not occur 1 Watchdog Upper Threshold Cross Over Event occurred
28 WTHL	Watchdog Lower Threshold Cross Over Event This field is set when Converted Data crosses Lower Threshold of WDG. It can be cleared by software writing '1' to clear. **NOTE:** This bit is also cleared by an acknowledgement from the DMA module when all of the following conditions are met: • SDADC_RSER[WTHDIRE]=1 (When this field is set by the occurrence of a watchdog lower threshold cross over event, a request is generated) • SDADC_SFR[WTHDIRS]=1 (The request generated when this field is set is a DMA request) • SDADC_RSER[GDIGE]=0 OR, if SDADC_RSER[GDIGE]=1, the external gating signal is asserted 0 Watchdog Lower Threshold Cross Over Event did not occur 1 Watchdog Lower Threshold Cross Over Event occurred
29 CDVF	Converted Data Valid Flag This field gives the actual status of data coming from the SDADC block. The converted data is not valid or is corrupted whenever there is a change in configuration settings determined by MCR, channel selection programmed in CSR. Any write access to the registers MCR and CSR will reset this flag. This flag is set automatically after an internal timer counts a number of output clock fd clock cycles specified by the value of SDADC_OSDR[OSD]. 0 Data output from SDADC is not valid 1 Data output from SDADC is valid
30 DFORF	Data FIFO Overrun Flag This field indicates that software or DMA failed to prevent FIFO from overflowing with converted datawords. Software can clear this bit by writing '1' to it after reading the FIFO contents through CDR. This flag remains set if software or DMA failed to clear the condition that caused this flag setting. If DFORF is set, further datawords will not be received into FIFO even if sufficient room exists. 0 No overrun has occurred since the last time the flag was cleared 1 Overrun has occurred or the DFORF has not been cleared since the last overrun occurred

Table continues on the next page...

SDADC_SFR field descriptions (continued)

Field	Description
31 DFFF	Data FIFO Full Flag This bit is set when the number of converted datawords in the FIFO is equal to or more than the number indicated by FCR[FTHLD]. Software can clear this bit by writing '1' to it. This bit is also cleared by an acknowledgement from the DMA controller when DMA request generation is selected. This bit remains set if software or DMA failed to clear the condition that caused this flag setting. Even if DFFF is set, datawords will continue to be received until an overrun condition occurs. Datawords will not be received if the converted data is not valid (CDVF = 0). **NOTE:** Whenever MCR[EN] is cleared in order to stop the SDADC or change the channel configuration, it is necessary to also clear the RSER[DFFDIRE] bit alongwith. Similarly if DMA or software is too slow in not reading the FIFO datawords resulting in DFFF condition it is advisable to stop the SDADC by clearing the MCR[EN] followed by clearing of RSER[DFFDIRE] bit. Both these action will ensure safe operation. 0 The number of datawords in FIFO is less than the number indicated by FCR[FTHLD] 1 The number of datawords in FIFO is equal to or greater than the number indicated by FCR[FTHLD] at some point in time since this flag was last cleared



34.26.5 Request Select and Enable Register (SDADC_RSER)

The Request Select and Enable Register (RSER) serves two purposes:

- Enables the flag bits in SFR to generate DMA requests or interrupt requests.
- Selects the type of request to generate.

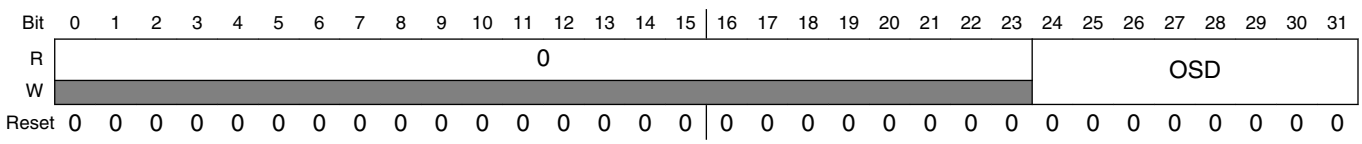
Refer to the field descriptions for the type of requests that are supported.

Address: 0h base + 10h offset = 10h

SDADC_RSER field descriptions

Field	Description
0–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14 WTHDIRS	WDG Threshold Cross Over Event DMA/Interrupt Request Select When SFR[WTHH/WTHL] and RSER[WTHDIRE] fields are set, this field selects between generating a DMA request or an interrupt request. 0 Interrupt request is selected 1 DMA request is selected
15 DFFDIRS	Data FIFO Full DMA/Interrupt Request Select When the SFR[DFFF] and SFR[DFFDIRE] fields are set, this field selects between generating a DMA request or an interrupt request. 0 Interrupt request is selected 1 DMA request is selected
16 GDIGE	Global DMA/Interrupt Gating Enable This field determines whether all module interrupts and DMA requests need to be gated by an external gating signal or not. 0 No impact of external gating signal on module DMA/interrupt requests 1 All module DMA/interrupt requests are qualified only when external gating signal is asserted
17–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28 WTHDIRE	WDG Threshold Cross Over Event DMA/Interrupt Request Enable This field enables the SFR[WTHH/WTHL] field to generate a request. The WTHDIRS field determines which is selected, a DMA request or an interrupt request. The final DMA/interrupt request also depends on the gating signal if enabled by the GDIGE field. 0 Interrupt/DMA request is disabled on WDG Threshold Cross Over Event 1 Interrupt/DMA request is enabled on WDG Threshold Cross Over Event
29 CDVEE	Conversion Data Valid Event Enable The status of SFR[CDVF] gated with RSER[CDVEE] is passed on as an event on “conversion_flag" output port, which can be used at SoC level for indication of valid data conversion window. Once enabled, the event output will remain asserted as long as valid data conversions are ongoing. 0 Event output disabled 1 Event output assertion/deassertion based on the SFR[CDVF] field
30 DFORIE	Data FIFO Overrun Interrupt Enable This bit enables the SFR[DFORF] field to generate an interrupt request. The final interrupt request also depends on the gating signal if enabled by the GDIGE field. 0 Interrupt request is disabled when data FIFO overrun condition occurs 1 Interrupt request is enabled when data FIFO overrun condition occurs
31 DFFDIRE	Data FIFO Full DMA/Interrupt Request Enable This field enables the SFR[DFFF] field to generate a request. The DFFDIRS field determines which is selected, a DMA request or an interrupt request. The final DMA/interrupt request also depends on the gating signal if enabled by the GDIGE field.

Table continues on the next page...



SDADC_RSER field descriptions (continued)

Field	Description
	0 Interrupt/DMA request is disabled when data FIFO full condition occurs 1 Interrupt/DMA request is enabled when data FIFO full condition occurs

34.26.6 Output Settling Delay Register (SDADC_OSDR)

The Output Settling Delay Register (OSDR) provides a delay value to qualify the converted output data coming from the SDADC.

Address: 0h base + 14h offset = 14h

SDADC_OSDR field descriptions

Field	Description
0–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–31 OSD	Output Settling Delay This field defines the delay to qualify the conversion data stored in CDR. Whenever the SDADC block is reset in order to start the conversion from a fresh state, an internal timer is loaded with this start value. The counter counts down with output clock f_d until it reaches zero, and then it generates a flag which qualifies the converted data. The output clock fd is equal to f_s / (2xOSR), where f_s is the input sampling clock frequency. See the electrical specifications for the settling delays. **NOTE:** Refer to the $t_{settling}$ and $t_{LATENCY}$ parameters in the device datasheet for the minimum allowed output settling delay values.

34.26.7 FIFO Control Register (SDADC_FCR)

The FIFO Control Register (FCR) provides the ability to enable or disable the FIFO functionality, and to control the amount of available FIFO depth to be used.

NOTE

1. It is important to note that the FIFO depth is set at the factory and cannot be changed but the amount of available FIFO space actually used can be set by specifying the value in the FTHLD field. The FSIZE field indicates the amount of FIFO space available. By setting the value of FTHLD to be less than the FIFO depth indicated by FSIZE, the FIFO is considered to be full when the number of data words in the FIFO is equal or greater than FTHLD.
2. This register may be read at any time, but should only be written when SDADC is disabled (MCR[EN] = 0).

Address: 0h base + 18h offset = 18h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0				FTHLD				0					FSIZE		FE
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	0

SDADC_FCR field descriptions

Field	Description
0–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20–23 FTHLD	FIFO Threshold When the number of datawords in the data FIFO is greater than the value in FTHLD field, the FIFO full event is flagged. An interrupt or a DMA request will be generated as determined by DFFDIRE and DFFDIRS fields of RSER. For proper operation, the value in the FTHLD field must be set to be less than or equal to the FIFO size as indicated by FSIZE.
24–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29–30 FSIZE	FIFO Size

Table continues on the next page...

SDADC_FCR field descriptions (continued)

Field	Description
	The maximum number of converted datawords that can be stored in the data FIFO before an overrun occurs. This field is read-only. The reset value of this field depends on the implementation parameter to define the FIFO size. 00 FIFO depth = 1 dataword 01 FIFO depth = 4 datawords 10 FIFO depth = 8 datawords 11 FIFO depth = 16 datawords
31 FE	FIFO Enable When this field is set the built-in FIFO structure is enabled. The size of the FIFO structure is indicated by the FSIZE field. If this field is not set then the FIFO depth is set to one dataword regardless of the value in the FSIZE field. 0 Data FIFO is not enabled for multiple datawords; FIFO depth is one dataword 1 Data FIFO is enabled; FIFO depth is indicated by FSIZE

34.26.8 Software Trigger Key Register (SDADC_STKR)

The Software Trigger Key Register (STKR) allows generating the trigger event output by a software write operation.

Address: 0h base + 1Ch offset = 1Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0																ST_KEY															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SDADC_STKR field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 ST_KEY	Software Trigger Key This bitfield, when written with FFFFh, is used to generate a trigger event output which can be used to trigger conversions of multiple SDADC blocks synchronously depending on the chip's implementation. Any write access to this register which is different from the predefined key is ignored. Read access will always return 0000h.

34.26.9 Converted Data Register (SDADC_CDR)

The Converted Data Register (CDR) stores the converted data in the data FIFO.

The conversion result in the CDATA word is a 16-bit, signed value.

NOTE

When SDADC_MCR[PGAN]=111b (programmable gain is 16), the least significant bit of the conversion data in SDADC_CDR[CDATA] is always 0.

Address: 0h base + 20h offset = 20h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0																CDATA

SDADC_CDR field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 CDATA	Converted Data Register (CDATA[13:0]) The converted datawords can be read from FIFO by reading this register. The data width is 16 bits which has actual 16-bit data (bits 15 down to 0) coming from ADC.

34.26.10 WDG Threshold Register (SDADC_WTHHLR)

This is the Converted Data Range WDG Threshold register.

NOTE

A single WDG monitor will check for lower and upper threshold crossover events.

Address: 0h base + 24h offset = 24h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	THRH																THRL															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SDADC_WTHHLR field descriptions

Field	Description
0–15 THRH	WDG Upper Threshold Value This indicates the upper threshold for the converted data on any channel, above which threshold a crossover event would be flagged through SFR[WTHH].
16–31 THRL	WDG Lower Threshold Value This indicates the lower threshold for the converted data on any channel, below which threshold cross over event would be flagged through SFR[WTHL].

34.2.7 Functional description

The SDADC has the following distinct available modes determined by fields in MCR:

- Differential input mode
- Single-ended input mode
- Low consumption mode

34.2.7.1 Differential input mode

Differential input mode is entered when the SDADC_MCR[MODE] field is set to '0' and the SDADC_MCR[EN] field is set to '1'. In differential input mode, a pair of analog inputs among AN[0:7] is connected to the input terminals of the SDADC modulator block. The module supports four differential pairs: AN[0,1], AN[2,3], AN[4,5], and AN[6,7].

The modulator block has two input terminals, positive (INP) and negative (INM). The selection of input pair depends on the SDADC_CSR[ANCHSEL] field. The connectivity of each analog input in a given differential pair, whether it is connected to positive or negative terminal, is determined according to the Analog input AN[0:7] selection table in the Channel Selection Register description.

The differential input mode can also be used to perform gain and offset calibration, where the input terminals are biased with fixed voltages coming from the bias block.

34.2.7.2 Single-ended input mode

Single-ended input mode is entered by setting the SDADC_MCR[MODE] and SDADC_MCR[EN] fields to '1'. In this mode, one of the analog inputs among AN[0:7] is selected via the SDADC_CSR[ANCHSEL] field and is connected to the positive terminal. The negative input terminal is biased with a fixed internal voltage. There are two internal bias voltages available: reference ground (VREFN) and half-scale bias (VREFP/2). The selection of this common mode voltage is controlled vua the SDADC_MCR[VCOMSEL] field.

34.2.7.3 Low consumption mode

This is the default mode after exiting from reset. This mode is exited by asserting the MCR[EN] field to enable the SDADC block. When data conversion is not required, the SDADC internal modulator can be put in low consumption mode to reduce power consumption.

34.2.7.4 Analog input multiplexing and bias support

The complete selection and connectivity of analog inputs AN[0:7] is based on the ANCHSEL field of CSR and the MODE and VCOMSEL bits of MCR, according to the Analog input AN[0:7] selection table in the Channel Selection Register description. Each analog input can be biased to half scale (AVDD/2) via on-chip 100 kΩ resistance. This allows simple AC coupling to the external analog inputs through a capacitor. This biasing is applicable irrespective of whether analog channel is selected through multiplexer or not.

34.2.7.5 Programmable gain and decimation rate

All analog inputs can be configured to have a selectable input gain as defined in the PGAN field description in MCR. This means the input signal is sampled and the result is amplified by the factor determined by PGAN before providing the same to modulator.

The SDADC module is provided with a fixed input sampling clock f_s. The input signal is grossly oversampled by the modulator in order to reduce quantization noise. To support different passbands with a fixed sampling clock, a programmable decimation rate is implemented. The process of decimation, to eliminate redundant data at the output while retaining the necessary information, is controlled by the field PDR in MCR.

34.2.7.6 High-pass filter support

For pure AC applications, it is useful to remove any DC component in the input signal. An optional high-pass filter is implemented which can be enabled by asserting the MCR[HPFEN] field. The –3 dB frequency of the filter is fixed (not programmable) and is specified in the device data sheet. This high-pass filter is implemented in the decimation filter logic of the SDADC.

34.2.7.7 Data conversion

The SDADC operates in a continuous conversion mode as soon as it is enabled. There is an inherent settling time required after SDADC startup before conversion data is considered valid.

NOTE

During that period, the Converted Data Valid Flag bit (SDADC_SFR[CDVF]) reads '0'.

Settling time duration depends on the latency and output settling time specifications. To account for the settling time, an internal timer is implemented that counts down from a start value determined by the value of the SDADC_OSDR[OSD] field.

The internal countdown timer is triggered by an SDADC reset, i.e., by writing the value 5AF0h to the SDADC_RKR[RESET_KEY] field.

NOTE

An SDADC reset is required any time there is a change to the SDADC configuration (via changes to the SDADC_MCR register settings), or a change to analog channel selection (via SDADC_CSR register settings).

When the timer reaches '0', the SDADC_SFR[CDVF] field is asserted and converted data is loaded into data FIFO on every rising edge of the output clock (f_d).

Any write access to the SDADC_MCR or SDADC_CSR register causes the SDADC_SFR[CDVF] flag to be cleared, indicating that data coming from SDADC is not valid. If the SDADC_SFR[CDVF] flag is '0', the following flags are blocked from becoming asserted:

- Data FIFO Full Flag (SDADC_SFR[DFFF])
- Data FIFO Overrun Flag (SDADC_SFR[DFORF])

If the SDADC_SFR[DFFF] bit is already set, the data FIFO is already full before SDADC_SFR[CDVF] deassertion.

Wraparound Control Mechanism: Here a wraparound logic includes all analog channels of the input mutiplexer from Ain("000") to Ain(CSR[ANCHSEL_WRAP]) in both Single ended and Differential ended mode in wraparound sequence triggered by hardware or software source:

- MCR[WRMODE] bit would enable or disable the wraparound mechanism. Clearing the WRMODE bit automatically switches FSM back to Software control mode.
- Every valid trigger advances the wraparound counter to next channel to be converted.
- Wraparound Counter: An internal wraparound counter which points to analog channel to be converted takes the initial entry value for the first loop of execution

from CSR[ANCHSEL] while entering wraparound mode. From next loop onwards the counter wraparounds to default initial value "000". Maximum value of the counter (wraparound value) should be programmed in CSR[ANCHSEL_WRAP] before entering wraparound mode. The definition of ANCHSEL and ANCHSEL_WRAP is provided in the Analog input AN[0:7] selection table in the Channel Selection Register description.

- Upon entering or during wraparound mode user should take care to program ANCHSEL value less than ANCHSEL_WRAP value; otherwise hardware would reject the new ANCHSEL value.
- Possible trigger sources:
  - SOURCE1 (Software Bit): writing to STKR.ST_KEY at any time during the wraparound mode (irrespective of MCR[TRIGEN or TRIGSEL] setting) generates a trigger pulse. Each such trigger initiates a fresh conversion and advances the wraparound counter by one.

NOTE

Care should be taken while programming the TRIGEN/ TRIGSEL of each SDADC instance that no unintended simultaneous SW triggering of multiple instances happen.

  - SOURCE2 (Hardware Trigger): Here external trigger output enabled by MCR[TRIGEN or TRIGEDSEL or TRIGSEL] before entering wraparound mode for selective or all SDADC instances provides trigger. Each such valid trigger initiates a fresh conversion and advances the wraparound counter by one. One of the hw_trig_in ports can be used to connect the external trigger output.
- Next channel number to be converted can be updated by software even in the middle of wraparound sequence execution. This can be done by rewriting CSR[ANCHSEL]. After CSR[ANCHSEL] is rewritten, the next trigger takes updated value and the wraparound counter would increment from the updated value.
- Current wraparound counter value can be read from the SFR[ANCHSEL_CNT] bitfield.

34.2.7.8 Hardware triggering

Software Control Mechanism: SDADC conversion can be triggered by various hardware events coming from either external pins or internal timers. The field TRIGSEL of MCR selects which hardware event is to be used for triggering conversions. This trigger event, which is synchronous to the peripheral clock, is enabled by asserting MCR[TRIGEN]. As soon as a trigger event is detected, reset input of SDADC block is asserted synchronously

for four cycles. This will ensure that SDADC starts from a fresh state when reacting to the input trigger event. The SDADC internal modulator must be enabled before enabling the trigger event — otherwise the trigger event will be ignored.

If the same trigger event is provided to multiple SDADC digital interface modules and the respective enable controls (TRIGEN bit MCR) are asserted, synchronous operation of multiple SDADC blocks can be achieved with output results being updated at the same time. Once the reset input is deasserted, the first valid conversion output is stored in data FIFO after a configurable delay determined by OSDR[OSD].

It is also possible to generate a software trigger event output by a write access of STKR with a predefined key. This event output can be used as a trigger to achieve synchronous software start of multiple SDADC blocks.

In case of a hardware trigger, the skew/jitter will be less than 100 ns. It will be more than one ADC clock cycle due to synchronization. In case of a software trigger, all SDADCs start synchronous sampling.

Wraparound Control Mechanism: In wraparound control mode, hardware and software triggers are equally valid. The hardware trigger source should be selected before enabling the wraparound mode.

34.2.7.9 Interrupt/DMA request support

The SDADC has one condition that generates interrupts only and another that generates interrupts or DMA request.

The DFFF field is asserted when the data FIFO full condition is detected, indicating that the number of converted datawords stored in data FIFO is equal to or greater than the value indicated by threshold determined by FCR[FTHLD]. The interrupt or DMA request is generated only when RSER[DFFDIRE] is asserted. RSER[DFFDIRS] selects whether a DMA request or an interrupt request is generated.

The data FIFO overrun flag (DFORF) indicates the FIFO overflow condition. Further converted datawords cannot be received and data is lost. The interrupt request is generated only when RSER[DFORIE] is asserted.

Apart from above, a WDG threshold crossover event can also generate an interrupt or DMA request.

If RSER[GDIGE] is set, all module interrupt/DMA requests are qualified only when an external global gating signal is asserted.

34.2.7.10 Gain calibration support

To perform gain calibration, the following sequence needs to be applied.

1. Select differential mode of operation by writing MCR[MODE] to '0'.
2. Enable gain error calibration mode by writing MCR[GECEN] to '1'.
3. Configure the mux selection ANCHSEL field of CSR to '110'. This configuration will apply VREFP on positive terminal and VREFN on negative terminal.
4. Disable the bias on all input analog channels by writing ENBIAS field of CSR to 00h.
5. Disable the high-pass filter by deasserting MCR[HPFEN].
6. Generate a reset event by writing 5AF0h to RESET_KEY of RKR.
7. Read the digital output (CDR[CDATA]) stored in FIFO after the output settling time. Expected output if there is no gain error is 0111_1001_1001_1001b, corresponding to full positive scale after attenuation inserted by the internal filter (1*0.95). The measurement should be repeated to reduce contribution of noise during the calibration process. D_p is the average value of attenuated positive full scale given by D_p = AVERAGE(CDR[CDATA]).
8. Change the mux selection ANCHSEL field of CSR to '111'. This configuration will apply VREFN on positive terminal and VREFP on negative terminal.
9. Generate a reset event by writing 5AF0h to RESET_KEY of RKR.
10. Read the digital output (CDR[CDATA]) stored in FIFO after the output settling time. Expected output if there is no gain error is 1000_0110_0110_0110b, corresponding to full negative scale after attenuation inserted by the internal filter (-1*0.95). The measurement should be repeated to reduce contribution of noise during calibration process. D_n is the average value of attenuated negative full scale given by D_n = AVERAGE(CDR[CDATA]).
11. The SDADC calibrated gain can be calculated as:
    $Gain = (D_p - D_n) / 2^{16}$
12. The measured gain value can be used to nullify the gain errors in the digital output. For calibrated conversion, the data CDR[CDATA] provided by the SDADC should be normalized using the calculated gain: $CDATA_{norm}$ is given by $CDATA_{norm}$ = CDR[CDATA]/Gain.

Note

a. The gain error calibration should only be done with gain equal to '1' (in other words, PGAN = 000). Nevertheless, the calculated gain can be applied to normalized data also for conversion with GAIN>1.
b. MCR[GECEN] = 1 ensures the accurate gain error mode is enabled. This bit should be set both during calibration process and after calibration, for application

data conversion. Application data conversion must then be normalized using the measured gain.

c. The higher the number of full-scale conversion (D_p, D_n) done, the higher the rejection of noise during the calibration. The number of conversion is dependent on application noise. It is recommended to run at least 16 conversions when calculating an average value.

34.2.7.11 Offset calibration support

To perform offset calibration, the following sequence must be applied.

1. Select differential mode of operation by writing SDADC_MCR[MODE] to '0'.
2. Configure the SDADC_CSR[ANCHSEL] mux selection field to '100' or '101' as required.
   a. SDADC_CSR[ANCHSEL] ='100' in case of data conversion after calibration in "single ended mode with negative input=$V_{SS_HV_ADR_D}$"
   b. SDADC_CSR[ANCHSEL] ='101' in case of data conversion after calibration in "differential mode" and "single ended mode with negative input = ($V_{DD_HV_ADR_D} - V_{SS_HV_ADR_D}$) / 2"
3. Disable the bias on all input analog channels by writing ENBIAS field of CSR to 00h.
4. Disable the high pass filter by deasserting SDADC_MCR[HPFEN].
5. Generate a reset event by writing 5AF0h to RESET_KEY of RKR.
6. Read the digital output stored in FIFO after the output settling time.
7. The measured offset can be used to nullify the offset error in the digital output. Expected output is 00_0000_0000_0000b. The SDADC offset can be calculated as:
   Offset = Expected Output – Actual Output

Note

The offset must be calculated for each SDADC_MCR[PGAN] field setting since it is expected to vary with gain configuration of SDADC.

34.2.8 Initialization information

To initialize the SDADC registers for data conversion, the following sequence is required.

1. Enable the SDADC by asserting MCR[EN].

2. Configure MCR to select the required mode, polarity, common mode voltage, input gain, and decimation rate.
3. Enable high-pass filter if required.
4. Select the required analog channel for data conversion. It is possible to select the bias for each channel for AC coupling applications.
5. Configure OSD delay according to SDADC startup time or latency from reset exit.
6. Generate a reset event by writing 5AF0h to RESET_KEY of RKR. Otherwise, if data conversion need to be triggered by a hardware event, assert MCR[TRIGEN].
7. DFFF interrupt or DMA request will be generated after the data FIFO has reached threshold to indicate that data can be transferred.

34.2.8.1 Data conversion step

To acquire a data from SDADC, the following sequence is required:

1. Enable the SDADC by asserting MCR[EN].
2. Configure MCR to select the required mode, polarity, common mode voltage, input gain, and decimation rate.
3. Enable high-pass filter is required.
4. Select the required analog channel for data conversion. It is possible to select the bias for each channel for AC coupling applications.
5. Configure OSD delay according to SDADC required startup time or latency from reset exit.
6. Generate a reset event writing 5AF0h in RESET_KEY field of RKR register.
7. Wait till FIFO empty flag DFEF of SFR register is clear.
8. Read data by CDATA of CDR register.

Repeat steps from 6 to 8 for new acquisitions.

NOTE

The time elapsed between reset event and Read data by CDATA field of CDR register are:

- Reset event <- -> Data Valid flag(CDVS) = Output settling Time delay (OSDR has to be set at least to 16) (Refer to the $t_{settling}$ and $t_{LATENCY}$ parameters in the device datasheet for the minimum allowed output settling delay values.).
- Data Valid flag <- -> Data FIFO is not empty = 0.5*CLK_Out + 3*CLK_In
- Data FIFO is not empty <- -> read Data (safety point) = 2*CLK_In, where CLK_Out = CLK_In/(2*OSR)

Chapter 35
Analog-to-Digital Converter (ADC)

35.1 Analog-to-Digital Converter (ADC) chip-specific information

35.1.1 Introduction

The following sections contain the chip-specific information for the on-chip SAR ADC modules. See Analog-to-Digital Converter (ADC) reference for detailed information on the SAR ADC modules.

35.1.2 SAR ADC block diagram

Figure 35-1 gives the block diagram of the SAR ADC and the integration into the MPC5746R. The IP is comprised of two pieces: the analog converter and the digital wrapper.

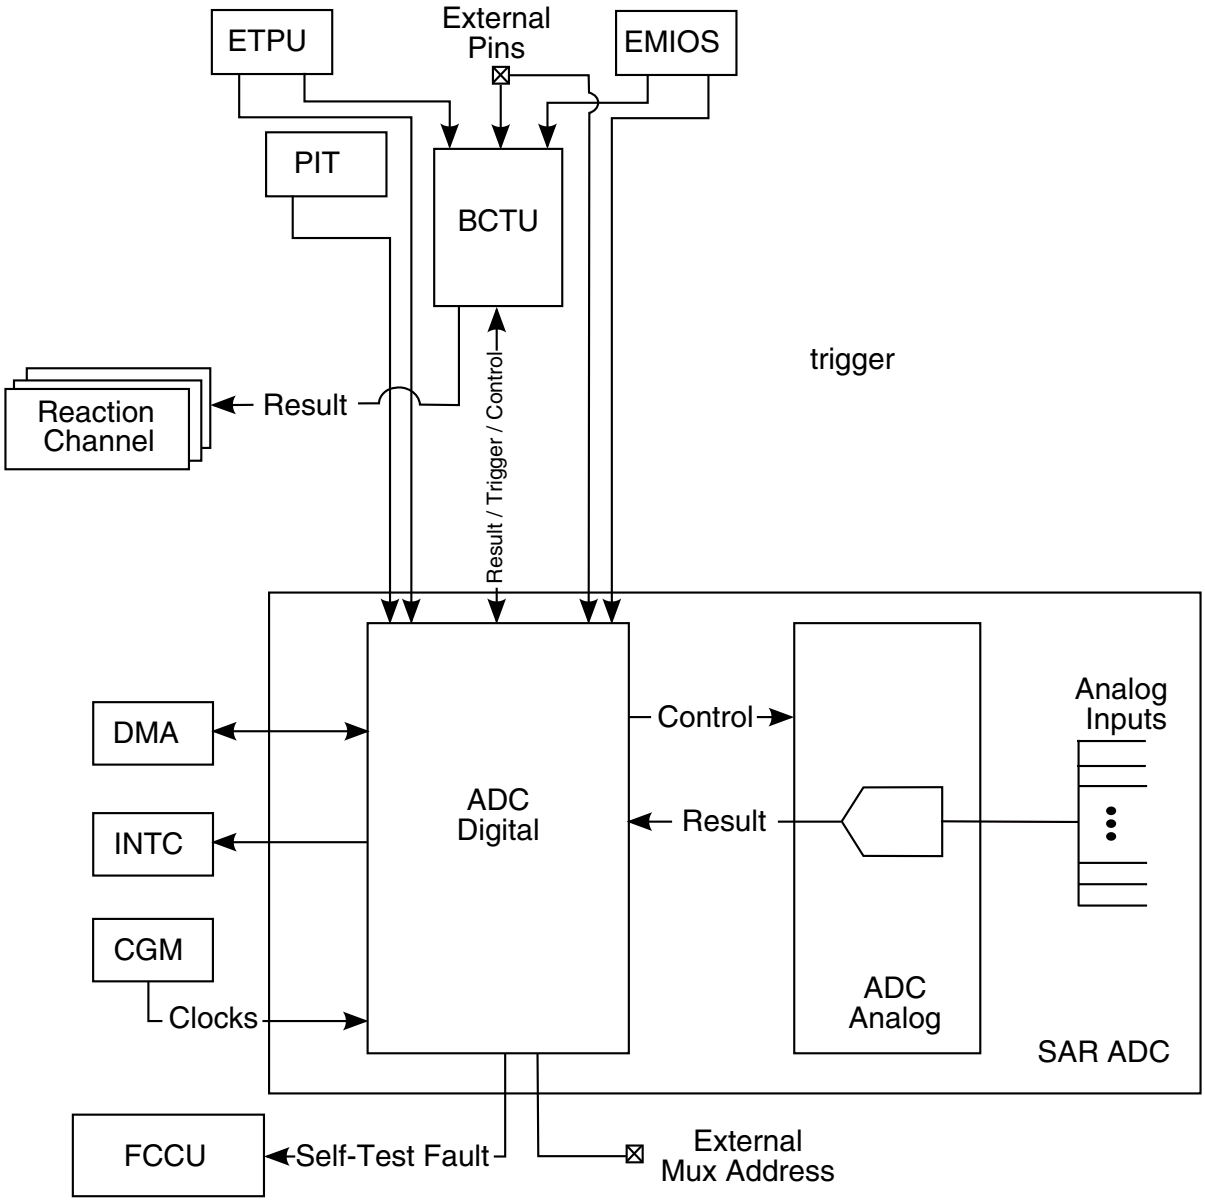

Figure 35-1. SAR ADC block diagram

35.1.3 SAR ADC external signal description

The SAR ADC external package pins are defined in the following sections.

NOTE

Please refer to the *MPC5746RMicrocontroller Data Sheet* for signal voltage specifications.

Table 35-1. SAR ADC external signal description

Signal Name	Signal Type	Description
PW[n],PX[n],PY[n]	Analog Input	Single-Ended Analog Input
VDD_HV_ADV_SAR	Analog Supply	SAR ADC Analog Power Supply
VSS_HV_ADV_SAR	Analog Ground	SAR ADC Analog Ground
VDD_HV_ADR_SAR	Analog Supply	SAR ADC Reference
VSS_HV_ADR_SAR	Analog Ground	SAR ADC Ground Reference

35.1.4 SARADC feature comparison

The following table lists the features for each of the 4 on-chip SAR ADC module.

Table 35-2. SAR ADC features

Feature	SARADC0	SARADC1	SARADC2	SARADC3
Resolution	12-bit	12-bit	12-bit	12-bit
No. of precision channels	32	32	32	21
No. of internal channels	7	6	4	4
Number of externally multiplexed channels	0	0	0	32
BCTU trigger mode support	yes	yes	yes	yes
BCTU control mode support	yes	yes	yes	yes
DMA support	yes	yes	yes	yes
Presampling support	yes	yes	yes	yes
No. of watchogs	4	4	4	4
BCTU asynchronous support	yes	yes	yes	yes
Self test support[1, 1]	yes	yes	yes	yes

1. ADC self test functions can only be initiated via the ADC registers. ADC self test cannot be initiated or controlled by the BCTU module.

35.1.5 SARADC channel map

The following table contains the channel map for each of the 4 on-chip SAR ADC module.

NOTE

In addition to the analog input pins in the device packages, there are internal voltage sources that must be monitored by the

SAR ADCs. These include the ADC temp sensor, bandgap reference, core and I/O supply voltages, LVD/HVD, and other internal monitors. Internal voltages mapped to SAR ADC channels are listed in the section of Table 35-3 labeled as **Internal Channels**.

1. The bandgap reference voltage (ADC_BGREF) can be sampled from either ADC0 or ADC1 but must not be sampled simultaneously. Failure to adhere to this restriction results in inaccurate conversion.
2. This channel is functional from 4.5V to 5.5V of the corresponding reference (VDD_HV_ADR_SAR).

35.1.6 SARADC control registers

Not all control registers are applicable to every on-chip SAR ADC. The following table shows the registers applicable to each.

Table 35-4. SAR ADC control register applicability

Register	ADC0	ADC1	ADC2	ADC3
Main Configuration Register (ADC_MCR)	yes	yes	yes	yes
Main Status register (ADC_MSR)	yes	yes	yes	yes
Interrupt Status Register (ADC_ISR)	yes	yes	yes	yes
Channel Pending register 0 (ADC_CEOCFR0)	yes	yes	yes	yes
Channel Pending register 1 (ADC_CEOCFR1)	yes	yes	yes	yes
Channel Pending register 2 (ADC_CEOCFR2)	no	no	no	yes
Interrupt Mask Register (ADC_IMR)	yes	yes	yes	yes
Channel Interrup Mask Register 0 (ADC_CIMR0)	yes	yes	yes	yes
Channel Interrup Mask Register 1 (ADC_CIMR1)	yes	yes	yes	yes
Channel Interrup Mask Register 2 (ADC_CIMR2)	no	no	no	yes
Watchdog Threshold Interrupt Status Register (ADC_WTISR)	yes	yes	yes	yes
Watchdog Threshold Interrupt Mask Register (ADC_WTIMR)	yes	yes	yes	yes
DMA Enable register (ADC_DMAE)	yes	yes	yes	yes
DMA Channel Select Register 0 (ADC_DMAR0)	yes	yes	yes	yes
DMA Channel Select Register 1 (ADC_DMAR1)	yes	yes	yes	yes
DMA Channel Select Register 2 (ADC_DMAR2)	no	no	no	yes
Threshold Register (ADC_THRHLR0)	yes	yes	yes	yes
Threshold Register (ADC_THRHLR1)	yes	yes	yes	yes

35.1.7 SAR ADC trigger inputs

The SAR ADC supports two trigger input modes, normal and injected. The timer channel and external pin trigger inputs to the BCTU are connected to the SAR ADC through the injected trigger, and the normal trigger input is connected to ETPU and EMIOS outputs and external pins through the SIUL2 MSCR registers.

Each SAR ADC has the same set of trigger inputs (ETPU, EMIOS, PIT, package pin) connected through the BCTU to the injected trigger. This allows triggering of more than one ADC from the same trigger source. Each SAR ADC also has the same set of normal trigger inputs and group of sources, but actual channel numbers and pins are different.

The mapping of ETPU, EMIOS, PIT, and package pins to BCTU trigger inputs and SAR normal trigger inputs is defined in the I/O Signal Description and Input Multiplexing Tables, which are included in a Microsoft Excel file attached to this document. Locate the paperclip symbol on the left side of the PDF window, and click it. Double-click on the Excel file to open it and select the I/O Signal Description Table tab.

35.1.8 SAR ADC externally muxed inputs

SAR_3 supports externally muxed ADC inputs. SAR_0, SAR_1, and SAR_2 do not support externally muxed ADC inputs.

SAR_3 supports 4 external multiplexers, with 8 channels each.

The following figure gives the external mux connections for SAR_3.

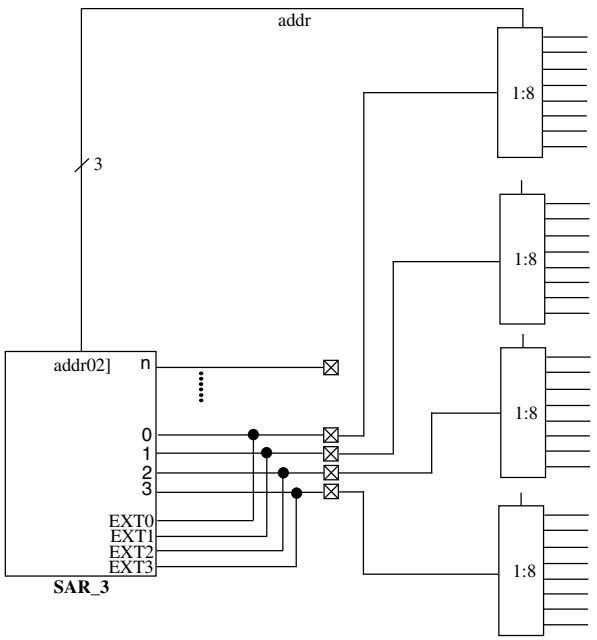

Figure 35-2. SAR_3 external mux inputs

The 3 address outputs to the external muxes are connected to package pins on the device. External mux addresses are available on the following pins:

- External mux address 0 : PF[0] , PG[1]
- External mux address 1 : PF[1] , PF[13]
- External mux address 2 : PF[2] , PF[12]

The following table shows the correspondence between the channels and the external mux addresses.

Table 35-5. Channel and External Mux Address Mapping

Channel	External Mux Input	External Mux Address
64	PX[5]	3'b000
65	PX[5]	3'b001

35.1.9 SAR ADC conversion result processing

SAR ADC conversions are written to the result registers in the digital interface, where they can be read by software. In addition, the conversion results can be transferred via DMA to system RAM or the decimation filter block input registers. When BCTU triggered conversions are enabled, results are automatically sent to the BCTU result registers, in addition to the ADC digital interface result registers.

35.2 Analog-to-Digital Converter (ADC) reference

35.2.1 Introduction

The analog-to-digital converter (ADC) uses Successive Approximation Register (SAR) architecture and provides accurate and fast conversions for a wide range of applications.

35.2.2 Overview

35.2.2.1 Parts of the ADC

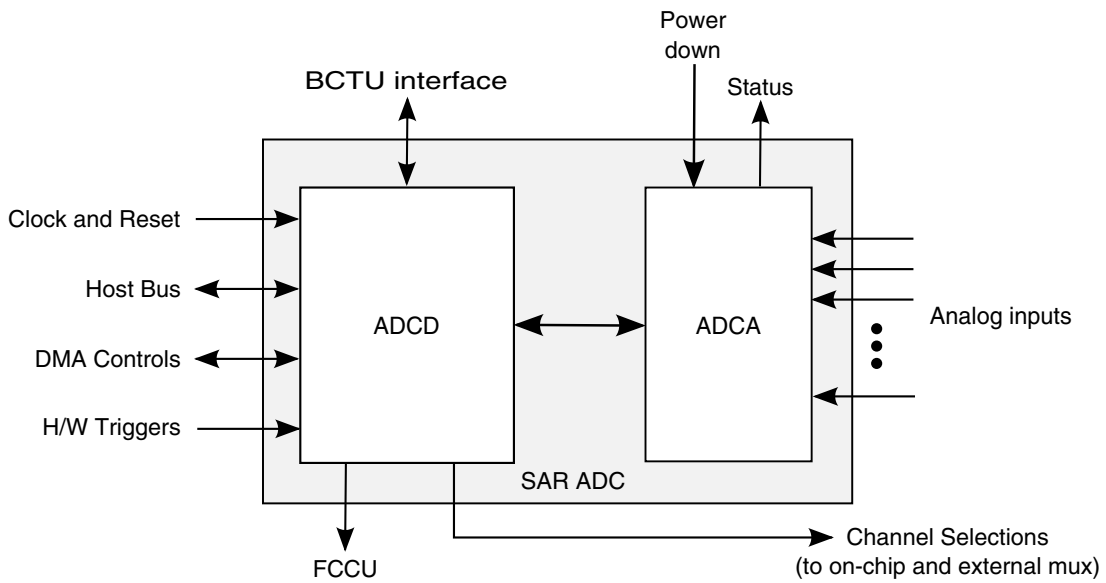

Figure 35-3. ADC high-level block diagram

The ADC is comprised of:

- An ADC digital interface (ADCD). The ADCD holds the configuration, control, and status registers accessible to software via the host bus. The converted value is stored in a register and then transferred through the DMA or host access.
- An ADC analog hard macrocell (ADCA). The analog channel inputs are fed to the inputs of the ADCA. Each channel is sampled for a specific duration and compared with an analog voltage generated with digital code via a digital-to-analog converter (DAC) in the ADCA. The comparison result is given to the ADCD to generate the converted digital value.

35.2.2.2 ADC clock signals

The ADC uses the following clock signals:

- Bus clock—bus clock at ADCD. Used to access the registers and the operating clock of inter-module interfaces.
- SAR_CLK—derived from *bus clock*, this signal serves as the operating clock for the ADCA and the SAR controller inside the ADCD.

The relation between the two clocks is determined by the setting of the ADC_MCR[ADCLKSEL] field.

- If ADC_MCR[ADCLKSEL] is 1, the clock signals are the same
- If ADC_MCR[ADCLKSEL] is 0, SAR_CLK is half of the bus clock.

NOTE

1. Regardless of the setting of the ADC_MCR[ADCLKSEL] field, the maximum clock speed for the ADC clock (SAR_CLK) is 80 MHz.
2. Depending on your chip's configuration and timing needs, MCR[ADCLKSEL] may always need to be 1.

If the bus clock for the microcontroller is 80 MHz and ADC_MCR[ADCLKSEL] is 1, the ADC clock (SAR_CLK) is 80 MHz.

If the bus clock for the microcontroller is 80 MHz and ADC_MCR[ADCLKSEL] is 0, the ADC clock (SAR_CLK) is 40 MHz.

See ADCLKSEL for details on the ADC_MCR register fields.

35.2.2.3 About ADC channels

ADC channels are divided into 3 groups, each with independent configuration settings. Each group may have different accuracy/performance levels depending on system need (check device configuration for details).

The groups are:

- Group 1, referred to as *precision* channels:
  - 0 - 31 (ADC0)
  - 0 - 31 (ADC1)

    - 0 - 31 (ADC2)
    - 0 - 20 (ADC3)
- Group 2, referred to as *internal* channels:
    - 32 - 39 (ADC0)
    - 32 - 38 (ADC1)
    - 32 - 36 (ADC2)
    - 32 - 38 (ADC3)
- Group 3, referred to as *external* channels[1, 1] :
    - none (ADC0)
    - none (ADC1)
    - none (ADC2)
    - 64 to 95 (ADC3)

NOTE

Accuracy of *external* channels can be increased by increasing the sampling duration, i.e., by increasing the value in the ADC_CTR*n*[INPSAMP] register field. This should be done with caution, though, because increasing sampling duration also increases total conversion time, resulting in a *decrease* in the number of samples per second.

35.2.2.3.1 Channel configuration

ADC channels can be configured in the following ways:

- The sampling duration of each channel type, i.e., *precision* channels, *internal* channels, *external* channels, is controlled independently, through programming the respective Conversion Timing Register (CTR).
- Separate mask registers for each channel type can be programmed to configure the channels to be converted (each bit in these registers represents one channel).
- External channel selection is provided through external decode signals and is available at the port. Each set of eight external channels can be mapped to an analog input. (See the chip-specific configuration for availability.)
- Temperature Sensor (TSENS) and other special channels (band gap, supply etc.) are available on specific channels. (See the chip-specific configuration for availability.)
- Analog watchdogs allow continuous hardware monitoring of the converted value from input channels. (See the chip-specific configuration for availability.)
- Capacitive self test
- Presampling

1. This group has an 8 x 1 external multiplexing option. A 3-bit output control is provided for shared use by 4 multiplexers.

NOTE

Each type of channel is converted in the same way.

35.2.2.3.2 Initiating conversions

Conversions can be initiated by either software or hardware.

The ADCD has an on-chip Cross-Triggering Unit (BCTU) interface that can also initiate conversions. The BCTU interface supports BCTU Trigger mode and BCTU Control mode (mode is selected via setting the ADC_MCR[CTU_MODE] field).

An example of an application for which BCTU triggering is suitable is a current control loop for lamps or LEDs. Using an on-chip timer module as trigger source, a BCTU can initiate periodic conversions.

35.2.2.3.3 Interrupt/DMA support

The ADCD provides interrupt/DMA support for each type of channel for various end-of-channel conversion conditions. Data can be transferred via DMA.

35.2.2.3.4 Self-test

The ADCD can be configured to periodically check the health of the ADCA through various self-tests and communicate any critical/non-critical faults to an on-chip Fault Collection and Control Unit (FCCU) if available (See the chip-specific section for availability). The severity (critical/noncritical) of the different tests is programmable.

35.2.3 Features

The following general features are implemented in the ADC. (See the chip-specific section for availability of features, as each instance of an ADC within a chip may support different features.)

- Resolution: 12-bit
- Maximum speed: 1 Mega samples/second at 80 MHz
- Up to 60 channels
- Separate sampling time register for each available range of channels:
  - *precision* channels:
    - 0 - 31 (ADC0)
    - 0 - 31 (ADC1)
    - 0 - 31 (ADC2)
    - 0 - 20 (ADC3)

  - *internal* channels:
    - 32 - 39 (ADC0)
    - 32 - 38 (ADC1)
    - 32 - 36 (ADC2)
    - 32 - 38 (ADC3)
  - *external* channels:
    - none (ADC0)
    - none (ADC1)
    - none (ADC2)
    - 64 to 95 (ADC3)

NOTE

The Temperature Sensor uses the value in the CTR1 register

- External decode signals available for (8 × 1) configuration (external channels only)
- Modes of operation:
  - Normal
  - Injected
  - BCTU
- Normal mode supports One-Shot/Scan (continuous)
- Injected mode supports One-Shot
- Presampling
- Power-Down mode
- Two abort features that allow you to abort either a single channel in a chain or the full chain in normal and injected mode
- Each channel has a dedicated register for conversion results and mode of operation (normal, injected, or BCTU)
- Analog watchdog support:
  - Up to 4 analog watchdogs
  - Configurable for different channels
- Auto clock-off feature
- Programmable clock prescaler (bus clock divided by 2)
- Two BCTU modes: Control and Trigger
- DMA support for each channel
- Interrupts for the following conditions:
  - End of conversion for a single channel for both normal and injected conversions
  - End of conversion for a chain for both normal and injected conversions
  - End of BCTU conversion
  - Watchdog thresholds crossover
- Software-initiated calibration
- Self-testing feature

35.2.4 Memory Map/Register Definition

The following tables describe the registers and bit meanings for this module.

NOTE

There will be an Access Error for Reserved and out-of-range addresses. Special exceptions are the Reserved spaces at 039Ch and 03A4h: Do not write or change any value in these locations, or the ADC might malfunction.

NOTE

See the chip-specific configuration information because not all registers are available in all ADC instances.

Control logic registers:

- Main Configuration Register (ADC_MCR)
- Main Status register (ADC_MSR)
- Interrupt Status Register (ADC_ISR)
- Channel Pending register 0 (ADC_CEOCFR0)
- Channel Pending register 1 (ADC_CEOCFR1)
- Channel Pending register 2 (ADC_CEOCFR2)
- Interrupt Mask Register (ADC_IMR)
- Channel Interrupt Mask Register 0 (ADC_CIMR0)
- Channel Interrupt Mask Register 1 (ADC_CIMR1)
- Channel Interrupt Mask Register 2 (ADC_CIMR2)
- Watchdog Threshold Interrupt Status Register (ADC_WTISR)
- Watchdog Threshold Interrupt Mask Register (ADC_WTIMR)
- Analog Watchdog Out of Range Register 0 (ADC_AWORR0)
- Analog Watchdog Out of Range Register 1 (ADC_AWORR1)
- Analog Watchdog Out of Range Register 2 (ADC_AWORR2)

DMA registers:

- DMA Enable register (ADC_DMAE)
- DMA Channel Select Register 0 (ADC_DMAR0)
- DMA Channel Select Register 1 (ADC_DMAR1)
- DMA Channel Select Register 2 (ADC_DMAR2)

Threshold registers:

These registers are used to store the user programmable lower and upper thresholds 12-bit values. These registers include:

- Threshold Register (ADC_THRHLR*n*)

Presampling registers:

- Presampling Control Register (ADC_PSCR)
- Presampling register 0 (ADC_PSR0)
- Presampling register 1 (ADC_PSR1)
- Presampling register 2 (ADC_PSR2)

Conversion timing registers:

- Conversion Timing Register 0 (ADC_CTR0)
- Conversion Timing Register 1 (ADC_CTR1)
- Conversion Timing Register 2 (ADC_CTR2)

Mask register: These registers are used to program which input channels must be converted during Normal and Injected conversion. These registers include:

- Normal Conversion Mask Register 0 (ADC_NCMR0)
- Normal Conversion Mask Register 1 (ADC_NCMR1)
- Normal Conversion Mask Register 2 (ADC_NCMR2)
- Injected Conversion Mask Register 0 (ADC_JCMR0)
- Injected Conversion Mask Register 1 (ADC_JCMR1)
- Injected Conversion Mask Register 2 (ADC_JCMR2)

Delay registers:

- Power Down Exit Delay Register (ADC_PDEDR)
- Decode Signals Delay Register (ADC_DSDR)

Data registers:

The conversion results for the internal channels are loaded into data registers. Each data register also gives information regarding the corresponding result. These registers start with CDR0:

- Channel Data Register *n* (Precision Channels) (ADC_CDR*n*)

Self test registers:

- Self Test Configuration Register 1 (ADC_STCR1)
- Self Test Configuration Register 2 (ADC_STCR2)
- Self Test Configuration Register 3 (ADC_STCR3)
- Self Test Status Register 1 (ADC_STSR1)
- Self Test Status Register 2 (ADC_STSR2)
- Self Test Status Register 3 (ADC_STSR3)
- Self Test Status Register 4 (ADC_STSR4)
- Self Test Baud Rate Register (ADC_STBRR)
- Self Test Analog Watchdog Register 0 (ADC_STAW0R)
- Self Test Analog Watchdog Register 4 (ADC_STAW4R)

- Self Test Analog Watchdog Register 1A (ADC_STAW1AR)
- Self Test Analog Watchdog Register 1B (ADC_STAW1BR)
- Self Test Analog Watchdog Register 2 (ADC_STAW2R)
- Self Test Analog Watchdog Register 5 (ADC_STAW5R)
- Self Test Data Register 1 (ADC_STDR1)
- Self Test Data Register 2 (ADC_STDR2)

Other registers include:

- Calibration, BIST Control and status Register (ADC_CALBISTREG)
- Offset and Gain User Register (ADC_OFSGNUSR)

35.24.1 Main Configuration Register (ADC_MCR)

Address: 0h base + 0h offset = 0h

ADC_MCR field descriptions

Field	Description
0 OWREN	Overwrite enable. 0 Older valid conversion data is not overwritten by newer conversion data. 1 Newer conversion result is always overwritten, irrespective of the validity of older conversion data.
1 WLSIDE	Write Left/Right aligned. 0 The conversion data is written right aligned from (32-resolution) to 31). 1 Data is left aligned (from 16 to (16 + resolution - 1).
2 MODE	One_Shot/Scan. 0 One_Shot Mode: configure the Normal conversion of one chain. 1 Scan Mode: configure continuous chain conversion mode; when the programmed chain conversion is finished it restarts immediately.
3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4 TRGEN	External trigger enable. When set, enables the external trigger to start a conversion; if the external trigger feature is needed this bit must be set.
5 EDGE	Start trigger edge detection. If TRGEN is 1 this bit selects the falling (EDGE = zero) or rising (EDGE = one) edge for the external trigger.
6 Reserved	This field is reserved. **NOTE:** User must not overwrite default value of this field.

Table continues on the next page...

ADC_MCR field descriptions (continued)

Field	Description
7 NSTART	Start of Normal conversion. Setting this field starts a normal conversion. In One shot mode: This field is cleared as soon as conversion is started. Setting this field during any ongoing conversion keeps this bit high until the requested conversion is started. **NOTE:** This bit cannot be set (1) when PWDN = 1. This bit is always cleared when PWDN = 1.
8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
9–10 Reserved	This field is reserved.
11 JSTART	Injection start. Setting this field will start the configured injected conversion chain. Resetting this field has no effect, as the injected chain conversion cannot be interrupted. Setting this field during ongoing Injected conversion keeps this field high value until the requested conversion is started.
12–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14 CTUEN	Crosstrigger Unit Enable. Enables the crosstriggering unit (BCTU). 0 The crosstriggering unit is disabled and the BCTU-triggered injected conversion cannot take place. 1 The crosstriggering unit is enabled and the BCTUtriggered injected conversion can take place.
15 CTU_MODE	Crosstrigger Unit MODE bit When both modes are present in an ADC instance, this bit sets the operating mode of the ADC with respect to the BCTU. Please see the chip-specific ADC section for whether a specific ADC instance has both modes. Otherwise, treat this bit as Reserved. 0 BCTU control mode is selected. 1 BCTU trigger mode is selected.
16 STCL	Self Testing Configuration Lock. 0 No lock 1 The self-testing configuration is locked i.e. STCR1, STCR2, STCR3, STBRR, STAW0R, STAW1AR, STAW1BR, STAW2R, STAW4R, STAW5R are write-protected. It can be used only in CPU and SCAN mode. The lock bit is cleared only by a peripheral reset.
17–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23 ADCLKSEL	Analog Clock frequency Selector. This field can be written in Power Down mode only. Please check device specific additional restriction on programming of this field. 0 ADC clock frequency is half of bus clock 1 ADC clock frequency is equal to bus clock
24 ABORT_CHAIN	Abort Chain. If this bit is set the ongoing Chain Conversion is aborted. This bit gets reset by hardware as soon as a new conversion is requested.

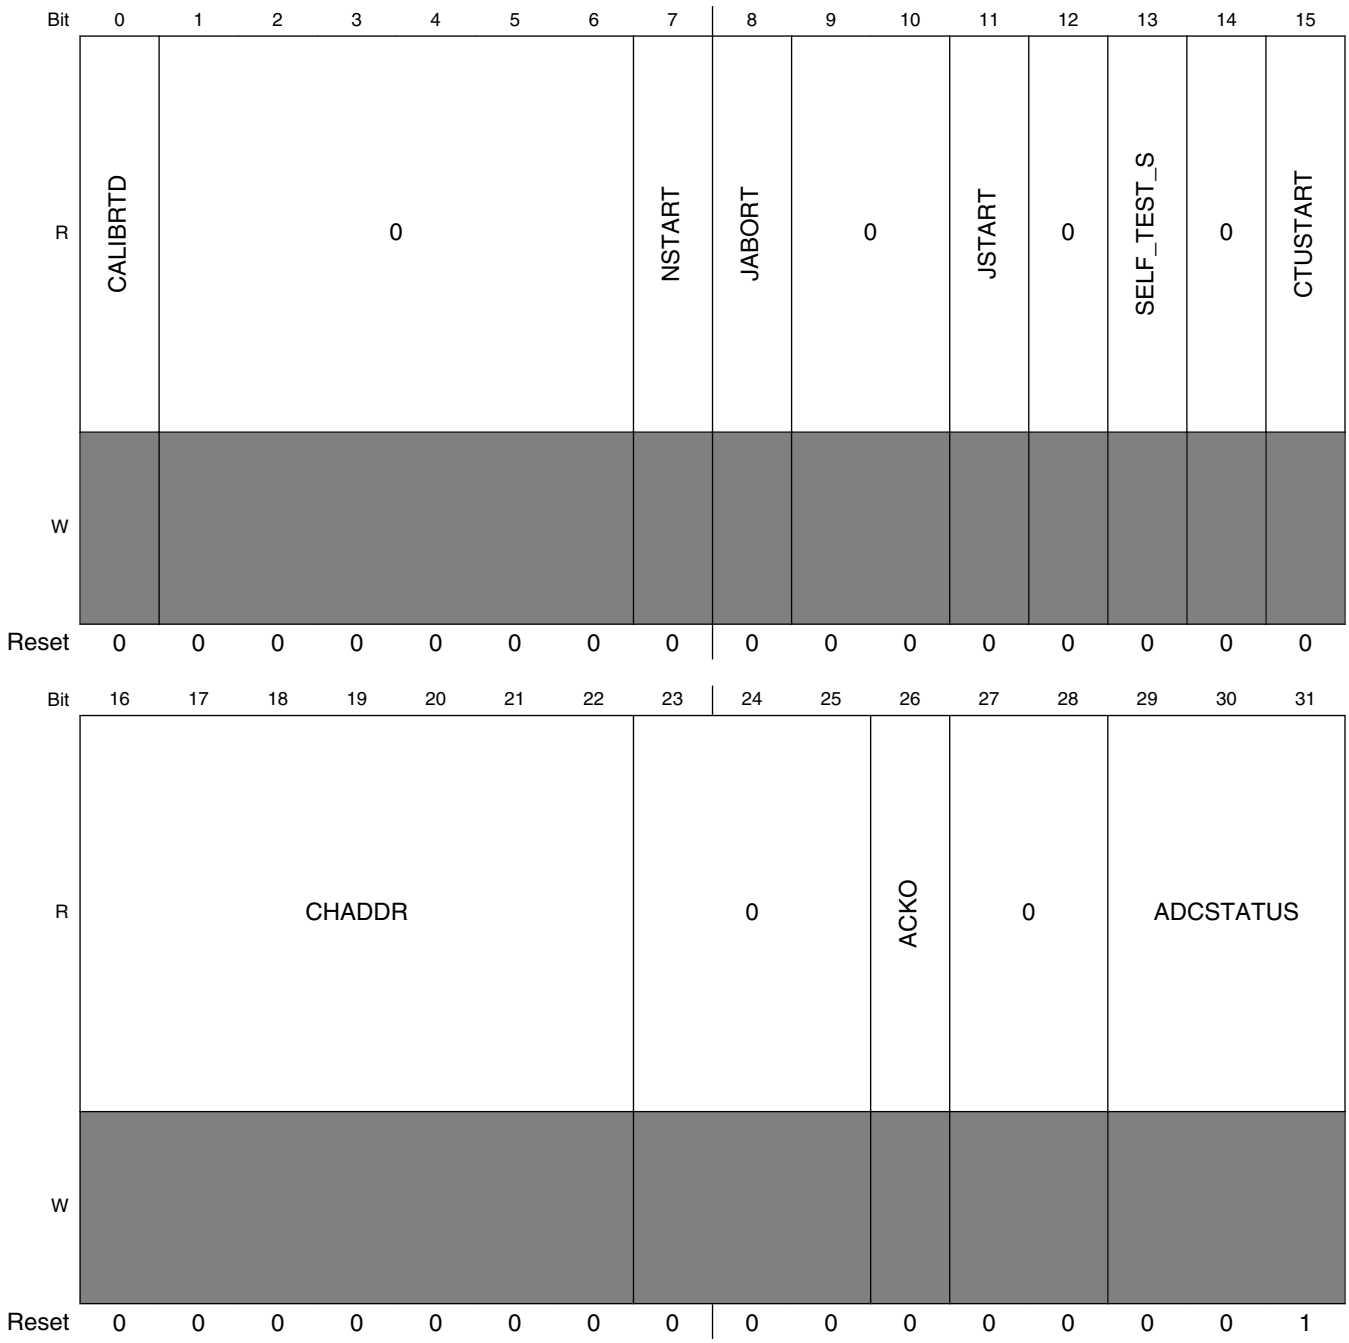

Table continues on the next page...

ADC_MCR field descriptions (continued)

Field	Description
	NOTE: Setting this bit in idle state (no normal/injected conversion is ongoing) has no effect. In this case it is reset immediately. During ongoing BCTU conversion this bit also cannot be programmed.
25 ABORT	Abort Conversion. If this bit is set, the ongoing channel conversion is aborted and the next channel conversion is invoked. This bit gets reset by hardware as soon as the new conversion is invoked. This bit cannot be written while self test conversion is ongoing. **NOTE:** Setting this bit in idle state (No Normal/injected conversion is ongoing) has no effect. In this case it is reset immediately. During ongoing BCTU conversion this bit cannot be programmed
26 ACKO	Auto clock off enable. If set, enables the Auto clock off feature.
27–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29–30 REFSEL	Reference voltage selection for ADC analog part. 00 Select VREFH as reference voltage 01 Reserved 10 Reserved 11 Reserved
31 PWDN	Power-down enable. When this bit is set, the analog module is requested to enter Power-Down mode. When the ADC's status is PWDN, resetting this bit will start the ADC's transition to IDLE mode. In BCTU control mode MCR[CTUEN] must be reset before entering into power-down mode.

35.24.2 Main Status register (ADC_MSR)

Address: 0h base + 4h offset = 4h

ADC_MSR field descriptions

Field	Description
0 CALIBRTD	This bit indicates the ADC calibration status. This bit gets updated after running the High Accuracy Calibration mode.

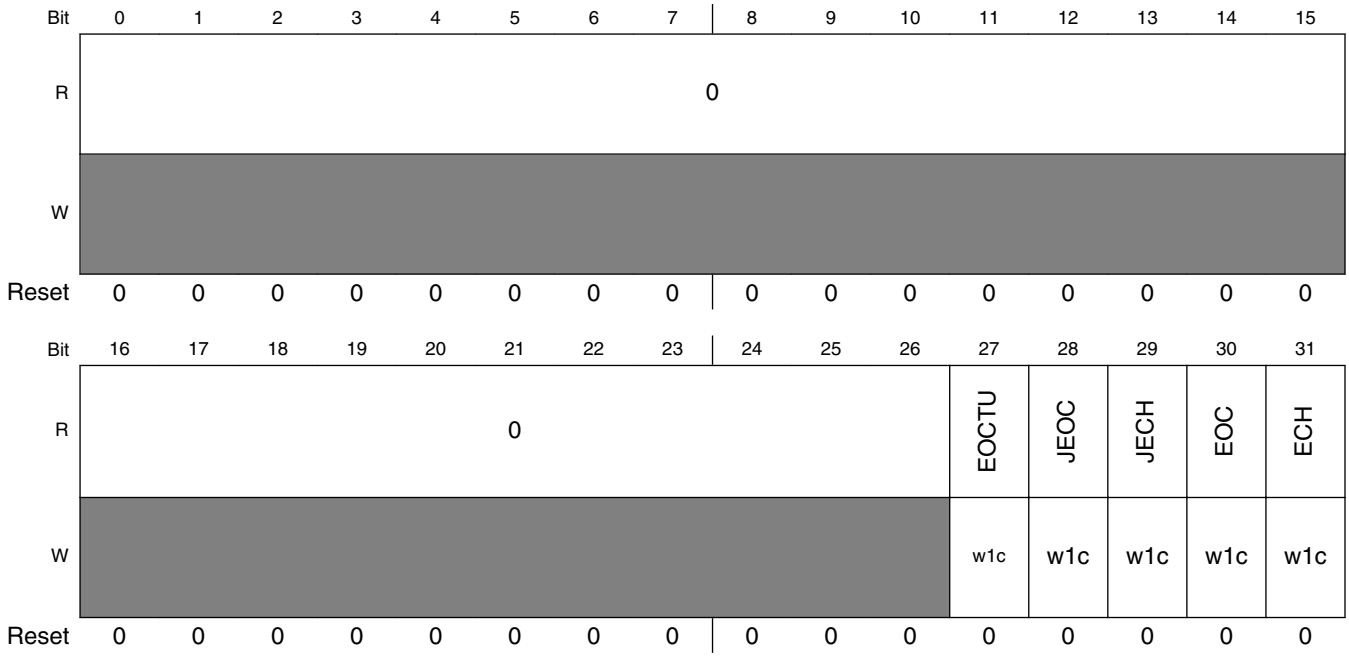

Table continues on the next page...

ADC_MSR field descriptions (continued)

Field	Description
	0 Uncalibrated or calibration unsuccessful 1 Calibration was run and it was successful
1–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 NSTART	This status bit is used to signal that a Normal conversion is ongoing.
8 JABORT	This status bit is used to signal that an Injected conversion has been aborted by BCTU. That bit is reset when a new injected conversion starts.
9–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11 JSTART	This status bit is used to signal that an Injected conversion is ongoing.
12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13 SELF_TEST_S	This status bit signals that self test conversion is ongoing.
14 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15 CTUSTART	This status bit is used to signal that a BCTU conversion is ongoing. This bit is set when a BCTU trigger pulse is received and the BCTU conversion starts.When BCTU trigger mode is enabled this bit is automatically reset when the conversion is completed.When Control Mode is enabled this bit is reset when the BCTU is disabled (CTUEN set to 0).
16–22 CHADDR	Channel under measure address. Status bits are used to signal which channel is under measure.
23–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26 ACKO	Auto clock off enable. This status bit is used to signal if the Auto clock off feature is on.
27–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29–31 ADCSTATUS	Status of the ADC. 000 Idle 001 Power Down 100 Sample 110 Conversion 010 Wait state (waiting to start conversion [external trigger]) The start of ADC conversion can be delayed (after a programmed duration in "DSDR" register) for a time after the application of trigger for External channels. During this wait period the ADCSTATUS is shown as "wait state". 011 Busy in Calibration

35.24.3 Interrupt Status Register (ADC_ISR)

Address: 0h base + 10h offset = 10h

ADC_ISR field descriptions

Field	Description
0–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 EOCTU	End of BCTU conversion. This bit is set for a digital end of conversion on a the BCTU Channel; active when set.
28 JEOC	End of injected channel conversion. This bit is set for a digital end of conversion on an injected channel; active when set.
29 JECH	End of injected chain conversion. This bit is set for a digital end of chain conversion on an injected channel; active when set. **NOTE:** If there is no channel selected in the ADC_JCMR*n* register(s) and there is a start of conversion trigger, then ADC_ISR[JECH] is set and a JECH interrupt is immediately issued (if enabled). Similarly, if no channel is selected in the ADC_NCMR*n* register and a normal conversion is triggered, ADC_ISR[ECH] is set and an ECH interrupt is immediately issued, if enabled.
30 EOC	End of channel conversion. This bit is set for a digital end of conversion on a Normal Channel; active when set.
31 ECH	End of chain conversion. This bit is set for a digital end of chain conversion on a Normal Channel; active when set. **NOTE:** If there is no channel selected in the ADC_NCMR*n* register(s) and there is a start of conversion trigger, then ADC_ISR[ECH] is set and an ECH interrupt is immediately issued (if enabled).

Table continues on the next page...

ADC_ISR field descriptions (continued)

Field	Description
	Similarly, if no channel is selected in the ADC_JCMR*n* register and an injected conversion is triggered, ADC_ISR[JECH] is set and a JECH interrupt is immediately issued, if enabled.

35.24.4 Channel Pending register 0 (ADC_CEOCFR0)

NOTE

This register may contain fields for channels that have not been implemented. See the chip-specific information to find which channels are applicable.

26 CIM69	Channel 69 interrupt enable. When this field is set, the interrupt for channel 69 is enabled.
27 CIM68	Channel 68 interrupt enable. When this field is set, the interrupt for channel 68 is enabled.
28 CIM67	Channel 67 interrupt enable. When this field is set, the interrupt for channel 67 is enabled.
29 CIM66	Channel 66 interrupt enable. When this field is set, the interrupt for channel 66 is enabled.
30 CIM65	Channel 65 interrupt enable. When this field is set, the interrupt for channel 65 is enabled.
31 CIM64	Channel 64 interrupt enable. When this field is set, the interrupt for channel 64 is enabled.

35.24.11 Watchdog Threshold Interrupt Status Register (ADC_WTISR)

The fields in this register, when set, indicate either the upper or lower threshold value has been crossed for a specific watchdog.

Address: 0h base + 30h offset = 30h

ADC_WTISR field descriptions

Field	Description
0–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24 WDG3H	This bit corresponds to the interrupt generated on the converted value being higher than the programmed higher threshold for a channel monitored by Watchdog 3 (WD3). **NOTE:** Write a '1' to this field to clear it.
25 WDG3L	This bit corresponds to the interrupt generated on the converted value being lower than the programmed lower threshold for a channel monitored by Watchdog 3 (WD3). **NOTE:** Write a '1' to this field to clear it.
26 WDG2H	This bit corresponds to the interrupt generated on the converted value being higher than the programmed higher threshold for a channel monitored by Watchdog 2 (WD2). **NOTE:** Write a '1' to this field to clear it.
27 WDG2L	This bit corresponds to the interrupt generated on the converted value being lower than the programmed lower threshold for a channel monitored by Watchdog 2 (WD2).

Table continues on the next page...

ADC_WTISR field descriptions (continued)

Field	Description
	NOTE: Write a '1' to this field to clear it.
28 WDG1H	This bit corresponds to the interrupt generated on the converted value being higher than the programmed higher threshold for a channel monitored by Watchdog 1 (WD1). **NOTE:** Write a '1' to this field to clear it.
29 WDG1L	This bit corresponds to the interrupt generated on the converted value being lower than the programmed lower threshold for a channel monitored by Watchdog 1 (WD1). **NOTE:** Write a '1' to this field to clear it.
30 WDG0H	This bit corresponds to the interrupt generated on the converted value being higher than the programmed higher threshold for a channel monitored by Watchdog 0 (WD0). **NOTE:** Write a '1' to this field to clear it.
31 WDG0L	This bit corresponds to the interrupt generated on the converted value being lower than the programmed lower threshold for a channel monitored by Watchdog 0 (WD0). **NOTE:** Write a '1' to this field to clear it.

35.24.12 Watchdog Threshold Interrupt Mask Register (ADC_WTIMR)

Address: 0h base + 34h offset = 34h

R	0								MSKWDG3H	MSKWDG3L	MSKWDG2H	MSKWDG2L	MSKWDG1H	MSKWDG1L	MSKWDG0H	MSKWDG0L
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ADC_WTIMR field descriptions

Field	Description
0–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24 MSKWDG3H	This bit enables/disables the interrupt generated by the converted value sampled from a channel monitored by Watchdog 3 (WD3) being higher than the programmed higher threshold. When set, the interrupt is enabled.

Table continues on the next page...

ADC_WTIMR field descriptions (continued)

Field	Description
25 MSKWDG3L	This bit enables/disables the interrupt generated by the converted value sampled from a channel monitored by Watchdog 3 (WD3) being lower than the programmed lower threshold. When set, the interrupt is enabled.
26 MSKWDG2H	This bit enables/disables the interrupt generated by the converted value sampled from a channel monitored by Watchdog 2 (WD2) being higher than the programmed higher threshold. When set, the interrupt is enabled.
27 MSKWDG2L	This bit enables/disables the interrupt generated by the converted value sampled from a channel monitored by Watchdog 2 (WD2) being lower than the programmed lower threshold. When set, the interrupt is enabled.
28 MSKWDG1H	This bit enables/disables the interrupt generated by the converted value sampled from a channel monitored by Watchdog 1 (WD1) being higher than the programmed higher threshold. When set, the interrupt is enabled.
29 MSKWDG1L	This bit enables/disables the interrupt generated by the converted value sampled from a channel monitored by Watchdog 1 (WD1) being lower than the programmed lower threshold. When set, the interrupt is enabled.
30 MSKWDG0H	This bit enables/disables the interrupt generated by the converted value sampled from a channel monitored by Watchdog 0 (WD0) being higher than the programmed higher threshold. When set, the interrupt is enabled.
31 MSKWDG0L	This bit enables/disables the interrupt generated by the converted value sampled from a channel monitored by Watchdog 0 (WD0) being lower than the programmed lower threshold. When set, the interrupt is enabled.

35.24.13 DMA Enable register (ADC_DMAE)

Address: 0h base + 40h offset = 40h

Table continues on the next page...

ADC_DMAR2 field descriptions (continued)

Field	Description
7 DMA88	DMA enable for channel 88. When set, transferring data in DMA mode is enabled for channel 88.
8 DMA87	DMA enable for channel 87. When set, transferring data in DMA mode is enabled for channel 87.
9 DMA86	DMA enable for channel 86. When set, transferring data in DMA mode is enabled for channel 86.
10 DMA85	DMA enable for channel 85. When set, transferring data in DMA mode is enabled for channel 85.
11 DMA84	DMA enable for channel 84. When set, transferring data in DMA mode is enabled for channel 84.
12 DMA83	DMA enable for channel 83. When set, transferring data in DMA mode is enabled for channel 83.
13 DMA82	DMA enable for channel 82. When set, transferring data in DMA mode is enabled for channel 82.
14 DMA81	DMA enable for channel 81. When set, transferring data in DMA mode is enabled for channel 81.
15 DMA80	DMA enable for channel 80. When set, transferring data in DMA mode is enabled for channel 80.
16 DMA79	DMA enable for channel 79. When set, transferring data in DMA mode is enabled for channel 79.
17 DMA78	DMA enable for channel 78. When set, transferring data in DMA mode is enabled for channel 78.
18 DMA77	DMA enable for channel 77. When set, transferring data in DMA mode is enabled for channel 77.
19 DMA76	DMA enable for channel 76. When set, transferring data in DMA mode is enabled for channel 76.
20 DMA75	DMA enable for channel 75. When set, transferring data in DMA mode is enabled for channel 75.
21 DMA74	DMA enable for channel 74. When set, transferring data in DMA mode is enabled for channel 74.
22 DMA73	DMA enable for channel 73. When set, transferring data in DMA mode is enabled for channel 73.
23 DMA72	DMA enable for channel 72. When set, transferring data in DMA mode is enabled for channel 72.
24 DMA71	DMA enable for channel 71.

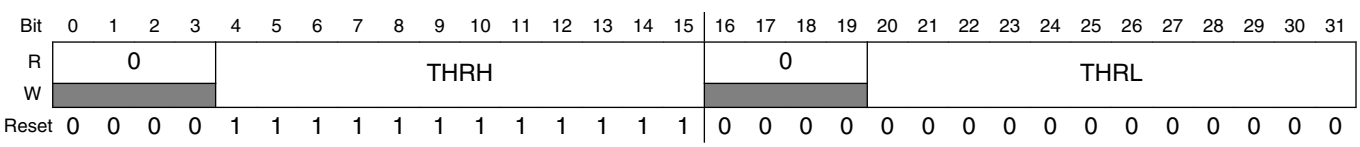

Table continues on the next page...

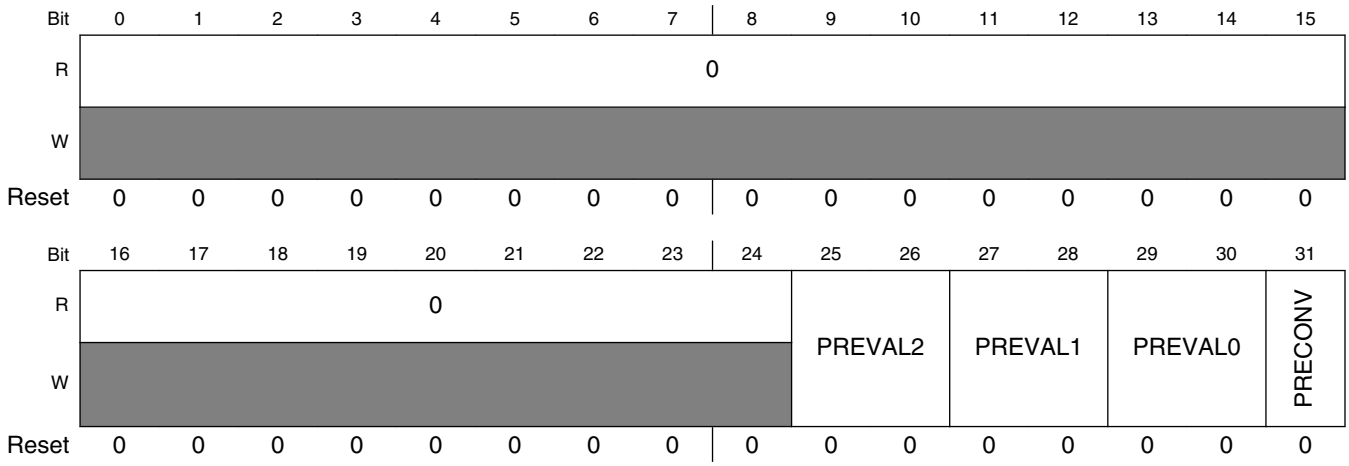
ADC_DMAR2 field descriptions (continued)

Field	Description
	When set, transferring data in DMA mode is enabled for channel 71.
25 DMA70	DMA enable for channel 70. When set, transferring data in DMA mode is enabled for channel 70.
26 DMA69	DMA enable for channel 69. When set, transferring data in DMA mode is enabled for channel 69.
27 DMA68	DMA enable for channel 68. When set, transferring data in DMA mode is enabled for channel 68.
28 DMA67	DMA enable for channel 67. When set, transferring data in DMA mode is enabled for channel 67.
29 DMA66	DMA enable for channel 66. When set, transferring data in DMA mode is enabled for channel 66.
30 DMA65	DMA enable for channel 65. When set, transferring data in DMA mode is enabled for channel 65.
31 DMA64	DMA enable for channel 64. When set, transferring data in DMA mode is enabled for channel 64.

35.24.17 Threshold Register (ADC_THRHLR*n*)

Address: 0h base + 60h offset + (4d × i), where i=0d to 3d



ADC_THRHLR*n* field descriptions

Field	Description
0–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4–15 THRH	High threshold value for watchdog n.
16–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20–31 THRL	Low threshold value for watchdog n.

35.24.18 Presampling Control Register (ADC_PSCR)

See the chip configuration details for the availability of this register.

Address: 0h base + 80h offset = 80h

ADC_PSCR field descriptions

Field	Description
0–24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25–26 PREVAL2	Internal voltage selection for Presampling Selects analog input voltage for presampling from the available four internal voltages for External channels (channel 64 to 95). Refer to Presampling channel enable.
27–28 PREVAL1	Internal voltage selection for Presampling. These two bits select analog input voltage for presampling from the available internal voltages using internal extended channels (channel 32 to 63). This is used for temperature sensor also. Refer to Presampling channel enable.
29–30 PREVAL0	Internal voltage selection for Presampling. These two bits select analog input voltage for presampling from the available four internal voltages for Internal precision channels (Channel 0 to 31). Refer to Presampling channel enable.
31 PRECONV	Convert Presampled value If bit PRECONV is set, presampling is followed by the conversion. Sampling will be bypassed and conversion of presampled data will be done. This bit has no effect on conversion of a channel when presampling on that channel is disabled (for examplei.e PSR*x*[PRES*y*] = 0 , where *x* = register index and *y* = channel number).

35.24.19 Presampling register 0 (ADC_PSR0)

See the chip configuration details for the availability of this register.

Field	Description
10 PRES85	Presampling enable for channel 85. When set, presampling is enabled for channel 85.
11 PRES84	Presampling enable for channel 84. When set, presampling is enabled for channel 84.
12 PRES83	Presampling enable for channel 83. When set, presampling is enabled for channel 83.
13 PRES82	Presampling enable for channel 82. When set, presampling is enabled for channel 82.
14 PRES81	Presampling enable for channel 81. When set, presampling is enabled for channel 81.
15 PRES80	Presampling enable for channel 80. When set, presampling is enabled for channel 80.
16 PRES79	Presampling enable for channel 79. When set, presampling is enabled for channel 79.
17 PRES78	Presampling enable for channel 78. When set, presampling is enabled for channel 78.
18 PRES77	Presampling enable for channel 77. When set, presampling is enabled for channel 77.
19 PRES76	Presampling enable for channel 76. When set, presampling is enabled for channel 76.
20 PRES75	Presampling enable for channel 75. When set, presampling is enabled for channel 75.
21 PRES74	Presampling enable for channel 74. When set, presampling is enabled for channel 74.
22 PRES73	Presampling enable for channel 73. When set, presampling is enabled for channel 73.
23 PRES72	Presampling enable for channel 72. When set, presampling is enabled for channel 72.
24 PRES71	Presampling enable for channel 71. When set, presampling is enabled for channel 71.
25 PRES70	Presampling enable for channel 70. When set, presampling is enabled for channel 70.
26 PRES69	Presampling enable for channel 69. When set, presampling is enabled for channel 69.
27 PRES68	Presampling enable for channel 68.

Table continues on the next page...

ADC_PSR2 field descriptions (continued)

Field	Description
	When set, presampling is enabled for channel 68.
28 PRES67	Presampling enable for channel 67. When set, presampling is enabled for channel 67.
29 PRES66	Presampling enable for channel 66. When set, presampling is enabled for channel 66.
30 PRES65	Presampling enable for channel 65. When set, presampling is enabled for channel 65.
31 PRES64	Presampling enable for channel 64. When set, presampling is enabled for channel 64.

35.24.22 Conversion Timing Register 0 (ADC_CTR0)

Conversion timing register. CTR0 is associated with channels 0 to 31.

NOTE

This register may contain fields for channels that have not been implemented. See the chip-specific information to find which channels are applicable.

Address: 0h base + 94h offset = 94h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

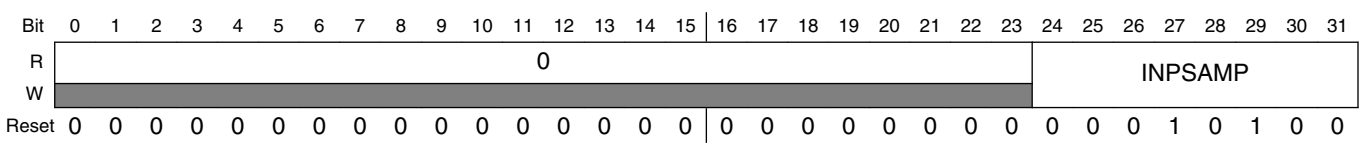
ADC_CTR0 field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 Reserved	This field is reserved.

Table continues on the next page...

ADC_CTR0 field descriptions (continued)



Field	Description
17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
18–19 Reserved	This field is reserved.
20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21–22 Reserved	This field is reserved.
23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–31 INPSAMP	Configuration of sampling phase duration. This value tells the sample period duration in terms of the SAR Controller operating clock. The minimum acceptable value is 8. Setting a lower value automatically takes 8 cycles. **NOTE:** The Bandgap voltage sampling time is controlled by CTR0[INPSAMP]. CTR0[INPSAMP] is also used for the external channel sample time. When the user software needs to sample the Bandgap voltage, it must change the CTR0[INPSAMP] value to allow for a longer time while the Bandgap is being sampled, then change its value back to the normal value for sampling external channels.

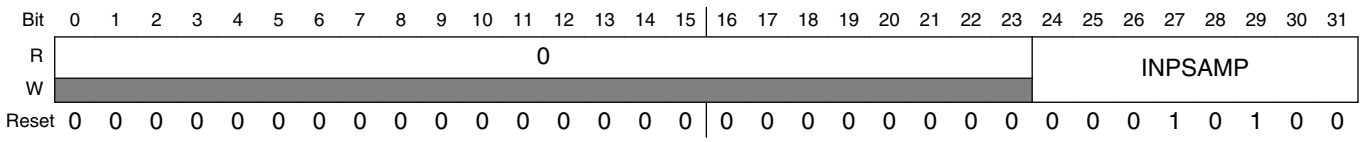
35.24.23 Conversion Timing Register 1 (ADC_CTR1)

CTR1 is associated with the temperature sensor and channels 32 to 63.

Please see the chip-specific configuration information as all channels may not be available in all ADC instances.

Address: 0h base + 98h offset = 98h

ADC_CTR1 field descriptions



Field	Description
0–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–31 INPSAMP	Configuration of sampling phase duration. This value tells the sample period duration in terms of the SAR Controller operating clock. The minimum acceptable value is 8. Setting a lower value automatically takes 8 cycles.

35.24.24 Conversion Timing Register 2 (ADC_CTR2)

CTR2 is associated to channels 64 to 95.

Please see the chip-specific configuration information as all channels may not be available in all ADC instances.

Address: 0h base + 9Ch offset = 9Ch

ADC_CTR2 field descriptions

Field	Description
0–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–31 INPSAMP	Configuration of sampling phase duration. This value tells the sample period duration in terms of the SAR Controller operating clock. The minimum acceptable value is 8. Setting a lower value automatically takes 8 cycles.

35.24.25 Normal Conversion Mask Register 0 (ADC_NCMR0)

NOTE

This register may contain fields for channels that have not been implemented. See the chip-specific information to find which channels are applicable.

Address: 0h base + A4h offset = A4h

24 CH39	Injected sampling enable for channel 39. When set, injected sampling is enabled for channel 39.

Table continues on the next page...

ADC_JCMR1 field descriptions (continued)

Field	Description
25 CH38	Injected sampling enable for channel 38. When set, injected sampling is enabled for channel 38.
26 CH37	Injected sampling enable for channel 37. When set, injected sampling is enabled for channel 37.
27 CH36	Injected sampling enable for channel 36. When set, injected sampling is enabled for channel 36.
28 CH35	Injected sampling enable for channel 35. When set, injected sampling is enabled for channel 35.
29 CH34	Injected sampling enable for channel 34. When set, injected sampling is enabled for channel 34.
30 CH33	Injected sampling enable for channel 33. When set, injected sampling is enabled for channel 33.
31 CH32	Injected sampling enable for channel 32. When set, injected sampling is enabled for channel 32.

35.24.30 Injected Conversion Mask Register 2 (ADC_JCMR2)

Enable bits of Injected Sampling for channel 64 to 95.

NOTE

This register may contain fields for channels that have not been implemented. See the chip-specific information to find which channels are applicable.

Address: 0h base + BCh offset = BCh

ADC_JCMR2 field descriptions

Field	Description
0 CH95	Injected sampling enable for channel 95. When set, injected sampling is enabled for channel 95.
1 CH94	Injected sampling enable for channel 94. When set, injected sampling is enabled for channel 94.
2 CH93	Injected sampling enable for channel 93. When set, injected sampling is enabled for channel 93.
3 CH92	Injected sampling enable for channel 92. When set, injected sampling is enabled for channel 92.
4 CH91	Injected sampling enable for channel 91. When set, injected sampling is enabled for channel 91.
5 CH90	Injected sampling enable for channel 90. When set, injected sampling is enabled for channel 90.
6 CH89	Injected sampling enable for channel 89. When set, injected sampling is enabled for channel 89.
7 CH88	Injected sampling enable for channel 88. When set, injected sampling is enabled for channel 88.
8 CH87	Injected sampling enable for channel 87. When set, injected sampling is enabled for channel 87.
9 CH86	Injected sampling enable for channel 86. When set, injected sampling is enabled for channel 86.
10 CH85	Injected sampling enable for channel 85. When set, injected sampling is enabled for channel 85.
11 CH84	Injected sampling enable for channel 84. When set, injected sampling is enabled for channel 84.
12 CH83	Injected sampling enable for channel 83. When set, injected sampling is enabled for channel 83.
13 CH82	Injected sampling enable for channel 82. When set, injected sampling is enabled for channel 82.
14 CH81	Injected sampling enable for channel 81. When set, injected sampling is enabled for channel 81.
15 CH80	Injected sampling enable for channel 80. When set, injected sampling is enabled for channel 80.
16 CH79	Injected sampling enable for channel 79. When set, injected sampling is enabled for channel 79.
17 CH78	Injected sampling enable for channel 78.

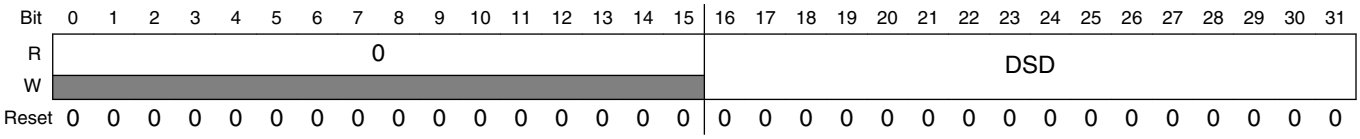

Table continues on the next page...

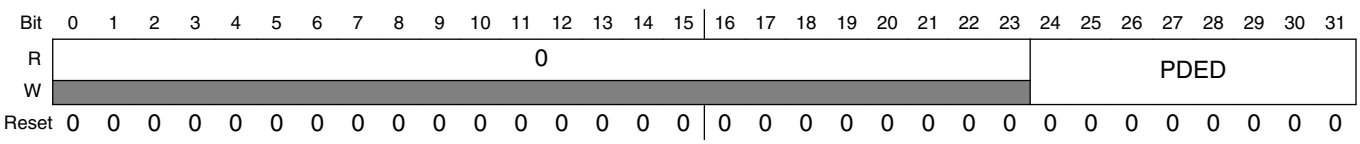
ADC_JCMR2 field descriptions (continued)

Field	Description
	When set, injected sampling is enabled for channel 78.
18 CH77	Injected sampling enable for channel 77. When set, injected sampling is enabled for channel 77.
19 CH76	Injected sampling enable for channel 76. When set, injected sampling is enabled for channel 76.
20 CH75	Injected sampling enable for channel 75. When set, injected sampling is enabled for channel 75.
21 CH74	Injected sampling enable for channel 74. When set, injected sampling is enabled for channel 74.
22 CH73	Injected sampling enable for channel 73. When set, injected sampling is enabled for channel 73.
23 CH72	Injected sampling enable for channel 72. When set, injected sampling is enabled for channel 72.
24 CH71	Injected sampling enable for channel 71. When set, injected sampling is enabled for channel 71.
25 CH70	Injected sampling enable for channel 70. When set, injected sampling is enabled for channel 70.
26 CH69	Injected sampling enable for channel 69. When set, injected sampling is enabled for channel 69.
27 CH68	Injected sampling enable for channel 68. When set, injected sampling is enabled for channel 68.
28 CH67	Injected sampling enable for channel 67. When set, injected sampling is enabled for channel 67.
29 CH66	Injected sampling enable for channel 66. When set, injected sampling is enabled for channel 66.
30 CH65	Injected sampling enable for channel 65. When set, injected sampling is enabled for channel 65.
31 CH64	Injected sampling enable for channel 64. When set, injected sampling is enabled for channel 64.

35.24.31 Decode Signals Delay Register (ADC_DSDR)

Address: 0h base + C4h offset = C4h



ADC_DSDR field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 DSD	The delay between the external decode signals and the beginning of the sampling phase. It is used to take into account the settling time of the external mux. The decode signal delay is calculated as (DSD x 1/ Frequency of System Clock).

35.24.32 Power Down Exit Delay Register (ADC_PDEDR)

Address: 0h base + C8h offset = C8h

ADC_PDEDR field descriptions

Field	Description
0–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–31 PDED	The delay between the power down bit reset and the start of conversion. The power down delay is calculated as (PDED x 1/[ADC_clock_frequency]).

35.24.33 Channel Data Register *n* (Precision Channels) (ADC_CDR*n*)

Note

It is important to note that the content of the CDATA field is affected by the setting of the ADC_MCR[WLSIDE] field, which controls whether the data is left aligned or right aligned. When ADC_MCR[WLSIDE]=1 (data to be left aligned), the CDATA field is left aligned from bit 16 to bit (16 + resolution - 1). When ADC_MCR[WLSIDE]=0 (data to be right aligned), the CDATA field is right aligned from bit (32-resolution) to bit 31. All other fields are unaffected.

Address: 0h base + 100h offset + (4d × i), where i=0d to 31d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0												VALID	OVERW	RESULT	
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	CDATA

ADC_CDR*n* field descriptions

Field	Description
0–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12 VALID	Used to notify when the data is valid (a new value has been written). It is automatically cleared when data is read.

Table continues on the next page...

ADC_CDR*n* field descriptions (continued)

Field	Description
13 OVERW	Overwrite data Used to notify when a conversion data is overwritten by a newer result. The new data is written or discarded according to the OWREN bit of MCR register.
14–15 RESULT	These two bits reflect the mode of conversion for the corresponding channel. 00 Data is a result of Normal conversion mode 01 Data is a result of Injected conversion mode 10 Data is a result of BCTU conversion mode 11 Reserved
16–31 CDATA	Converted Data 11:0. **Note:** It is important to note that the content of the CDATA field is affected by the setting of the ADC_MCR[WLSIDE] field, which controls whether the data is left aligned or right aligned. When ADC_MCR[WLSIDE]=1 (data to be left aligned), the CDATA field is left aligned from bit 16 to bit (16 + resolution - 1). When ADC_MCR[WLSIDE]=0 (data to be right aligned), the CDATA field is right aligned from bit (32-resolution) to bit 31. All other fields are unaffected.

35.24.34 Channel Data Register *n* (Internal Channels) (ADC_CDR*n*)

Note

It is important to note that the content of the CDATA field is affected by the setting of the ADC_MCR[WLSIDE] field, which controls whether the data is left aligned or right aligned. When ADC_MCR[WLSIDE]=1 (data to be left aligned), the CDATA field is left aligned from bit 16 to bit (16 + resolution - 1). When ADC_MCR[WLSIDE]=0 (data to be right aligned), the CDATA field is right aligned from bit (32-resolution) to bit 31. All other fields are unaffected.

Address: 0h base + 180h offset + (4d × i), where i=0d to 15d

ADC_AWORR1 field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 AWOR_CH47	Analog watchdog out of range for channel 47. When set, indicates the converted data is out of range for channel 47.
17 AWOR_CH46	Analog watchdog out of range for channel 46. When set, indicates the converted data is out of range for channel 46.
18 AWOR_CH45	Analog watchdog out of range for channel 45. When set, indicates the converted data is out of range for channel 45.
19 AWOR_CH44	Analog watchdog out of range for channel 44. When set, indicates the converted data is out of range for channel 44.
20 AWOR_CH43	Analog watchdog out of range for channel 43. When set, indicates the converted data is out of range for channel 43.
21 AWOR_CH42	Analog watchdog out of range for channel 42. When set, indicates the converted data is out of range for channel 42.
22 AWOR_CH41	Analog watchdog out of range for channel 41. When set, indicates the converted data is out of range for channel 41.
23 AWOR_CH40	Analog watchdog out of range for channel 40. When set, indicates the converted data is out of range for channel 40.
24 AWOR_CH39	Analog watchdog out of range for channel 39. When set, indicates the converted data is out of range for channel 39.
25 AWOR_CH38	Analog watchdog out of range for channel 38. When set, indicates the converted data is out of range for channel 38.
26 AWOR_CH37	Analog watchdog out of range for channel 37. When set, indicates the converted data is out of range for channel 37.
27 AWOR_CH36	Analog watchdog out of range for channel 36. When set, indicates the converted data is out of range for channel 36.
28 AWOR_CH35	Analog watchdog out of range for channel 35. When set, indicates the converted data is out of range for channel 35.
29 AWOR_CH34	Analog watchdog out of range for channel 34. When set, indicates the converted data is out of range for channel 34.
30 AWOR_CH33	Analog watchdog out of range for channel 33. When set, indicates the converted data is out of range for channel 33.
31 AWOR_CH32	Analog watchdog out of range for channel 32. When set, indicates the converted data is out of range for channel 32.

35.24.50 Analog Watchdog Out of Range Register 2 (ADC_AWORR2)

Analog watchdog out of range register for channels 64 to 95.

NOTE

This register may contain fields for channels that have not been implemented. See the chip-specific information to find which channels are applicable.

Address: 0h base + 2F8h offset = 2F8h

ADC_AWORR2 field descriptions

Field	Description
0 AWOR_CH95	Analog watchdog out of range for channel 95. When set, indicates the converted data is out of range for channel 95.
1 AWOR_CH94	Analog watchdog out of range for channel 94. When set, indicates the converted data is out of range for channel 94.
2 AWOR_CH93	Analog watchdog out of range for channel 93. When set, indicates the converted data is out of range for channel 93.

Table continues on the next page...

ADC_AWORR2 field descriptions (continued)

Field	Description
3 AWOR_CH92	Analog watchdog out of range for channel 92. When set, indicates the converted data is out of range for channel 92.
4 AWOR_CH91	Analog watchdog out of range for channel 91. When set, indicates the converted data is out of range for channel 91.
5 AWOR_CH90	Analog watchdog out of range for channel 90. When set, indicates the converted data is out of range for channel 90.
6 AWOR_CH89	Analog watchdog out of range for channel 89. When set, indicates the converted data is out of range for channel 89.
7 AWOR_CH88	Analog watchdog out of range for channel 88. When set, indicates the converted data is out of range for channel 88.
8 AWOR_CH87	Analog watchdog out of range for channel 87. When set, indicates the converted data is out of range for channel 87.
9 AWOR_CH86	Analog watchdog out of range for channel 86. When set, indicates the converted data is out of range for channel 86.
10 AWOR_CH85	Analog watchdog out of range for channel 85. When set, indicates the converted data is out of range for channel 85.
11 AWOR_CH84	Analog watchdog out of range for channel 84. When set, indicates the converted data is out of range for channel 84.
12 AWOR_CH83	Analog watchdog out of range for channel 83. When set, indicates the converted data is out of range for channel 83.
13 AWOR_CH82	Analog watchdog out of range for channel 82. When set, indicates the converted data is out of range for channel 82.
14 AWOR_CH81	Analog watchdog out of range for channel 81. When set, indicates the converted data is out of range for channel 81.
15 AWOR_CH80	Analog watchdog out of range for channel 80. When set, indicates the converted data is out of range for channel 80.
16 AWOR_CH79	Analog watchdog out of range for channel 79. When set, indicates the converted data is out of range for channel 79.
17 AWOR_CH78	Analog watchdog out of range for channel 78. When set, indicates the converted data is out of range for channel 78.
18 AWOR_CH77	Analog watchdog out of range for channel 77. When set, indicates the converted data is out of range for channel 77.
19 AWOR_CH76	Analog watchdog out of range for channel 76. When set, indicates the converted data is out of range for channel 76.
20 AWOR_CH75	Analog watchdog out of range for channel 75.

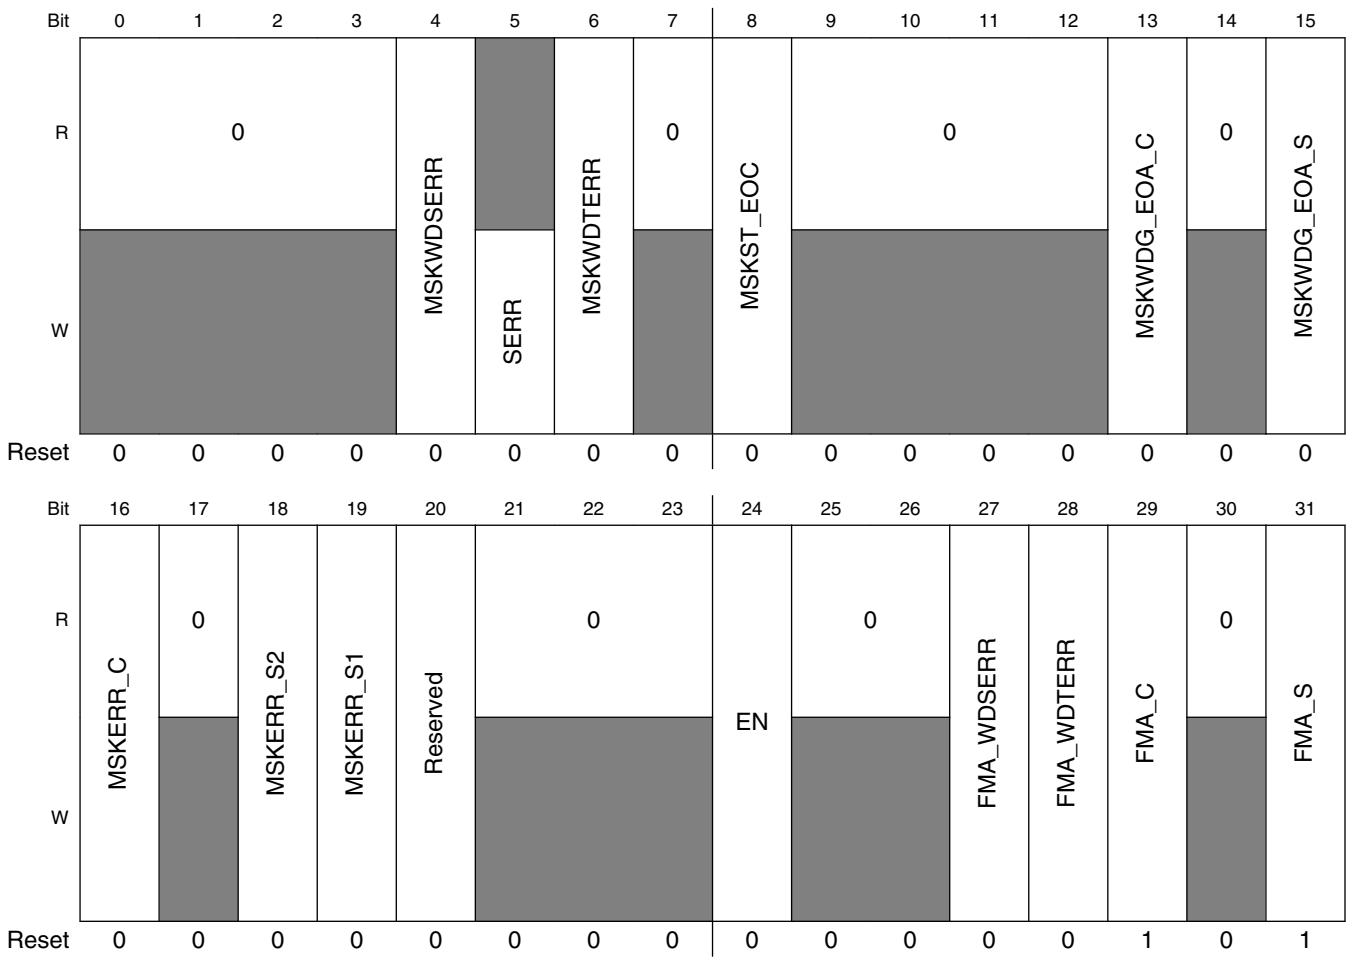
Table continues on the next page...

ADC_AWORR2 field descriptions (continued)

Field	Description
	When set, indicates the converted data is out of range for channel 75.
21 AWOR_CH74	Analog watchdog out of range for channel 74. When set, indicates the converted data is out of range for channel 74.
22 AWOR_CH73	Analog watchdog out of range for channel 73. When set, indicates the converted data is out of range for channel 73.
23 AWOR_CH72	Analog watchdog out of range for channel 72. When set, indicates the converted data is out of range for channel 72.
24 AWOR_CH71	Analog watchdog out of range for channel 71. When set, indicates the converted data is out of range for channel 71.
25 AWOR_CH70	Analog watchdog out of range for channel 70. When set, indicates the converted data is out of range for channel 70.
26 AWOR_CH69	Analog watchdog out of range for channel 69. When set, indicates the converted data is out of range for channel 69.
27 AWOR_CH68	Analog watchdog out of range for channel 68. When set, indicates the converted data is out of range for channel 68.
28 AWOR_CH67	Analog watchdog out of range for channel 67. When set, indicates the converted data is out of range for channel 67.
29 AWOR_CH66	Analog watchdog out of range for channel 66. When set, indicates the converted data is out of range for channel 66.
30 AWOR_CH65	Analog watchdog out of range for channel 65. When set, indicates the converted data is out of range for channel 65.
31 AWOR_CH64	Analog watchdog out of range for channel 64. When set, indicates the converted data is out of range for channel 64.

35.24.51 Self Test Configuration Register 1 (ADC_STCR1)

Address: 0h base + 340h offset = 340h



Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

ADC_STCR1 field descriptions

Field	Description
0–7 INPSAMP_C	Sampling phase duration for the test conversions related to self test algorithm C. Minimum value should be set as per default (18h). Maximum can be FFh.
8–15 Reserved	This field is reserved.
16–23 INPSAMP_S	Sampling phase duration for the test conversions related to self test algorithm S. Minimum value should be set as per default (25h). Maximum can be FFh.
24–31 Reserved	This field is reserved.

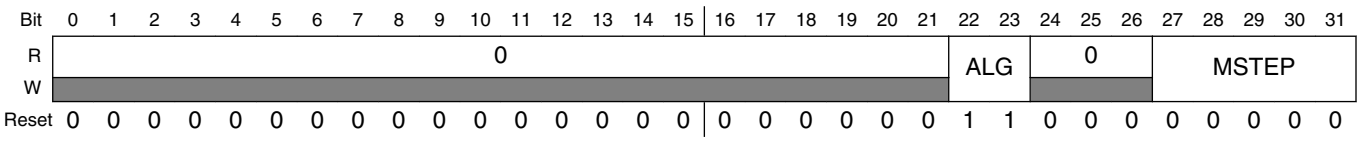
35.24.52 Self Test Configuration Register 2 (ADC_STCR2)

Address: 0h base + 344h offset = 344h

ADC_STCR2 field descriptions

Field	Description
0–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4 MSKWDSERR	Interrupt enable (STSR1[WDSERR] status bit) 0 Interrupt disabled 1 Enables the STSR1[WDSERR] status bit to generate an interrupt indication.
5 SERR	Error fault injection bit (write only). Writing 1 to this bit sets the STSR1[ERRx] status bits once only. Reading always returns 0. Setting this bit does not affect any of the self test data registers.
6 MSKWDTERR	Interrupt enable (STSR[WDTERR] status bit) 0 Interrupt disabled 1 Enables the STSR1[WDTERR] status bit to generate an interrupt indication.
7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8 MSKST_EOC	Interrupt Enable bit for STSR2[ST_EOC] 0 Interrupt disabled 1 Enables the STSR1[ST_EOC] status bit to generate an interrupt indication. (IMR[MSKEOC] must also be enabled.)
9–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13 MSKWDG_EOA_C	Interrupt enable (WDG_EOA_C status bit) 0 Interrupt disabled 1 Enables the STSR1[WDG_EOA_C] status bit to generate an interrupt indication.
14 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15 MSKWDG_EOA_S	Interrupt enable (WDG_EOA_S status bit) 0 Interrupt disabled 1 Enables the STSR1[WDG_EOA_S] status bit to generate an interrupt indication.
16 MSKERR_C	Interrupt enable (ERR_C status bit) 0 Interrupt disabled 1 Enables the STSR1[ERR_C] status bit to generate an interrupt indication.
17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
18 MSKERR_S2	Interrupt enable (ERR_S2 status bit) 0 Interrupt disabled 1 Enables the STSR1[ERR_S2] status bit to generate an interrupt indication.
19 MSKERR_S1	Interrupt enable (ERR_S1 status bit) 0 Interrupt disabled 1 Enables the STSR1[ERR_S1] status bit to generate an interrupt indication.
20 Reserved	This field is reserved.

Table continues on the next page...



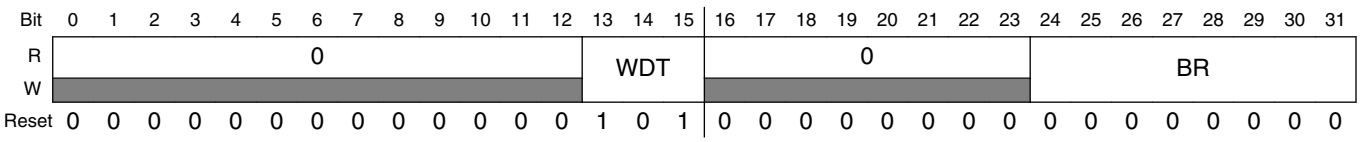
ADC_STCR2 field descriptions (continued)

Field	Description
21–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24 EN	Self testing channel enable. The TEST conversions are enabled. Enables the TEST channel only in CPU mode. This bit should be set before starting the normal conversion and should not be changed while conversion is ongoing. This bit should be reset only after end of conversion for the last self test channel has been received. 0 Disabled 1 Enabled
25–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 FMA_WDSERR	Fault mapping for the Watchdog Sequence error. By default a failure on the watchdog sequence is mapped on the NCF fault line. 0 NCF mapping 1 CF mapping
28 FMA_WDTERR	Fault mapping for the Watchdog Timer error. By default a failure on the watchdog sequence is mapped on the NCF fault line. 0 NCF mapping 1 CF mapping
29 FMA_C	Fault mapping for self test algorithm C. By default a failure on the self test C algorithm is mapped on the CF fault line. 0 NCF mapping 1 CF mapping
30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 FMA_S	Fault mapping for the self test algorithm BGAP. By default a failure on the Supply algorithm is mapped on the CF fault line. 0 NCF mapping 1 CF mapping

35.24.53 Self Test Configuration Register 3 (ADC_STCR3)

This register defines ADC self testing capabilities.

Address: 0h base + 348h offset = 348h



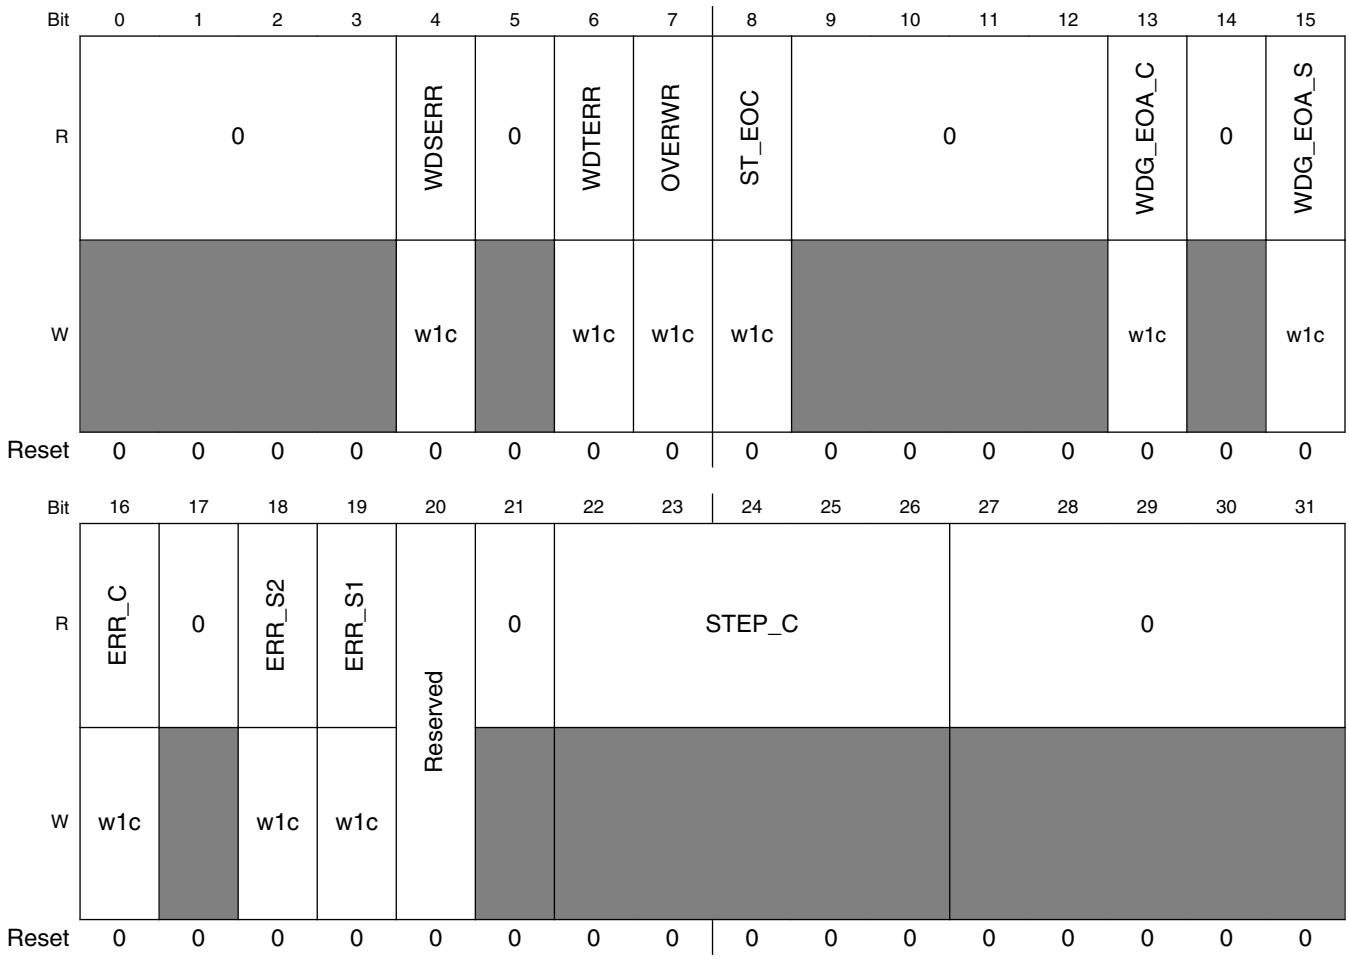
ADC_STCR3 field descriptions

Field	Description
0–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22–23 ALG	Algorithm scheduling. ONE-SHOT mode algorithm scheduling: • 00: Algorithm S (single step=MSTEP) • 01: Reserved • 10: Algorithm C (single step=MSTEP) • 11: Algorithm S (default) For test/debug purposes. SCAN mode algorithm scheduling: • 00: Algorithm S • 01: Reserved • 10: Algorithm C • 11: Algorithm S + Algorithm C (default) The baud rate for the execution of the selected algorithm is defined by the STBRR register.
24–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27–31 MSTEP	One shot mode: Current step for Algorithm S or Algorithm C. • MSTEP = 0 to (NUM_SUPPLY_STEPS-1) for algorithm S • MSTEP = 0 to (NUM_C_STEPS-1) for algorithm C Scan mode: This field is not used in scan mode as always single step execution (interleaved mode) is performed. It should be programmed to zero in scan mode. **NOTE:** All unused valued are RESERVED and should not be used.

35.24.54 Self Test Baud Rate Register (ADC_STBRR)

Used to set the baud rate for the selected baud rate in SCAN mode as well as the watchdog timer value.

Address: 0h base + 34Ch offset = 34Ch



ADC_STBRR field descriptions

Field	Description
0–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13–15 WDT	The watchdog timer value is used to monitor that the algorithm sequence is correctly executed within the safe time period. The self testing watchdog is enabled setting the STAWxR[WDTE] control bits. Default value is 10 ms. A fixed pre-scaler runs on the ADCdig clock (80 MHz). (Prescalar value is fixed at 1024). 000 0.1 ms ((0008h * Prescalar) cycles at 80 MHz) 001 0.5 ms ((0027h * Prescalar) cycles at 80 MHz) 010 1 ms ((004Eh * Prescalar) cycles at 80 MHz) 011 2 ms ((009Ch * Prescalar) cycles at 80 MHz) 100 5 ms ((0187h * Prescalar) cycles at 80 MHz) 101 10 ms ((030Dh * Prescalar) cycles at 80 MHz) 110 20 ms ((061Ah * Prescalar) cycles at 80 MHz) 111 50 ms ((0F42h * Prescalar) cycles at 80 MHz)
16–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–31 BR	Baud rate for the selected algorithm in SCAN mode (MCR[MODE] = 1). 00h Max scheduling rate (NOMINAL rate) ... FFh Min scheduling rate (NOMINAL rate scaled by 255) This field should be programmed when ST_EN is zero i.e. before enabling self test channel.

35.24.55 Self Test Status Register 1 (ADC_STSR1)

Address: 0h base + 350h offset = 350h

ADC_STSR1 field descriptions

Field	Description
0–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4 WDSERR	Watchdog sequence error of the ADC sub-system (check for algorithm step sequence). The WDSERR status bit is cleared writing 1. A 0 write is an invariant operation. It generates an interrupt if enabled (STCR2[MSKWDSERR] = 1). It provides the fault indication to an outside module such as the FCCU, asserting the Critical type or Non-Critical type lines according to the STCR2[FMA_WDSERR] mapping. **NOTE:** This bit is set only if STAWxR[WDTE] = '1'. 0 No failure 1 Failure occurred
5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

ADC_STSR1 field descriptions (continued)

Field	Description
6 WDTERR	Watchdog timer error of the ADC sub-system (algorithm check for completion within safe time). The WDTERR status bit is cleared writing 1. A 0 write is an invariant operation. It generates an interrupt if enabled (STCR2[MSKWDTERR] = 1). It provides the fault indication to an outside module such as the FCCU, asserting the Critical type or Non-Critical type lines according to the STCR2[FMA_WDTERR] mapping. 0 No failure 1 Failure occurred
7 OVERWR	Overwrite error. Used to notify when the STSR1[ERRx] bit is overwritten by a newer one. The OVERWR status bit is cleared writing 1. A 0 write is an invariant operation. The new error status is written or discarded according to the MCR[OWREN] bit value. To avoid OVERWR indication, the ERRx status bit must be cleared (via software).
8 ST_EOC	Self Test EOC Bit. This bit is set along with EOC bit when end_of_conversion signal is received from ADC analog for self test channel. The ST_EOC status bit is cleared by writing 1b. A 0b write is an invariant operation. It generates an interrupt if enabled by STCR2[MSKST_EOC]. (Also, IMR[MSKEOC] has to be enabled.)
9–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13 WDG_EOA_C	This bit indicates that Algorithm C has been completed. This bit is generated after the last STEP of algorithm C is executed. The WDG_EOA_C status bit is cleared by writing 1. A 0 write is an invariant operation. It generates an interrupt if enabled (STCR2[MSKWDG_EOA_C] = 1). This bit is set only if STAW4R[WDTE] = 1.
14 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15 WDG_EOA_S	This bit indicates that Algorithm S has been completed. This bit is generated after the last STEP of algorithm S is executed. The WDG_EOA_S status bit is cleared writing 1. A 0 write is an invariant operation. It generates an interrupt if enabled (STCR2[MSKWDG_EOA_S] = 1). This bit is set only if STAW0R[WDTE] = ‘1’.
16 ERR_C	Indicates an error on the self testing channel (algorithm C). The ERR_C status bit is cleared writing 1b. A 0b write is an invariant operation. It generates an interrupt if enabled (STCR2[MSKERR_C] = 1). It provides the fault indication to an outside module such as the FCCU, asserting the programmed fault line (STCR2[FMAx]). The ERR_C bit can be also set via SW (fault injection) writing 1b into the STCR2[SERR] bit. In this case the Critical type or Non-Critical type lines are asserted according to the STCR2[FMAx] mapping. 0 No C-algorithm ERROR 1 C-algorithm ERROR occurred
17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
18 ERR_S2	Indicates an error on the self testing channel (algorithm SUPPLY, step2). The ERR_S2 status bit is cleared by writing a 1b. A 0b write is an invariant operation. It generates an interrupt (“ipi_int_er” line) if enabled (STCR2[MSKERR_S2] = 1). It provides the fault indication to an outside module such as the FCCU, asserting the programmed fault line (STCR2[FMAx]). The ERR_S2 bit can be also set via SW (fault injection) writing 1b into the STCR2[SERR] bit. In this case the Critical / Non-Critical lines are asserted according to the STCR2[FMAx] mapping. 0 No ERROR occurred on the sampled signal 1 ERROR occurred on the sampled signal

Table continues on the next page...

ADC_STSR1 field descriptions (continued)

Field	Description
19 ERR_S1	Indicates an error on the self testing channel (algorithm SUPPLY, step1). The ERR_S1 status bit is cleared writing 1. A 0 write is an invariant operation. It generates an interrupt if enabled (STCR2[MSKERR_S1] = 1). It provides the fault indication to an outside module such as the FCCU, asserting the programmed fault line (STCR2[FMAx]). The ERR_S1 bit can be also set via SW (fault injection) writing 1b into the STCR2[SERR] bit. In this case the Critical / Non-Critical lines are asserted according to the STCR2[FMAx] mapping. 0 No VDD ERROR 1 VDD ERROR occurred
20 Reserved	This field is reserved.
21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22–26 STEP_C	Step of the algorithm C when an ERR_C has occurred. 0.. (NUM_C_STEPS-1) => algorithm C
27–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

35.24.56 Self Test Status Register 2 (ADC_STSR2)

If MCR[OVERWR] bit is set, registers STSR2-4 are overwritten if another error occurs.

Address: 0h base + 354h offset = 354h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	OVFL	0			DATA1											
W

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ADC_STSR2 field descriptions

Field	Description
0 OVFL	Overflow Bit This bit is set when the divisor is zero. Also, the STSR1[ERR_S1] bit is set if overflow occurs.
1–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4–15 DATA1	Test channel converted data when the ERR_S1 has occurred. Algorithm S (step1) => fractional part of the ratio TEST(step1)/TEST (step0) = VDD/VBGAP
16–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20–31 DATA0	Test channel converted data when the ERR_S1 has occurred. Algorithm S (step1) => integer part of the ratio TEST(step1)/TEST (step0) = VDD/VBGAP

35.24.57 Self Test Status Register 3 (ADC_STSR3)

If MCR[OVERWR] bit is set, registers STSR2-4 are overwritten if another error occurs.

Address: 0h base + 358h offset = 358h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

ADC_STSR3 field descriptions

Field	Description
0–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4–15 DATA1	Test channel converted data when the ERR_S2 has occurred. Algorithm S (step2) => TEST channel data = VREF/VREF
16–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

35.24.58 Self Test Status Register 4 (ADC_STSR4)

If MCR[OVERWR] bit is set, registers STSR2-4 are overwritten if another error occurs.

Address: 0h base + 35Ch offset = 35Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

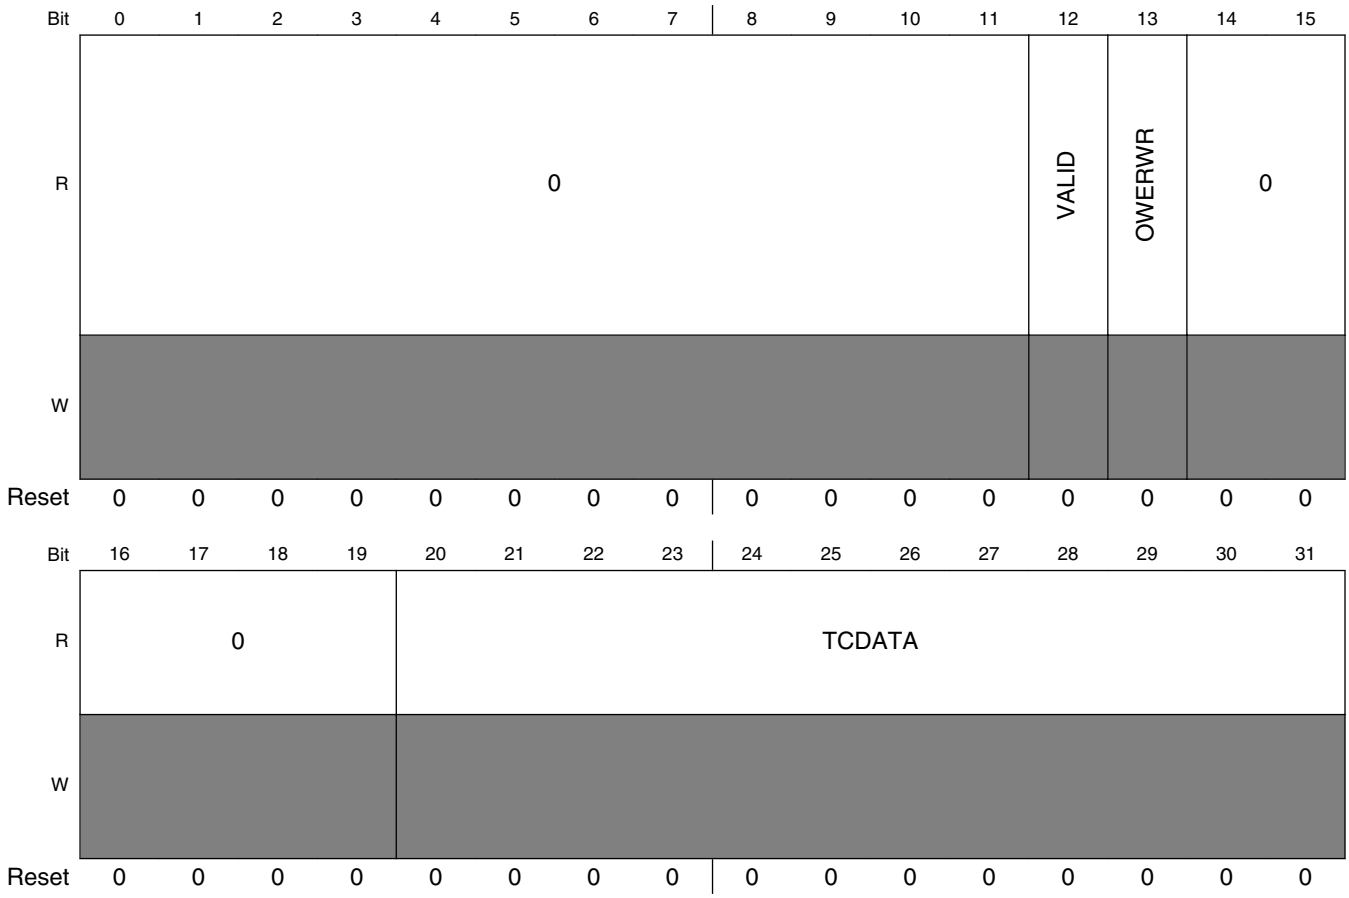
ADC_STSR4 field descriptions

Field	Description
0–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4–15 DATA1	Test channel converted data when the ERR_C has occurred. Algorithm C => TEST channel data
16–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

35.24.59 Self Test Data Register 1 (ADC_STDR1)



The ADC_STDR1 register contains the most current result data for conversions executed during ADC self test. Additionally, the register contains status bits to indicate whether result data has been read and whether existing conversion data has been overwritten by a newer result.

NOTE

1. For Algorithm S step 1, the result data contained in this register is not the final step 1 result. The step 1 data is the conversion of the analog supply (VDDA). This VDDA conversion result is divided by the Algorithm S step 0 conversion data and the result is written to the ADC_STDR2 register.
2. The least significant 3 bits of the analog supply (VDDA) conversion executed during Algorithm S step 1 processing are always '0'. The conversion performed in Algorithm S Step 1 is not on the full scale analog supply. Instead, the voltage sampled is VDDA / 8. The prescaling is done to avoid issues that can arise in the analog portion of the ADC

when VREFH = VDDA = 3.3 V, or VDDA is slightly higher than VREFH. The conversion result is multiplied by 8 before being written to this register to scale the result to the expected level, which results in the 3 least significant bits having a value of '0'.

Address: 0h base + 370h offset = 370h

ADC_STDR1 field descriptions

Field	Description
0–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12 VALID	Valid data. Used to notify when the data is valid (a new value has been written). It is automatically cleared when data is read.
13 OWERWR	Overwrite data. Used to notify when a conversion data is overwritten by a newer result. The new data is written or discarded according to the MCR[OWREN] bit value.
14–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

20–31 IDATA	Integer part of the ratio TEST(step1)/TEST (step0) = VDD/VBGAP for the algorithm S.

35.24.61 Self Test Analog Watchdog Register 0 (ADC_STAW0R)

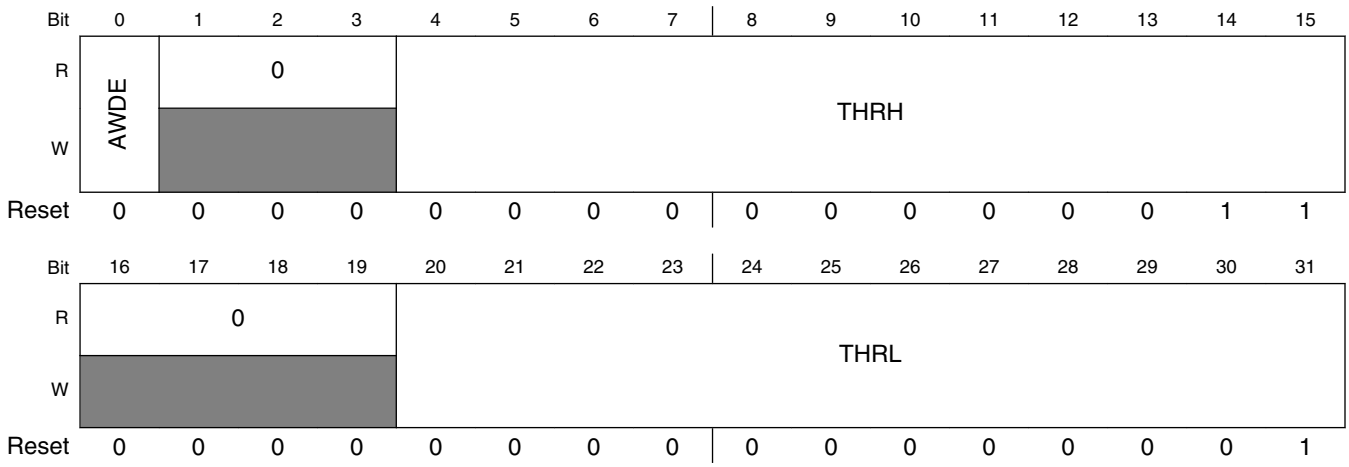
This register provides control values associated with the ADC's supply self test step 0, which samples bandgap voltage.

Address: 0h base + 380h offset = 380h

ADC_STAW0R field descriptions

Field	Description
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 WDTE	Watchdog timer enable (related to the algorithm S) Enables/disables the watchdog timer monitoring function for all ADC supply self test steps. The watchdog timer verifies: • Correct sequence of the algorithm (step sequence) • Execution of the algorithm within the safe time period as defined by STBRR[WDT]

Table continues on the next page...



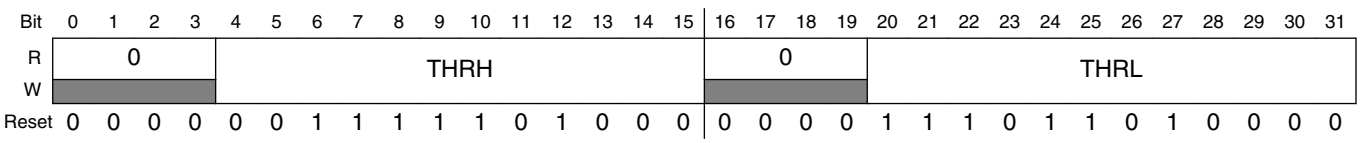
ADC_STAW0R field descriptions (continued)

Field	Description
	As soon as the watchdog timer is enabled the algorithm execution must be detected within the safe time period. The watchdog timer is reset each time the algorithm restarts. This bit should be set only in scan mode. 0 Disabled 1 Enabled
2–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4–15 THRH	High threshold value for Algorithm S step 0 If the analog watchdog is enabled, the STSR1[ERRx] status bit is set if STDR1[TCDATA]) > THRH. **NOTE:** The recommended watchdog threshold values are set according to expected and tested results in a noise-controlled environment, i.e., introduction of noise from outside of the device minimized. The setting may need to be adjusted to prevent a given threshold value from falsely reporting fault detections in applications operating in noisier environments.
16–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20–31 THRL	Low threshold value for Algorithm S step 0 If the analog watchdog is enabled, the STSR1[ERRx] status bit is set if STDR1[TCDATA]) < THRL. **NOTE:** The recommended watchdog threshold values are set according to expected and tested results in a noise-controlled environment, i.e., introduction of noise from outside of the device minimized. The setting may need to be adjusted to prevent a given threshold value from falsely reporting fault detections in applications operating in noisier environments.

35.24.62 Self Test Analog Watchdog Register 1A (ADC_STAW1AR)

This register contains values associated with the ADC's supply self test step 1, in which the analog supply (VDDA) is sampled and a fixed point division is performed, dividing the conversion result by the result from step 0 (bandgap voltage). The integer portion of the result is handled separately from the fractional part, i.e., they have separate data registers and threshold fields. Thresholds in this register are applied to the integer portion of the result. Thresholds in the ADC_STAW1BR register are applied to the fractional portion of the result.

Address: 0h base + 384h offset = 384h



ADC_STAW1AR field descriptions

Field	Description
0 AWDE	Analog watchdog enable related to the algorithm S (step1).
1–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4–15 THRH	High threshold value (integer part) for test channel for algorithm S (step 1) (unsigned coding). **NOTE:** The recommended watchdog threshold values are set according to expected and tested results in a noise-controlled environment, i.e., introduction of noise from outside of the device minimized. The setting may need to be adjusted to prevent a given threshold value from falsely reporting fault detections in applications operating in noisier environments.
16–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20–31 THRL	Low threshold value (integer part) for test channel for algorithm S (step 1) (unsigned coding). **NOTE:** The recommended watchdog threshold values are set according to expected and tested results in a noise-controlled environment, i.e., introduction of noise from outside of the device minimized. The setting may need to be adjusted to prevent a given threshold value from falsely reporting fault detections in applications operating in noisier environments.

35.24.63 Self Test Analog Watchdog Register 1B (ADC_STAW1BR)

This register contains values associated with the ADC's supply self test step 1, in which the analog supply (VDDA) is sampled and a fixed point division is performed, dividing the conversion result by the result from step 0 (bandgap voltage). The integer portion of the result is handled separately from the fractional part, i.e., they have separate data registers and threshold fields. Thresholds in this register are applied to the fractional portion of the result. Thresholds in the ADC_STAW1AR register are applied to the integer portion of the result.

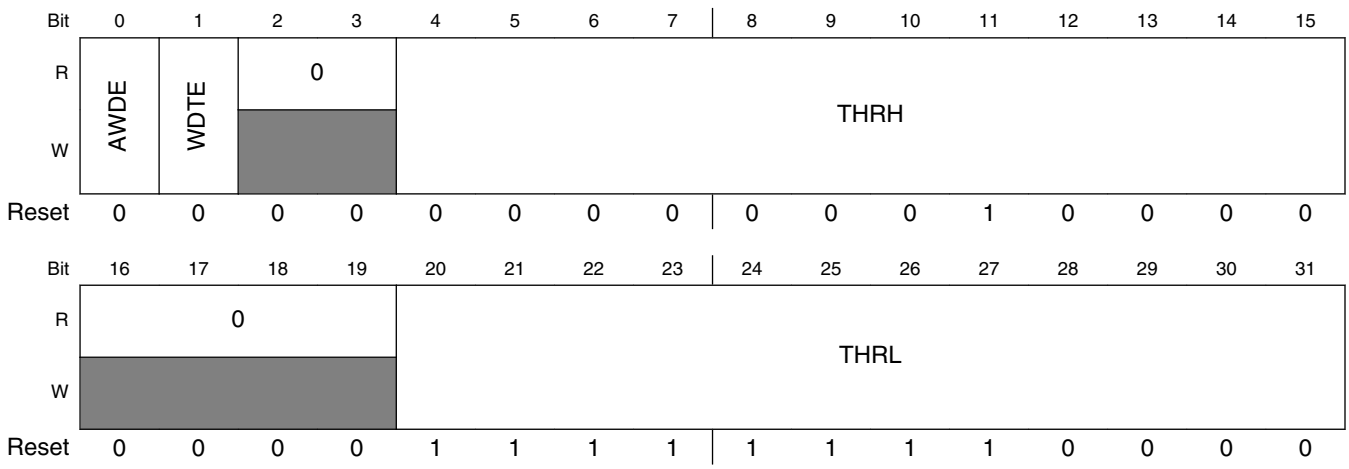
0–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4–15 THRH	High threshold value (fractional part) for test channel for algorithm S (step 1)(unsigned coding). **NOTE:** The recommended watchdog threshold values are set according to expected and tested results in a noise-controlled environment, i.e., introduction of noise from outside of the device minimized. The setting may need to be adjusted to prevent a given threshold value from falsely reporting fault detections in applications operating in noisier environments.
16–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20–31 THRL	Low threshold value (fractional part) for test channel for algorithm S (step 1) (unsigned coding). **NOTE:** The recommended watchdog threshold values are set according to expected and tested results in a noise-controlled environment, i.e., introduction of noise from outside of the device minimized. The setting may need to be adjusted to prevent a given threshold value from falsely reporting fault detections in applications operating in noisier environments.

35.24.64 Self Test Analog Watchdog Register 2 (ADC_STAW2R)

This register contains control values associated with the ADC's supply self test step 2, in which the ADC's high reference voltage is sampled and converted. Note that there is no upper threshold value in this register since the conversion result should ideally be FFFh (12-bit) or 3FF (10-bit).

Address: 0h base + 38Ch offset = 38Ch



ADC_STAW2R field descriptions

Field	Description
0 AWDE	Analog watchdog enable related to the algorithm S (step2).
1–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20–31 THRL	Low threshold value for channel x (unsigned coding). If the analog watchdog is enabled, the STSR1[ERR_S2] status bit is set if STDR1[TCDATA] < THRL. **NOTE:** The recommended watchdog threshold values are set according to expected and tested results in a noise-controlled environment, i.e., introduction of noise from outside of the device minimized. The setting may need to be adjusted to prevent a given threshold value from falsely reporting fault detections in applications operating in noisier environments.

35.24.65 Self Test Analog Watchdog Register 4 (ADC_STAW4R)

This register contains ADC self test configuration controls associated with the ADC's capacitive self test (also referred to as "Algorithm C") sequence, which samples voltages from the ADC's internal capacitor matrix. The watchdog enable fields (AWDE and WDTE) affect all Algorithm C steps; the threshold fields (THRH and THRL) fields are specific to Algorithm C Step 0.

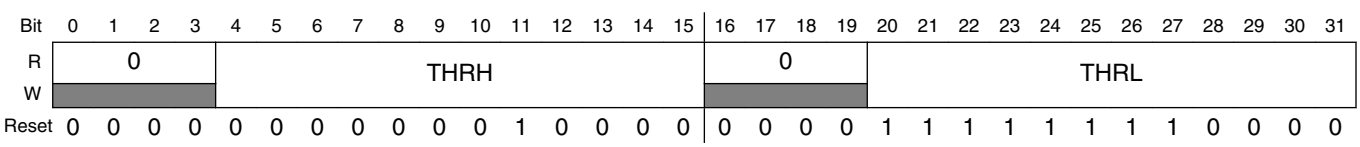
Address: 0h base + 394h offset = 394h

ADC_STAW4R field descriptions

Field	Description
0 AWDE	Analog watchdog enable (related to the algorithm C) Enables/disables the analog watchdog monitoring function for all ADC capacitive self test steps. 0 Disabled 1 Enabled
1 WDTE	Watchdog timer enable (related to the algorithm C). Enables/disables the watchdog timer monitoring function for all ADC capacitive self test steps. The watchdog timer verifies: • Correct sequence of the algorithm (step sequence) • Execution of the algorithm within the safe time period as defined by STBRR[WDT] As soon as the watchdog timer is enabled, execution must be detected within the safe time period. The watchdog timer is reset each time the algorithm restarts. This bit should be set only in scan mode. 0 Disabled 1 Enabled
2–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4–15 THRH	High threshold value for step 0 of C algorithm.

Table continues on the next page...

ADC_STAW4R field descriptions (continued)



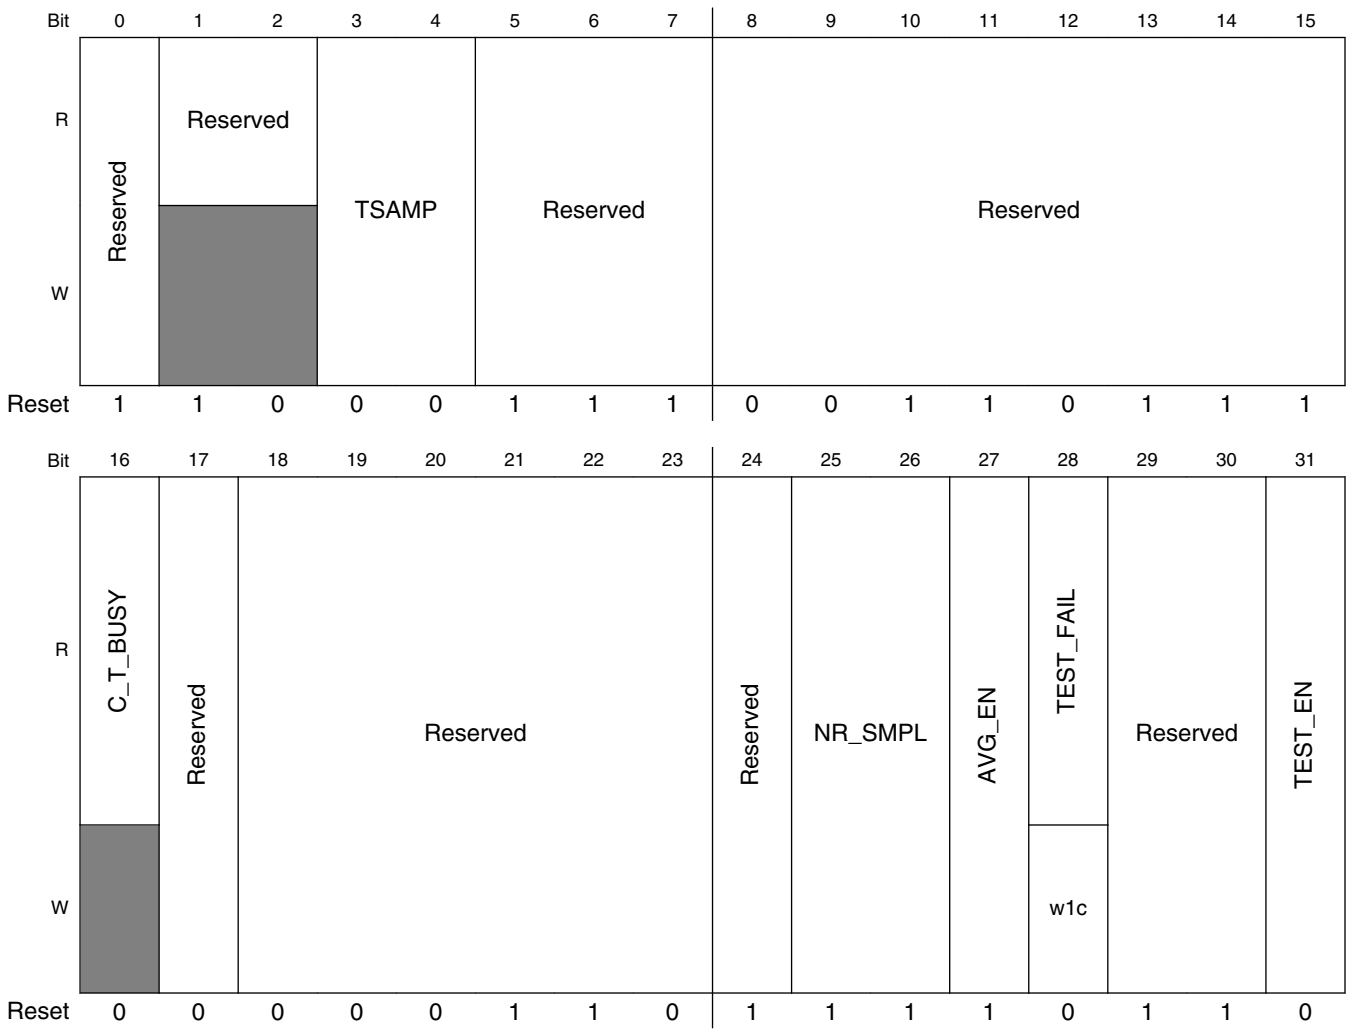
Field	Description
	This value is read by the ADC as twos-complement, but should be written positive. If the watchdog is enabled (STAW4R[AWDE] = 1) and STDR1[TCDATA] > STAW4R[THRH], then STSR1[ERR_C] is set. **NOTE:** The recommended watchdog threshold values are set according to expected and tested results in a noise-controlled environment (for example, introduction of noise from outside of the device minimized). The setting may need to be adjusted to prevent a given threshold value from falsely reporting fault detections in applications operating in noisier environments.
16–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20–31 THRL	Low threshold value for step 0 of C algorithm. This value is read by the ADC as twos-complement, and it should be the negative of STAW4R[THRH]. If the watchdog is enabled (STAW4R[AWDE] = 1) and STDR1[TCDATA] < STAW4R[THRL], then STSR1[ERR_C] is set. **NOTE:** The settings in this register are applicable only to step 0 of the ADC's capacitive self test. Refer to the ADC_STAW5R register for settings applicable to other capacitive self test steps. The recommended watchdog threshold values are set according to expected and tested results in a noise-controlled environment (for example, introduction of noise from outside of the device minimized). The setting may need to be adjusted to prevent a given threshold value from falsely reporting fault detections in applications operating in noisier environments.

35.24.66 Self Test Analog Watchdog Register 5 (ADC_STAW5R)

This register contains ADC self test threshold values associated with all capacitive self test (also referred to as "Algorithm C") steps other than Step 0, which is controlled by fields in the ADC_STAW4R register.

Note that the threshold values in this register are distinctly different than those in the ADC_STAW4R register. The threshold values in this register do not represent a voltage conversion value relative to the ADC high reference voltage, but instead represent the upper and lower thresholds for the absolute difference between the voltage sampled and converted in an Algorithm C step and the voltage sampled and converted in Algorithm C Step 0. Ideally, the difference will be zero.

Address: 0h base + 398h offset = 398h



ADC_STAW5R field descriptions

Field	Description
0–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4–15 THRH	High threshold value for step N of C algorithm (N = 1 to CS-1). This value is read by the ADC as twos-complement, but should be written positive. If the watchdog is enabled (STAW4R[AWDE] = 1) and (STDR1[TCDATA] (step-N) – STDR1[TCDATA] (step-0)) > STAW5R[THRH], then STSR1[ERR_C] is set. **NOTE:** The recommended watchdog threshold values are set according to expected and tested results in a noise-controlled environment (for example, introduction of noise from outside of the device minimized). The setting may need to be adjusted to prevent a given threshold value from falsely reporting fault detections in applications operating in noisier environments.
16–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20–31 THRL	Low threshold value for step 0 of C algorithm. This value is read by the ADC as twos-complement, and it should be the negative of STAW5R[THRH]. If the watchdog is enabled (STAW4R[AWDE = 1]) and (STDR1[TCDATA] (step-N) – STDR1[TCDATA] (step-0)) < STAW5R[THRL], then STSR1[ERR_C] is set. **NOTE:** The recommended watchdog threshold values are set according to expected and tested results in a noise-controlled environment (for example, introduction of noise from outside of the device minimized). The setting may need to be adjusted to prevent a given threshold value from falsely reporting fault detections in applications operating in noisier environments.

35.24.67 Calibration, BIST Control and status Register (ADC_CALBISTREG)

This register controls the Offset calculation, Calibration and BIST functionality with Averaging option. The averaging function has no effect in other conversion modes.

Address: 0h base + 3A0h offset = 3A0h

ADC_CALBISTREG field descriptions

Field	Description
0 Reserved	This field is reserved. When writing to this register, do not change the default value of this field.
1–2 Reserved	This field is reserved. When writing to this register, do not change the default value of this field.
3–4 TSAMP	Test Sample period in Calibration, BIST and Offset calculation process. 00 22 cycles of ADC clk

Table continues on the next page...

ADC_CALBISTREG field descriptions (continued)

Field	Description
	01 8 cycles of ADC clk 10 16 cycle of ADC clk 11 32 cycle of ADC clk
5–7 Reserved	This field is reserved.
8–15 Reserved	This field is reserved. When writing to this register, do not change the default value of this field.
16 C_T_BUSY	This bit indicates that ADC is doing internal operations for BIST or Calibration. This is set when the TEST_EN bit is set. 0 ADC is ready for use 1 ADC is busy in calibration or test operation
17 Reserved	This field is reserved.
18–23 Reserved	This field is reserved. When writing to this register, do not change the default value of this field.
24 Reserved	This field is reserved. The default value must not change. Always write the default value to this field.
25–26 NR_SMPL	Number of Samples for averaging. **NOTE:** The 16 samples setting is used only when the application needs quicker calibration (reduced time) to trade off with accuracy. For the best accuracy, it is necessary to use 512 samples. The minimum recommended number of samples is 32 samples. 00 16 samples 01 32 samples 10 128 samples 11 512 samples
27 AVG_EN	Average Enable (for Calibration only). 0 Disable 1 Enable
28 TEST_FAIL	Test Fail. This bit indicates the status of Calibration output. This bit sets automatically if tests are aborted prematurely by any normal conversion or tests complete but one of them fails. This bit is cleared by writing 1 to it or on restarting of test by writing 1 to TEST_EN 0 Test passed 1 Test failed
29–30 Reserved	This field is reserved.
31 TEST_EN	Enable the test. 0 Disable the test 1 Enable the test (self clearing) (once set it cannot be overwritten till it resets)

35.24.68 Offset and Gain User Register (ADC_OFSGNUSR)

This register contains the user configured offset and Gain values used by ADC for data processing and have all the bits valid (MSB through LSB).

OFFSET and Gain Calibration values can be either positive or negative, so they need to be in 2's complement format with MSB as sign bit.

Address: 0h base + 3A8h offset = 3A8h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

ADC_OFSGNUSR field descriptions

Field	Description
0–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6–15 GAIN_USER	Gain User (2's complement format)
16–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–31 OFFSET_USER	Offset User (2's complement format)

35.2.5 Functional description

The following sections detail the ADCD interfaces as well as the functionality of this module.

35.2.5.1 Conversion

After power-up or reset, the ADC is in power-down mode until the MCR[PWDN] field is written. There are some configurations, listed below, available only in power-down mode, that must be handled before exiting power down.

- Clock selection for SAR Controller (SAR_CLK): MCR [ADCLKSEL]
- Operating mode of ADC for BCTU (Trigger / Control): MCR [CTU_MODE] (if available)

After the above configurations, ADC need to be taken out from power-down mode by writing '0' into MCR [PWDN], Conversions can be initiated now in the following modes:

- Normal

- Injected
- BCTU Triggered

35.2.5.1.1 Normal conversion

The conversion mode generally used to convert channels is called normal conversion. Programming the available Normal Conversion Mask Register(s) (ADC_NCMR*n*) selects the channel(s). Each channel can be individually enabled by setting a bit in the corresponding field of the appropriate NCMR*n* register.

- NCMR0 serves *precision* channels:
  - 0 - 31 (ADC0)
  - 0 - 31 (ADC1)
  - 0 - 31 (ADC2)
  - 0 - 20 (ADC3)
- NCMR1 serves *internal* channels:
  - 32 - 39 (ADC0)
  - 32 - 38 (ADC1)
  - 32 - 36 (ADC2)
  - 32 - 38 (ADC3)
- NCMR2 serves *external* channels:
  - none (ADC0)
  - none (ADC1)
  - none (ADC2)
  - 64 to 95 (ADC3)

The mask register(s) must be programmed before starting the conversion and cannot be changed until the conversion of all the selected channels ends. Conversion always starts from the lowest channel number selected and sequentially goes to the highest number.

35.2.5.1.1.1 Starting a normal conversion

After programming the MCR and NCMR0*n* register(s), a normal conversion is started via *software* by setting the MCR[NSTART] bit.

To start a normal conversion via *external trigger*, enable external trigger by setting the (MCR[TRGEN] bit. A programmed event (rising/falling edge depending on MCR[EDGE] bit) on the normal trigger input starts the conversion.

Detection of an active edge defined by MCR[EDGE] bit (rising=1, falling=0) on the external trigger will start the normal conversion.

35.2.5.1.2 Normal conversion operating modes

Two operating modes are available for normal conversion:

- One-Shot mode
- Scan mode

The MCR[MODE] bit determines which mode is used during a normal conversion. The first phase of the conversion process involves sampling the analog channel. The next phase is the conversion phase, during which the sampled analog value is converted to digital as shown in the figure below.

Figure 35-156. Normal conversion flow

35.2.5.1.2.1 One shot mode

In one shot mode (MCR[MODE] = 0) a sequential conversion specified in the following mask register(s) is performed only once:

- NCMR0
- NCMR1
- NCMR2

At the end of each conversion, the digital result of the conversion is stored into the corresponding data register(CDRx, x = channel number).

For example: Channels A-B-C-D-E-F-G-H are present in the device where channels B-D-E are to be converted in One-Shot mode. Conversion starts with channel B, followed by the conversion of channels D and E. At the end of conversion of channel E, the scanning of channels will stop.

The MSR[NSTART] status bit is automatically set when the normal conversion starts. At the same time, MCR[NSTART]is reset by hardware, allowing the software to program a new start of conversion in advance. In this case, the newly requested conversion starts after completing the running/current conversion. However, for the sake of simplicity and straightforwardness, it is advisable to program the NSTART bit for the new conversion only after the completion of the running conversion. To know the end of conversion of running chain, application will either wait for an End of Chain (ECH) Interrupt or check the status of MSR[NSTART] prior to setting MCR[NSTART] again.

If the conversion chain is started by the external trigger, the trigger input will not be observed by the ADC block until the current conversion chain is finished. After the chain is over, the next chain can be invoked/triggered by another hardware trigger edge.

35.2.5.1.2.2 Scan mode

In scan mode (MCR[MODE] = 1), a sequential conversion of *n* channels specified in the NCMR*n* register(s) is continuously performed. At the end of each conversion, the converted result is stored into the corresponding data registers, as in One-Shot mode.

The MSR[NSTART] status bit is automatically set when the normal conversion starts. Unlike One-Shot mode, the MCR[NSTART] bit is not reset automatically in Scan mode. It can be reset by software when you need to stop Scan mode. In that case, the ADC completes the current chain and, after the last conversion, resets MSR[NSTART].

For example: Channels A-B-C-D-E-F-G-H are present in the device where channels B-D-E are to be converted in Scan mode. MCR[MODE] = 1 is set for Scan mode. Conversion starts from channel B, followed by the conversion of channels D and E. At the end of the conversion of channel E, the conversion of channel B starts again, followed by the conversion of channels D and E. This sequence repeats itself until MCR[NSTART] is reset by software.

This scan chain can be stopped by writing 0 to MCR[NSTART]. The conversion stops when the ongoing chain is finished.

NOTE

If the conversion is started by an external trigger, MCR[NSTART] is not set. As a consequence, once started, the only way to stop a Scan mode conversion started by an external trigger is to set the MCR[MODE] bit to 0.

35.2.5.1.2.3 End of conversion

In both modes, at the end of each conversion an end-of-conversion (EOC) interrupt is issued if enabled by the corresponding mask bit in the following register(s):

- CIMR0
- CIMR1
- CIMR2

Additionally, the EOC interrupt must enabled in the IMR register. After the conversion of all the channels selected in the NCMR*n* register(s) is completed and the conversion operation is considered finished, ISR[ECH] is set and an end-of-chain (ECH) interrupt is issued (if enabled in IMR[MSKECH]). The corresponding channel bit within the appropriate CEOCFR*n* register is updated to indicate that data is available on the data

register (CDR*n*) of the respective channel. If there is no channel selected in the NCMR*n* register(s) and there is a start of conversion trigger, then ISR[ECH] is set and an ECH interrupt is immediately issued (if enabled).

NOTE

To add or remove channels to/from the ongoing chain:

1. Clear the MCR[NSTART] bit
2. Set/clear mask bit for the needed channels in NCMR*n*
3. Set the MCR[NSTART] bit

35.2.5.1.3 Injected conversion

An injected conversion is a conversion chain that can be injected at any time, including into an ongoing normal conversion chain. To do so, configure the injected mask register(s):

- JCMR0
- JCMR1
- JCMR2

As in a normal conversion, each internal or external channel can be individually selected for injected conversion.

- JCMR0 controls *precision* channels:
  - 0 - 31 (ADC0)
  - 0 - 31 (ADC1)
  - 0 - 31 (ADC2)
  - 0 - 20 (ADC3)
- JCMR1 controls *internal* channels:
  - 32 - 39 (ADC0)
  - 32 - 38 (ADC1)
  - 32 - 36 (ADC2)
  - 32 - 38 (ADC3)
- JCMR2 controls *external* channels:
  - none (ADC0)
  - none (ADC1)
  - none (ADC2)
  - 64 to 95 (ADC3)

Injected conversion can only be run in One-Shot mode, and can only interrupt a normal conversion. Please note, that a BCTU conversion cannot be interrupted by an injected conversion. In this case, the injected conversion is discarded. When an injected chain is inserted into an ongoing normal chain, the ongoing normal channel is suspended and the

injected channel request is processed. After completing the last channel in the injected chain, normal conversion resumes from the channel at which it was suspended as shown in the following figure.

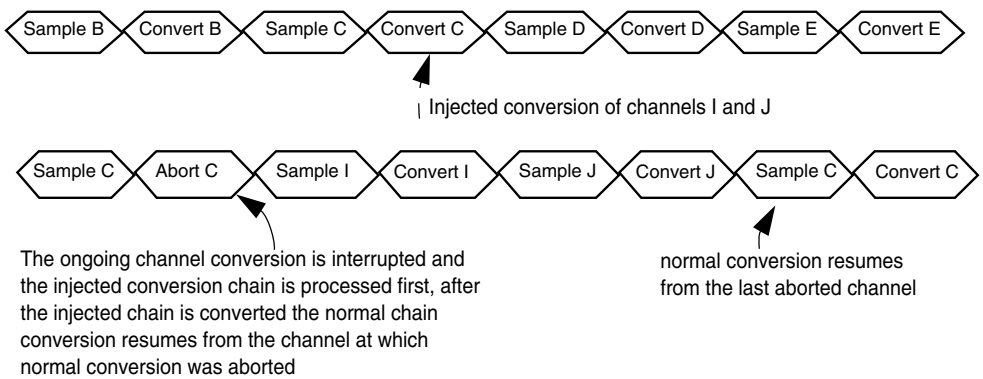

Figure 35-157. Injected sample/conversion sequence

35.2.5.1.3.1 Starting injected conversion

The injected conversion can be started via *software* by setting the MCR[JSTART] bit to start an injected conversion; the current normal conversion is suspended and the injected chain is converted.

The MSR[JSTART] status bit is automatically set when the injected conversion starts. At the same time, the MCR[JSTART] bit is reset, allowing software to program a new start of conversion in advance. In that case, the new requested conversion starts after the running conversion is completed.

At the end of each conversion, an End Of Injected Conversion (JEOC) interrupt is issued (if enabled by the corresponding mask bit in IMR) and at the end of the chain an End Of Injected Chain (JECH) interrupt is issued (if enabled by the corresponding mask bit in IMR). The status bit ISR[JECH] is also set.

If the content of all the injected conversion mask registers (JCMRn) is zero (i.e., no channel is selected) the interrupt JECH is immediately issued to resume normal operation or conversion mode.

The corresponding channel bit in the appropriate CEOCFR*n* register is updated to indicate that data is available in the data register (CDR) of the respective channel.

Once started, injected chain conversion cannot be interrupted by Normal or another Injected conversion. A BCTU trigger has the higher priority; injected conversion has a lower priority. Therefore, only a BCTU trigger can interrupt an ongoing injected conversion. In this case, the injected conversion will be discarded.

35.2.5.1.4 Aborting conversions

Two different abort functions are provided:

- A single channel abort
- A chain abort

You can abort the ongoing conversion by setting the MCR[ABORT] bit. The current conversion is aborted and the conversion of the next channel of the chain is immediately started. The abort action may take 1 to 4 cycles of the bus clock to abort the current conversion depending on the state of the conversion. At the start of any conversion and at the end of a particular conversion, when internal state counters are changing, then abort is delayed by a maximum of 3 cycles to take all states in stable condition. Abort also should not be programmed along with and within 3 cycles of programming the MCR[NSTART] or MCR[JSTART]. This may not have a significant impact from software point of view since on any SoC the next write access comes only after a minimum of 3 clock cycles.

NOTE

Programming Abort or Abort chain with NSTART or JSTART in idle condition has no effect.

For a Normal conversion chain having only one channel:

1. Abort re-runs the conversion again from the Abort point
2. If Interrupted by BCTU (in Trigger mode) Normal conversion runs twice instead of just once

In the case of an abort operation, the MSR[NSTART/JSTART] bit remains set, if not in last channel of chain, and the MCR[ABORT] bit is reset as soon as the channel is aborted. The EOC corresponding to the aborted channel is not generated. This behavior is true for Normal or Injected conversion modes. If the last channel of a chain is aborted, the end of chain is reported by generating an ECH interrupt.

It is also possible to abort the current chain of conversions by setting the MCR[ABORTCHAIN] bit. In that case, the behavior of the ADC depends on the MCR[MODE] bit (One-Shot/Scan) for Normal conversion. In One-Shot mode, MSR[NSTART] is automatically reset together with the MCR[ABORTCHAIN]. Otherwise, in Scan mode, a new chain is started, and the current chain is aborted. The EOC of the current aborted conversion is not generated, but an ECH interrupt is generated to signal the end of the chain. For Injected conversion, the behavior of ABORTCHAIN is same as for One-shot Normal conversion. In this case, MSR[JSTART] is automatically reset together with the MCR[ABORTCHAIN].

When an ABORTCHAIN is requested while an injected chain is running over a suspended normal chain, both injected and normal chains are aborted; both MSR[NSTART] and MSR[JSTART] are reset. ABORT and ABORTCHAIN requests are ignored during BCTU conversion. ABORT requests are also discarded during Self-Test conversion.

35.2.5.2 Crosstriggering Unit interface

The Crosstriggering Unit (BCTU) interface enhances the injected conversion capability of the ADC. The BCTU contains multiple event inputs that can be used to select the channels to be converted from the appropriate event configuration register. The BCTU/ ADC interface is shown in the figure below. The BCTU generates a trigger and a channel number to be converted. A single channel is converted for each request. After performing the conversion, the ADC returns the result.

The conversion result is also saved in the corresponding data register and it is compared with watchdog thresholds if requested.DMA and interrupt feature of ADC can also be used during CTU conversion.

The BCTU and ADCD can work on asynchronous clock domain. The signals ctu_trigger, ctu_nextcmd, ctu_push are toggle based, meaning any toggle (high-to-low or low-to-high) means one active command. The ADCD internally synchronizes the toggle and generates a trigger. The channel number needs to be fixed until the next active trigger. Similarly, the data remains valid from one toggle to the next toggle of the push command. The speed is marginally slower in asynchronous operation than synchronous due to synchronization overhead.

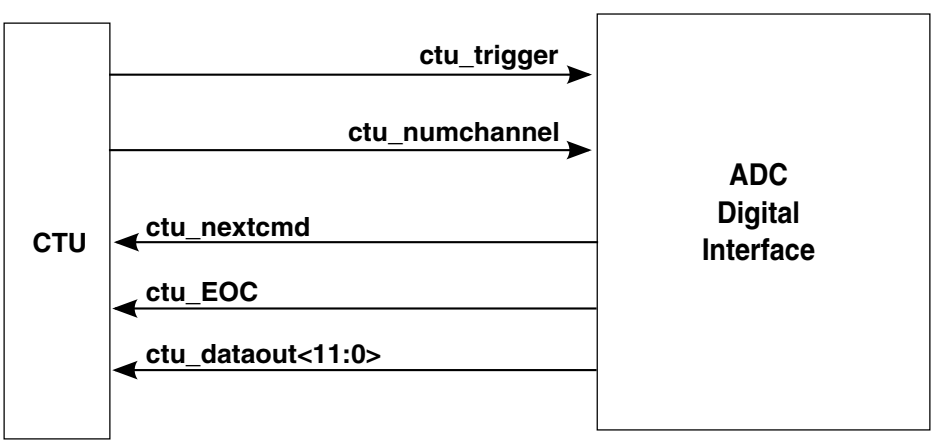

Figure 35-158. ADC Crosstriggering Unit

The BCTU interface has two modes of operation: Trigger and Control.

The BCTU interface is enabled by programming the MCR[CTUEN] bit. The BCTU interface operating mode is programmed by MCR[CTU_MODE] bit.

35.2.5.2.1 BCTU Trigger mode

In trigger mode, normal and injected conversions are enabled along with BCTU conversion, allowing all kinds of conversions to run.

When a trigger is received, the channel number is taken as the channel value and the BCTU conversion starts. The MSR[CTUSTART] bit is set automatically at this point and it is also automatically reset when the BCTU conversion is completed.

BCTU conversions should be requested after calibration is over. If a BCTU trigger is received during calibration, the calibration fails and BCTU conversion is started.

If a BCTU trigger is received during an ongoing injected conversion, then the injected chain is aborted immediately and only the BCTU conversion proceeds. The MSR[JSTART] bit is reset. Aborting of the injected conversion is indicated through the status bit of MSR[JABORT].

If a BCTU trigger is received during a ongoing normal conversion, the ongoing normal channel is suspended and the BCTU conversion is processed. Normal conversion resumes from the suspended channel after completion of BCTU triggered conversion.

If another BCTU trigger is received before ctu_nextcmd signal, that triggered conversion request is discarded.

If a Normal conversion is requested during BCTU conversion (MSR[CTUSTART] bit equal to ‘1’), the Normal conversion starts after the BCTU conversion is completed (MSR[CTUSTART] bit reset).

Injected conversion requests are discarded during a BCTU conversion, and the MCR[JSTART] bit is immediately reset.

35.2.5.2.2 BCTU Control mode

In BCTU Control mode, if enabled via MCR[CTUEN], the CPU is able to write in the ADC registers, but it cannot start a conversion. Conversion requests can be generated only by a BCTU trigger. If a normal or injected conversion is requested when the BCTU is enabled (MCR[CTUEN]), it will be automatically discarded.

Along with BCTU trigger the ctu_numchannel is taken as channel and BCTU conversion starts. MSR[CTUSTART]is set automatically at this point and it remains set unless the BCTU is disabled by resetting MCR[CTUEN].

BCTU conversions must be requested when calibration is over. If a BCTU trigger is received during calibration, the calibration stops immediately in order to satisfy the BCTU request. Calibration will fail in this case.

If another BCTU trigger is received before the ctu_nextcmd signal, the new request is discarded.

35.2.5.3 ADC clock prescaler and sample time settings

The clock (SAR_CLK) provided to the ADC's SAR controller, which controls the ADCA, must satisfy particular conditions of frequency and duty cycle. The maximum acceptable frequency is 80 MHz with a duty cycle equal to 50% (±5%).

The SAR_CLK frequency can be scaled by programming the MCR[ADCLKSEL] bit. If this bit is set, SAR_CLK frequency is the same as the bus clock. Otherwise, SAR_CLK frequency is half of the bus clock. MCR[ADCLKSEL] can only be written in power-down, when MCR[PWDN] = 1.

Sampling times are controlled by settings in the Conversion Timing Register (CTR*n*). A CTR register is provided for each channel type.

- CTR0 controls sampling time for *precision* channels:
  - 0 - 31 (ADC0)
  - 0 - 31 (ADC1)
  - 0 - 31 (ADC2)
  - 0 - 20 (ADC3)
- CTR1 controls sampling time for *internal* channels:
  - 32 - 39 (ADC0)
  - 32 - 38 (ADC1)
  - 32 - 36 (ADC2)
  - 32 - 38 (ADC3)
- CTR2 controls sampling time for *external* channels:
  - none (ADC0)
  - none (ADC1)
  - none (ADC2)
  - 64 to 95 (ADC3)

The exception is the Temperature Sensor channel, which always uses the CTR1 value. See Conversion Timing Register 1 (ADC_CTR1) for details.

35.2.5.4 Presampling

Presampling allows the ADC internal capacitor to precharge or discharge to a defined level before it starts the actual sampling/conversion of the analog input coming from the pads. This is useful for resetting information (history effect/offset) regarding the last converted data. During presampling, the ADC samples the internally generated voltage while, during sampling, the ADC samples the analog input coming from the pads.

Presampling can be enabled/disabled on an individual channel by setting the corresponding bit in the applicable PSR*n* register.

- PSR0 controls precision channels
- PSR1 controls internal channels
- PSR2 controls external channels

After enabling the presampling for a channel, the normal sequence of operation is presampling + sampling + evaluation for that channel. Sampling of the channel can be bypassed by setting PSCR[PRECONV]. When sampling of a channel is bypassed, the presampled voltage will be converted.

See Conversion time for the conversion's timing equation.

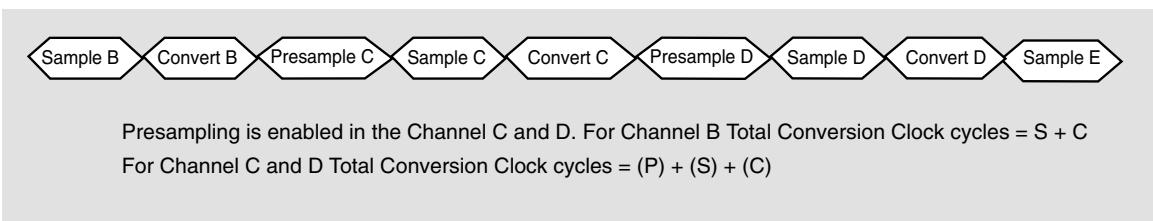

Figure 35-159. Presampling sequence

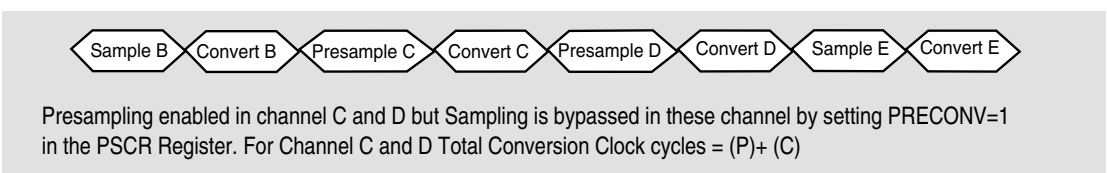

Figure 35-160. Presampling sequence with PRECONV = 1

35.2.5.4.1 Presampling channel enable

The presampling channels are selected by programming the presampling register (Presampling Control Register (ADC_PSCR)). These are used to enable analog switches that samples an internally generated voltage. It is possible to select presample voltage from four internally available voltages depending on the value of PREVAL*x* [*x* = 0,1,2] fields in the PSCR register as given in Table 35-159.

Table 35-159. Presample voltage selection

PREVAL*n*	Presampling voltage
00b	Presample voltage 1: VSS_HV_ADV_SAR
01b	Presample voltage 2: VDD_HV_ADV_SAR/8
10b	Presample voltage 3: VSS_HV_ADR_SAR
11b	Presample voltage 4: VDD_HV_ADR_SAR

The PREVALn fields are associated with specific channels, as shown in Table 35-160.

Table 35-160. PREVAL*n* channel association

Field	Channels
PREVAL0	• 0 - 31 (ADC0) • 0 - 31 (ADC1) • 0 - 31 (ADC2) • 0 - 20 (ADC3)
PREVAL1	• 32 - 39 (ADC0) • 32 - 38 (ADC1) • 32 - 36 (ADC2) • 32 - 38 (ADC3)
PREVAL2	• none (ADC0) • none (ADC1) • none (ADC2) • 64 to 95 (ADC3)

The temperature sensor channel is an exception. It can be mapped with any of the channels, but it uses the configuration of extended internal channel. So when this is selected, ADC takes PREVAL1 value to select the presample voltage because its physical properties may be different than the other internal precision channels.

35.2.5.5 Programmable analog watchdog

NOTE

The number of analog watchdogs and channels may vary depending on the ADC instance on your chip. Please see the chip-specific section for how many are available on each instance.

The analog watchdogs are used for determining whether the result of a conversion lies within a given guard area (as shown in Figure 35-161) specified by an upper and a lower threshold value named THRH and THRL, respectively.

After the conversion of the selected channel, a comparison is performed between the converted value and the threshold values. If the converted value lies outside the guard area, then the corresponding threshold violation interrupt is generated.

The comparison result is stored as WTISR[WDGxH] and WTISR[WDGxL], as explained in the following table. Depending on the WTIMR[MSKWDGxL] and WTIMR[MSKWDGxH] mask bits, an interrupt is generated upon threshold violation.

Table 35-161. Values of WDGxH and WDGxL fields

WDGxH	WDGxL	Converted data
1	0	converted data > THRH
0	1	converted data < THRL
0	0	THRH ≤ converted data ≤ THRL

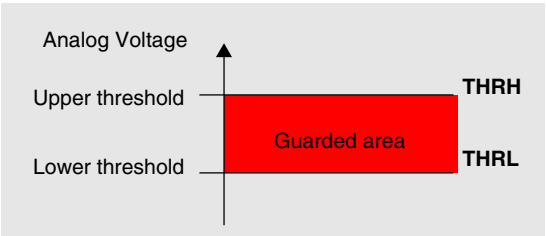

Figure 35-161. Guarded Area

35.2.5.5.1 Analog watchdog setting

For each watchdog there is one Threshold value (Low and High) Register (THRHLR).

The analog watchdog for each channel can be enabled independently by programming CWENR*n* register bits.

- CWENR0 controls *precision* channels:
  - 0 - 31 (ADC0)
  - 0 - 31 (ADC1)
  - 0 - 31 (ADC2)
  - 0 - 20 (ADC3)
- CWENR1 controls *internal* channels:
  - 32 - 39 (ADC0)
  - 32 - 38 (ADC1)
  - 32 - 36 (ADC2)
  - 32 - 38 (ADC3)
- CWENR2 controls *external* channels:
  - none (ADC0)
  - none (ADC1)
  - none (ADC2)
  - 64 to 95 (ADC3)

The availability of these registers depends on device configuration.

Threshold values for each channel can be selected independently from a maximum of 16 threshold registers (THRHLRx,(x=0..15)) by the WSEL_CHx field of CWSELRx (x=0..11) register.

Each CWSELRx register holds selection for 8 consecutive channels. CWSELR0 holds 8 WSEL_CH fields for channel 0 to 7. Likewise CWSELR1 is for channel 8 to 15 and so on. The availability of fields and registers depends on device configuration.

If the converted value for a particular channel lies outside the range specified by threshold values, then the corresponding bit is set in the Analog Watchdog Out of Range Register (AWORR).

For example, if channel number 12 is to be monitored with the threshold values in register THRHLR3, then CWSELR1[WSEL_CH4] needs to be programmed with 3. The enabling will be done by setting the bit corresponding to channel 12 in the CWENR0 register.

A set of threshold values (THRHLRx) can be linked to several ADC channels. The threshold values to be selected for a channel needs be programmed only once in the CWSELRx register.

35.2.5.6 DMA functionality

A Direct Memory Access (DMA) request can be programmed after the conversion of every channel by setting the respective masking bit in the following register(s):

- DMAR0
- DMAR1
- DMAR2

The DMA masking registers must be programmed before starting any conversion.

The DMA transfers can be enabled using the ADC_DMAE[DMAEN] bit. When the DMAE[DCLR] bit is set, the DMA request is cleared on the reading of the register for which DMA transfer has been enabled.

35.2.5.7 Interrupts

ADC generates the following maskable interrupt signals:

- End-of-conversion interrupt (EOC) request
- End-of-chain interrupt (ECH) request
- End-of-injected conversion interrupt (JEOC) request

- End-of-injected chain interrupt (JECH) request
- End-of-CTU conversion interrupt (EOCTU) request
- Watchdog threshold interrupt (WDGxL and WDGxH) requests

Interrupts are generated during the conversion process to signal events, like the end of a conversion, as explained in the register description for the Interrupt Status Register (ISR). The ISR and the Interrupt Mask Register (IMR) allow you to check and enable the interrupt request.

Interrupts can be individually enabled on a channel-by-channel basis by programming the Channel Interrupt Mask Register (CIMR).

Three Channel Pending Registers (CEOCFR*n*) are also provided in order to signal which of the channels' measurement has been completed.

Analog Watchdog interrupts are enabled by Watchdog Threshold Interrupt Mask Register (WTIMR) and the status can be checked at Watchdog Threshold Interrupt Status Register (WTISR). The watchdog interrupt source sets two fields, WDGxH and WDGxL, for each channel monitored in the WTISR.

In particular, the EOC, ECH, EOCTU, JEOC, and JECH interrupt lines are combined (OR-ed) on the same line. The EOC interrupt request is cleared by clearing either ISR[EOC] or all bits of CEOCFR. The JEOC interrupt request is cleared by clearing either ISR[JEOC] or all bits of CEOCFR. The EOCTU interrupt request is cleared by clearing either ISR[EOCTU] or all bits of CEOCFR. Also, the self-test end of algorithm interrupts STSR1[WDG_EOA_S] and STSR1[WDG_EOA_C] are combined.

All WDGxH and WDGxL requests are combined on the second line.

Another interrupt on the third line is a combination of WDSERR, WDTERR, ERR_S0, ERR_S1, ERR_S2, and ERR_C in STSR1.

The ISR register contains the interrupt pending request status. If you want to clear a particular interrupt event status, then writing a 1 to the corresponding status bit will clear the pending interrupt flag. (At this write operation, all the other bits of the ISR register must be programmed to 0.)

35.2.5.8 External Decode signals Delay

The ADC provides three external decode signals to be used to select one channel out of eight channels in external Analog multiplexers. There can be a maximum of four such multiplexers that are used for the 32 external channels to be converted. In order to take

into account the control of switching time of the external analog mux, a Decode Signals Delay (DSD) register is provided. This register allows you to program the delay between the decoding signal selection and the actual start of conversion.

If presampling is enabled then the DSD delay starts after the presample phase (presampling time is same as sample time).

35.2.5.9 Power-Down mode

The analog part of the ADC can be put in Power-Down mode by setting the MCR[PWDN] bit, which shuts off the ADCA and stops the clock in the SAR controller. After power-on or device reset, the ADCA is kept in Power-Down mode by default, so this state must be exited before starting any operation by resetting the MCR[PWDN] bit. In Power-Down mode, no conversion and calibration can be started. Trigger from BCTU during power down is discarded. In the ADC power-down mode, the BCTU must not start any conversion.

The MCR[PWDN] bit may be programmed high at any time. However, if a conversion is ongoing, then the ADCA cannot be sent immediately into Power-down mode. In fact, the ADC enters Power-down mode only after completing the ongoing conversion. Otherwise, the ongoing operation should be aborted manually by resetting the NSTART bit and using the ABORTCHAIN function.

The ADC status in MSR[ADCSTATUS] field shows Power-down status only when ADC enters in Power-down mode.

If BCTU is enabled and MSR[CTUSTART] is 1, then the MCR[PWDN] bit cannot be set. When BCTU Control mode is enabled, the application needs to reset the CTUEN bit before entering Power-Down mode.

After the power-down phase is complete, the process ongoing before the power-down phase must be restarted manually .

NOTE

Resetting the MCR[PWDN] bit and setting the MCR[NSTART] or MCR[JSTART] bit during the same cycle is forbidden.

35.2.5.10 Auto-Clock-Off mode

To reduce power consumption in Idle mode (without going into Power-Down mode), an auto-clock-off feature can be enabled by setting MCR[ACKO]. When enabled, the analog clock is automatically switched off when no operation is ongoing (that is, when no conversion has been programmed).

NOTE

This feature must remain off during calibration.

35.2.5.11 Calibration and Self Test

The ADC is calibrated and tested runtime through the same set of test conversions. The test result is used for computation and stored during the calibration process and only checked in self test. The two modes of running tests are as follows:

1. High-Accuracy mode/Calibration. Needs to be run after power-on reset and whenever required in runtime operation. Calibrates the ADC and updates calibration-related registers.
2. Quick-Check mode/Self-Test. Used for runtime functional self-tests to improve reliability. Catches any runtime fault or accuracy shift from previously calibrated values. Please see the chip-specific configuration information as self-test may not be available in all ADC instances.

The following sections describe both and the steps for executing them.

35.2.5.11.1 Calibration (High Accuracy mode)

The functioning of the analog block of ADC depends on the accuracy of values of its various parts and parameters, such as the value of capacitors, the gain of the amplifier, and so on. Due to variations in manufacturing and various runtime environmental effects, the actual values may differ from the ideal values for which the ADC is targeted.

Because of these deviations, the ADC's converted values contain errors. To eliminate these errors, the ADC must be calibrated prior to any conversion.

In the calibration process, a fixed known reference voltage (VrefH) is sampled many times and converted under various controlled conditions to check for deviations between these converted values and predefined values.

The deviations, known as offsets or modified values, are used to eliminate errors during the data processing of normal conversions.

Note

The ADC must be recalibrated if the operating conditions (particularly VrefH) change significantly. Calibration should also be performed again if the Self-Test indicates that a recalibration is needed.

Recommended settings:

- Clock frequency = 40 MHz
- Averging – Maximum (512)

The calibration process will take ~12ms of time with the above recommended settings.

NOTE

If the ADC clock frequency is > 40MHz during calibration, the accuracy of the calibration process will be compromised, hence the performance of the ADC. Thus, it is strongly recommended to run the calibration with 40 MHz clock.

As calibration is a time consuming process, it can be performed after a long interval – probably several hours of operation – but it is not necessary to recalibrate frequently. The goal is to maximize the possible accuracy delivered from conversion and to catch any structural fault to flag the error.

The calibration routine sets the fail flag (CALBISTREG[TEST_FAIL]) to indicate:

- A fault in ADC
- A premature abort of the calibration

Calibration is aborted if a normal conversion is initiated during calibration; this is called *premature termination*. The terminating conversion and the immediate next one to it will have invalid result in this case.

CALBISTREG[TEST_FAIL] = 1 indicates that the ADC health is not good and that it will not meet specifications.

To execute this routine, follow these steps:

1. Configure the ADC to 40 MHz.
   - Put the ADC in power down mode: set MCR[PWDN]
   - Configure clock divider selection: reset MCR[ADCLKSEL]
   - Power-up the ADC: reset MCR[PWDN]
2. Configure the Calibration, BIST Control, and Status Register (CALBISTREG). The default values are set for maximum accuracy (recommended).
3. Start calibration: set CALBISTREG[TEST_EN].

4. Wait for calibration to complete. Check MSR[ADCSTATUS] or till CALBISTREG[C_T_BUSY] becomes 0.
5. Check the value of MSR[CALIBRTD] to determine whether calibration was successful.
6. If MSR[CALIBRTD] = 1, calibration was successful; otherwise, it failed, and CALBISTREG[TEST_FAIL] = 1.
7. If required, reconfigure the ADC clock frequency for normal operation.

35.2.5.11.2 Self test (Quick-Check/Safety mode)

For devices used for very critical applications requiring high reliability it is important to check at regular intervals if the ADC is functioning correctly. For this purpose, Self Testing feature (Quick Check) has been incorporated inside ADC.

The following testing algorithms are available for checking:

- Supply Self test: algorithm S. It includes the conversion of the supply and VREF voltages. It includes a sequence of three test conversions (steps). The supply test conversions must be an atomic operation (no functional conversions interleaved).
- Capacitive Self test: algorithm C. It includes a sequence of 12 test conversions (steps) to check the capacitive array.

The capacitive test of ADC requires only 12 steps to test itself.

The capacitive array is used as DA converter to generate from V_{REFH} 12 different voltages by distributing and partially discharging portions of the capacity array. These 12 voltages are sampled using some redundant capacities. C algorithm may be compared to providing 12 different voltages to ADC and validate the conversion result.

Two kinds of tests are performed in this mode, as shown in the following table.

Table 35-162. Quick-Check mode tests

STCR3 [ALG]	STCR3 [MSTEP]	Description	Outcome	Comment
00 supply test	0	Supply self-test (Reserved)	Reserved	—
	1	Supply self-test (analog supply)	Measures the analog supply voltage (VDDA) and divides the result by the bandgap voltage (result from Algorithm S step 0). The VDDA conversion result is written to ADC_STDR1[TCDATA]. The final result (after division) consists of an integer portion and a fractional portion, both of which are written to the ADC_STDR2 register.	The least significant 3 bits of the analog supply (VDDA) conversion executed during Algorithm S step 1 processing and written to ADC_STDR1[TCDATA]) are always '0'. The conversion performed in Algorithm S Step 1 is not the full scale analog supply. Instead, the voltage sampled is VDDA / 8. The prescaling is done to avoid issues that can arise in the analog portion of the ADC when VREFH = VDDA = 3.3 V, or VDDA is slightly higher than VREFH. The conversion result is multiplied by 8 within the digital part of the ADC to scale the result to the expected level, which results in the 3 least significant bits having a value of '0'.
	2	Supply self-test (reference voltage high)	Measures the high reference voltage of the ADC	—
01	Reserved	—	—	—
10 capacitive test	0–11	One of the ADC-BIST steps is being run	The difference or error of individual value from the previously calibrated value is being returned (unsigned) as an ADC result that is compared with a programmed value in the analog watchdog register(s) to detect any fault. The difference or error may be caused by any runtime fault, runtime accuracy shift, or device noise.	Ideally, the result value is expected to be 0. If the returned value is higher, this indicates runtime fault or accuracy shift. This indicates that ADC should be recalibrated in High-Accuracy mode to check whether the reported error can be handled by recalibrating or whether permanent damage to ADC has occurred.
11	Supply test followed by Capacitive test in same sequence as shown above	—	—	—

This mode is described in the following sections.

35.2.5.11.2.1 Self test initialization and application information

ADC samples the internal V_{REFH} for the C algorithm and samples different supplies (V_{DD} and V_{REFH}) for the supply algorithm. It also provides signals for the following:

- Scheduling self-testing algorithms using configuration registers
- Monitoring the converted data using analog watchdog registers
- Flagging the error to FCCU in case a failure occurs in any of the algorithms

35.2.5.11.2.2 CPU mode

In this case, the test channel works similarly to a normal conversion. The test channel is enabled by setting STCR2[EN].

Self-test conversions are executed by interleaving the Normal conversions. The sequencing of steps of the selected algorithm for test channel depends on the operating mode of normal conversion, selected by MCR[MODE].

In One-Shot mode, if the test channel is enabled, only one step of the selected self-testing algorithm is executed at the end of the chain. The step number and algorithm to be executed are programmed in the STCR3 register. So, in One-Shot mode, the sequence is as follows:

1. Program NCMR*n* register(s) to select channels to be converted for normal conversion.
2. Modify the Sample period of normal conversion to 20 d cycles, write ADC_CTRx[INPSAMP] = 20 d (for 1 MSPS operation)
3. Program MCR[MODE] = 0 to select One-Shot mode.
4. Program sampling duration for self test conversion in STCR1[INPSAMPx].
5. Select the self-testing algorithm in STCR3[ALG]. The default is algorithm S.
6. Enable the self-testing channel by setting STCR2[EN].
7. Start the normal conversion by setting MCR[NSTART].
8. All normal conversions are executed as usual.
9. At the end of allnormal conversions, the step number programmed in STCR3[MSTEP] of the self-testing algorithm selected by STCR3[ALG] is executed similar to a normal functional channel.
10. On receiving an end-of-conversion for the test channel, the digital result is written in STDR1[TCDATA] andSTDR1[VALID] is set. Also, ISR[EOC], ISR[ECH], and STSR1[ST_EOC] are set. See the register descriptions (Self Test Data Register 1 (ADC_STDR1), Interrupt Status Register (ADC_ISR), and Self Test Status Register 1 (ADC_STSR1)) for details of settings for each test.
11. The state machine returns to the Idle state.

For example: in a device with channels A-B-C-D-E-F-G-H, channels B-D-E are to be converted in One-Shot mode. MODE = 0 is set for One-Shot mode. Refer to Conversion. Conversion for channels B-D-E are done. After channel E test channel conversion is done and ISR[ECH] and ISR[EOC] are set.

MSR[NSTART] is automatically set when the normal conversion starts; it is reset at the end of conversion for the test channel.

In Scan mode, the consecutive steps of the selected self test algorithm are converted continuously at the end of each chain of normal conversions. The number of channels converted at the end of each chain is 1 (except for algorithm S, in which all the steps are performed at once without any functional conversion interleaved). So, in Scan mode the sequence is as follows:

1. Program the NCMR*n* registers to select channels to be converted for normal conversion.
2. Modify the Sample period of normal conversion to 20 d cycles, write ADC_CTRx[INPSAMP] = 20 d (for 1 MSPS operation)
3. Program MCR[MODE] = 1 to select Scan mode.
4. Program sampling duration for self test conversion in STCR1[INPSAMPx].
5. Select the self-testing algorithm in STCR3[ALG]. By default, all algorithms are selected (that is, all algorithms are executed step-by-step one after the other).
6. Enable the self-testing channel by setting STCR2[EN].
7. Start the normal conversion by setting MCR[NSTART].
8. All normal conversions are executed as usual.
9. At the end of chain forthe normal conversions (assuming a default value of STCR3[ALG]), all steps of algorithm S are performed (as algorithm S is always atomic). MSR[SELF_TEST_S] is set.
10. At the end of conversion of test channel for the last step of algorithm S, the digital result is written in STDR1[TCDATA] and STDR1[VALID] is set. At the same time, MSR[SELF_TEST_S] is reset. For step 1, the integral part and fractional part are written in STDR2[IDATA] and STDR2[FDATA]. Also, ISR[EOC], ISR[ECH], and STSR2[ST_EOC] are set.
11. The next normal conversion chain starts.
12. At the end of the normal conversion chain, Step0 of the C algorithm is executed.
13. At the end of conversion of test channel for Step0 of the C algorithm, the digital result is stored in STDR1[TCDATA] and STDR1[VALID] is set (if MCR[OVERWR] is set). Also, ISR[EOC], ISR[ECH], andSTSR2[ST_EOC] are set.
14. The next normal conversion chain starts.
15. At the end of the normal conversion chain, step1 of C algorithm is executed.
16. This process continues for all steps of all algorithms.
17. The state machine returns to the Idle state when MCR[NSTART] is written to 0.

NOTE

- Instead of starting a normal conversion with software (by setting MCR[NSTART]), if it is started by external trigger, the test channel behavior remains the same.
- Test channel conversion is not performed during injected conversions. It is performed only during normal conversions.
- If, during a test channel conversion, injection conversion arrives, then the test channel is aborted (just as a normal functional channel) and injected conversions are done. After injected conversions are completed, the test channel resumes from the step at which it was aborted. In this case, MSR.SELF_TEST_S remains high during the injected conversion.
- For self testing, MCR[MODE]should be programmed at least one cycle *before* setting MCR[NSTART]. It should not be changed thereafter until a conversion is ongoing.

35.2.5.11.2.3 Abort and Abort Chain for self-test channel

Setting MCR[ABORT] during self-test channel has no effect.

In One-Shot mode, if MCR[ABORTCHAIN] is set when the test channel conversion is ongoing, the test channel is aborted and ECH is set. In this case, EOC for the test channel is not generated.

In Scan mode, if MCR[ABORTCHAIN] is set when test channel STEP N is ongoing, then the test channel STEP N is aborted and the next chain conversion starts. At the end of this chain, STEP N conversion is performed again. (If algorithm S is ongoing, the full algorithm is executed again.)

35.2.5.11.2.4 Self-test analog watchdog

ADCD also provides a monitor for the values returned by the ADC analog macro for self-test algorithms. The analog watchdogs are used to determine whether the result of conversion for self-test algorithms lie in a particular guard area. For this purpose, separate Self-Test Analog Watchdog Registers are provided for each algorithm.

If the analog watchdog feature is enabled (STAWxR[AWDE] = 1), a comparison is performed between the converted value and the threshold values after the conversion of each step of an algorithm. If the converted value does not lie between the upper and

lower threshold values specified by the Analog Watchdog Register of the particular algorithm, the corresponding error bit (STSR1[ERR_x]) is set and the step number during which the error occurred is updated in STSR1[STEP_x] (in case of the C algorithm) and erroneous data is written in STSR4[DATAx]. STSR1[ERR_x] generates an interrupt if enabled by the corresponding mask bit in STCR2. The fault indication is also given to the FCCU via the Critical and Non-Critical fault lines, so that necessary action can be taken at chip level.

The analog watchdog feature works differently in the case of algorithm S. As already mentioned, algorithm S is always an atomic operation. So, separate error bits are provided in STSR1 for each step of algorithm S to avoid an overwrite in case an error occurs in more than one step. Hence, there are separate mask bits for each step in STCR1. For the same reason, separate fields in the status registers (STSR2 and STSR3) exist to store erroneous data for each step.

In step 1 of supply algorithm, ADC measures the Analog supply (Vdda) for the ADC, and then a fixed point division is performed with the result of step 1 (ADC supply voltage) and step 0 (band gap voltage). It takes around 26 cycles after EOC for step 1 to get a divided value, and it is the divided value on which analog watchdog checks are applied. So, the value to be compared for step 1 contains the integer as well as fractional part; two registers (STAW1AR and STAW1BR) are provided for this. The comparison is done first for the integer part using the threshold values programmed in STAW1AR. If the integer part lies in the range, the fractional part comparison is skipped; otherwise, it is compared with the values programmed in STAW1BR. The following table summarizes this feature for step 1.

Table 35-163. Algorithm S (step 1) threshold comparison

STDR2[IDATA] (integer part)	STDR2[FDATA] (fractional part)	STSR1[ERR_S1]
> STAW1AR[THRH]	Any value	Set
< STAW1AR[THRL]	Any value	Set
== STAW1AR[THRH]	> STAW1BR.THRH	Set
== STAW1AR[THRL]	< STAW1BR.THRL	Set

In step 2 of supply algorithm, ADC measures the High Reference voltage (Vrh); (VREF/ VREF) is measured in order to check the integrity of sampling signal. For this particular conversion, no higher threshold value is required as the ideal value is 0xFFF. Only the lower threshold value is programmed in STAW2R.

In the supply self-test algorithm, the band gap is measured with regard to the reference voltage (Vrh) in step 0. The result is capable of catching mismatches between them. Step 1 measures the supply with regard to reference (Vrh), and the result is taken to do a ratio

(Vdda/Vbg). If the band gap voltage remains within +/-1.25% of its ideal value of 1.2 V, then by setting appropriate values of THRH and THRL in watchdog registers, the ADC self-test can catch more than 4% variation in supply and reference faithfully.

Algorithm C has total 12 steps. Output data of step 0 is compared with the threshold values stored in STAW4R, if enabled in the same register. The result of step 0 is used as an offset for rest of the steps (step 1 to 11). The absolute difference between the converted data of each of the steps (1 to 11) with the data of step 0 are compared with the threshold values of STAW5R, if enabled in STAW4R. Error in any step is indicated by STSR1[ERR_C] and the data in error case is captured in STSR4.

Calculation of Threshold values:

S1 Algorithm: Calculated voltage comparison method:

The user software can implement a method of calculating S1 algorithm IDATA, FDATA, the THRH values, and the THRL values to voltages and then perform a comparison of the calculated voltage to the calculated THRH voltage and calculated THRL voltage.

The steps involved in this method are as follows:

1. Calculate the high threshold voltage:

   (STAW1AR [THRH] + (STAW1BR [THRH] / 4096)) * Vbandgap

2. Calculate the low threshold voltage:

   (STAW1AR [THRL] + (STAW1BR [THRL] / 4096)) * Vbandgap

3. Calculate the converted results to voltage:

   (STDR2 [IDATA] + (STDR2 [FDATA] / 4096)) * Vbandgap

4. Compare result from step 3 to THRH and THRL.S1 algorithm passes

   If (low threshold voltage <= converted voltage <= high threshold voltage).

35.2.5.11.2.5 Watchdog timer

The watchdog timer is an additional check that monitors the sequence of the self-testing algorithm implemented and checks that the algorithm completes within a safe time period. Each algorithm has a different watchdog timer that runs independently of the other. The watchdog timer for a particular algorithm can be enabled by setting STAWxR[WDTE]. The safe time value can be programmed in STBRR[WDT] (the default value is 10 ms, assuming an 80 MHz clock).

The safe time is measured starting from step 0 of the algorithm (including all normal chain conversions in between) to the point at which step 0 of the same algorithm starts again.

The sequence is as follows:

1. Program NCMR0 to select channels to be converted for normal conversion in Scan mode (MODE = 1).
2. Modify the Sample period of normal conversion to 20 d cycles, write ADC_CTRx[INPSAMP] = 20 d (14 h) (for 1 MSPS operation)
3. Select the self-testing algorithm in STCR3[ALG]. By default, all algorithms are selected; that is, all algorithms will be executed step-by-step, one after the other.
4. Enable the self-testing channel by setting STCR2[EN].
5. Program the safe period value in STBRR[WDT].
6. Enable the watchdog timer by setting STAWxR[WDTE]. Assume the setting of WDTE to be t0. (It is important to do all the programming first and to then enable WDTE as the safe time check is also performed between the setting of WDTE and the start of step 0 to check that algorithm has started within the safe time).
7. Start the normal conversion by setting MCR[NSTART].
8. After first chain conversion ends, step 0 of algorithm S is executed. Lets assume the start of STEP0 to be t1.
9. Step 1 and step 2 of algorithm S are executed.
10. The next chain conversions are performed.
11. When chain conversion completes, step 0 of C algorithm is performed.
12. After each chain conversion, a consecutive step of the C algorithm is performed. A similar sequence follows for algorithm C.
13. After the last step of the C algorithm is performed, another chain conversion is executed. At the end of this chain conversion, step 0 of algorithm S starts, repeating the whole sequence. Let's assume this time (starting of step 0) to be t2.
14. For algorithm S, if (t1 – t0) > Safe Period, or if (t2 – t1) > Safe Period, then the watchdog timer flags an error and STSR1[WDTERR] is set. A critical fault is asserted and an interrupt is also generated if enabled by STCR2[MSKWDTERR]. Otherwise, the watchdog timer counter is reset and starts again to monitor the same for the next sequence.
15. A similar sequence is followed for watchdog timers for algorithm C.

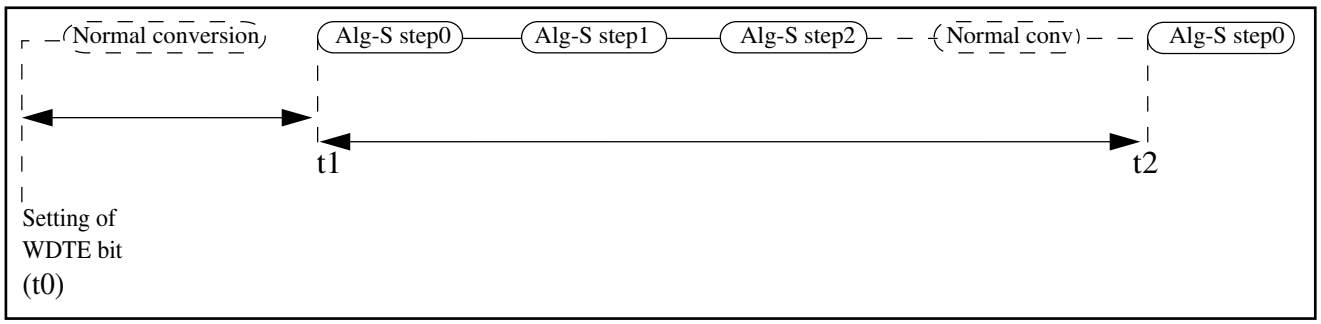

Figure 35-162. Watchdog timer monitor for algorithm S

Notes:

- Take care not to enable the watchdog timer for an algorithm that is not to be executed.

35.2.5.11.2.5.1 Watchdog sequence checking

The watchdog timer also incorporates sequence checking features that check the order of a particular algorithm's steps. If the steps are not in order, then an error is flagged by setting the STSR1[WDSERR]. A critical fault is asserted and an interrupt is also generated if enabled by STCR2[MSKWDSERR].

A watchdog sequence error is flagged in the following cases:

- If the steps of any algorithm are not executed in the proper order.
- If an abort chain occurs during a test channel conversion, that step has to be repeated at the end of the next chain. This will give a sequence error as soon as test channel conversion starts again.
  - Exception: If an abort chain occurs during the last step of algorithm S, then sequence errors are not flagged as the whole algorithm has to be repeated again.

If injected conversion occurs during the test channel, watchdog sequence errors are *not* flagged a lthough the ongoing step number is aborted and repeated again.

Note

The watchdog timer feature is applicable only for Scan mode, not for One-Shot mode.

35.2.5.11.2.6 Baud rate control for test channel

It defines the scheduling of the test channel between normal conversions. The scheduling rate is specified by STBRR[BR].

By default, if the test channel is enabled, one step of the selected algorithm is executed after every chain of normal conversion. The bandwidth consumed by the test channel depends on the number of channels in a normal chain. For example, if there are 100 normal conversions in a chain, then the test channel consumes only 1% of the total bandwidth, which is very small. However, if the number decreases to just four channels, then the bandwidth consumed by the test channel is 25%, which is significant (and may not be desirable as it slows down the normal conversion rate).

STBRR[BR] provides flexibility by scheduling the test channel conversion to be performed, not at the end of every chain, but at the end of BR + 1 number of chains. For example, if BR = 5, a single step of the selected algorithm for the test channel is performed after six chain conversions, then the next step is performed at end of the next six chain conversions, and so on. By default, the value of BR is 0.

Notes:

- This feature is applicable only for Scan mode, not for One-Shot mode. STBRR[BR] should be set to 0 for one shot mode.
- To use the baud rate feature in Scan mode, the NCMR register should have nonzero value.

35.2.5.11.2.6.1 Abort chain when baud rate is non-zero

As previously described, a nonzero value of STBRR[BR] means that the test channel conversion is performed at the end of BR + 1 number of chains. If an abort chain occurs during the chain in which the test channel is scheduled to be converted, then the test channel is converted after the next BR + 1 number of chains.

For example, if STBRR[BR] is programmed to 2, the sequence will be two normal chains (without any test channel conversion) followed by a chain with the test channel converted at the end. Now, if an abort chain occurs during first two chains it is treated as a normal chain abort and the test channel is converted at the end of the third chain only (as the case without any abort chain). But if the abort chain occurs during the third chain in which the test channel is scheduled to be converted, then the test channel is converted after next three chains (that is, at the end of sixth chain, counting from the beginning).

35.2.5.12 Conversion time

Total conversion time depends on ADC-SAR controller's operating clock. This clock can be prescaled to bus clock ÷ 2. The ADC-SAR operating clock (SAR_CLK) is always synchronous with bus clock. The frequency of SAR_CLK is dependent on settings of ADC_MCR[ADCLKSEL].

If ADC_MCR[ADCLKSEL] = 0, then SAR_CLK = (bus clock ÷ 2)

If ADC_MCR[ADCLKSEL] = 1, then SAR_CLK = bus clock

The various components of conversion time and affecting configurations are shown and described in Figure 35-163.

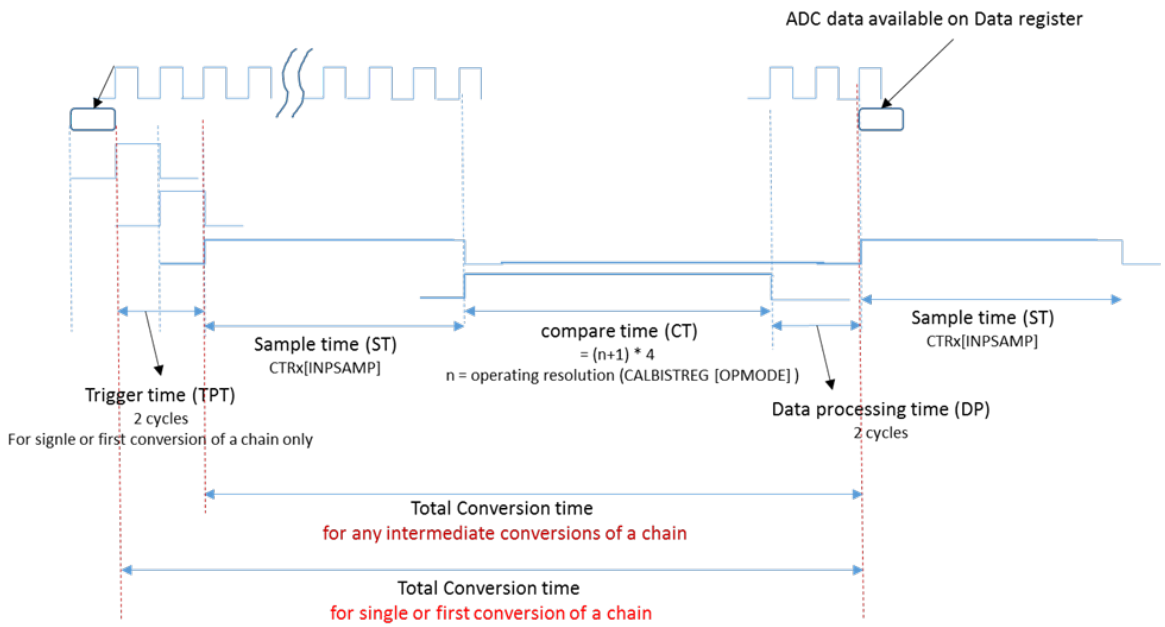

Figure 35-163. Conversion time

- Trigger processing time (TPT):
  To prepare the channel and start the operation, two clock cycles of bus clock is required by the ADC for the first conversion and for subsequent conversions in a chain, or for a continuous conversion, this time is not required as it is hidden in the pipeline operation. Triggers from Synchronous CTU interface requires two cycle of bus clock for first conversion and for back-to-back CTU conversions it takes only one cycle for trigger processing as the other cycle is hidden in pipeline operation. Triggers from Asynchronous CTU interface requires three cycles of bus clock for synchronization and processing.
- Sample phase time (ST):
  Sample time duration is controlled by the INPSAMP[7:0] field of Conversion timing Registers ADC_CTR*x* (*x* = 0...2) for different types of channels. Value in each register affects the sample time in similar way. The value in the register represents units of cycle of the SAR_CLK. The minium value of sample time is 8. If the value programmed is less than 8, then it has no effect on sample time duration and in this case sample time will be 8 SAR_CLK cycles.
- Compare phase time (CT):

The compare phase of the ADC dependends on the resolution setting (which is 13 for this chip), and takes ((13 + 1) × 4) cycles of SAR_CLK.

- Data processing time (DP):

  The ADC takes 2 cycles of SAR_CLK to post process and load the data int registers.
- Total Conversion Time:

  The total time required for single or first conversion is [TPT+ST+CT+DP] cycles of AD_clk and for subsequent conversion is a chain or continuous conversion is [ST+CT+DP] cycles of AD_clk.

  Examples:

  - CTR*x*[INPSAMP] = 20d; software/hardware triggered (NSTART):
    - Single/First Conversion: 2 + 20 + ((13 + 1) × 4) + 2 = 2 + 20 + 56 + 2 = 80 cycles of SAR_CLK
    - Subsequent/continuous conversion: 20 + ((13 + 1) × 4) + 2 = 20 + 56 + 2 = 78 cycles of SAR_CLK
  - CTR*x*[INPSAMP] = 20d; CTU triggered:
    - Single/First Conversion: 2 + 20 + ((13 + 1) × 4) + 2 = 2 + 20 + 56 + 2 = 80 cycles of SAR_CLK
    - Subsequent/continuous conversion: 1 + 20 + ((13 + 1) × 4) + 2 = 1 + 20 + 56 + 2 = 79 cycles of SAR_CLK
- Pre-Sampling:

  When pre-sampling is enabled, the ADC does pre-sampling prior to starting the actual channel sampling as described in pre-sampling section. This phase takes CTR*x*[INPSAMP] cycles of SAR_CLK. Additionally, to switch from pre-sample phase to actual channel sampling phase, it takes another two cycles of SAR_CLK. So, total CTR*x*[INPSAMP] + 2 cycles additionally required for a conversion to be completed. Thus, in case of pre-sample, all the equations and examples above are valid with the addition of (CTR*x*[INPSAMP] + 2) cycles.

35.2.5.12.1 Conversion time for BCTU interface

The BCTU can work in a different clock domain, and for this there is an asynchronous domain crossing that occurs before the CTU trigger is processed. Data is also processed after domain crossing. These times need to be considered in the conversion time calculation. The synchronization may take a maximum of two additional ADC clock cycles and three BCTU clock cycles over normal conversion time.

The total conversion time taking BCTU timing into consideration is as follows:

Total conversion time = Synchronization time + TPT + ST + CT + DP + Reverse synchronization time in BCTU

The figure below shows the different components of total conversion time.

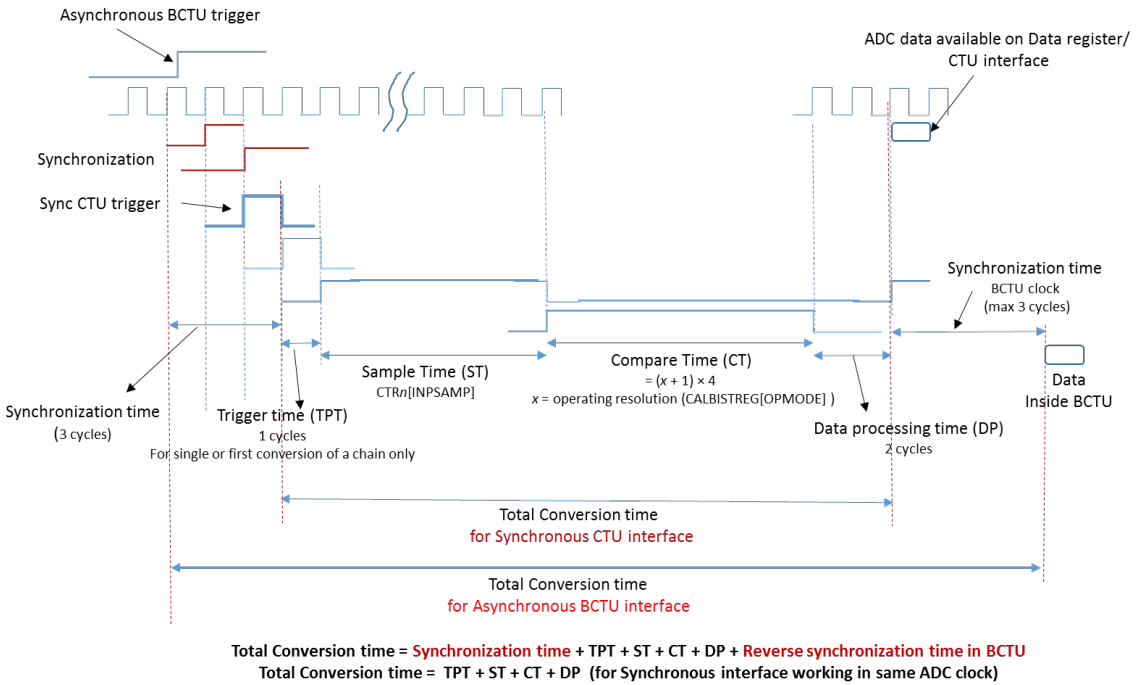

Figure 35-164. Normal Conversion time from BCTU (asynchronous, not working in ADC clock)

35.2.5.13 Conversion data processing

The raw converted ADC data contains many types of errors such as offset, gain, DC bias, and so on. Thus, to generate error-free results, raw converted data is processed before it is written to a result register. The process of error correction goes bit-by-bit during conversion with the values generated during the offset calculation and calibration process. This helps in reducing final data processing time as only one addition/addition (2's complement) is performed parallely with conversion.

35.2.6 Clock frequency

The ADC internal blocks are designed to work with an 80 MHz clock. Thus, the specified speed can be met with this clock frequency. If the clock is faster than this, ADCA cannot work properly and the ADC may malfunction. If the clock is slower, then the ADC speed

will be lower, but it will work properly. It should be noted that there is an absolute maximum value of the sampling time that the analog portion of the ADC can support. For slower clocks, the sampling clock count will need to be programmed accordingly.

Chapter 36
Decimation Filter (DECFILTER)

36.1 Decimation Filter chip-specific module information

The device has two instances of the Decimation Filter.

- The Decimations are used for digital signal processing on the SAR and SD ADC conversion results.
- Two Decimation Filters can be used in cascaded mode.
- There is no direct hardware interface from the SAR and Sigma-Delta ADCs to the Decimation Filters on the device.
- Transfer of ADC conversion results to the Decimation Filters for application processing is handled entirely by the DMA and CPU.
- All interrupts are connected to the Interrupt Controller according to Interrupt sources.
- Similarly all DMA requests are connected to appropriate DMA channel muxes according to DMA request mapping.

36.2 Introduction

This chapter describes the Decimation Filter block.

36.2.1 Overview

The decimation filter is a dedicated hardware block, designed to decimate fixed point sample conversion results. An interface is provided for use by the CPU, allowing setup of the filter parameters and read/write of the configuration registers and filter samples.

The Decimation Filter receives data samples from the master blocks (CPU) in the RX sub-block. Each sample arrives at the decimation filter with an identifier tag and associated commands. The input information is decoded by the RX and control logic sub-blocks. When receiving a filtering command, the data is transferred to the filter tap register's sub-block and is processed by the filter using the MAC (Multiply and

Accumulate) unit, the coefficient register, and the control logic sub-blocks. The result is then returned to the master block by the TX sub-block, accompanied by the corresponding tag information that provides an address for the data.

The decimation filter functions in a standalone mode. In this mode, the input data is supplied and the output results are read by the chip core processor (CPU) using status and interrupt signals or DMA requests.

An integrator unit independently accumulates the values of filter outputs. The integration can be restricted to time windows defined by hardware signals or software.

Two or more decimation filter blocks can also be configured to work in the cascade mode of operation to obtain a more complex filtering function. The output result of a filter block is connected to the input of the next filter by means of a dedicated interface.

All signals in the interface are generated in the system clock domain.

Figure 36-1 shows the block diagram for the decimation filter.

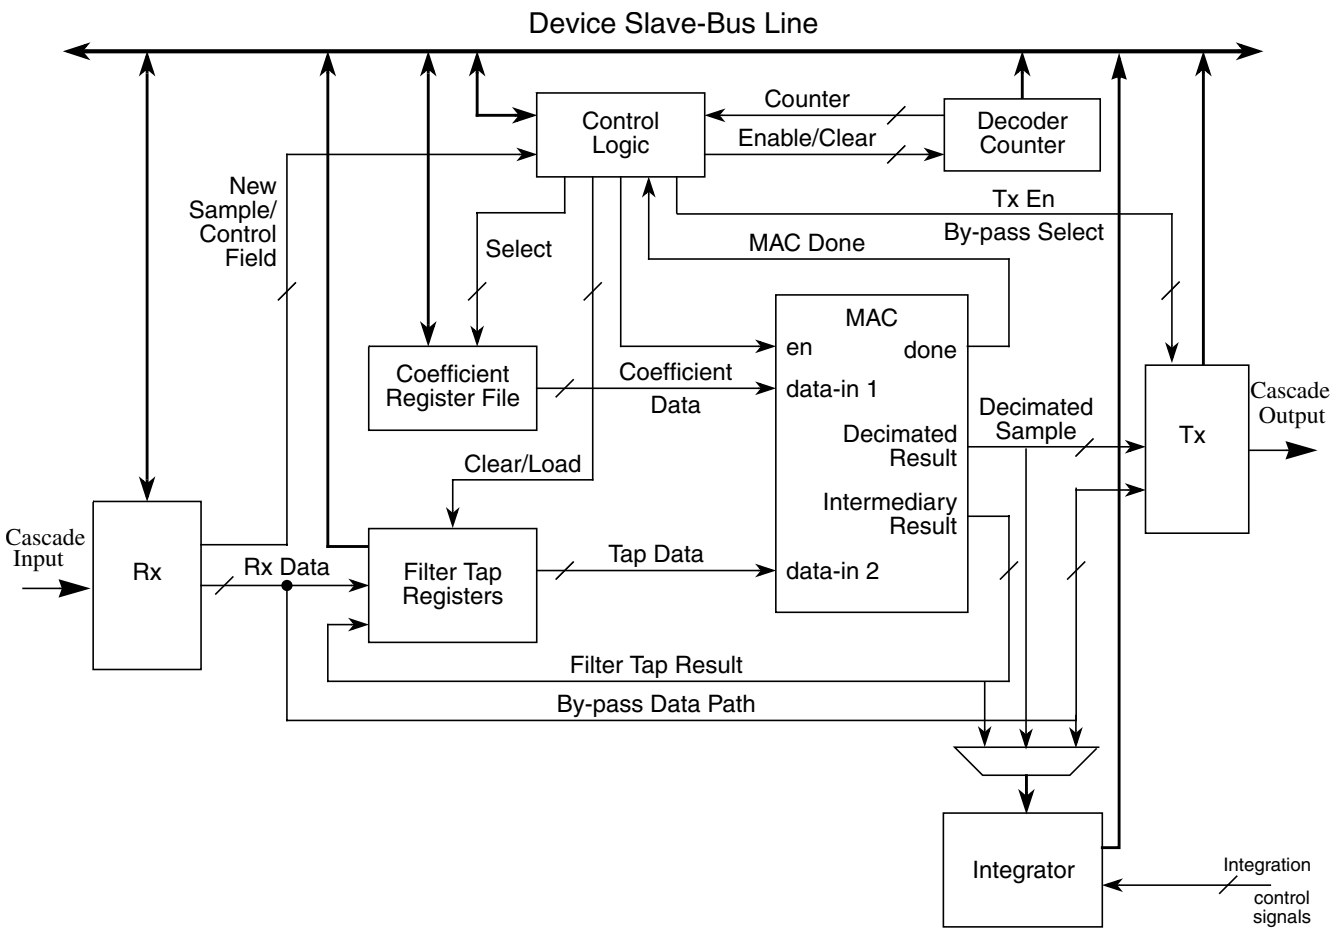

Figure 36-1. Decimation Filter Block Diagram

36.2.2 Features

The Decimation Filter block includes these distinctive features:

- Selectable 4th order IIR filter, or an 8th order FIR filter
  - Input/output with 16-bit (fixed point) two's complement signed values
  - Internal taps with 16-bit (feed-forward portion of first IIR) and 24-bit (feedback portion) resolutions (fixed point) for two's complement signed value
  - 24-bit programmable filter coefficients (fixed point) for two's complement signed value
  - MAC unit with 51-bit fixed point accumulator
  - Convergent rounding methodology
  - Two's complement overflow or saturation selection
  - 58 clock cycles to process the input
- Input and output buffers with DMA capability
- Slave-bus interface to device
- Filter taps access for debug
- Filter initialization (flush) and stabilization (prefill) commands
- Decimation controlled by an internal counter
- Integrator unit accumulates filter output values, signaled or absolute, with 32-bit resolution. The integrator can be controlled by software or hardware signals.
- Cascade of two or more individual blocks to compose a more complex filter.

36.2.3 Modes of operation

This section describes the operation modes of the Decimation Filter. The modes are selected using the following DECFILTER_MCR register fields: MDIS, FREN, FRZ, ISEL,, and CASCD (see Module Configuration Register (DECFILTER_MCR)).

The mode selection is summarized in the following table.

Table 36-1. Operation Mode Selection

Mode	MDIS	FREN, FRZ	ISEL	CASCD
Standalone	0	(0, 0)	1	00
Cascade		or (0, 1) or (1, 0)	0 or 1	01 or 10 or 11
Freeze[1]		1, 1	X	X
Low Power	1	X	X	X
Reserved	All other combinations			

1. Freeze mode can also be activated from outside the Decimation Filter if FREN=1.

36.2.3.1 Standalone mode

Data is provided by the central processor using the device slave-bus interface or DMA interface signals. Once the data is filtered the decimated result is available in the Output Buffer register. The filter output is also consumed by a CPU or DMA mastering the same device slave-bus interface. This operation mode can be used to debug the filter stability or to decimate data in System RAM.

36.2.3.2 Cascade mode

Cascade mode is a filter structure mode with two or more individual filter blocks connected in a chain to form a more complex filter function. The output result of the first block (head block) is connected to the input of the next block (middle or tail block) to be filtered again. More details in Cascade mode description.

36.2.3.3 Low Power mode

Low power mode corresponds to the module disable mode or stop mode. In the module disable mode the filter input is disabled and it is not possible to enter Freeze mode. The system clock is stopped. In stop mode, the system clock is also stopped.

36.2.3.4 Freeze mode

Freeze mode is also known as debug mode. All filter action is frozen, either through software or by the hardware SoC debug request signal. If a freeze request comes when the filter is processing an input, it enters freeze mode only after the processing finishes.

36.3 External signal description

Note

The Decimation Filter does not provide metastability protection or filtering for these signals.

36.3.1 Integrator enable signal

The integrator enable signal is used to enable the hardware integrator. For more details, see Integrator Enabling and Halting.

36.3.2 Integrator halt signal

The integrator halt signal is used to halt the hardware integrator. For more details, see Integrator Enabling and Halting.

36.3.3 Integrator reset signal

The integrator reset signal is used to reset the hardware integrator. For more details, see Integrator Reset.

36.3.4 Integrator output request signal

The integrator output request signal is used to update the integrator output result. For more details, see Integrator Outputs.

36.4 Memory map and register definition

This section provides the memory maps and detailed descriptions of all registers. Accesses to reserved areas of the memory map can return a bus error.

This module communicates with the slave-bus line that is related to the device integration.

The addresses of the Decimation Filter registers are specified as offsets from the module's base address, described in the following table. The registers allocated in this memory map are sufficient for a 4th order IIR filter implementation.

All registers are 32-bit wide.

NOTE

Reserved fields in the registers should not be written.

DECFILTER memory map

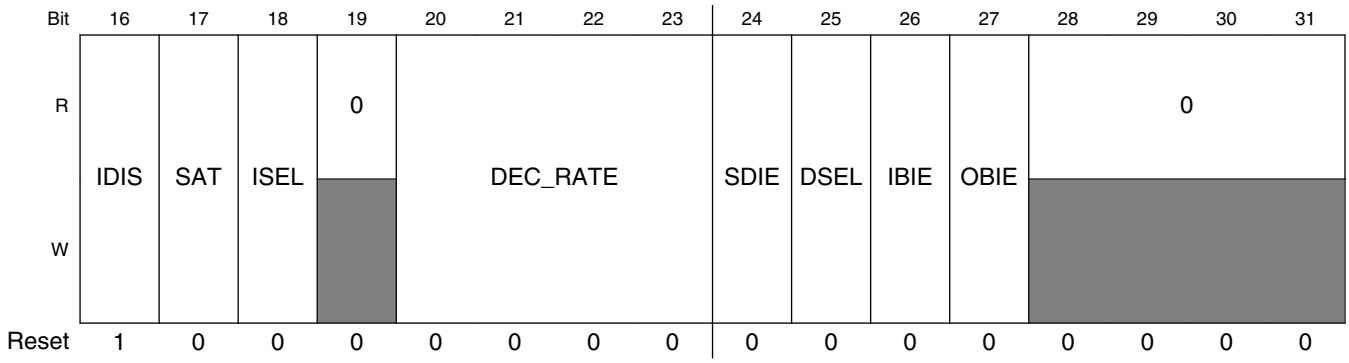
36.4.1 Module Configuration Register (DECFILTER_MCR)



The Decimation Filter module configuration register provides configuration control bits for the Decimation Filter internal logic.

NOTE

One must not modify this register contents when the status bit BSY is set, except for fields FREN, FRZ, and IDIS. To guarantee that BSY does not set during the read-modify-write operation, set IDIS=1 and wait for BSY=0 beforehand.

DECFILTER_MCR field descriptions

Field	Description
0 MDIS	Module Disable The MDIS bit puts the Decimation Filter in low power mode. Writes to the configuration register are allowed with the exception of writes to the FREN and SRES bits, which are ignored. Writes to the Coefficient registers are also allowed. The Decimation Filter cannot enter Freeze mode once in disable mode. Once the module is disabled it no longer receives the system clock. 0 Normal Mode 1 Low Power Mode
1 FREN	Freeze Enable The FREN bit enables the Decimation Filter to enter freeze mode if the SoC debug request signal or the FRZ bit is asserted. See Freeze Mode Description for more details. 0 Decimation Filter Freeze mode disabled 1 Decimation Filter Freeze mode enabled
2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3 FRZ	Freeze Mode The FRZ bit controls the freeze mode of the Decimation Filter. For this bit to take effect the FREN freeze enable bit also needs to be asserted. While in freeze mode the MAC operations are halted. See Freeze Mode Description for more details. 0 Decimation Filter in Normal Mode 1 Decimation Filter in Freeze Mode
4 SRES	Software-reset bit The SRES is a self-negated bit which provides the CPU with the capability to initialize the Decimation Filter through the slave-bus interface. This bit always reads as zero. See Soft-Reset Command Description for more details. 0 No action 1 Software-Reset
5–6 CASCD	Cascade Mode Configuration The CASCD[1:0] bit field configures the block to work in cascade mode of operation. For more details about the cascade mode, see Cascade mode description.

Table continues on the next page...

DECFILTER_MCR field descriptions (continued)

Field	Description
	NOTE: Any change to this field must follow the procedure described in Cascade Freeze, Stop, and Configuration Change Procedures. 00 No cascade mode (single block) 01 Cascade Mode, Head block config. 10 Cascade Mode, Tail block config. 11 Cascade Mode, Middle block config.
7 IDEN	Input Data Interrupt Enable The IDEN bit enables the Decimation Filter to generate interrupt requests on all new input data written to the Interface Input Buffer register or Input/Output Buffers register. 0 Input Data Interrupt Disabled 1 Input Data Interrupt Enabled
8 ODEN	Output Data Interrupt Enable The ODEN bit enables the Decimation Filter to generate interrupt requests on all new data written to the filter Output buffer. It is independent of how ISEL is set. 0 Output Data Interrupt Disabled 1 Output Data Interrupt Enabled
9 ERREN	Error Interrupt Enable The ERREN bit enables the Decimation Filter to generate interrupt requests based on the assertion of the DECFILTER_MSR register error flags OVF, DIVR, SVR, OVR, or IVR. 0 Error Interrupts Disabled 1 Error Interrupts Enabled
10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11–12 FTYPE	Filter Type Selection bits The FTYPE[1:0] bits select the filter type. **NOTE:** Bypass must not be configured in cascade mode (see field CASCD). 00 Filter Bypass In Bypass configuration the filter is disabled. 01 IIR Filter - 1 x 4th order 10 FIR Filter - 1 x 8th order 11 reserved
13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14–15 SCAL	Filter Scaling Factor The SCAL[1:0] bit field selects the scaling factor used by the filter algorithm. 00 Scaling Factor = 1 01 Scaling Factor = 4 10 Scaling Factor = 8 11 Scaling Factor = 16

Table continues on the next page...

DECFILTER_MCR field descriptions (continued)

Field	Description
16 IDIS	Input Disable The IDIS bit disables the block input, so that writes to the input buffer have no effect (from the device slave-bus), and input DMA or interrupt requests are not issued. Input disabling is needed to change the block configuration to or from cascade mode. **NOTE:** IDIS resets in 1 (hardware reset only), and the module configuration procedures for previous versions (without IDIS bit) are upward compatible provided that the DECFILTER_MCR register is written with 0 into the IDIS position (previously reserved). 0 Input enabled 1 Input disabled
17 SAT	Saturation Enable The SAT bit enables the saturation of the filter output. See Saturation for more details. 0 Disables Saturation 1 Enable Saturation
18 ISEL	Input Selection The ISEL bit selects the source of input data to the Filter. The data source is the CPU/DMA on the device slave-bus interface. Each device slave-bus write to the Interface Input Buffer register or DMA transfer to the input buffer is interpreted as a new sample to be processed by the filter. 0 Reserved 1 Filter input from the device slave-bus interface
19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20–23 DEC_RATE	Decimation Rate Selection The DEC_RATE[3:0] field selects the decimation rate used by the Decimation Filter. The decimation rate defines the number of data samples from the master block that is required to generate one decimated result in the Decimation Filter output. 0000 No Decimation: one filter output for each sample input 0001 - 1111 One filter output for each (DEC_RATE+1) sample inputs
24 SDIE	Integrator Data Interrupt Enable The SDIE field enables output buffer interrupts due to integrator data result being ready (at registers DECFILTER_FINTVAL and DECFILTER_FINTCNT): 0 Integration ready does not cause an output interrupt. 1 Integration ready causes an output interrupt
25 DSEL	DMA Selection The DSEL bit determines whether the data transfers — to the input buffer (write to) and from the output buffer (read from) — are performed by DMA requests or by interrupt requests. 0 Interrupt requests are generated 1 DMA requests are generated
26 IBIE	Input Buffer Interrupt Request Enable The IBIE bit enables the Decimation Filter to generate interrupt requests when:

Table continues on the next page...

DECFILTER_MCR field descriptions (continued)

Field	Description
	• deviceslave-bus input is selected (ISEL=1) and DSEL=0 when the input buffer is available to receive new data; 0 Input Buffer Interrupt Request Disabled 1 Input Buffer Interrupt Request Enabled
27 OBIE	Output Buffer Interrupt Request Enable The OBIE bit enables the Decimation Filter interrupt requests when outputs are directed to the device slave-bus and DMA is not selected (DSEL=0). 0 Output Buffer Interrupt Request Disabled 1 Output Buffer Interrupt Request Enabled
28–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

36.4.2 Module Status Register (DECFILTER_MSR)

Address: 0h base + 4h offset = 4h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	BSY	0	DEC_COUNTER				0	0	0	0	0	0	0	0	0	0
W							IDFC	ODFC		IBIC	OBIC			OVFC	OVRC	IVRC
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0						IDF	ODF	0	IBIF	OBIF	0	0	OVF	OVR	IVR
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DECFILTER_MSR field descriptions

Field	Description
0 BSY	Decimation Filter Busy indication

Table continues on the next page...

DECFILTER_MSR field descriptions (continued)

Field	Description
	The BSY bit indicates that the Decimation Filter is processing new input data from the master block in normal mode or from the device core in standalone mode. BSY is not asserted when the filter is disabled (FTYPE = 00). However, the BSY bit is asserted when the soft reset is executed. 0 Decimation Filter Idle 1 Decimation Filter Busy
1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2–5 DEC_COUNTER	Decimation Counter The DEC_COUNTER[3:0] field indicates the current value of the DEC_COUNTER Decimation Counter (see Figure 36-1), which counts the number of input data samples received by the Decimation Filter. When the value of this counter matches the DEC_RATE[3:0] Configuration Register field, one decimated result is generated and the DEC_COUNTER counter is re-initialized at zero. This register is cleared by a soft reset or a flush command.
6 IDFC	Input Data Flag Clear bit The IDFC bit clears the IDF Flag bit in the Status Register. This bit is self negated, therefore it is always read as zero. 0 No action 1 Clears IDF
7 ODFC	Output Data Flag Clear bit The ODFC bit clears the ODF Flag bit in the Status Register. This bit is self negated, therefore it is always read as zero. 0 No action 1 Clears ODF
8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
9 IBIC	Input Buffer Interrupt Request Clear bit The IBIC bit clears the IBIF Flag bit in the Status Register. This bit is self negated, therefore it is always read as zero. 0 No action 1 Clears IBIF
10 OBIC	Output Buffer Interrupt Request Clear bit The OBIC bit clears the OBIF Flag bit in the Status Register. This bit is self negated, therefore it is always read as zero. 0 No action 1 Clears OBIF
11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13 OVFC	OVF Clear bit

Table continues on the next page...

DECFILTER_MSR field descriptions (continued)

Field	Description
	The OVFC bit clears the OVF Output Overflow bit in the Status Register. This bit is self negated, therefore it is always read as zero. 0 No action 1 Clears OVF
14 OVRC	OVR Clear bit The OVRC bit clears the OVR Output Overrun bit in the Status Register. This bit is self negated, therefore it is always read as zero. 0 No action 1 Clears OVR
15 IVRC	IVR Clear bit The IVRC bit clears the IVR Filter Input Overrun indication bit in the Status Register. This bit is self negated, therefore it is always read as zero. 0 No action 1 Clears IVR
16–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22 IDF	Input Data Flag The IDF bit flag indicates when new data is available at the DECFILTER_IB register or at the PSI bus data, input and output. This flag generates an Interrupt Request if enabled by the IDEN bit in the Configuration Register. This Flag is cleared by the IDFC Status bit or by a soft reset of the decimation filter. **NOTE:** OBS: This flag is not used for read / write requests. It is used only to announce the input data event. For read / write request flag, refer to IBIF. 0 Sample not received 1 New Sample received
23 ODF	Output Data Flag The ODF bit flag indicates when a new decimated sample is available at the DECFILTER_OB register or at the PSI bus data, input and output. This flag generates an Interrupt Request if enabled by the ODEN bit in the Configuration Register. This Flag is cleared by the ODFC Status bit or by a soft reset of the decimation filter. **NOTE:** OBS: This flag is not used for read requests. It is used only to announce the output data event. For read request flag, refer to OBIF. 0 No new Decimated Output Sample available 1 New Decimated Output Sample available
24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25 IBIF	Input Buffer Interrupt Request Flag The IBIF bit flag indicates that the input buffer DECFILTER_IB is available to be filled with new data. IBIF assertion also asserts the interrupt signal when enabled by the IBIE bit in the Configuration Register when DMA is not selected (DSEL=0). This Flag is cleared by the IBIC Status bit or by a soft reset of the decimation filter.

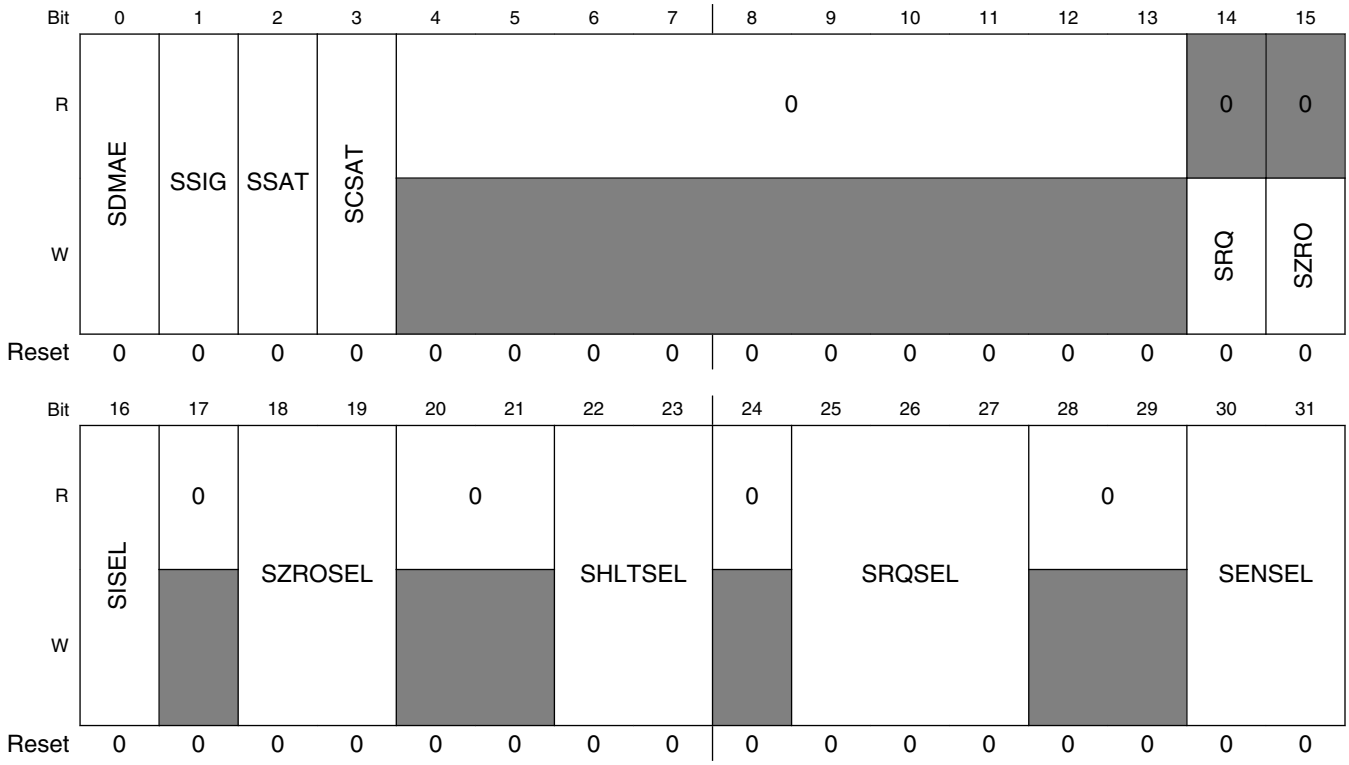

Table continues on the next page...

DECFILTER_MSR field descriptions (continued)

Field	Description
	0 No action 1 New Sample is requested.
26 OBIF	Output Buffer Interrupt Request Flag The OBIF bit flag indicates that a new decimated sample is available at the DECFILTER_OB register. This flag generates an Interrupt Request if enabled by the OBIE bit in the Configuration Register and with DSEL=0. This Flag is cleared by the OBIC Status bit or by a soft reset of the decimation filter. 0 No new Decimated Output available 1 New Decimated Output available
27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29 OVF	Filter Overflow Flag The OVF bit indicates that an overflow occurred in the filtered sample result. This flag generates an Interrupt Request if enabled by the ERREN bit in the Configuration Register. This Flag is cleared by the OVFC Status bit or by a soft reset of the decimation filter. 0 No overflow 1 Overflow occurred
30 OVR	Output Interface Buffer Overrun The OVR bit indicates that a decimated sample was overwritten by a new sample in the Interface Output Buffer Register. This flag generates an Interrupt Request if enabled by the ERREN bit in the Configuration Register. This Flag is cleared by the OVRC Status bit or by a soft reset of the decimation filter. 0 No Output Overrun 1 Filter Output Overrun occurred
31 IVR	Input Interface Buffer Overrun The IVR bit indicates that a received sample in the Filter Interface Input Register was overwritten by a new sample. This was probably caused by a violation of the Decimation Filter maximum throughput. This flag generates an Interrupt Request if enabled by the ERREN bit in the Configuration Register. This Flag is cleared by the IVRC Status bit or by a soft reset of the decimation filter. **NOTE:** IVR does not set due to input register writes when input is disabled (DECFILTER_MCR bit IDIS=1). 0 Input Buffer Overrun did not occur 1 Input Buffer Overrun occurred

36.4.3 Module Extended Config Register (DECFILTER_MXCR)

Address: 0h base + 8h offset = 8h

DECFILTER_MXCR field descriptions

Field	Description
0 SDMAE	Integrator DMA Enable The SDMAE bit enables the DMA request when an integrator output is requested (see Integrator Outputs). **NOTE:** The DMA channel used is the same one used for filter outputs, and any configuration that generates DMA requests from both of those sources is not allowed. 0 integrator DMA request disabled 1 integrator DMA request enabled
1 SSIG	Integrator Signal operation selection The SSIG bit defines how the filtered data signal is treated for integration: 0 integrator input takes the absolute value of filter output 1 integrator input takes signaled filter output
2 SSAT	Integrator Saturated operation selection The SSAT bit defines how the integrator accumulator behaves in case of an overflow.

Table continues on the next page...

DECFILTER_MXCR field descriptions (continued)

Field	Description
	NOTE: In saturated operation the overflown integration sum holds the value 0xFFFFFFFF for absolute integration (SSIG=0), or values 0x7FFFFFFF (positive saturation) and 0x80000000 (negative saturation) for signaled integration (SSIG=1). **NOTE:** Non-saturated mode is not supported with signaled integration, therefore one must not configure SSIG=1 and SSAT=0. 0 integrator accumulator holds a modulo 2^{17} value (considering the 15-bit fractional part) on an overflow. 1 integrator accumulator saturates on an overflow
3 SCSAT	Integrator Counter Saturated operation selection The SCSAT bit defines how the integrator sample counter behaves in case of an overflow. 0 integrator sample counter holds a modulo 2^{32} value on an overflow. 1 integrator sample counter saturates on an overflow, holding a value of 0xFFFFFFFF.
4–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14 SRQ	Integrator Output Request The SRQ bit is used to command the update of the integrator output, reflected in the registers DECFILTER_FINTVAL and DECFILTER_FINTCNT. It may also cause a DMAor interrupt request, depending on the DECFILTER_MCR bit SDIE and DECFILTER_MXCR bit SDMAE. This is a write-only bit, so reads always return 0. For more details see Integrator Reset. 0 no integrator output update request 1 requests integrator output update
15 SZRO	Integrator Zero The SZRO bit is used to zero the integrator sum. This is a write-only bit, reads always return 0. For more details see Integrator Reset. **NOTE:** If bits SRQ and SZRO are both written 1 at the same time, the integrator is reset only after the registers DECFILTER_FINTVAL and DECFILTER_FINTCNT are updated. 0 does not zero integrator sum 1 zeroes integrator sum
16 SISEL	Integrator Input Selection The SISEL bit selects the input of the integrator. For more details see Integrator Inputs. 0 decimated filter outputs feed the integrator 1 filter outputs before the decimation feed the integrator
17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
18–19 SZROSEL	Integrator Zero Control Mode Selection The SZROSEL field defines the use of the integrator zero hardware input signal. For more details see Integrator Reset. 00 hardware integrator zero request disabled 01 integrator zero on toggle of hardware signal 10 integrator zero on rising edge of hardware signal 11 integrator zero on falling edge of hardware signal

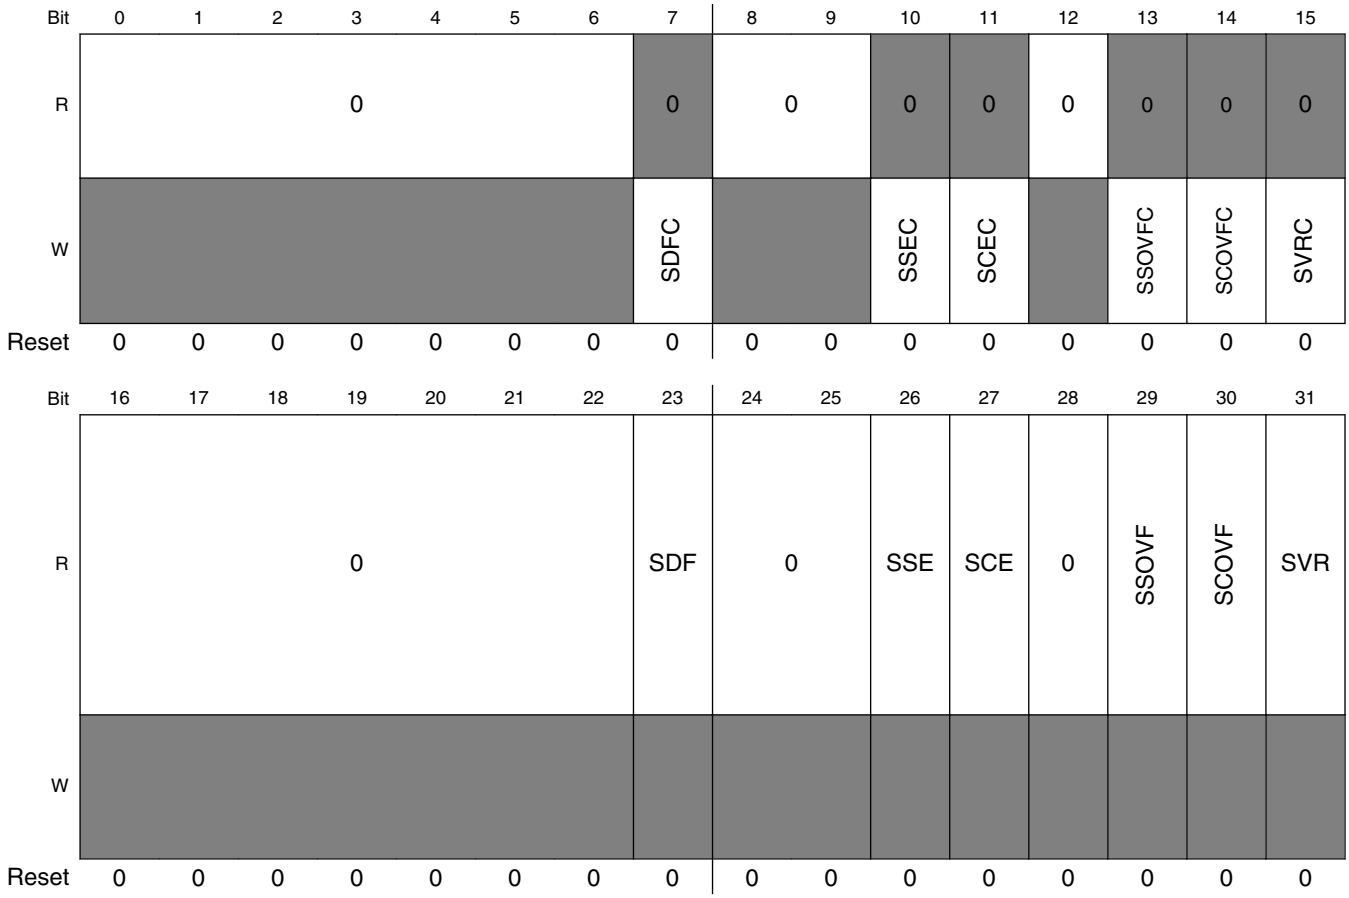

Table continues on the next page...

DECFILTER_MXCR field descriptions (continued)

Field	Description
20–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22–23 SHLTSEL	Integrator Halt Control Selection The SHLTSEL field defines the integrator halting mechanism. When the integrator is halted, the integration accumulator remains unaltered on filter outputs independently of the enabling selected by SENSEL. For more details see Integrator Enabling and Halting. 00 hardware halt control signal disabled 01 integrator halted, independently of the hardware signal 10 integrator halted when signal is at logical 0 11 integrator halted when signal is at logical 1
24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25–27 SRQSEL	Integrator Output Read Request Mode Selection The SRQSEL field defines the use of the integrator output request hardware input signal. An integrator output request updates the registers DECFILTER_FINTVAL and DECFILTER_FINTCNT, also causing a DMA or interrupt request. Note that DMA or interrupt requests due to integrator output updates depend on the DECFILTER_MXCR bit SDMAE and DECFILTER_MCR bit SDIE. When continuous output is on, an integrator output request is issued whenever a new filter output is accumulated. For more details see Integrator Outputs. 000 hardware output request disabled 001 integrator output request on toggle of hardware signal 010 integrator output request on rising edge of hardware signal 011 integrator output request on falling edge of hardware signal 100 reserved 101 continuous output request on, independently of hardware signal 110 continuous output request on when signal is at logical 0 111 continuous output request on when signal is at logical 1
28–29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30–31 SENSEL	Integrator Enable Control Selection The SENSEL field defines the integrator enabling mechanism. When the integrator is enabled, filter outputs selected by the SISEL bit are added to the integration accumulator. When the integrator is disabled, the integration accumulator remains unaltered on filter outputs. For more details see Integrator Enabling and Halting. 00 integrator disabled, independently of the hardware enable control signal 01 integrator enabled, independently of the hardware signal 10 integrator enabled when signal is at logical 0 11 integrator enabled when signal is at logical 1

36.4.4 Module Extended Status Register (DECFILTER_MXSR)

Address: 0h base + Ch offset = Ch

DECFILTER_MXSR field descriptions

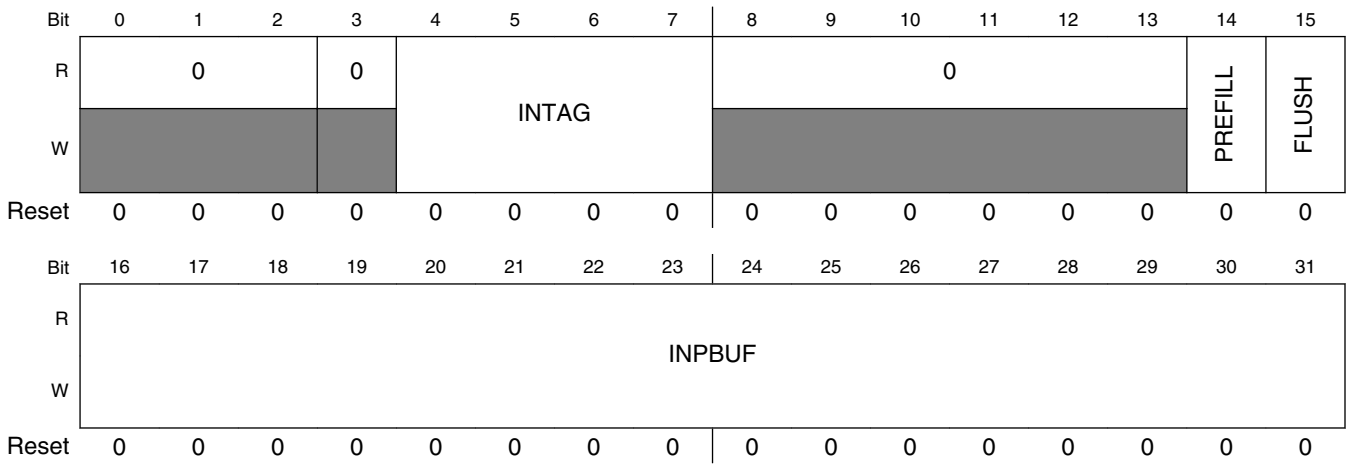
Field	Description
0–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 SDFC	Integrator Output Data Flag Clear bit The SDFC bit clears the SDF Flag bit in the Status Register. This bit is self negated, therefore it is always read as zero. 0 No action 1 Clears SDF
8–9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
10 SSEC	Integrator Sum Exception Clear bit The SSEC bit clears the SSE flag bit in the Status Register. This bit is self negated, therefore it is always read as zero.

Table continues on the next page...

DECFILTER_MXSR field descriptions (continued)

Field	Description
	0 No action 1 Clears SSE
11 SCEC	Integrator Count Exception Clear bit The SCEC bit clears the SCE flag bit in the Status Register. This bit is self negated, therefore it is always read as zero. 0 No action 1 Clears SCE
12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13 SSOVFC	Integrator Sum Overflow Clear bit The SSOVFC bit clears the SSOVF Flag bit in the Status Register. This bit is self negated, therefore it is always read as zero. 0 No action 1 Clears SSOVF
14 SCOVFC	Integrator Count Overflow Clear bit The SCOVFC bit clears the SCOVF Flag bit in the Status Register. This bit is self negated, therefore it is always read as zero. 0 No action 1 Clears SCOVF
15 SVRC	SVR Clear bit The SVRC bit clears the SVR Integrator Data Overrun indication bit in the Status Register. This bit is self negated, therefore it is always read as zero. 0 No action 1 Clears SVR
16–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23 SDF	Integrator Data Flag The SDF bit flag indicates when a new integrator result is available at the DECFILTER_FINTVAL register. This flag generates an Interrupt Request if enabled by the SDIE bit in the Configuration Register. This flag is cleared by the SDFC Status bit or by a soft reset of the decimation filter. 0 no new integrator result available 1 new integrator result available
24–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26 SSE	Integrator Sum Exception flag The SSE bit indicates an exceptional condition of the integrator accumulator. This flag generates an Interrupt Request if enabled by the DECFILTER_MCR bit ERREN, and it is cleared by the SSEC bit or by a soft reset. Integrator exceptions are defined in section“Integrator Exceptions”.

Table continues on the next page...



DECFILTER_MXSR field descriptions (continued)

Field	Description
	0 No exception in the integrator accumulator. 1 Integrator accumulator exception.
27 SCE	Integrator Count Exception flag The SCE bit indicates an exceptional condition of the integrator counter. This flag generates an Interrupt Request if enabled by the DECFILTER_MCR bit ERREN, and it is cleared by the SCEC bit or by a soft reset. Integrator exceptions are defined in section“Integrator Exceptions”. 0 No exception in the integrator counter. 1 Integrator counter exception.
28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29 SSOVF	Integrator Sum Overflow Flag The SSOVF bit indicates an overflow of the integrator accumulator. This flag is cleared by the SSOVFC bit or by a soft reset. **NOTE:** The SSOVF bit samples the integrator accumulator overflow condition when and only when either registers DECFILTER_FINTVAL or DECFILTER_CINTCNT are updated. Therefore, only one of the register pairs (DECFILTER_FINTVAL/DECFILTER_FINTCNT and DECFILTER_CINTVAL/ DECFILTER_CINTCNT) must be used by the application, in order to avoid races. 0 No overflow in the integrator accumulator. 1 Integrator accumulator overflown.
30 SCOVF	Integrator Count Overflow Flag The SCOVF bit flag indicates an overflow of the internal integrated sample counter. This flag is cleared by the SCOVFC bit or by a soft reset. **NOTE:** The SCOVF bit samples the integrator accumulator overflow condition when and only when either registers DECFILTER_FINTVAL or DECFILTER_CINTCNT are updated. Therefore, only one of the register pairs (DECFILTER_FINTVAL/DECFILTER_FINTCNT and DECFILTER_CINTVAL/ DECFILTER_CINTCNT) must be used by the application, in order to avoid races. 0 No overflow in the integrator sample counter. 1 Integrator sample counter overflown.
31 SVR	Integrator Data Overrun The SVR bit indicates that an integration value and count in the registers DECFILTER_FINTVAL and DECFILTER_FINTCNT was overwritten by a new integrator output request and was not read by the CPU or DMA. This flag generates an Interrupt Request if enabled by the ERREN bit in the Configuration Register. This Flag is cleared by the SVRC bit or by a soft reset. 0 Integrator Data Overrun did not occur. 1 Integrator Data Overrun occurred.

36.4.5 Interface Input Buffer (DECFILTER_IB)

The Input Buffer Register provides access to the Input buffer of the decimation filter when the filter is in the standalone mode of operation. Writes to this register are interpreted as requests to the Decimation Filter to process new sample data.

Address: 0h base + 10h offset = 10h

DECFILTER_IB field descriptions

Field	Description
0–2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4–7 INTAG	Decimation filter input tag bits The INTAG[3:0] bit field is defined as a selector signal and it is used to identify different destinations for the INPBUF[15:0] data.
8–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14 PREFILL	Decimation Filter Prefill/Filter control bit The PREFILL bit selects the Decimation Filter operation mode. For more details, see Filter Prefill Control Description 0 Decimation Filter normal sample 1 Decimation Filter prefill sample
15 FLUSH	Decimation Filter Flush control bit Assertion of the FLUSH bit initializes the Decimation Filter to a initial state, as defined in Flush Command Description. This bit is self negated and it is cleared only when the data is read and the flush is executed.

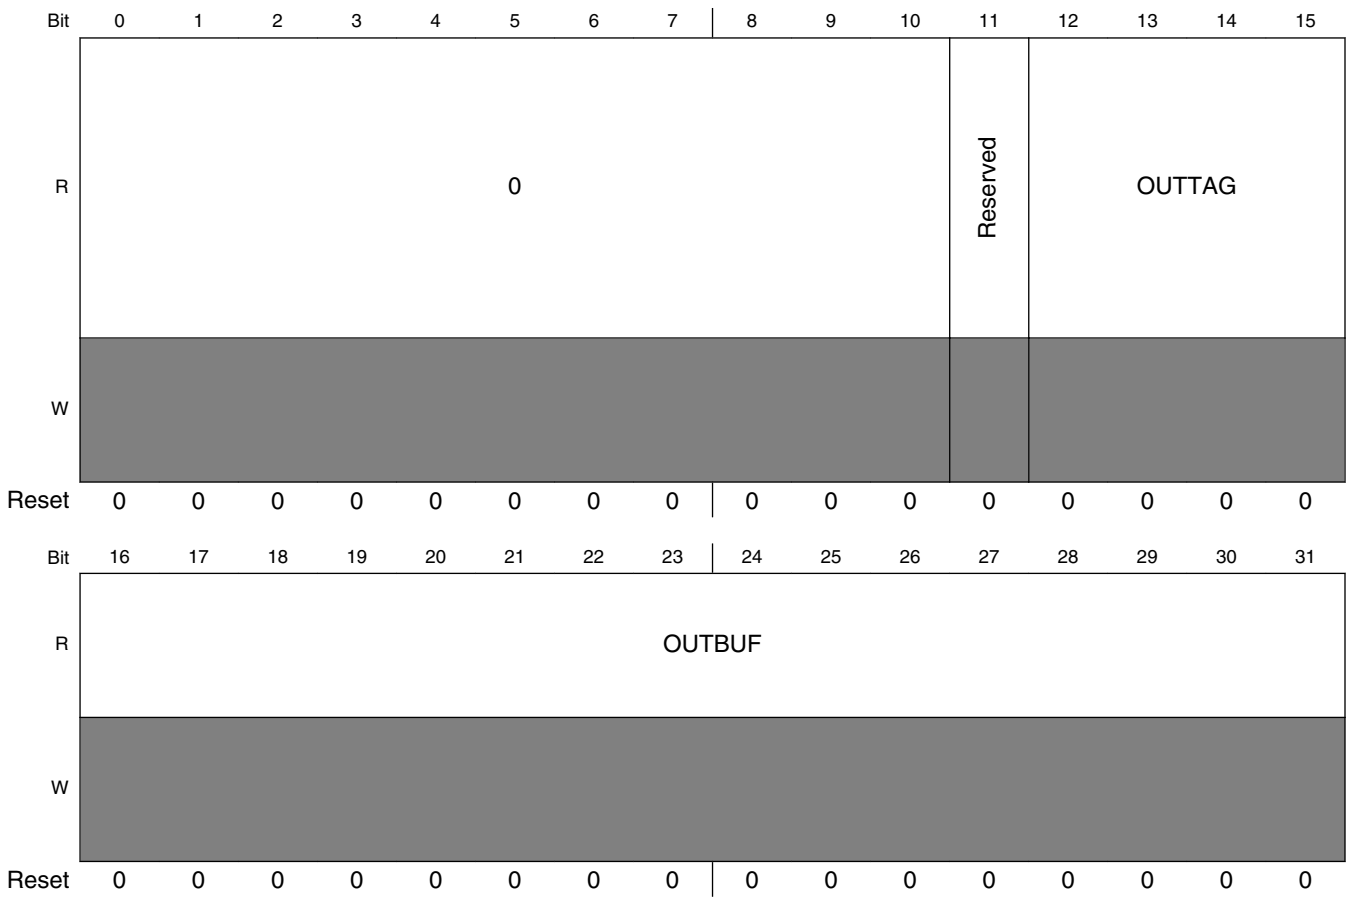


Table continues on the next page...

DECFILTER_IB field descriptions (continued)

Field	Description
	0 no flush request 1 flush request
16–31 INPBUF	Input Buffer Data The INPBUF[15:0] bit field carries the sample data to be filtered. See Input Buffer Description for more details.

36.4.6 Interface Output Buffer (DECFILTER_OB)

Address: 0h base + 14h offset = 14h

DECFILTER_OB field descriptions

Field	Description
0–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11 Reserved	This field is reserved.

Table continues on the next page...

DECFILTER_OB field descriptions (continued)

Field	Description
12–15 OUTTAG	Decimation filter output tag bits The OUTTAG[3:0] bit field is defined as a selector signal and it is used to identify different destinations for the OUTBUF[15:0] data.
16–31 OUTBUF	Output Buffer Data The OUTPBUF[15:0] bit field is the result data in the decimation filter Output Buffer. It represents a fixed point signed number in two's complement format and is updated only when a decimated result is ready to be transmitted, meaning it contains the last decimated result from the filter.

36.4.7 Filter Coefficient (DECFILTER_COEF*n*)

Address: 0h base + 20h offset + (4d × i), where i=0d to 8d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	COEFnSIGNR								COEFn																							
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DECFILTER_COEF*n* field descriptions

Field	Description
0–7 COEFnSIGNR	COEFn sign repeated Bit COEFn[23] is repeated 8 times.
8–31 COEFn	Coefficient n field The COEFn[23:0] bit fields are the digital filter coefficients registers. The coefficients are fractional signed values in two's complement format, in the range (Coef is greater than or equal to -1 and less than 1). **NOTE:** Reads to this register are sign-extended, meaning the coefficient's sign bit is copied to all 8 most significant register bits. **NOTE:** Writing to these fields when BSY=1 is not allowed.

36.4.8 Filter TAP (DECFILTER_TAP*n*)

The TAP register stores, on each filter node, the input sample data and, for the IIR type, the filter intermediary results.

Address: 0h base + 78h offset + (4d × i), where i=0d to 7d

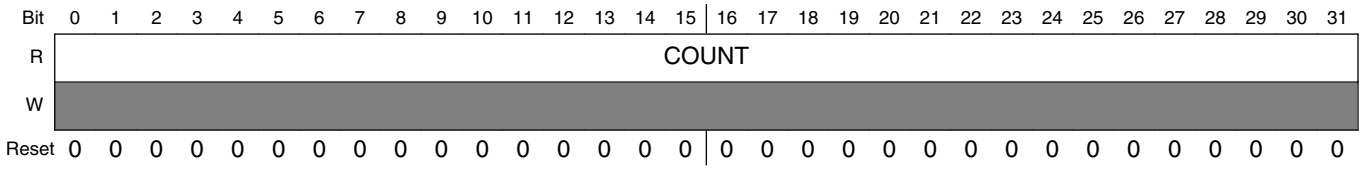
Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	TAPnSIGNR								TAPn																							
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DECFILTER_TAP*n* field descriptions

Field	Description
0–7 TAPnSIGNR	TAPn sign repeated Bit TAPn[23] is repeated 8 times.
8–31 TAPn	TAPn Register The read-only TAPn[23:0] bit fields shows the contents of the digital filter tap registers, as fractional signed values in two's complement format, in the range (Coef is greater than or equal to -1 and less than 1). **NOTE:** Reads to this register are sign-extended, meaning the coefficient's sign bit is copied to all 8 most significant register bits. The content of these registers is meaningless when BSY=1.

36.4.9 Final Integer Value Register (DECFILTER_FINTVAL)

Address: 0h base + E0h offset = E0h



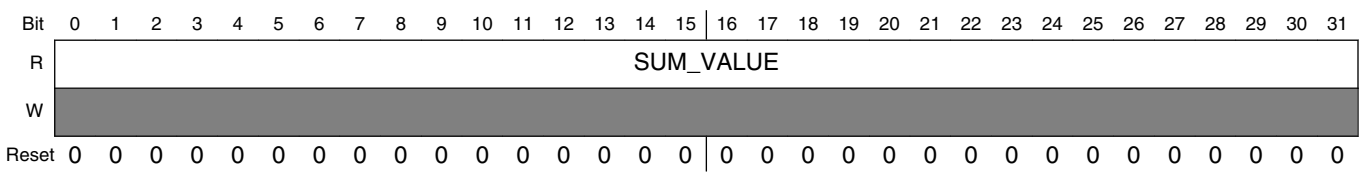
Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	SUM_VALUE																															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DECFILTER_FINTVAL field descriptions

Field	Description
0–31 SUM_VALUE	Integration Sum Value The SUM_VALUE[31:0] field holds the sum of filtered output values. The 17 most significant bits hold the integer part, and the 15 least significant ones the fractional part of the integration value. The control of the integration sum and update of this register is determined by the register DECFILTER_MXCR. The register is updated only upon an integration output request. SUM_VALUE should be taken as an unsigned number when the integrator is configured for absolute operation (DECFILTER_MXCR bit SSIG=0), and a two's complement signed number otherwise. **NOTE:** If the DEFILTER_MXCR bit SSAT=1, the integration sum is saturated, so that if the accumulation overflows DECFILTER_FINTVAL holds the value 0xFFFFFFFF for absolute integration (SSIG=0), or values 0x7FFFFFFF (positive saturation) and 0x80000000 (negative saturation) for signaled integration (SSIG=1). If SSAT=0, DECFILTER_FINTVAL holds the integration sum modulo 2^{17} (considering the 15-bit fractional part).

36.4.10 Final Integer Count Register (DECFILTER_FINTCNT)

Address: 0h base + E4h offset = E4h



DECFILTER_FINTCNT field descriptions

Field	Description
0–31 COUNT	Integration Count Value The COUNT field holds the count of filtered outputs integrated. The control of the integration sum and update of this register is determined by the register DECFILTER_MXCR. The register is updated together with DECFILTER_FINTVAL, only upon an integration output request.

36.4.11 Current Integer Value Register (DECFILTER_CINTVAL)

Address: 0h base + E8h offset = E8h

DECFILTER_CINTVAL field descriptions

Field	Description
0–31 SUM_VALUE	Integration Sum Value The SUM_VALUE[31:0] field holds an unsigned number representing the sum of filtered output values, continuously updated as the integration proceeds. The control of the integration sum is determined by the register DECFILTER_MXCR. **NOTE:** If the DEFILTER_MXCR bit SSAT=1, the integration sum is saturated, so that if the accumulation overflows DECFILTER_CINTVAL holds the value 0xFFFFFFFF for absolute integration (SSIG=0), or values 0x7FFFFFFF (positive saturation) and 0x80000000 (negative saturation) for signaled integration (SSIG=1). If SSAT=0, DECFILTER_FINTVAL holds the integration sum modulo 2^{17} (considering the 15-bit fractional part). **NOTE:** A read on this register automatically commands an update of the register DECFILTER_CINTCNT.

36.4.12 Current Integer Count Register (DECFILTER_CINTCNT)

Address: 0h base + ECh offset = ECh

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	COUNT																															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DECFILTER_CINTCNT field descriptions

Field	Description
0–31 COUNT	Integration Count Value The COUNT field holds the count of filtered outputs integrated. The value is updated only when register DECFILTER_CINTVAL is read, to keep the coherency between the integration and count values.

36.5 Functional Description

36.5.1 Overview

Figure 36-1 shows the block diagram of the Decimation Filter. The Control Logic provides the control signals for all other sub-modules. The data interface is sub-divided into two sub-modules, transmitter and receiver, that are accessed by slave-bus interfaces. The bypass path is used when the filter is disabled and the incoming data can be transmitted back to the master block without being processed by the Filter algorithm. The Filter hardware is implemented in such a way that an IIR (1 x 4 poles) or FIR filter type can be implemented. The selection between the two types of filter algorithms is implemented by the Control Logic sub-block.

The Coefficient register file provides the digital filter coefficients. This block is a register bank with read/write access by the deviceslave-bus interface. The Filter TAP registers are also accessed through the device slave-bus line interface, providing additional debug capabilities to the Decimation Filter block. The MAC (Multiply Accumulate) sub-block executes the filter arithmetic operations controlled by the Control Logic. The MAC results are routed to the Filter TAP registers and to the output buffer when the result is a decimated filter sample.

36.5.2 Data Interface sub-block description

This section describes the operation of the data interface sub-block which is responsible for communication and data exchange between the slave-bus and the Decimation Filter block. It is important to note that there are only one internal input buffer and only one internal output buffer.

The decimation filter receives sample data from the memory . The input data bus format is presented in Interface Input Buffer (DECFILTER_IB). The sample data arrives along with the control bits. These control bits are decoded and the proper action is decided in the Control Logic sub-block. When the decimation filter finishes its processing and a result is available, the read request signal is issued to the selected master block. This data transfer request remains set until the result is read by the master block.

36.5.3 Input Buffer Description

The decimation filter receives data samples for filtering from the CPU using the device slave bus interface. The data source is selected by the ISEL bit (ISEL=1) of the module configuration register DECFILTER_MCR.

When the device slave bus interface is selected and DMA operation is chosen (DECFILTER_MCR bit DSEL=1), the input data request signal is asserted when the input buffer is empty. When DMA operation is not chosen (DSEL=0) in standalone, the logic asserts an input interrupt request and the input buffer waits for data from the device slave bus interface.

Input buffer filling is flagged by the DECFILTER_MSR bit IDF. The IDF flag remains set, even after the input data has been consumed and the buffer is free, until it is cleared by software.

Input buffer overrun is detected and flagged by the DECFILTER_MSR bit IVR. The idle (BSY=0) Decimation Filter is able to receive two consecutive input writes without input overrun. For more details, see Input Buffer Overrun.

Soft reset clears the input buffer indication flags and any data write/read request that was generated in any mode.

36.5.3.1 Input Buffer Overrun

An input overrun occurs when the input buffer is holding input data and new data is received by the filter. See Input Buffer Description for details of the input buffer.

The input buffer overrun can occur only when the input is enabled (DECFILTER_MCR bit IDIS=0).

36.5.4 Output Buffer Description

The decimation filter has an output buffer to send filtering results to the CPU using the device slave-bus, as selected through the DECFILTER_MCR bits ISEL.

Filtering of prefill inputs do not update the output buffer, so the flag ODF is not set.

When in filter operation mode with input from the device slave-bus (ISEL=1), only sample data is processed by the filter. When the filter result from the MAC is ready, this is immediately written to the output buffer when the decimation count is reached. The flag ODF is set when the buffer is updated. It also generates a DMA read request if DSEL=1 in standalone mode.

When the filter is bypassed (FTYPE=00), and the device slave-bus is selected as output (standalone mode), the data written into the input buffer is immediately written into the output buffer. The flag ODF is set when the buffer is updated and a DMA read request is asserted if DSEL=1.

Soft reset clears the output buffer, as well as any data read request generated in any mode.

36.5.4.1 Output Buffer Overrun

An output overrun occurs when the output buffer is holding output data that has not been read is overwritten with another word of data.

Output overruns are flagged by the DECFILTER_MSR bit OVR, if the output buffer is updated when not empty. The output buffer empty condition depends on the mode and output selection as follows:

- If cascade mode is selected, the output buffer is considered empty if the last output request was acknowledged.
- If the device slave-bus is selected (standalone mode) for output and DMA is selected (DSEL=1), the output buffer is considered empty if the last output has been read.
- If the device slave-bus is selected (standalone mode) for output and DMA is not selected (DSEL=0), the output buffer is considered empty when the ODF flag is negated.

Note

When the device slave-bus is selected (standalone mode) for output and DMA is not selected (DSEL=0), the ODF flag must be cleared to avoid overrun, even if its corresponding interrupt is not used (ODEN=0).

Prefill inputs do not cause IIR or FIR output overrun in standalone, and cascade tail mode, but can cause overruns in cascade head or middle configurations (see Cascade mode).

When bypass is selected, the output overrun does not occur because the data written into the input buffer is written into the output buffer only when this buffer is empty, but an input overrun may still occur (see Input Buffer Overrun).

36.5.5 Bypass Configuration Description

Bypass operation is configured by setting the field FTYPE[1:0] of module configuration register DECFILTER_MCR to 00. In this case, the input sample and tag are sent to the output with no change. This behavior is independent of the ISEL setting. The following applies to the bypass configuration:

- flush is ignored
- prefill is ignored
- counted decimation is ignored
- BSY bit is not set
- the input and output flags are set

Note

Bypass must not be configured in cascade mode (see Cascade mode description).

36.5.6 IIR and FIR Filter

This section describes the IIR filters implemented in the Decimation Filter block. Figure 36-31 shows the filters functional diagrams. The figure shows a IIR filter of fourth order (4poles). The filter topology, not the hardware, is represented. The hardware implementation is based on a MAC unit controlled by an FSM which implements the filter algorithm.

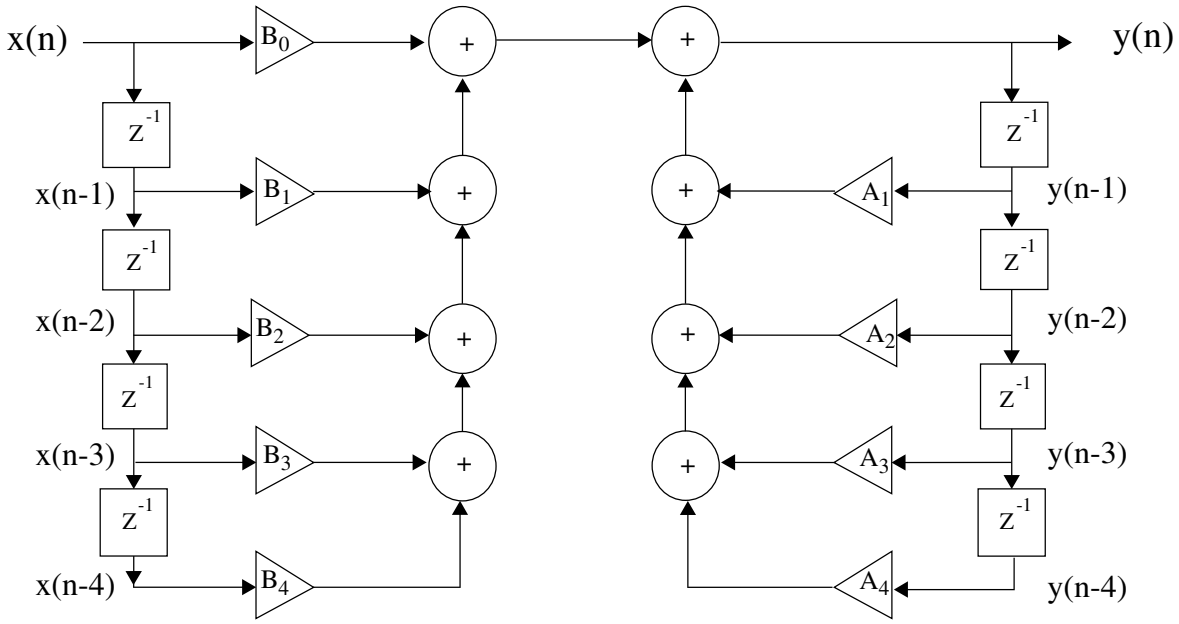


Figure 36-31. 1 x 4 Poles IIR Filter Functional Diagram

The difference equation for the IIR filter of Figure 36-31 can be written as:

$$y(n) = \sum_{i=0}^{N} B_i x(n-i) + \sum_{j=1}^{M} A_j y(n-j)$$

Figure 36-32. Eqn-1

where $x(n)$ is the filter input at time n, $y(n)$ is the filter output at time n, N is the number of feed-forward filter coefficients minus one, B_i are the feed-forward filter coefficients, M is the number of feed-back filter coefficients, and A_j are the feedback filter coefficients.

Figure 36-32 can be written as:

$$y(n) = S\left\{\sum_{i=0}^{N} \frac{B_i}{S} x(n-i) + \sum_{j=1}^{M} \frac{A_j}{S} y(n-j)\right\}$$

Figure 36-33. Eqn-2

Where all the coefficients are scaled down by S. The block diagram for Figure 36-33 is shown in Figure 36-34 in a fourth-order IIR filter implementation where the coefficients A_j and B_i are called *coefficient n*, where n=0-8.

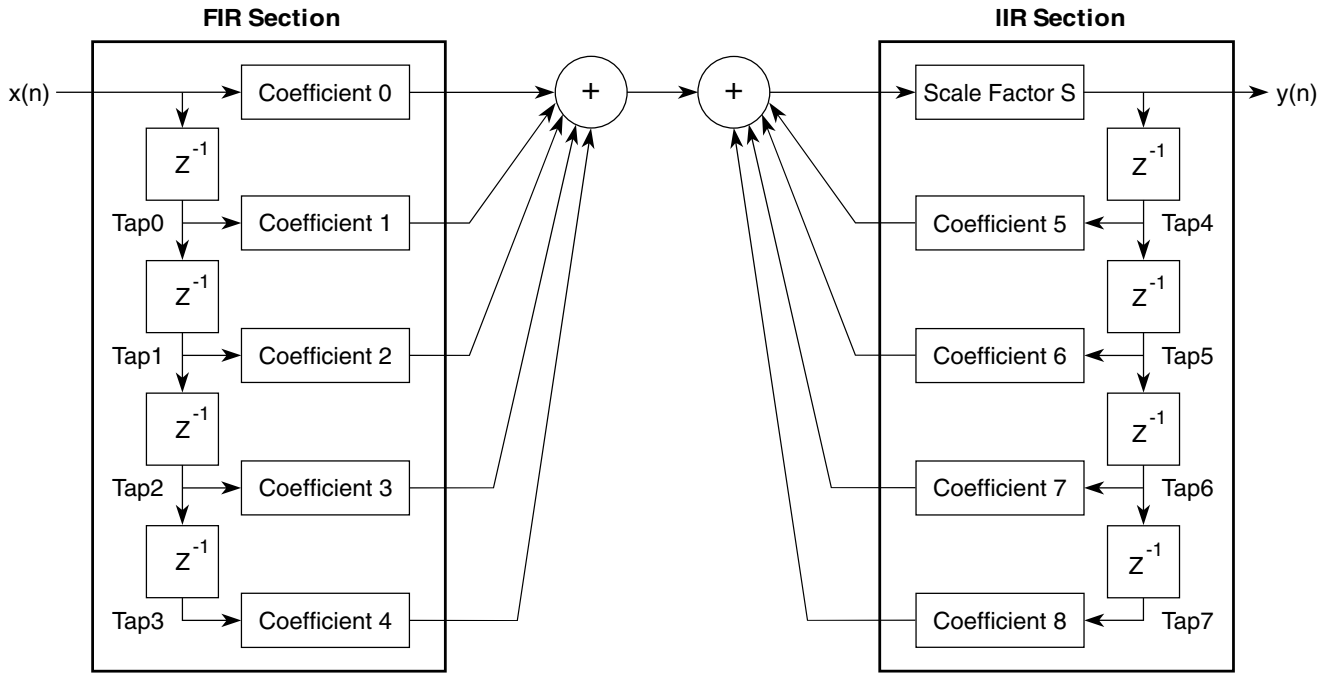

Figure 36-34. Fourth Order IIR Filter Implementation Block Diagram

The fourth order IIR filter is implemented with a FIR section followed by an IIR section. If the FIR type filter mode is selected, the IIR section is converted into an FIR section. In this case the order of the FIR filter is twice the IIR filter order, since all the TAP and coefficient registers are allocated for the FIR section. The Filter configuration paths are shown in Figure 36-35. Multiplexer A controls the *bypass* filter path and multiplexer B controls/selects the filter mode of operation, to either IIR mode or FIR mode. The selection is controlled by the FTYPE[1:0] bits in the Filter Module Configuration register. The order of the filter can be controlled by setting the appropriate *filter coefficients* to *zero*.

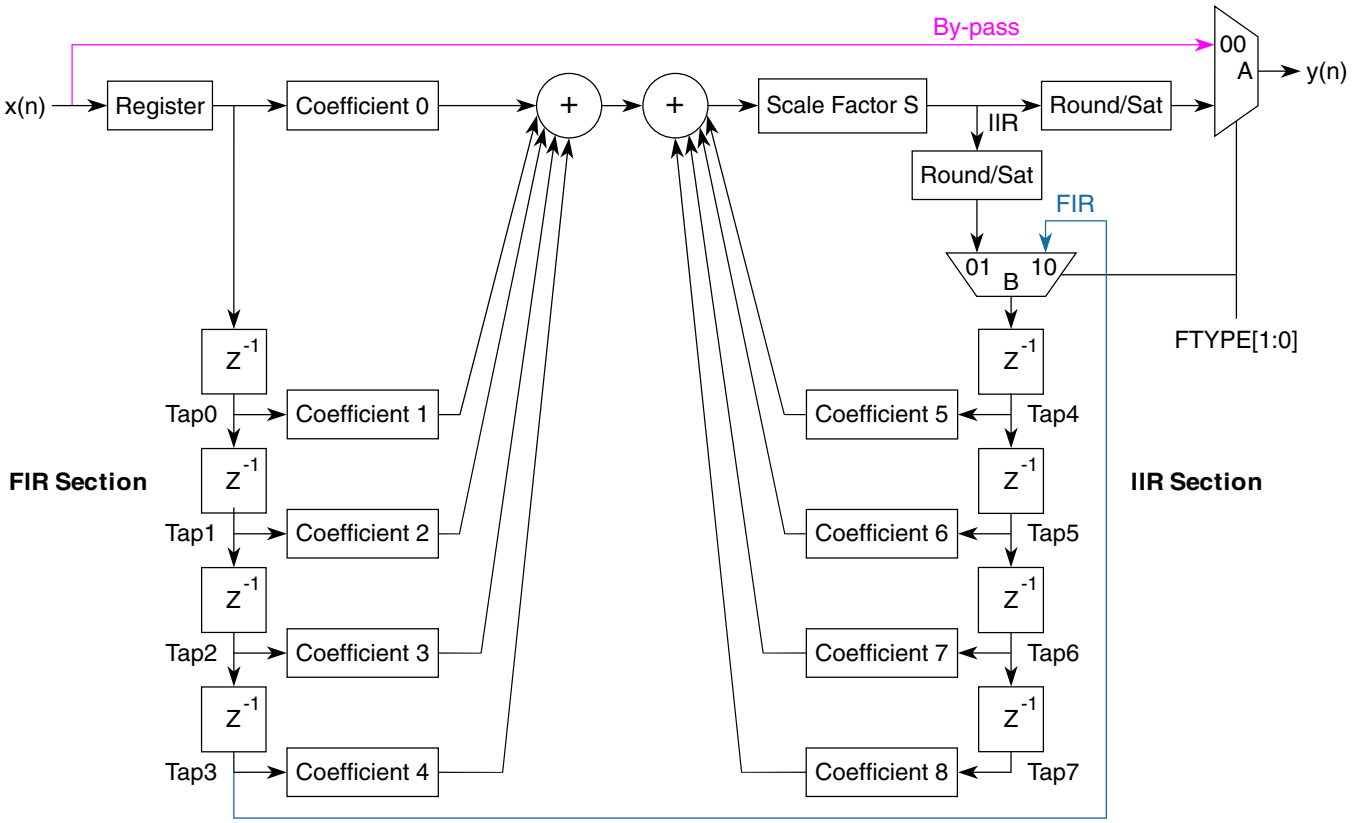

Figure 36-35. Filter Configuration Paths (FIR or 1x4Poles IIR)

36.5.6.1 Rounding

The Decimation Filter performs rounding operations in two different locations, as shown in Figure 36-35 :

- to obtain the filter output result with 16 bits
- to obtain the IIR feedback result to be stored in tap4 registers with 24 bits

The rounding mechanism implements the Convergent Rounding methodology (also known as round-to-nearest even number), which makes the decision on rounding up or down based on the value of the lower portion of data to be rounded (LS_WORD). The rounding up/down condition is equal to the traditional rounding except when the LS_WORD has the format {1000…00}. In this particular case, the rounding procedure is like the example of Figure 36-36. If the MS_WORD is odd, the value is rounded up. Otherwise the value is rounded down.

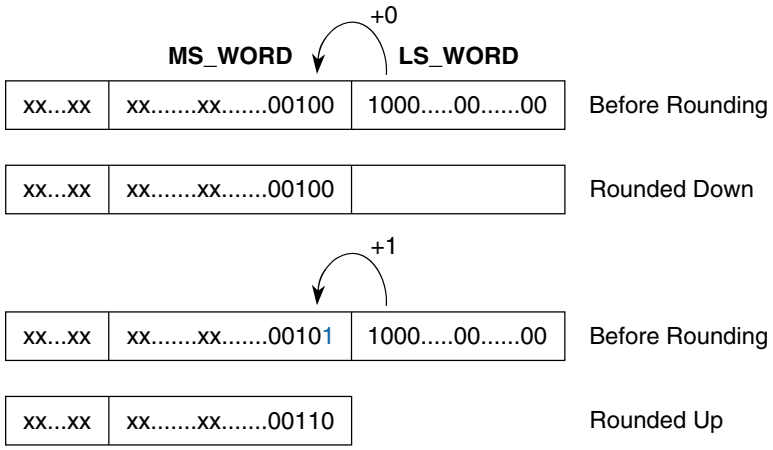

Figure 36-36. Convergent Rounding Methodology

36.5.6.2 Saturation

Filter output saturation occurs when an overflow or underflow condition of the filter is detected by dedicated logic, and if it is enabled by the SAT control bit of the configuration register DECFILTER_MCR. In this condition, the filter output is set to a saturated value equal to the maximum or minimum value that can be represented by the 16-bit output port. Also, for the IIR filter an equivalent logic is used to assert the saturation for the 24-bit feedback result.

36.5.7 Filter Prefill Control Description

A prefill indicates that the input data should be accepted by the Decimation Filter, but no decimated output should be generated while the control field indicates prefill. Therefore the prefill function is used in the beginning of the filter operation to initialize and stabilize the Decimation Filter without generating decimated samples. In addition, the prefill does not operate when the filter is in bypass (FTYPE=0b00).

When ISEL=1, it is controlled by the PREFILL field in the DECFILTER_IB register. The prefill control is usually activated only in a certain number of words of sample data in the beginning of the input data sequence.

When the prefill control is set, the decimation filter block operates as follows:

- Input data is processed normally by the digital filter and tap values are updated.
- The decimation counter is maintained in reset value.

- The output buffer is not updated and no output interrupt or read request is generated.
- The overflow detector/flag operates normally and the error interrupt request is set if enabled.

In Cascade Mode, prefill control is ignored in all cascaded filters except the Tail one: the prefill samples are filtered, decimated and forwarded to the next block with the prefill indication. The Tail block takes the samples with prefill indication, filter them and discard the result.

Note

The combined decimation count of the cascade combo may not be reset after the last prefill sample. Unlike in a single (non-cascaded) filter, the number of non-prefill inputs until an output comes out depends on the number of past prefill inputs.

36.5.8 Flush Command Description

The flush signal is used by the Decimation Filter to execute a partial reset of the filter. This is useful when the same filter is used on a new set of data samples after finishing the filtering of another set of data.

When the flush control is detected, all filter TAPs are cleared and the DEC_COUNTER[3:0] field in the status register DECFILTER_MSR is reset.

The flush function does not clear the Coefficient registers file in the Decimation Filter, thus it is not required to re-write these registers after a flush. The integrator accumulator and sample count are not cleared either. The output buffer also keeps the last result and may be retrieved until the next output is posted.

The flush control precedes the input data to be filtered. Therefore, the corresponding sample data is processed by the block after the flush. When ISEL=1, the field FLUSH in the DECFILTER_IB register is processed. Note that a word of valid sample data can be available at the same time the flush signal is asserted. In this case the flush is executed and the sample is processed after the flush.

When the filter is disabled by the FTYPE[1:0] control bit field, the flush command is not executed.

Note

In Cascade Mode, the flush command is forwarded to the next cascaded block together with the output, after the decimation count. Therefore it is possible that, in a given moment, the taps of a cascaded block are zeroed after a flush input, while the following ones still retain the old values.

36.5.9 Soft-Reset Command Description

The Soft-Reset command is requested through the self-negated bit SRES of the DECFILTER_MCR register and provides the CPU with the capability to initialize the Decimation Filter through the slave-bus interface. The procedure below must be performed for a software reset when the filter is active:

1. Disable filter inputs, writing DECFIL_MCR bit IDIS = 1.
2. Poll the register DECFIL_MSR until the bit BSY is 0.
3. Repeat the step 2 polling; this is necessary to cover the case when a sample is left in the input buffer.
4. Write DECFILTER_MCR bit SRES = 1.

After the software reset is issued, all internal Filter TAP registers, the decimation counter, the integrator outputs (except DECFILTER_CINTCNT), and the state machine are put in the initial state. The status register DECFILTER_MSR is also cleared. The Coefficient registers are not affected by the SRES. In case there is some filter processing, the filter process is aborted and the last sample is discarded. In addition, data in the input buffer waiting to be processed, and data in the output buffer waiting to be read, are discarded (the requests of service are cleared). The software reset command has high priority and the BSY bit is set during its operation.

The configuration registers DECFILTER_MXCR and DECFILTER_MCR are also not affected by a soft reset, except the bit SRES that is self-negated and is always read as zero.

When in debug or freeze mode, the soft reset is executed but the filter remains in debug or freeze mode.

Note

It is recommended to clear the IBIE bit before a software reset, especially if ISEL changes, in order to avoid unwanted interrupt requests.

Note

DMA transfers must not be active during soft reset. Data loss can occur.

36.5.10 Interrupts Requests Description

36.5.10.1 Block Interrupt Request

There are several interrupt request events that can be enabled using the module configuration register DECFILTER_MCR. Basically, the interrupt request can be issued under any of the following conditions:

- when a word of input data is received
- when a word of output data is available
- when an error has occurred.

The input data flag IDF is set when a word of data is received from the CPU when in standalone mode. It is not used to generate the read or write requests (as defined in Input Buffer Interrupt Request) when DSEL=0.

Output data is available and its flag (ODF) is set when the input data sample is processed by the filter and the decimation counter matches the decimation rate value. It is not used to generate the read requests (as defined in Output Buffer Interrupt Request) when DSEL=0.

An error event in the decimation filter block is defined as one of these events:

- Overflow in the filter, flagged by OVF
- Overrun in the decimation filter input, flagged by IVR
- Overrun in the decimation filter output, flagged by OVR
- Integrator overrun, flagged by SVR
- Integrator value exception, flagged by SSE
- Integrator count exception, flagged by SCE

An overflow occurs when the two's-complement result value from the MAC accumulator is out of the range of values that can be stored in tap register 4 (IIR) or in the output register.

An input overrun occurs when the input buffer is holding a word of input data and one more word of data is received by the filter. See Input Buffer Overrun, for more details.

An output overrun occurs when a new word of data is sent to the output buffer but the previous word of data has not been handled yet. See Output Buffer Overrun, for more details.

These flags are only cleared by:

- the CPU, or
- by the soft reset command in the DEC_FILTER_MCR, or
- by the clear flag registers in the DEC_FILTER_MSR register.

36.5.10.2 Input Buffer Interrupt Request

This interrupt is enabled by the register IBIE in the DECFILTER_MCR register and is asserted only when DSEL=0. This request is flagged in the DECFILTER_MSR by field IBIF.

In standalone mode, the input buffer interrupt request is asserted when the input buffer is available to receive a conversion sample and DMA operation is not selected (DSEL=0), meaning the block is requesting data to be written into the input buffer. The interrupt request is cleared when the CPU writes a "1" in field IBIC of the DECFILTER_MSR register, or by the soft reset command.

36.5.10.3 Output Buffer Interrupt Request

This interrupt is enabled by the register OBIE in the DECFILTER_MCR register and is asserted only when DSEL=0. This request is also indicated in the field OBIF of the DECFILTER_MSR register.

When in standalone mode, the output buffer can be read by the CPU with the DMA disabled. The output buffer interrupt request is asserted when the output buffer receives a new result from the filter sub-block. This means the block is requesting data to be read by the CPU.

The output buffer interrupt request can also be asserted due to an integrator result being ready, as flagged by the DECFILTER_MXSR bit SDF, when the DECFILTER_MCR bit SDIE=1. Note that both the filter output and integrator share the same interrupt source.

This interrupt request is cleared when a "1" is written in the bit OBIC and/or bit SDFC of the DECFILTER_MXSR register, or by the soft reset command.

36.5.11 DMA Requests Description

The DMA function for input and output buffers is enabled using DSEL=1 in the DECFILTER_MCR register. The DMA function for integrator result is described in another section.

36.5.11.1 Input Buffer DMA Request

This DMA request is enabled by the ISEL and DSEL bits in the DECFILTER_MCR register.

When in standalone mode, the input buffer can be written by the DMA. The input buffer DMA request is asserted when the input buffer is available to receive a conversion sample (it is not holding a word of data). This DMA request is cleared when an input data word is written in the input buffer. Therefore, the DMA request is always cleared before it is asserted again.

This DMA request is cleared when the DMA transfer is complete or by soft reset.

36.5.11.2 Output Buffer DMA Request

This DMA request is enabled by the ISEL and DSEL bits in the DECFILTER_MCR register.

When in standalone mode, the output buffer can be read using the DMA. The output buffer DMA request is asserted when the output buffer receives a new result from the internal filter sub-block. This DMA request is cleared when the output buffer is read by the processor.

The output buffer DMA request is also asserted when an integrator output is ready, if DECFILTER_MXCR bit SDMAE=1 with DSEL=0 .

The DMA request is also cleared by soft reset.

36.5.12 Freeze Mode Description

The freeze mode operation is asserted using the FREN enable bit and FRZ bit in the DEC_FILTER_MCR register or by the modules debug input .

It is not possible to enter freeze mode when the module is disabled by the configuration bit MDIS.

In case of a freeze mode request during the processing of an input sample, the current processing is finished and then the module enters freeze mode.

Access to input and output buffers remain operational in freeze, as well as their related flags.

Note

For cascaded blocks (see Cascade mode description), it is recommended to freeze only the Head block. If it is really necessary to freeze all the blocks, it is recommended that they are frozen sequentially starting from the Head block towards the Tail one. Unfreezing is recommended to be done sequentially from the Tail block towards the Head one.

36.5.13 Integrator

The hardware sample integrator accumulates the filter output values for determined periods.

36.5.13.1 Integrator Inputs

The integrator can be fed either by raw or decimated filter outputs, selected by the DECFILTER_MXCR bit SISEL (see Module Extended Config Register (DECFILTER_MXCR)). The accumulated input value taken can be the filtered sample "as is" (signaled), or its absolute value, depending on the DECFILTER_MXCR register bit SSIG.

Note

The integrator accumulates input samples when bypass is selected.

36.5.13.2 Integrator Outputs

The integrator output is either:

- the 32-bit, fixed point unsigned accumulation of the absolute values from the filter output, when the integrator is configured for absolute operation (DECFILTER_MXCR bit SSIG=0). This resolution allows a minimum of 131071 samples to be integrated before an overflow occurs in absolute operation, or 65536 samples in signed operation.
- the 32-bit, fixed point signed two's complement accumulation of the signed values from the filter output, when the integrator is configured for signed operation (SSIG=1).

The fractional part of the accumulation is 15 bits wide in both cases.

An accumulation overflow is flagged by the DECFILTER_MXSR bit SSOVF. The accumulator can overflow in either of the ways below, selected through the DECFILTER_MXCR bit SSAT:

- saturated accumulation (SSAT=1), so that an overflow results in the value of 0xFFFFFFFF for absolute value accumulation (SSIG=0), or 0x7FFFFFFF (positive) and 0x80000000 (negative) for signaled accumulation (SSIG=1).
- non-saturated accumulation (SSAT=0), so that an overflow results in the modulo 2^{17} accumulation value. This operation is only allowed in absolute accumulation (SSIG=0).

The integrator output value becomes available in register DECFILTER_FINTVAL (see Final Integer Value Register (DECFILTER_FINTVAL)) when an integrator output request is issued. The integrator output request can be issued in the following ways:

- by hardware, controlled by an external signal; the enabling and the selection of the signal request modes is done through the DECFILTER_MXCR field SRQSEL (see Module Extended Config Register (DECFILTER_MXCR));
- by software, writing 1 to the DECFILTER_MXCR bit SRQ;

The SSOVF flag is asserted upon an integrator output request, based on the overflow state of the internal accumulator. This internal overflow state is cleared upon an output request, just after SSOVF is asserted, or upon an integrator reset (see Integrator Reset).

The internal overflow state is also cleared by writing SSOVFC to 1, but only in saturated accumulation. Therefore, a non-saturated overflow that occurs before an SSOVF clear is still flagged in the next output request.

The integrator output request also updates the register DECFILTER_FINTCNT, which holds the number of samples accumulated into the register DECFILTER_FINTVAL. This internal accumulated sample counter can operate either in a saturated or "wrapped" count mode, as selected by the DECFILTER_MXCR bit SCSAT. In both cases, the counter overflow is flagged by the DECFILTER_MXSR bit SCOVF.

The SCOVF flag is asserted upon an integrator output request, based on the overflow state of the internal counter. This internal overflow state is negated upon an output request, just after SCOVF is asserted, or upon an integrator reset (see Integrator Reset). The internal overflow state is also negated by writing SCOVFC to 1, but only in saturated count. Therefore, a non-saturated overflow that occurs before an SCOVF clear is still flagged in the next output request.

An integrator output update can also issue a DMA or interrupt request. The interrupt and DMA requests are the same ones used for the filter output buffer (see Output Buffer Interrupt Request and Output Buffer DMA Request). The DECFILTER_MCR bit SDIE is used to enable integrator interrupts, and the DECFILTER_MXCR bit SDMAE enables the DMA integrator requests. The integrator DMA request uses the same signal as the filter output DMA request, so one must never use any configuration that allows both the integrator and filter output to make DMA requests.

Integrator output updates are flagged by the DECFILTER_MXSR bit SDF. The integrator overrun is detected in the same way as a filter output buffer overrun, and is flagged by DECFILTER_MXSR bit SVR. An integrator overrun also generates an error interrupt if the DECFILTER_MCR bit ERREN=1 (see Output Buffer Overrun).

Registers DECFILTER_CINTVAL and DECFILTER_CINTCNT provide a way to poll intermediate integration values and sample counts, respectively (see Current Integer Value Register (DECFILTER_CINTVAL) and Current Integer Count Register (DECFILTER_CINTCNT)). DECFILTER_CINTVAL is updated whenever the integrator is reset or a new sample is accumulated. DECFILTER_CINTCNT is updated only when DECFILTER_CINTVAL is read, so that coherency between the value and count values is guaranteed. Therefore, the read access order of that pair of registers must be DECFILTER_CINTVAL first, followed by DECFILTER_CINTCNT.

Note

The flags SSOVF and SCOVF can also be asserted when DECFILTER_CINTVAL is read. The SSOVF and SCOVF set and clearing rules apply for the DECFILTER_CINTVAL read the same way as for an integrator output request.

36.5.13.3 Integrator Reset

The integration value is reset to the value of zero, in the following ways:

- by hardware: on hardware reset, or controlled by an external signal; the enabling and the selection of the zero signal modes is done through the DECFILTER_MXCR field SZROSEL (see Module Extended Config Register (DECFILTER_MXCR));
- by software: on software reset, or writing 1 to the DECFILTER_MXCR bit SZRO;

The integrator reset also zeroes the internal counter of accumulated samples and the internal overflow state (but not SSOVF and SCOVF). Software and hardware resets reset all integrator registers immediately. Integrator zero command from external signal or by software (SZRO) affects the integrator registers and flags as follows:

- DECFILTER_CINTVAL resets immediately;
- DECFILTER_CINTCNT does not reset immediately; it is updated only upon a DECFILTER_CINTVAL read, loaded with the number of integrated samples occurred after the reset;
- DECFILTER_FINTVAL and DECFILTER_FINTCNT do not reset immediately; being updated only upon a new output request (see Integrator Outputs); if a integrator software zero command (through SZRO bit) and an integrator output request (through SRQ bit) are made at the same time, the registers DECFILTER_FINTVAL and DECFILTER_FINTCNT are updated with the last internal values before reset; the same applies to simultaneous integrator zero command and output request by hardware signal;
- the SSOVF and SCOVF flags do not negate; however, the internal overflow states which assert SSOVF and SCOVF do reset immediately, so that the next output update (either by hardware request, software request or DECFILTER_CINTVAL read) before an overflow does not assert SSOVF/SCOVF.

Note

The integrator reset does not depend on the integrator enabling (see Integrator Enabling and Halting).

36.5.13.4 Integrator Enabling and Halting

Two mechanisms, enabling and halting, drive the integrator accumulation, allowing it to be controlled by a combination of two distinct sources, both software, both hardware, or one hardware and other software. Values are accumulated when the integrator is enabled and not halted. The integrator halt and enable states can be controlled in the following ways:

- by hardware, through external signals ; the enabling and the selection of the signal request modes is done through the DECFILTER_MXCR fields SENSEL and SHLTSEL, respectively (see Module Extended Config Register (DECFILTER_MXCR));
- by software, through the same DECFILTER_MXCR fields SENSEL and SHLTSEL. Note that these fields are in different bytes, so that two distinct, concurrent software tasks can avoid coherency problems by changing the fields using byte read-modify-write accesses.

Note

Enabling and halting does not affect output requests or integrator reset.

36.5.13.5 Integrator Exceptions

Integrator may run into exception states due to overflow, either of the accumulated value or the sample counter. Exceptions are flagged by the DECFILTER_MXSR bits SSE, for sum value exception, and SCE, for counter exception. These flags generate an error interrupt, if it is enabled (see Block Interrupt Request).

The accumulator exception condition depends on whether it operates in saturated mode or not, as follows:

- In Saturated operation (DECFILTER_MXCR bit SSAT=1): a sum exception occurs (SSE=1) whenever an overflow is flagged; SSE asserts together with SSOVF.

- In Non-saturated operation (DECFILTER_MXCR bit SSAT=0): a sum exception occurs (SSE=1) when an overflow is flagged and the DECFILTER_MXSR bit SSOVF is already set to 1.
- In Non-saturated operation, an accumulator exception also occurs if the accumulator overflows twice without any update of the final integrator value DECFILTER_FINTVAL or the current integrator counter DECFILTER_CINTCNT (by a read to the DECFILTER_CINTVAL register), neither an integrator reset occurs. The SSOVF flag does not assert in this situation.

Note

The SSOVF flag can only be asserted upon a hardware request, a software request, or when DECFILTER_CINTVAL is read, based on the internal accumulator overflow state.

Similarly, the sample counter exception condition depends on whether it operates in saturated mode or not, as follows:

- In Saturated operation (DECFILTER_MXCR bit SCSAT=1): a counter exception occurs (SCE=1) whenever an overflow is flagged; SCE asserts together with SCOVF.
- In Non-saturated operation (DECFILTER_MXCR bit SCSAT=0): a counter exception occurs (SCE=1) when an overflow is flagged and the DECFILTER_MXSR bit SCOVF is already set to 1.
- In Non-saturated operation, a counter exception also occurs if the counter overflows twice without any update of the final count DECFILTER_FINTCNT or the current integrator counter DECFILTER_CINTCNT (by a read to the DECFILTER_CINTVAL register), neither an integration reset occurs. The SCOVF flag does not assert in this situation.

Note

The SCOVF flag can only be asserted upon a hardware request, a software request, or when DECFILTER_CINTVAL is read (also updating DECFILTER_CINTCNT), based on the internal counter overflow state.

36.5.14 Cascade mode description

The cascade mode is defined as a configuration mode of the decimation filter to work together with other ones in a chain arrangement. All blocks in the arrangement, hereafter called a **cascade combo**, are configured to operate in cascade mode by the CASCD[1:0] field in the DECFILTER_MCR register. Figure 36-37 shows an example of cascade combo:

NOTE

As this device only has two DECFILTER instances, all description about the "Middle" block and references to more than two filters do not apply.

- The figure shows data input and data output in standalone mode.
- The left most block, named Head receives the raw data to be filtered from the device slave-bus interface in standalone mode. The head type is configured using CASCD[1:0] = 01 in the configuration register DECFILTER_MCR.
- The right most block, named Tail, is the last filter block in the chain. It sends the output result back to the device slave-bus interface in standalone mode. This type of cascaded block is configured using CASCD[1:0] = 10.
- The blocks in between, named Middle, do not exchange data (receive / transmit) with the device slave-bus, only with other decimation filter blocks. This type of block is configured by setting CASCD[1:0] = 11. Middle blocks are optional in a cascaded combo: two blocks, one Head block feeding a Tail one, can be used in cascade.
- Each decimation filter block has one cascade-in and one cascade-out ports. The arrows show how they are physically connected. The bold arrows show the connections used in cascade mode.
- The block configurations as Head, Tail or Middle must respect their physical connections such that all the following apply:
  - a Head block feeds a Middle or Tail one
  - a Middle block feeds another Middle block or a Tail one
  - Tail feeds no other block, and Head is fed by no other block.
- As a consequence of the conditions above, there must be one and only one Head block and one and only one Tail block in a cascade combo.

- A group of physically chained blocks can form more than one cascade combo. For instance, Figure 36-38 shows the same physical chain, but now with blocks 1 and 2 configured as Head and Tail, respectively, forming one combo. The remaining blocks form another combo starting with block 3 (Head), and ending with block N (Tail).
- Blocks not used in a cascaded chain can be used normally, isolated (DEFILTER_MCR field CASCD[1:0] = 00), as exemplified in Figure 36-39.
- The optional connection show from block N to block 1 in Figure 36-37 allows block N to be configured as Head or Middle, feeding block 1 configured as Middle or Tail, yielding more flexibility, as in the last example of Figure 36-39.

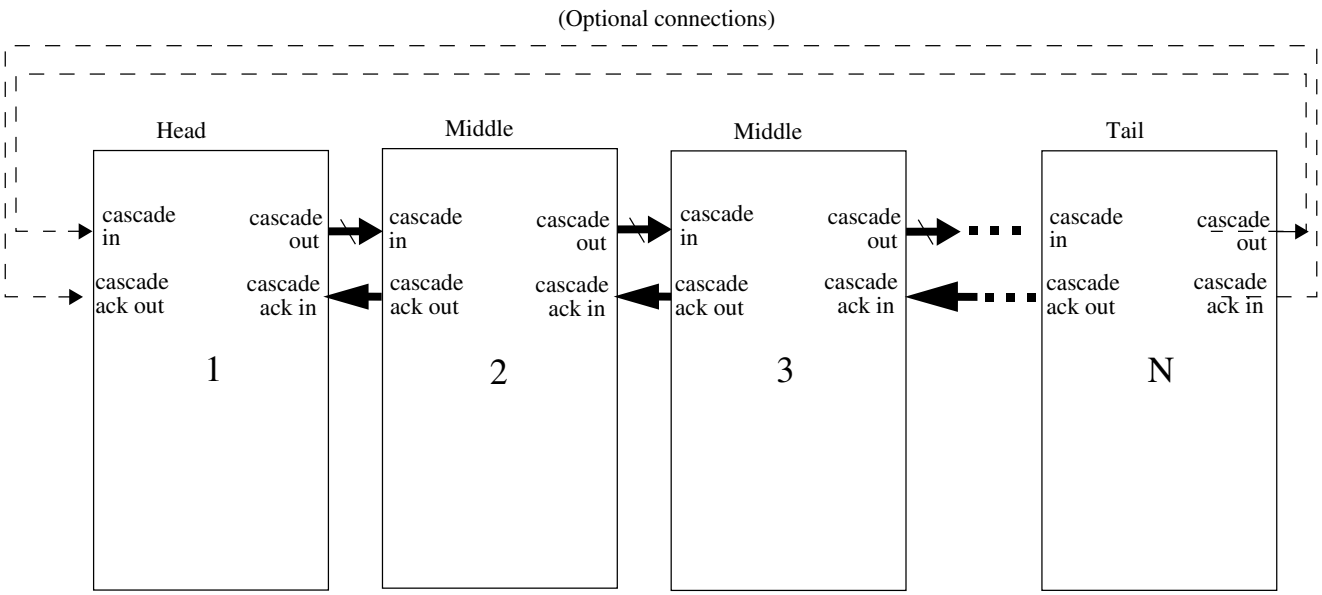

Figure 36-37. Cascade Mode Chain Structure

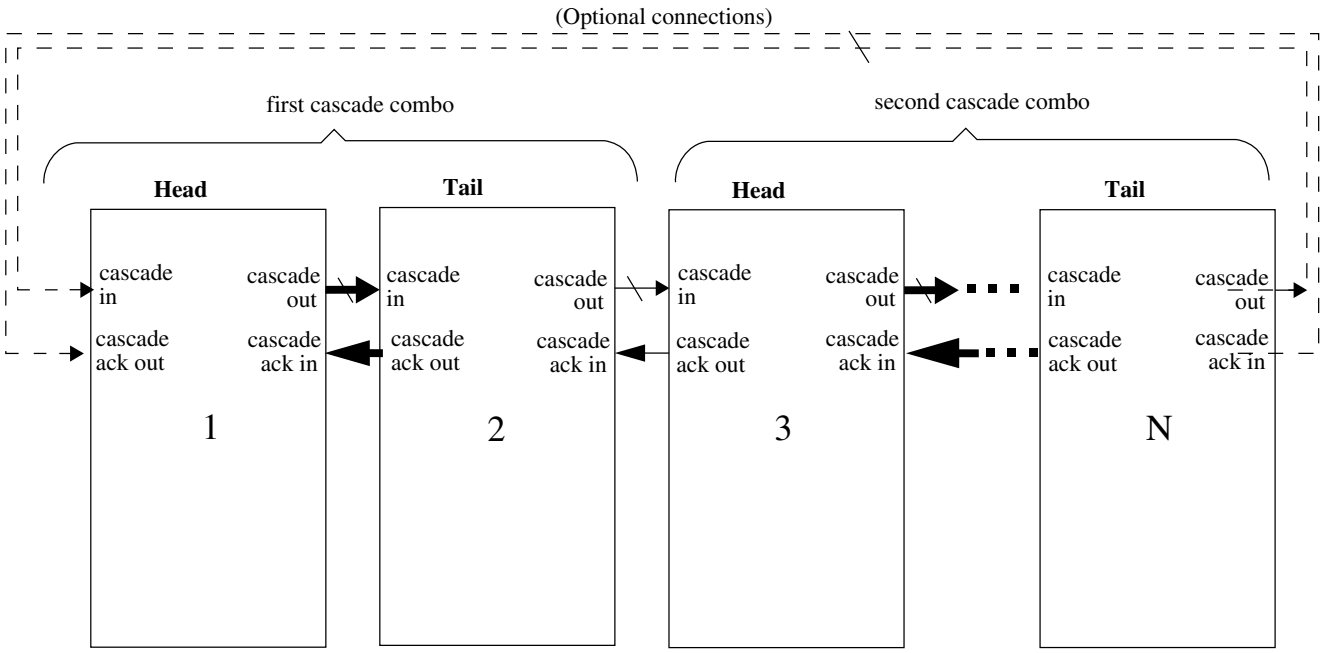

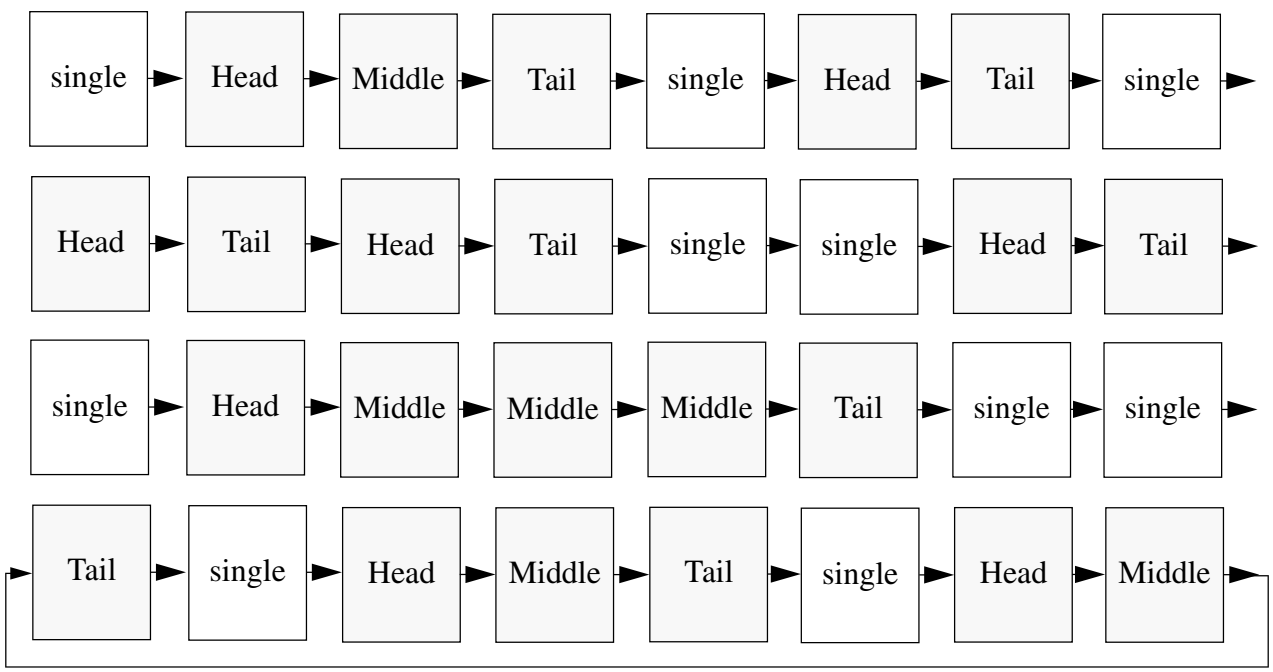

Figure 36-38. Multiple Cascade Mode Chain Structure

(arrows show just the physical cascading order)

Figure 36-39. Examples of mixed Cascaded and single blocks

36.5.14.1 Cascade Freeze, Stop, and Configuration Change Procedures

To change a block configuration mode to or from cascade mode, the following safe procedures must be observed:

- To modify a cascade combo, either to single or any other cascade combo combination, all the cascade combo blocks must have their inputs disabled (using DECFILTER_MCR bit IDIS), in order, from the Head to the Tail block. After a block IDIS bit has been set to 1 (one), one must wait for its DECFILTER_MSR bit BSY to be 0 (zero) before disabling the input of the next block in the sequence.
- Each block in a new cascade combo must be configured with its input disabled. When the mode configuration is done, the combo blocks must have their inputs enabled in order, from the Tail towards the Head block.
- A single block must also be reconfigured the same way, to or from a cascade combo configuration: first disabling its input, and then waiting for a non-busy state before writing DECFILTER_MCR field CASCD.

To take cascade combo blocks to or from freeze or low power modes, a similar procedure must be used:

- Take the Head to freeze or low-power first, wait for DECFILTER_MSR bit BSY=0, and repeat the procedure for the other blocks in the chain in sequence, towards the Tail block.
- Take the blocks out of freeze or low-power modes in the inverse sequence, from Tail to Head.

36.6 Initialization Information

Following are some simple initialization steps to be done before using the decimation filter block. These steps assume that the user has already calculated the filter coefficients using a filter design tool.

36.6.1 Initialization Procedure

The sequence of steps for the block initialization is as follows:

1. Program the configuration registers DECFILTER_MCR and DECFILTER_MXCR as desired for your application.
2. Write all filter coefficient registers DECFILTER_COEFn with the previously calculated values.
3. Enable the filter input, writing DECFILTER_MCR bit IDIS=0.
4. Run a soft-reset cycle if necessary.
5. The module is ready to receive data from the device slave-bus interface.

36.7 Filter Example Simulation

The decimation filter block operation was checked in a Verilog simulation using calculated filter coefficient values and noisy input data. The expected output values and the RMS error were then calculated.

36.7.1 Coefficients Calculation

The coefficients were calculated using a digital filter design tool. We have supplied some hypothetical filter parameters to the tool and obtained the filter coefficients. The input parameters are:

- Filter characteristics: elliptic/low pass
- Filter type: 4th order IIR
- Input sample rate: 800k sample/s
- Passband edge: 100 kHz
- Stopband edge: 150 kHz
- Passband attenuation: ≤ 1 dB

The software tool gives the IIR filter coefficients in the Z-transform format expressed by Figure 36-40 :

$$\frac{Y(s)}{X(s)} = \frac{B_0+B_1s+B_2s^2+B_3s^3+B_4s^4}{A_0+A_1s+A_2s^2+A_3s^3+A_4s^4}$$

Figure 36-40. Eqn-3

The coefficient results in fixed point decimal representation are shown in Table 36-32.

Table 36-32. Coefficient Values Given by SPW Digital Filter Design Tool

Coefficient	Decimal Value		Coefficient	Decimal Value
B0	0.0221455		A0	1.0
B1	0.00445582948893748		A1	-2.69772868375858
B2	0.0318517846509088		A2	3.234056294853
B3	0.00445582948893748		A3	-1.92028561712454
B4	0.0221455		A4	0.47939080709495

Comparing Figure 36-33 with Figure 36-40, we obtain the relationship between the calculated values of coefficients and the values to be loaded in the DECFILTER_COEFn registers. Note that A0=1 in both cases and that the coefficients A1 to A4 in Figure 36-40 has the opposite signal from Figure 36-33.

See Table 36-33 below to obtain the coefficients. A scale factor of eight is used, being the smallest divider factor to have all coefficient values in the range (-1 ≤ Coef < +1).

Table 36-33. Coefficient Values for Decimation Filter

SCALE	S=1	S=8	
COEFn	Decimal Value	Decimal Value	Hexadecimal Values (24 bits)
Coef0 = B0/S	0.0221455	0.00276815891266	0x005AB5
Coef1 = B1/S	0.00445582948893748	0.00055694580078	0x001240
Coef2 = B2/S	0.0318517846509088	0.00398147106171	0x008277
Coef3 = B3/S	0.00445582948893748	0.00055694580078	0x001240
Coef4 = B4/S	0.0221455	0.00276815891266	0x005AB5
Coef5 = -A1/S	2.69772868375858	0.33721613883972	0x2B29E6
Coef6 = -A2/S	-3.234056294853	-0.40425717830658	0xCC414E
Coef7 = -A3/S	1.92028561712454	0.24003565311432	0x1EB97D
Coef8 = -A4/S	-0.47939080709495	-0.05992400646210	0xF8546A

36.7.2 Input Data Calculation

The 24-bit words of input data are samples of a sum of two tones: one tone of 30kHz and another tone of 250kHz. The samples were calculated at the rate of 800k samples per second. The tones have the same amplitude and it is assured that the resultant amplitude is smaller than 1 so as to obtain samples in the range (-1 ≤ sample < +1). It is supposed the input data are signed values in the two's complement format in the range (-1 ≤ sample < +1).

36.7.3 Filter Results

The decimation filter was simulated using the calculated coefficients and the input data samples. A scaling factor of eight in the configuration register DECFILTER_MCR, and no decimation factor, were used to obtain the maximum of output results from the filter.

The theoretical expected values from this filter were also calculated, and these results were compared with those from the decimation filter. The resultant RMS error when considering about 500 samples was about -97 dB.

Chapter 37
Temperature Sensor (TSENS)

37.1 Introduction

The device includes two on-chip temperature sensors. The temperature sensor module monitors device temperature and delivers one analog output signal and two digital output signals each (under- and over-temperature flags). The analog output consists of a voltage signal directly proportional to the internal junction temperature. The analog output is connected to an input channel of an ADC on the device (see the ADC details for the channel number). The internal junction temperature must be calculated by software based on the sampled temperature sensor voltage; sampled bandgap reference voltage, which comes from another module; and calibration parameter values stored in internal flash memory. The two digital outputs, connected to the PMC module, are used to signal under- and over-temperature operating conditions.

The digital outputs signal when the junction temperature drifts below the low temperature threshold or above the high temperature threshold. These signals notify the device to take action to appropriately adjust the device temperature in response to an out-of-specification low or high temperature operating condition. Calibration parameter values associated with the temperature threshold detection feature are determined and stored in internal flash memory during production testing at the factory.

37.2 Functional Description

The temperature sensor generates one analog output voltage, $V_{TSENS}(T)$, which is proportional to the absolute current junction temperature of the device, and two digital outputs that signal whether the junction temperature has reached either a pre-set low temperature threshold or a pre-set high temperature threshold.

An on-chip ADC module is used to convert the analog output voltage, as well as the bandgap reference voltage, into a digital representation. These values, along with parameter values stored in on-chip flash memory, are used by software to calculate the device junction temperature.

37.2.1 Temperature threshold detection (digital output generation)

Temperature threshold trimming values are adjusted through calibration during factory test and stored in on-chip flash memory. While enabled, if a new trimming value is loaded into the Temperature Sensor module, it may take up to 1 microsecond for the digital outputs to be updated to reflect the new trimming condition.

When the temperature threshold detection feature is enabled, the temperature sensor monitors the internal junction temperature of the chip and asserts a signal if any of the following temperature thresholds are crossed.

- The low temperature digital output signals if the junction temperature falls below the low temperature threshold (-40°C).
- The high temperature digital output signals if the junction temperature rises above the high temperature threshold (150°C).

The threshold detection circuit is calibrated with respect to the factory-test temperatures: the low temperature threshold is trimmed to match the cold insertion test temperature (nominally equal to –40°C), and the high temperature threshold is trimmed to match the hot insertion test temperature (nominally equal to 150°C). In other words, the thresholds are not trimmed to absolute values of temperature but to the specific temperatures for which the device is validated during factory test.

Hysteresis is applied whenever outputs transition to a logic level low in order to eliminate spurious toggling. Digital output behavior is illustrated on Figure 37-1.

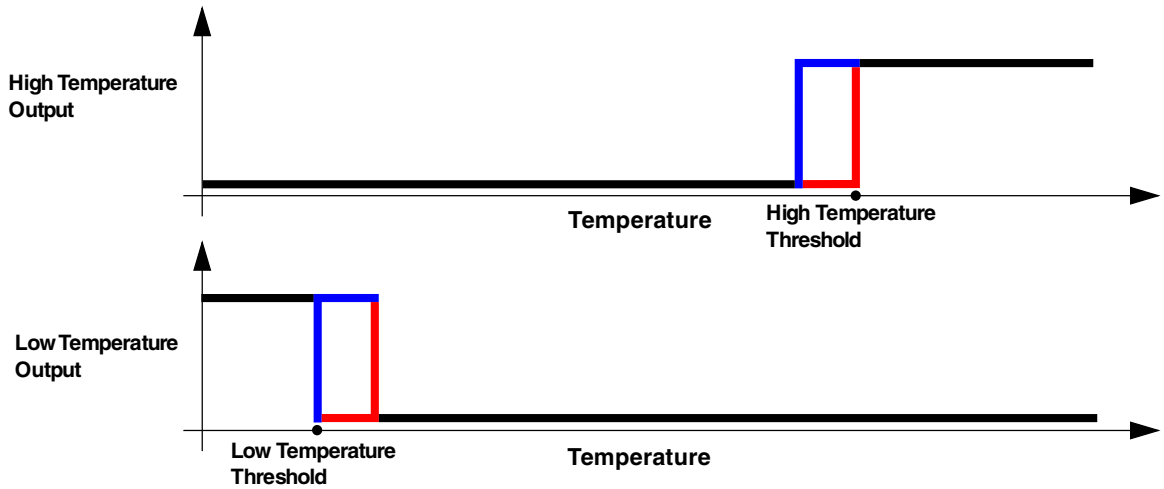

Figure 37-1. Digital output behavior with temperature

37.2.2 Linear temperature sensor (analog output generation)

When analog output generation is enabled, the temperature sensor outputs a voltage proportional to the internal junction temperature of the chip. This analog voltage signal is converted into a digital code by an on-chip ADC. The temperature value is obtained from a linear voltage-temperature relation with coefficients adjusted by calibration parameters extracted during factory test and programmed into flash memory.

37.3 Temperature formula

The system chain that translates device junction temperature into a digital variable is composed of the temperature sensor, a bandgap reference voltage source and the on-chip ADC. Both analog output voltages of the temperature sensor and the bandgap reference voltage source must be converted by the ADC into digital codes to obtain the device junction temperature. The temperature formula shown in Figure 37-2 is used to calculate internal device junction temperature.

$$T \times 2^2 = \frac{(K_1 \times V_{BG_CODE}(T)) \times 2^{-1} + (K_2 \times V_{TSENS_CODE}(T)) \times 2^3}{[(K_3 \times V_{BG_CODE}(T)) \times 2^2 + (K_4 \times V_{TSENS_CODE}(T))] \times 2^{-10}} \quad [K]$$

$$V_{TSENS_CODE}(T) = \frac{V_{TSENS}(T)}{V_{ref}} \times 2^{12} \qquad V_{BG_CODE}(T) = \frac{V_{BG}(T)}{V_{ref}} \times 2^{12}$$

- T is the internal junction temperature in Kelvin
- $V_{TSENS}(T)$ is the temperature sensor output sampled by the ADC
- $V_{BG}(T)$ is the bandgap reference voltage sampled by the ADC
- V_{ref} is the ADC reference voltage in normal usage of the device
- K1, K2, K3, and K4 are 16-bit signed integer constants in two's-complement representation stored in flash memory (obtained from factory calibration)

Figure 37-2. Temperature formula

Parameters K1, K2, K3, and K4 are 16-bit signed integer constants in two's-complement representation that are stored in flash memory during factory test and calibration. These constants must be used in the temperature formula to calculate device junction temperature.

37.4 Calculating device temperature

Software must perform the following steps in order to calculate device temperature.

1. Measure the bandgap reference voltage using the on-chip ADC module and calculate $V_{BG_CODE}(T)$ according to the formula shown in Figure 37-2.
2. Measure the temperature sensor output voltage using the on-chip ADC module and calculate $V_{TSENS_CODE}(T)$ according to the formula shown in Figure 37-2
3. Retrieve parameters K1, K2, K3, and K4 from flash memory.
4. Calculate T according to the formula shown in Figure 37-2.

Note

Temperature Formula may be calculated using signed 32-bit (integer) operations showing negligible precision loss.

Chapter 38
Timers Overview

38.1 Timers Overview

Three types of timers are implemented on the MPC5746R:

Table 38-1. Timers

Timer	Instances	Core	Feature Note
Sytem Timer Module (STM)	STM0	CPU0	
	STM1	CPU1	
Software Watchdog Timer (SWT)	SWT0	CPU0	Supports Fixed address mode and Incremental address modes.
	SWT1	CPU1	
	SWT3	n/a	Serviced by CPU0 and CPU1 while executing security routing. Does not support Fixed address mode and Incremental address modes. No IAC servicing
Periodic Interrupt Timer (PIT)	PIT0	Shared among all cores	8 channels with RTI
	PIT1		2 chained channels without RTI

There are two instances of the System Timer Module. Each of the two main cores has a dedicated STM. The checker core does not have an STM.

There are three instances of the Software Watchdog Timer. Each computational core has a dedicated SWT. The checker core does not have a dedicated SWT. SWT3 is different from the other two in that it does not have Instruction Address Compare servicing.

There are two instances of the Periodic Interrupt Timer, both which are shared among all cores. PIT1 does not have Real Time Interrupt.

Chapter 39
System Timer Module (STM)

39.1 System Timer Module (STM) configuration

39.1.1 STM chip-specific module information

MPC5746R implements two STMs: STM0 and STM1.

Table 39-1. System Timer Module (STM) instances

Instance	Description	Number of Channels	Number of Registers (32-bit)
STM0	Intended for Main Core_0 in the high-speed computational clock domain. However, by properly programming the INTC_PSR PRC_SEL field, interrupt requests generated by STM0 can still be serviced by the Core_1 and vice-versa.	4	14
STM1	Intended for Main Core_1 in the high-speed computational clock domain.	4	14

39.2 Introduction

This section provides an overview, list of features, and modes of operation for the STM.

39.2.1 Overview

The System Timer Module (STM) is a 32-bit timer designed to support commonly required system and application software timing functions. The STM includes a 32-bit up counter and four 32-bit compare channels with a separate interrupt source for each channel. The counter is driven by the system clock divided by an 8-bit prescale value (1 to 256).

39.2.2 Features

The STM has the following features:

- One 32-bit up counter with 8-bit prescaler
- Four 32-bit compare channels
- Independent interrupt source for each channel
- Counter can be stopped in debug mode

39.2.3 Modes of operation

The STM supports two device modes of operation: normal and debug. When the STM is enabled in normal mode, its counter runs continuously. In debug mode, operation of the counter is controlled by the FRZ bit in the STM_CR register. If the FRZ bit is set, the counter is stopped in debug mode, otherwise it continues to run.

39.3 External signal description

The STM does not have any external interface signals.

39.4 Memory map and registers

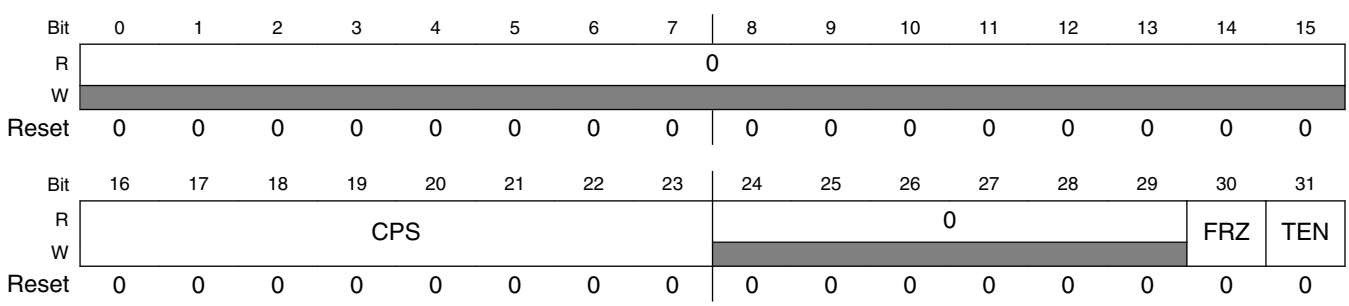
The STM programming model includes a group of 32-bit registers—a module control register, a counter value register, and three registers for each channel.

The STM registers can only be accessed using 32-bit (word) accesses. Attempted references using a different size or to a reserved address generates a bus error termination.

STM memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	STM Control Register (STM_CR)	32	R/W	0000_0000h	39.4.1/1195

Table continues on the next page...



STM memory map (continued)

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
4	STM Count Register (STM_CNT)	32	R/W	0000_0000h	39.4.2/1196

38	STM Channel Compare Register (STM_CMP2)	32	R/W	0000_0000h	39.4.5/1198
40	STM Channel Control Register (STM_CCR3)	32	R/W	0000_0000h	39.4.3/1197
44	STM Channel Interrupt Register (STM_CIR3)	32	w1c	0000_0000h	39.4.4/1197
48	STM Channel Compare Register (STM_CMP3)	32	R/W	0000_0000h	39.4.5/1198

39.4.1 STM Control Register (STM_CR)

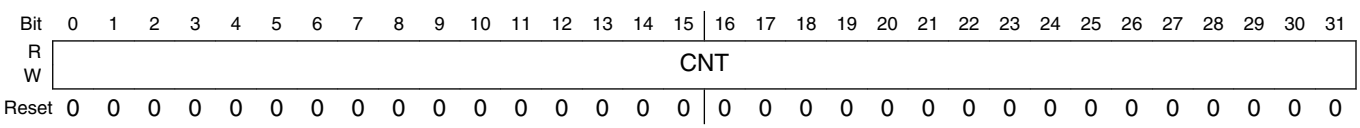
The STM Control Register includes the prescale value, freeze control and timer enable bits.

Address: 0h base + 0h offset = 0h

STM_CR field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–23 CPS	Counter Prescaler. Selects the clock divide value for the prescaler (1 - 256). 0x00 Divide system clock by 1 0x01 Divide system clock by 2

Table continues on the next page...



STM_CR field descriptions (continued)

Field	Description
	---------- 0xFF Divide system clock by 256
24–29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30 FRZ	Freeze. Allows the timer counter to be stopped when the device enters debug mode. **NOTE:** When the MCU enters debug mode, the STM is notified and uses the FRZ bit to determine counter mode. 0 STM counter continues to run in debug mode. 1 STM counter is stopped in debug mode.
31 TEN	Timer counter Enabled. 0 Counter is disabled. 1 Counter is enabled.

39.4.2 STM Count Register (STM_CNT)

The STM Count Register holds the timer count value.

Address: 0h base + 4h offset = 4h

STM_CNT field descriptions

Field	Description
0–31 CNT	Timer count value used as the time base for all channels. When enabled, the counter increments at the rate of the system clock divided by the prescale value.

39.4.3 STM Channel Control Register (STM_CCR*n*)

The STM Channel Control Register (STM_CCRn) has the enable bit for channel n of the timer.

Address: 0h base + 10h offset + (16d × i), where i=0d to 3d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

STM_CIR*n* field descriptions

Field	Description
0–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 CIF	Channel Interrupt Flag 0 No interrupt request. 1 Interrupt request due to a match on the channel.

39.4.5 STM Channel Compare Register (STM_CMP*n*)

The STM channel compare register (STM_CMPn) holds the compare value for channel n.

Address: 0h base + 18h offset + (16d × i), where i=0d to 3d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	CMP																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

STM_CMP*n* field descriptions

Field	Description
0–31 CMP	Compare value for channel n. If the STM_CCRn[CEN] bit is set and the STM_CMPn register matches the STM_CNT register, a channel interrupt request is generated and the STM_CIRn[CIF] bit is set.

39.5 Functional description

The STM has one 32-bit up counter (STM_CNT) that is used as the time base for all channels. When enabled, the counter increments at the system clock frequency divided by a prescale value. The STM_CR[CPS] field sets the divider to any value in the range from 1 to 256. The counter is enabled with the STM_CR[TEN] bit. When enabled in normal mode, the counter continuously increments. When enabled in debug mode, the counter operation is controlled by the STM_CR[FRZ] bit. When the STM_CR[FRZ] bit is set, the counter is stopped in debug mode; otherwise, it continues to run in debug mode. The counter rolls over at 0xFFFF_FFFF to 0x0000_0000 with no restrictions at this boundary.

The STM has four identical compare channels. Each channel includes a channel control register (STM_CCR*n*), a channel interrupt register (STM_CIR*n*), and a channel compare register (STM_CMP*n*). The channel is enabled by setting the STM_CCR*n*[CEN] bit.

When enabled, the channel will set the STM_CIR*n*[CIF] bit and generate an interrupt request when the channel compare register matches the timer counter. The interrupt request is cleared by writing 1 to the STM_CIR*n*[CIF] bit. A write of 0 to the STM_CIR*n*[CIF] bit has no effect.

NOTE

The STM counter does not advance when the system clock is stopped.

Chapter 40
Software Watchdog Timer (SWT)

40.1 Software Watchdog Timer (SWT) chip-specific module information

40.1.1 Implementation

- Internal 16MHz RC oscillator clock is used for timer operation
- Programmable selection of “instruction address” or “legacy” servicing
  - For “instruction address” servicing: programmable selection of fixed or changing address
  - For “legacy” servicing: Programmable selection of fixed or keyed servicing
- Master access protection

40.1.2 Configuration

MPC5746R implements three SWTs:

- SWT0 (CPU0)
- SWT1 (CPU1), enabled by default

NOTE

CPU1 can access SWT0 and CPU0 can access SWT1, but by using SMPU we can restrict the access of CPU0 to only SWT0 and same can be done for CPU1.

- SWT3 (Security: accessible by CPU0 and CPU1)

MPC5746R-specific register reset values are shown in the following table:

Table 40-1. Register reset values

Register	Reset value
SWT0_CR	0xFF00_010A
SWT0_TO	0x0005_FCD0
SWT1_CR	0xFF00_011B
SWT1_TO	0x0003_FDE0
SWT3_CR	0xFF00_010A
SWT3_TO	0x0003_FDE0

SWT_TO register: The IRCOSC is used to drive the down counter.

40.1.3 SWT_TO register minimum value

The SWT Time-out Register (SWT_TO) holds the watchdog time-out period in clock cycles. The minimum value is 100h. If a value smaller than the minimum value is written to the register, the time-out value is set to 100h.

40.1.4 SWT time-out events: configuring reset and interrupt requests

Configure the outcomes of SWT time-out events by programming ITR in the SWT Control Register (SWT_CR) as well as FCCU reactions to associated non-critical faults (NCFs). The following table shows the NCFs to which the SWT generates reset and interrupt requests.

Table 40-2. SWT reset and interrupt request routing

SWT instance	SWT_CR[ITR] is 0	SWT_CR[ITR] is 1	
	Any time-out generates reset request to	Initial time-out generates interrupt request to	Second consecutive time-out generates reset request to
SWT_0	NCF[21]	IRQ[32] and NCF[20]	NCF[21]
SWT_1	NCF[19]	IRQ[33]	NCF[19]
SWT_3	NCF[17]	IRQ[35]	NCF[17]

CAUTION

For any NCF that receives an SWT reset request: If the default FCCU reaction is no reset but the intended application requires a reset, configure the FCCU's reaction to be a long functional reset or short functional reset.

40.2 Introduction

This section provides an overview, list of features, and modes of operation for the SWT.

40.2.1 Overview

The Software Watchdog Timer (SWT) is a peripheral module that can prevent system lockup in situations such as software getting trapped in a loop or if a bus transaction fails to terminate. When enabled, the SWT requires periodic execution of a watchdog servicing operation. The servicing operation resets the timer to a specified time-out period. If this servicing action does not occur before the timer expires, the SWT generates an interrupt or hardware reset request. The SWT can be configured to generate a reset request or interrupt on an initial time-out. The SWT always generates a reset request on a second consecutive time-out.

40.2.2 Features

The SWT has the following features:

- 32-bit time-out register to set the time-out period
- Programmable selection of window mode or regular servicing
- Programmable selection of reset or interrupt on an initial time-out
- Programmable selection of the servicing mode
- Master access protection
- Hard and soft configuration lock bits
- Reset configuration inputs allow timer to be enabled out of reset

40.2.3 Modes of operation

The SWT supports three device modes of operation: normal, debug and stop. When the SWT is enabled in normal mode, its counter runs continuously. In debug mode, operation of the counter is controlled by the FRZ bit in the SWT_CR. If the FRZ bit is set, the counter is stopped in debug mode, otherwise it continues to run. In stop mode, operation of the counter is controlled by the STP bit in the SWT_CR. If the STP bit is set, the counter is stopped in stop mode, otherwise it continues to run.

40.3 External signal description

The SWT module does not have any external interface signals.

40.4 Memory Map and Registers

The SWT programming model has seven 32-bit registers. The programming model can only be accessed using 32-bit (word) accesses. References using a different size are invalid. Other types of invalid accesses include: writes to read-only registers, incorrect values written to the service register when enabled, accesses to reserved addresses and accesses by masters without permission. If the RIA bit in the SWT_CR is set then the SWT generates a system reset on an invalid access otherwise a bus error is generated. If either the HLK or SLK bits in the SWT_CR are set, then the SWT_CR, SWT_TO, SWT_WN, and SWT_SK registers are read-only.

The SWT memory map is shown in the following table.

SWT memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	SWT Control Register (SWT_CR)	32	R/W	See section	40.4.1/1205
4	SWT Interrupt Register (SWT_IR)	32	R/W	0000_0000h	40.4.2/1208
8	SWT Time-out Register (SWT_TO)	32	R/W	See section	40.4.3/1208
C	SWT Window Register (SWT_WN)	32	R/W	0000_0000h	40.4.4/1209
10	SWT Service Register (SWT_SR)	32	W	0000_0000h	40.4.5/1209

40.4.1 SWT Control Register (SWT_CR)

NOTE

The reset value of this register is implementation specific. See the chip-specific SWT information.

The SWT_CR contains fields for configuring and controlling the SWT.

This register is read-only if either the SWT_CR[HLK] or SWT_CR[SLK] bits are set.

Address: 0h base + 0h offset = 0h

* Notes:

- The reset value of this register is implementation specific. See the chip-specific SWT information.

SWT_TO field descriptions

Field	Description
0–31 WTO	Watchdog time-out period in clock cycles. An internal 32-bit down counter is loaded with this value or 0x100, whichever is greater, when the service sequence is written or when the SWT is enabled.

40.4.4 SWT Window Register (SWT_WN)

The SWT Window (SWT_WN) register contains the 32-bit window start value. This register is cleared on reset. This register is read-only if either the SWT_CR[HLK] or SWT_CR[SLK] bits are set.

Address: 0h base + Ch offset = Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	WST																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SWT_WN field descriptions

Field	Description
0–31 WST	Window Start Value When window mode is enabled, the service sequence can only be written when the internal down counter is less than this value.

40.4.5 SWT Service Register (SWT_SR)

The SWT Service (SWT_SR) register is the target for service operation writes used to reset the watchdog timer.

Address: 0h base + 10h offset = 10h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SWT_SR field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 WSC	Watchdog Service Code This field is used to service the watchdog and to clear the soft lock bit (SWT_CR[SLK]). If the SWT_CR[SMD] field is 01b, two pseudorandom key values are written to service the watchdog, see Functional description for details. Otherwise, the sequence 0xA602 followed by 0xB480 is written to the WSC field. To clear the soft lock bit (SWT_CR[SLK]), the value 0xC520 followed by 0xD928 is written to the WSC field. When read, the WSC field always returns zero.

40.4.6 SWT Counter Output Register (SWT_CO)

The SWT Counter Output (SWT_CO) register is a read-only register that shows the value of the internal down counter when the SWT is disabled.

Address: 0h base + 14h offset = 14h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	CNT																															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SWT_CO field descriptions

Field	Description
0–31 CNT	Watchdog Count. When the watchdog is disabled (SWT_CR[WEN]=0), this field shows the value of the internal down counter. When the watchdog is enabled (SWT_CR[WEN]=1), this field is cleared (the value is 0x0000_0000). Values in this field can lag behind the internal counter value for up to six system plus eight counter clock cycles. Therefore, the value read from this field immediately after disabling the watchdog may be higher than the actual value of the internal counter.

40.4.7 SWT Service Key Register (SWT_SK)

The SWT Service Key (SWT_SK) register holds the previous (or initial) service key value. This register is read-only if either the SWT_CR[HLK] or SWT_CR[SLK] bits are set.

Address: 0h base + 18h offset = 18h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0																SK															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SWT_SK field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 SK	Service Key This field is the previous (or initial) service key value used in keyed service mode. If SWT_CR[SMD] is 01b, the next key value to be written to the SWT_SR is (17*SK+3) mod 2^{16} .

40.5 Functional description

40.5.1 Introduction

The SWT is a 32-bit window watchdog timer designed to enable the system to recover in situations such as software getting trapped in a loop or if a bus transaction fails to terminate. It includes:

- a control register (SWT_CR),
- an interrupt register (SWT_IR),
- a time-out register (SWT_TO),
- a window register (SWT_WN),
- a service register (SWT_SR),
- a counter output register (SWT_CO), and
- a service key register (SWT_SK).

Accesses to SWT registers occur with no peripheral bus wait states. (The peripheral bus bridge may add one or more system wait states.) However, due to synchronization logic in the SWT design, recognition of the service sequence or configuration changes may require up to three system plus seven counter clock cycles.

40.5.1.1 SWT_CR register

The SWT_CR register includes bits to enable the timer, set configuration options, and lock configuration of the module. The watchdog is enabled by setting the SWT_CR[WEN] bit. The reset value of the SWT_CR[WEN] bit is device specific.[3] If the reset value of this bit is 1, the watchdog starts operation automatically after reset is released. Some devices can be configured to clear this bit automatically during the boot process.

40.5.1.2 SWT_TO register

The SWT_TO register holds the watchdog time-out period in clock cycles unless the value is less than 0x100, in which case the time-out period is set to 0x100. When the SWT is enabled, the time-out period is loaded into an internal 32-bit down counter each time a valid service operation is performed. See the Configuration section to determine the source that is used to clock the down counter.

40.5.1.3 SWT_CO register

The SWT_CO register shows the value of the down counter when the watchdog is disabled. When the watchdog is enabled this register is cleared. The value shown in this register can lag behind the value in the internal counter for up to six system plus eight counter clock cycles.

The SWT_CO register can be used during a software self test of the SWT. For example, the SWT can be enabled and not serviced for a fixed period of time less than the time-out value. Then the SWT can be disabled (SWT_CR[WEN] cleared) and the value of the SWT_CO register read to determine if the internal down counter is working properly.

3. See the chip-specific SWT information.

40.5.2 Configuration locking

The configuration of the SWT can be locked through use of either a soft lock or a hard lock. In either case, when locked, the SWT_CR, SWT_TO, SWT_WN and SWT_SK registers are read-only.

40.5.2.1 Hard lock

The hard lock is enabled by setting the SWT_CR[HLK] bit, which can only be cleared by a reset.

40.5.2.2 Soft lock

The soft lock is enabled by setting the SWT_CR[SLK] bit and is cleared by writing the unlock sequence to the service register.

40.5.3 Unlock sequence

The unlock sequence is a write of 0xC520 followed by a write of 0xD928 to the SWT_SR[WSC] field. There is no timing requirement between the two writes. The unlock sequence logic ignores service sequence writes and recognizes the 0xC520, 0xD928 sequence regardless of previous writes. The unlock sequence can be written at any time and does not require the SWT_CR[WEN] bit to be set.

40.5.4 Servicing operations

When enabled, the SWT requires periodic execution of a servicing operation that is determined by the SWT_CR[SMD] field. Properly servicing the watchdog loads the internal down counter with the time-out period. The servicing modes are:

- fixed service sequence
- keyed service sequence
- fixed execution address
- incremental execution address

40.5.4.1 Fixed service sequence mode

If the SWT_CR[SMD] field is 00b, the fixed service sequence mode is selected, which requires writing 0xA602, then 0xB480 to the SWT_SR[WSC] field to service the watchdog. There is no timing requirement between the two writes and the service sequence logic ignores unlock sequence writes.

40.5.4.2 Keyed service sequence mode

If the SWT_CR[SMD] field is 01b, then the keyed service sequence mode is selected, which requires writing two pseudorandom keys to the SWT_SR[WSC] field to service the watchdog. The key values are determined by the pseudorandom key generator defined by the equation in the following figure. This algorithm will generate a sequence of 2^{16} different key values before repeating. The state of the key generator is held in the SWT_SK register. For example, if SWT_SK[SK] is 0x0100, then the service sequence keys are 0x1103, 0x2136. In this mode, each time a valid key is written to the SWT_SR register, the SWT_SK register is updated. So, after servicing the watchdog by writing 0x1103 and then 0x2136 to the SWT_SR[WSC] field, SWT_SK[SK] is 0x2136 and the next key sequence is 0x3499, 0x7E2C.

$$SK_{n+1} = (17 \times SK_n + 3) \bmod 2^{16}$$

Figure 40-8. Pseudorandom Key Generator

40.5.4.3 Fixed execution address mode

If the SWT_CR[SMD] field is set to 10b, the fixed execution address mode is selected, which requires executing code at the address loaded into the designated IAC register to service the watchdog. In this mode, the IAC register cannot be updated while the watchdog is enabled.

40.5.4.4 Incremental execution address mode

If the SWT_CR[SMD] field is set to 11b, the incremental execution address mode is selected, which requires executing code at the address loaded into the designated IAC register to service the watchdog. In this mode, the IAC register can be updated while the watchdog is enabled.

40.5.4.5 Window mode

If window mode is enabled (SWT_CR[WND] bit is set), the service sequence must be performed in the last part of the time-out period defined by the window register. The window is open when the down counter is less than the value in the SWT_WN register. Outside of this window, service sequence writes are invalid accesses and generate a bus error or reset depending on the value of the SWT_CR[RIA] bit. For example, if the SWT_TO register is set to 5000 and SWT_WN register is set to 1000, then the service sequence must be performed in the last 20% of the time-out period. There is a short lag in the time it takes for the window to open due to synchronization logic in the watchdog design. This delay could be up to three system plus four counter clock cycles.

40.5.5 Time-out

The Interrupt Then Reset bit (SWT_CR[ITR]) controls the SWT's action taken when a time-out occurs.

- If the SWT_CR[ITR] bit is 0, the SWT generates a reset request immediately on any time-out.
- If the SWT_CR[ITR] bit is 1, an initial time-out causes the SWT to generate an interrupt and load the down counter with the time-out period.
  - The interrupt is indicated by the Time-out Interrupt Flag (SWT_IR[TIF]).
  - Clear the interrupt by writing 1 to SWT_IR[TIF].

  If the service sequence is not written before the second consecutive time-out, the SWT generates a reset request.

40.5.6 Initialization

All registers should be initialized before setting the SWT_CR[WEN] bit to enable the watchdog. Registers can be initialized in any sequence.

Chapter 41
Periodic Interrupt Timer (PIT-RTI)

41.1 Periodic Interrupt Timer (PIT-RTI) chip-specific module information

41.1.1 Overview

The PIT is an array of timers that can be used to raise interrupts and trigger DMA channels. On some devices it provides a dedicated Real Time interrupt Timer (RTI), which runs on a separate IRC clock and can be used for system wake-up.

41.1.2 Configuration

MCP5746R implements two instances of the Periodic Interrupt Timer Module (PIT), PIT0 and PIT1. Each has a different feature set as shown in the following table.

Table 41-1. PIT0 and PIT1 feature set differences

Feature	PIT0	PIT1
Real Time Interrupt (RTI)	Yes	No
Lifetime Timer	No	Yes
Timer Chaining to create a 64-bit timer	No	Yes
Number of 32-bit timer channels	8	2
Timer value unchanged by a non-destructive reset	No	Yes

41.1.3 General-use PIT

The following sections describe the superset of features available for the PIT module and might describe features not implemented on this MCU. The table above shows features that are implemented on this MCU.

PIT0 has eight 32-bit timer channels. Accordingly, the register map shows eight each of the LDVAL, CVAL, TCTRL, and TFLG registers. PIT1 has only two channels and therefore the latter six of the eight registers that are shown would not be implemented.

41.2 Introduction

The following sections show the PIT's:

- Block diagram
- Features

41.2.1 Block diagram

The following figure shows the block diagram of the PIT-RTI module.

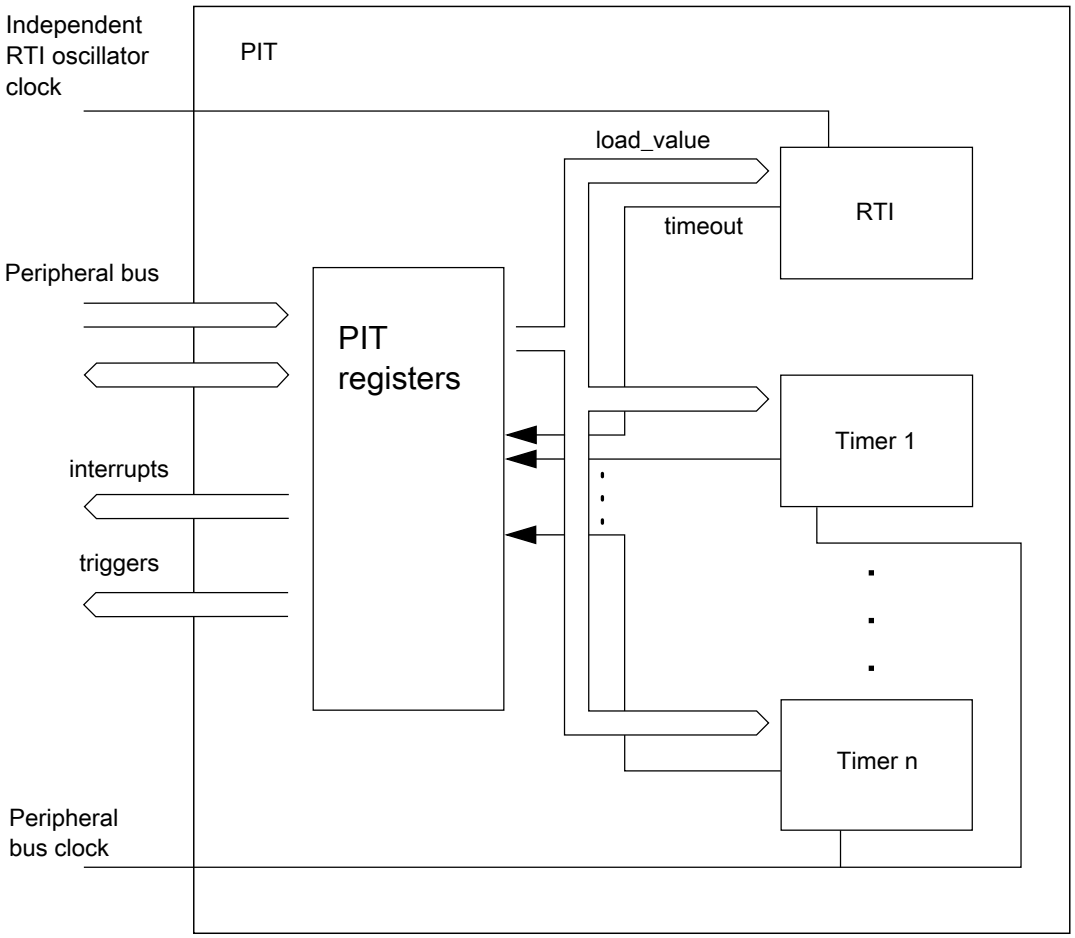

Figure 41-1. Block diagram of the PIT-RTI

NOTE

See the chip-specific PIT information for the number of PIT channels used in this MCU.

41.2.2 Features

The main features of this block are:

- One RTI (Real-Time Interrupt) timer to wakeup the CPU in stop mode
- Ability of timers to generate DMA trigger pulses
- Ability of timers to generate interrupts
- Maskable interrupts
- Option to raise RTI interrupt, even when the bus clock is switched off

- Power saving with a separate input clock for the RTI timer. All other timers share one common core clock.
- Independent timeout periods for each timer

41.3 Modes of operation

This subsection describes briefly all operating modes supported by the PIT.

- Run Mode

  All functional parts of the PIT are running during normal Run Mode.

- Stop Mode

  The RTI can continue to run in STOP mode.

41.4 Signal description

The PIT module has no external pins.

41.5 Memory map/register description

This section provides a detailed description of all registers accessible in the PIT_RTI module.

- Reserved registers will read as 0, writes will have no effect.
- See the chip-specific PIT information for the number of PIT channels used in this MCU.
- The RTI registers should be programmed only when the RTI clock is running.

NOTE

When a chip has more than one instance of the PIT, the different instances might have different feature and register sets. Please see the configuration information.

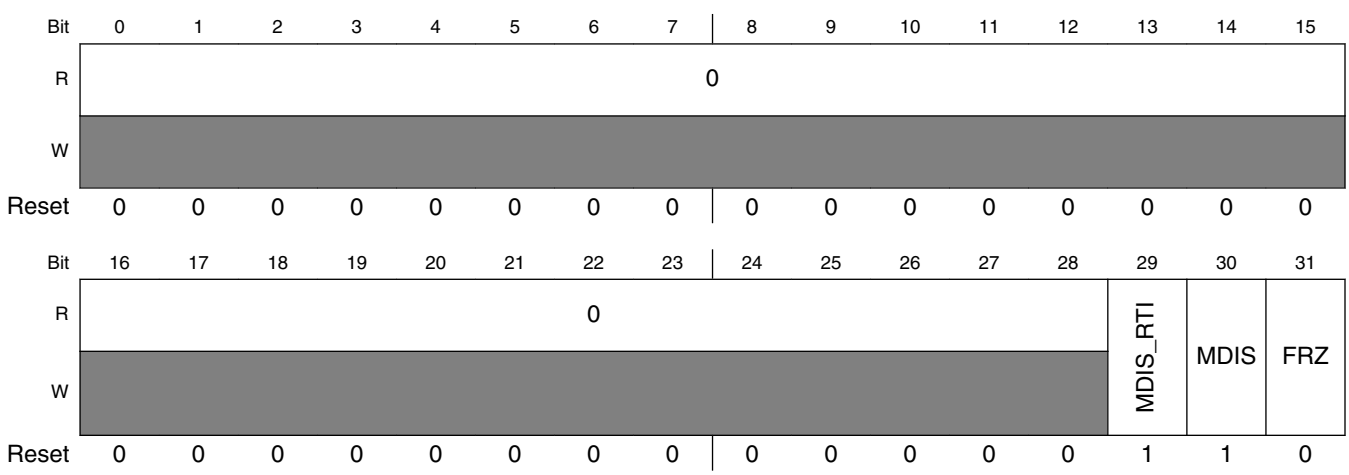
PIT memory map (continued)



Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
15C	Timer Flag Register (PIT_TFLG5)	32	R/W	0000_0000h	41.5.11/ 1229
160	Timer Load Value Register (PIT_LDVAL6)	32	R/W	0000_0000h	41.5.8/1227
164	Current Timer Value Register (PIT_CVAL6)	32	R	0000_0000h	41.5.9/1227
168	Timer Control Register (PIT_TCTRL6)	32	R/W	0000_0000h	41.5.10/ 1228
16C	Timer Flag Register (PIT_TFLG6)	32	R/W	0000_0000h	41.5.11/ 1229
170	Timer Load Value Register (PIT_LDVAL7)	32	R/W	0000_0000h	41.5.8/1227
174	Current Timer Value Register (PIT_CVAL7)	32	R	0000_0000h	41.5.9/1227
178	Timer Control Register (PIT_TCTRL7)	32	R/W	0000_0000h	41.5.10/ 1228
17C	Timer Flag Register (PIT_TFLG7)	32	R/W	0000_0000h	41.5.11/ 1229

41.5.1 PIT Module Control Register (PIT_MCR)

This register enables or disables the PIT timer clocks and controls the timers when the PIT enters the Debug mode.

Access: User read/write

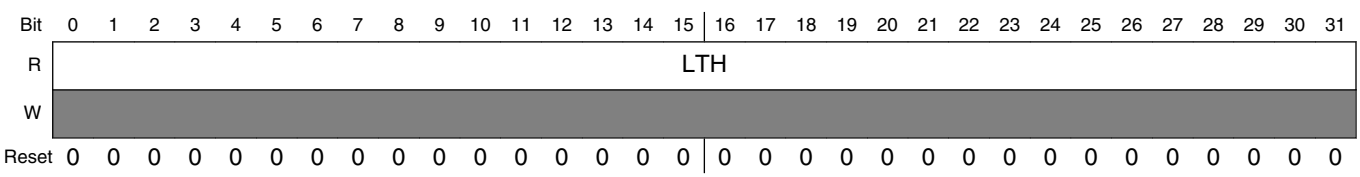
Address: 0h base + 0h offset = 0h

PIT_MCR field descriptions

Field	Description
0–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

PIT_MCR field descriptions (continued)



Field	Description
29 MDIS_RTI	Module Disable - RTI section This is used to disable the RTI timer. This bit must be enabled before any RTI setup is done. 0 Clock for RTI Timers is enabled 1 Clock for RTI Timers is disabled
30 MDIS	Module Disable - (PIT section) Disables the standard timers.The RTI timer is not affected by this field. This field must be enabled before any other setup is done. **NOTE:** Always write to this bit after at least 3 bus clock cycles of enabling the PIT clock gate in the device clock generation module. 0 Clock for standard PIT timers is enabled. 1 Clock for standard PIT timers is disabled.
31 FRZ	Freeze Allows the timers to be stopped when the device enters the Debug mode. 0 Timers continue to run in Debug mode. 1 Timers are stopped in Debug mode.

41.5.2 PIT Upper Lifetime Timer Register (PIT_LTMR64H)

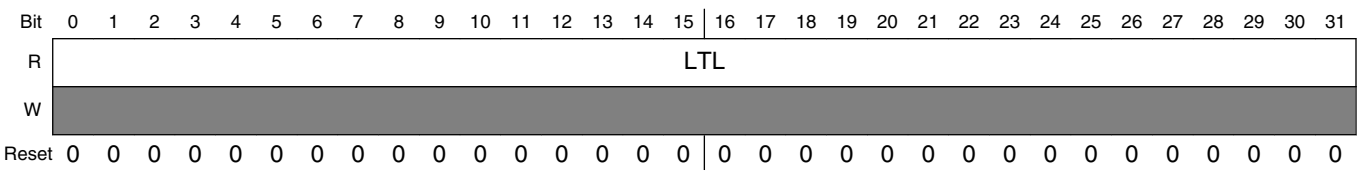
This register is intended for applications that chain timer 0 and timer 1 to build a 64-bit lifetimer.

Access: User read only

Address: 0h base + E0h offset = E0h

PIT_LTMR64H field descriptions

Field	Description
0–31 LTH	Life Timer value Shows the timer value of timer 1. If this register is read at a time t1, LTMR64L shows the value of timer 0 at time t1.



41.5.3 PIT Lower Lifetime Timer Register (PIT_LTMR64L)

This register is intended for applications that chain timer 0 and timer 1 to build a 64-bit lifetimer.

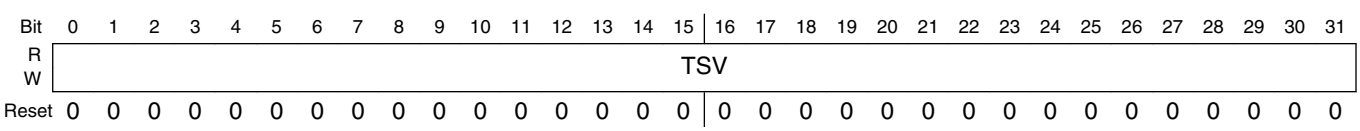
To use LTMR64H and LTMR64L, timer 0 and timer 1 need to be chained. To obtain the correct value, first read LTMR64H and then LTMR64L. LTMR64H will have the value of CVAL1 at the time of the first access, LTMR64L will have the value of CVAL0 at the time of the first access, therefore the application does not need to worry about carry-over effects of the running counter.

Access: User read only

Address: 0h base + E4h offset = E4h

PIT_LTMR64L field descriptions

Field	Description
0–31 LTL	Life Timer value Shows the value of timer 0 at the time LTMR64H was last read. It will only update if LTMR64H is read.



41.5.4 Timer Load Value Register (PIT_RTI_LDVAL)

These registers select the timeout period for the timer interrupts.

In the case of the RTI, it will take several cycles until this value is synchronized into the RTI clock domain. For all other timers the value change is visible immediately. The synchronisation mechanism allows 0 wait states in this case.

Access: User read/write

Address: 0h base + F0h offset = F0h

PIT_RTI_LDVAL field descriptions

Field	Description
0–31 TSV	Timer Start Value Sets the timer start value. The timer will count down until it reaches 0, then it will generate an interrupt and load this register value again. Writing a new value to this register will not restart the timer; instead the value will be loaded after the timer expires. To abort the current cycle and start a timer period with the new value, the timer must be disabled and enabled again. **NOTE:** The RTI timer must not be set to a value lower than 32 cycles, otherwise interrupts may be lost, as it takes several cycles to clear the RTI interrupt. For the other timers, this limit does not apply, however there will be practical limits, since the processor will require several cycles to service an interrupt.

41.5.5 Current Timer Value Register (PIT_RTI_CVAL)

These registers indicate the current timer position.

For the RTI timers, they show a value which is several cycles old, since it originates from a potentially different clock domain.

Access: User read only

Address: 0h base + F4h offset = F4h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

PIT_RTI_TCTRL field descriptions

Field	Description
0–29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30 TIE	Timer Interrupt Enable When an interrupt is pending or, RTI_TFLG[TIF] is set, enabling the interrupt will immediately cause an interrupt event. To avoid this, the associated RTI_TFLG[TIF] flag must be cleared first. 0 Interrupt requests from the RTI Timer are disabled. 1 Interrupt will be requested whenever TIF is set.
31 TEN	Timer Enable Bit This bit enables or disables the timer. 0 RTI Timer is disabled. 1 RTI Timer is active.

41.5.7 Timer Flag Register (PIT_RTI_TFLG)

These registers hold the PIT interrupt flags.

Access: User read/write

Address: 0h base + FCh offset = FCh

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

PIT_TFLG*n* field descriptions

Field	Description
0–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 TIF	Timer Interrupt Flag Sets to 1 at the end of the timer period. Writing 1 to this flag clears it. Writing 0 has no effect. If enabled, or, when TCTRLn[TIE] = 1, TIF causes an interrupt request. 0 Timeout has not yet occurred. 1 Timeout has occurred.

41.6 Functional description

This section provides the functional description of the module.

41.6.1 General operation

This section gives detailed information on the internal operation of the module. Each timer can be used to generate trigger pulses and interrupts. Each interrupt is available on a separate interrupt line. Additionally the RTI timer can be used to wake up the processor.

41.6.1.1 Timers / RTI

The timers generate triggers at periodic intervals, when enabled. The timers load the start values as specified in their LDVAL registers, count down to 0 and then load the respective start value again. Each time a timer reaches 0, it will generate a trigger pulse and set the interrupt flag.

All interrupts can be enabled or masked by setting TCTRLn[TIE]. A new interrupt can be generated only after the previous one is cleared. Since in the case of the RTI, clearing the interrupt crosses clock domains, a minimum load value of 32 must be maintained.

If desired, the current counter value of the timer can be read via the CVAL registers. The value of the RTI counter can be delayed considerably, as it is synchronized to the bus clock from the RTI clock domain.

The counter period can be restarted, by first disabling, and then enabling the timer with TCTRLn[TEN]. See the following figure.

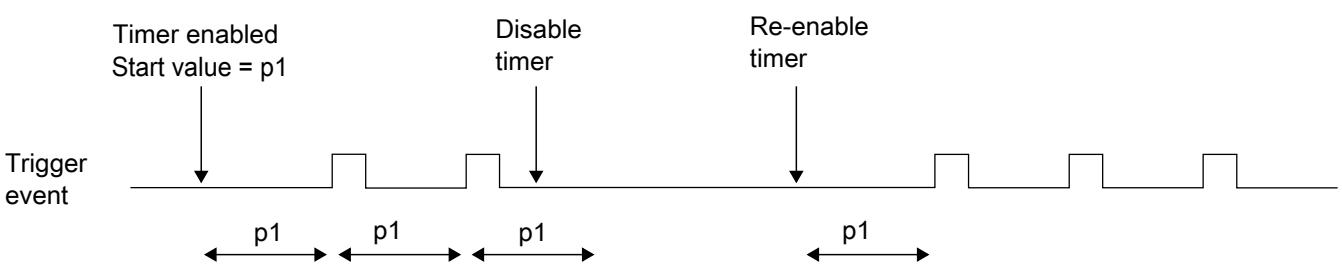

Figure 41-45. Stopping and starting a timer

The counter period of a running timer can be modified, by first disabling the timer, setting a new load value, and then enabling the timer again. See the following figure.

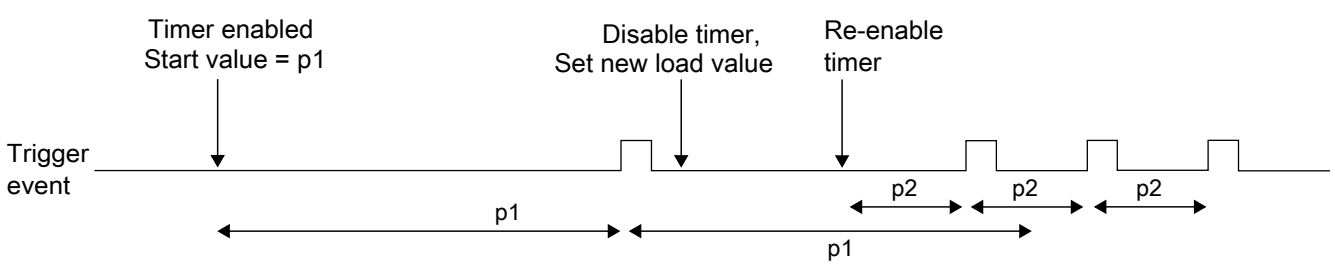

Figure 41-46. Modifying running timer period

It is also possible to change the counter period without restarting the timer by writing LDVAL with the new load value. This value will then be loaded after the next trigger event. See the following figure.

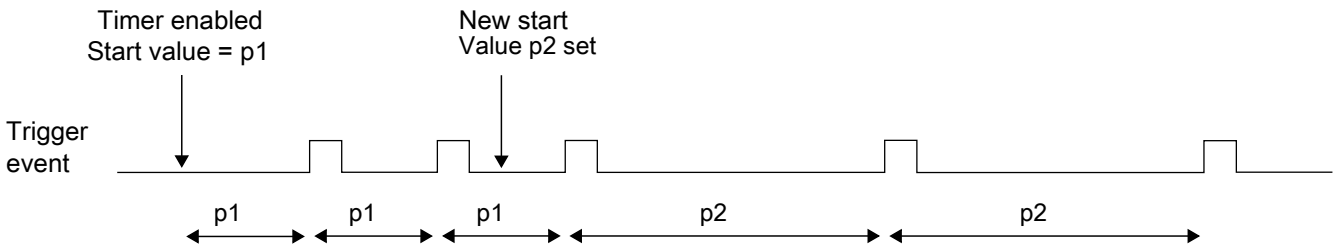

Figure 41-47. Dynamically setting a new load value

41.6.1.2 Debug mode

In Debug mode, the timers will be frozen based on MCR[FRZ]. This is intended to aid software development, allowing the developer to halt the processor, investigate the current state of the system, for example, the timer values, and then continue the operation.

41.6.2 Interrupts

All the timers support interrupt generation. The RTI is typically used for system wakeup, but can be used for interrupt generation as well. See the MCU specification for related vector addresses and priorities.

Timer interrupts can be enabled by setting TCTRLn[TIE]. TFLGn[TIF] are set to 1 when a timeout occurs on the associated timer, and are cleared to 0 by writing a 1 to the corresponding TFLGn[TIF].

The PIT_RTI generates a real time interrupt when the selected interrupt time period elapses. The RTI interrupt is disabled locally by setting TCTCRLn[TIE] to zero. The real time interrupt flag (TIF) is set to 1 when a timeout occurs, and is cleared by writing a 1 to the corresponding TFLGn[TIF]. The flag will be set regardless whether the interrupt is enabled.

The RTI can be used for periodic wakeup from STOP mode. It can also be used to generate a general-purpose interrupt.

41.6.3 Chained timers

When a timer has chain mode enabled, it will only count after the previous timer has expired. So if timer n-1 has counted down to 0, counter n will decrement the value by one. This allows to chain some of the timers together to form a longer timer. The first timer (timer 0) cannot be chained to any other timer.

41.7 Initialization and application information

In the example configuration:

- The PIT clock has a frequency of 50 MHz.
- The RTI clock has a frequency of 10 MHz.
- The RTI creates a wakeup interrupt every 500 ms.
- Timer 1 creates an interrupt every 5.12 ms.
- Timer 3 creates a trigger event every 30 ms.

The PIT module must be activated by writing a 0 to MCR[MDIS].

The 50 MHz clock frequency equates to a clock period of 20 ns and the 10 MHz frequency equates to a clock period of 100 ns. Therefore, the RTI timer needs to trigger every 500 ms/100 ns = 5,000,000 cycles. Timer 1 needs to trigger every 5.12 ms/20 ns = 256,000 cycles and Timer 3 every 30 ms/20 ns = 1,500,000 cycles. The value for the LDVAL register trigger is calculated as:

LDVAL trigger = (period / clock period) -1

This means RTI LDVAL will be written with 004C4B3F hex; LDVAL1 and LDVAL3 must be written with 0x0003E7FF and 0x0016E35F respectively.

To generate the wakeup interrupt, the interrupt line must be enabled by writing 1 to the RTI TIE bit in the TCTRL register. To start the RTI, the TEN in the RTI TCTRL register must also be set.

The interrupt for Timer 1 is enabled by setting TCTRL1[TIE]. The timer is started by writing 1 to TCTRL1[TEN].

Timer 3 shall be used only for triggering. Therefore, Timer 3 is started by writing a 1 to TCTRL3[TEN]. TCTRL3[TIE] stays at 0.

The following example code matches the described setup:

```
// turn on PIT
PIT_MCR = 0x00;

// RTI
PIT_RTI_LDVAL = 0x004C4B3F; // setup RTI for 5000000 cycles
PIT_RTI_TCTRL = PIT_TIE; // let RTI generate interrupts
PIT_RTI_TCTRL |= PIT_TEN; // start RTI

// Timer 1
PIT_LDVAL1 = 0x0003E7FF; // setup timer 1 for 256000 cycles
PIT_TCTRL1 = TIE; // enable Timer 1 interrupts
PIT_TCTRL1 |= TEN; // start Timer 1

// Timer 3
PIT_LDVAL3 = 0x0016E35F; // setup timer 3 for 1500000 cycles
PIT_TCTRL3 |= TEN; // start Timer 3
```

41.8 Example configuration for chained timers

In the example configuration:

- The PIT clock has a frequency of 100 MHz.
- Timers 1 and 2 are available.
- An interrupt shall be raised every 1 minute.

The PIT module needs to be activated by writing a 0 to MCR[MDIS].

The 100 MHz clock frequency equates to a clock period of 10 ns, so the PIT needs to count for 6000 million cycles, which is more than a single timer can do. So, Timer 1 is set up to trigger every 6 s (600 million cycles). Timer 2 is chained to Timer 1 and programmed to trigger 10 times.

The value for the LDVAL register trigger is calculated as number of cycles-1, so LDVAL1 receives the value 0x23C345FF and LDVAL2 receives the value 0x00000009.

The interrupt for Timer 2 is enabled by setting TCTRL2[TIE], the Chain mode is activated by setting TCTRL2[CHN], and the timer is started by writing a 1 to TCTRL2[TEN]. TCTRL1[TEN] needs to be set, and TCTRL1[CHN] and TCTRL1[TIE] are cleared.

The following example code matches the described setup:

```
// turn on PIT
PIT_MCR = 0x00;

// Timer 2
```

```
PIT_LDVAL2 = 0x00000009; // setup Timer 2 for 10 counts
PIT_TCTRL2 = TIE; // enable Timer 2 interrupt
PIT_TCTRL2 |= CHN; // chain Timer 2 to Timer 1
PIT_TCTRL2 |= TEN; // start Timer 2

// Timer 1
PIT_LDVAL1 = 0x23C345FF; // setup Timer 1 for 600 000 000 cycles
PIT_TCTRL1 = TEN; // start Timer 1
```

41.9 Example configuration for the lifetime timer

To configure the lifetimer timer, channels 0 and 1 need to be chained together.

First the PIT module needs to be activated by writing a 0 to the MDIS bit in the CTRL register, then the LDVAL registers need to be set to the maximum value.

The timer is a downcounter.

The following example code matches the described setup:

```
// turn on PIT
PIT_MCR = 0x00;

// Timer 1
PIT_LDVAL1 = 0xFFFFFFFF; // setup timer 1 for maximum counting period
PIT_TCTRL1 = 0x0; // disable timer 1 interrupts
PIT_TCTRL1 |= CHN; // chain timer 1 to timer 0
PIT_TCTRL1 |= TEN; // start timer 1

// Timer 0
PIT_LDVAL0 = 0xFFFFFFFF; // setup timer 0 for maximum counting period
PIT_TCTRL0 = TEN; // start timer 0
```

To access the lifetime, read first LTMR64H and then LTMR64L.

```
current_uptime = PIT_LTMR64H<<32;
current_uptime = current_uptime + PIT_LTMR64L;
```

Chapter 42
Enhanced Modular IO Subsystem (eMIOS200)

42.1 Enhanced Modular IO Subsystem (eMIOS253) chip-specific module information

42.1.1 Configuration

This chapter describes the full set of features offered by this eMIOS200 module, some of which may have been configured differently for this MPC5746R MCU.

In order to meet the enhanced safety requirements of MPC5746R, two identical eMIOS200 modules are implemented. They are located on separate peripheral bridges.

The following table describes the configuration of both eMIOS200 modules used on this MCU.

Table 42-1. Module configuration for this MCU

Item	Configuration
Channels implemented	8–23 (0–7 and 24–31 should not be used)
Channel modes	All modes are available for each channel.
Timer width	24-bits
STAC bus enabled?	Yes
UC prescaler width value	2
Clock source	DPLL0 clock (through a divider)

42.1.2 Global Timebase Enabling

The global time base enable output signal (GTBE_OUT) of both eMIOS and eTPU are ORed together and connected to the enable input signal (GTBE_IN). This has the effect that when the global time base enable bit is written in one module, all of the timebases in all of the other modules become enabled as well.

42.1.3 Clocking

The eMIOS253 is clocked by the PLL0 clock through a divider.

42.1.4 STAC bus

The eMIOS is a STAC bus client module and the STAC bus is connected to both eMIOS 253 modules.

NOTE

If the STAC-bus Export/Import feature is used, the clock ratio of eTPU : eMIOS should be 1:1 or 2:1, such as the following:

- eTPU 100MHz : eMIOS 100MHz
- eTPU 200MHz : eMIOS 100MHz

This applies whether the STAC-bus Export/Import is used from eTPU to eMIOS or used between eTPUs.

42.1.5 Output Disable Inputs

There are four output disable inputs to eMIOS200 module. The source of these inputs can be either eMIOS200 Flag output or Reaction channels output. The source selection is controlled through the following SIUL_MSCRn registers:

- eMIOS_0: SIUL2_MSCR606, SIUL2_MSCR607, SIUL2_MSCR608, and SIUL2_MSCR609
- eMIOS_1: SIUL2_MSCR632, SIUL2_MSCR633, SIUL2_MSCR634, and SIUL2_MSCR635

Please refer to the Device Input Multiplexing Tables (Excel file).

42.2 eMIOS200 Introduction

42.2.1 Overview

The configurable enhanced Modular Input/Output Subsystem (eMIOS200) provides functionality to generate or measure time events. Its overall architecture resembles that of the MIOS timer.

The predecessor MIOS timer block provides a framework in which a set of sublocks with different timer functions are assembled to attend to the specific needs of an SoC. The eMIOS200 builds on this concept by using a Unified Channel module that provides a superset of the functionality of all the individual MIOS channels, while also providing a consistent user interface. This allows more flexibility as each Unified Channel can be programmed for different functions in different applications of the SoC. In addition, eMIOS200 architecture allows the use of Dedicated Channels which perform specific functions not included in MIOS inheritance.

The block diagram of the configurable eMIOS200 block is shown below.

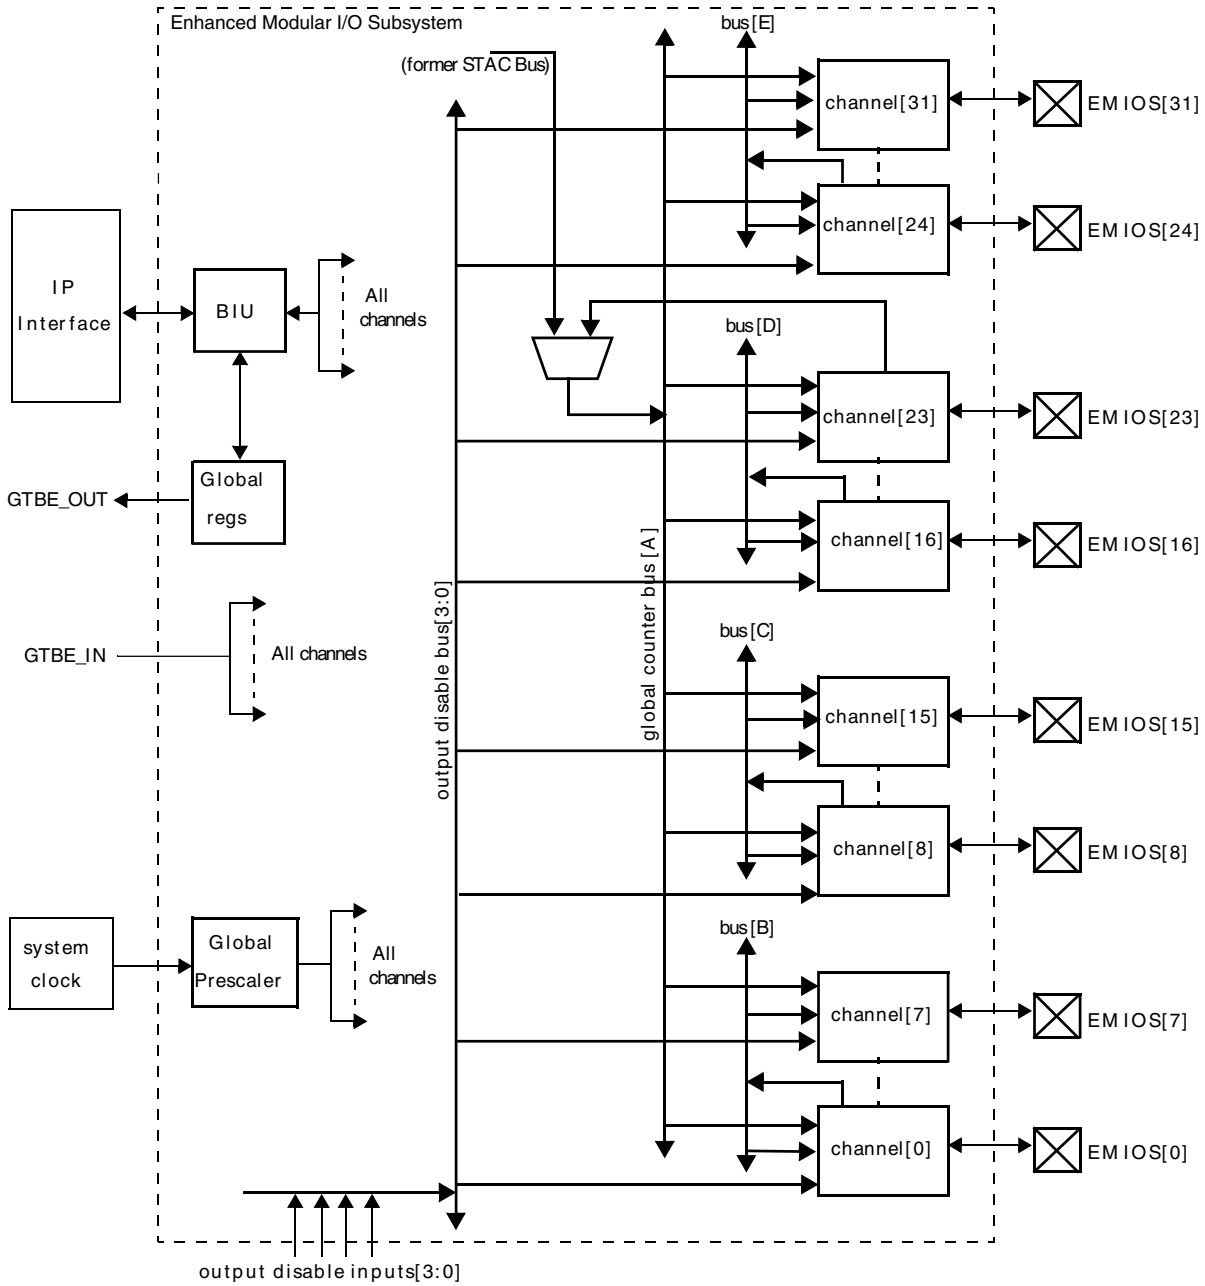

Figure 42-1. eMIOS200 full channel configuration using Unified Channels only (see Configuration section)

42.2.2 Features

The eMIOS200 has the following features:

- Up to 32 channels chosen among Unified or Dedicated Channels, not necessarily numbered in a continuous sequence. (See Configuration information)
- Data registers of either 8-, 16-, 24-, or 32-bit width. (See Configuration information)
- Counter buses B, C, D, and E can be driven by Unified Channels 0, 8, 16, and 24, respectively. (See Configuration information)
- Counter bus A can be driven by Unified Channel 23 or by the external shared timer bus(Red-Line Client).
- Each channel has its own timebase, alternative to the counter buses.
- One global prescaler
- One prescaler per channel (CP)
- Timebases shared through the counter buses
- One STAC Client (STAC)
- Control and status bits grouped in separated registers
- Synchronization among timebases
- Shadow FLAG register
- State of the Unified Channels can be frozen for debug purposes
- Motor control capability

42.2.3 Modes of operation

The Unified Channels can be configured to operate in the following modes:

- General-Purpose Input/Output (GPIO)
- Single-Action Input Capture (SAIC)
- Single-Action Output Compare (SAOC)
- Input Pulse-Width Measurement (IPWM)
- Input Period Measurement (IPM)
- Double-Action Output Compare (DAOC)
- Pulse/Edge Accumulation (PEA)
- Pulse/Edge Counting (PEC)

- Quadrature Decode (QDEC)
- Windowed Programmable Time Accumulation (WPTA)
- Modulus Counter (MC)
- Modulus Counter Buffered (MCB)
- Output Pulse-Width and Frequency Modulation (OPWFM)
- Output Pulse-Width and Frequency Modulation Buffered (OPWFMB)
- Center Aligned Output Pulse Width Modulation with Dead Time Insertion (OPWMC)
- Center Aligned Output Pulse Width Modulation with Dead Time Insertion Buffered (OPWMCB)
- Output Pulse-Width Modulation (OPWM)
- Output Pulse-Width Modulation Buffered (OPWMB)
- Output Pulse-Width Modulation with Trigger (OPWMT)

These modes are described in Unified Channel modes of operation.

Each channel can have a specific set of modes.

42.3 Memory map / register definition

42.3.1 Memory map

The overall address map organization is shown in the table below.

Whenever an access to either an absent register, absent channel, or reserved address space is performed, the transfer is terminated with an error.

Table 42-2. eMIOS200 Memory Map

eMIOS200[n] Base Address	Description
0x000	Module Configuration register (EMIOSMCR)
0x003	
0x004	Global FLAG register (EMIOSGFLAG)
0x007	
0x008	Output Update Disable (EMIOSOUDIS)
0x00B	

Table continues on the next page...

Table 42-2. eMIOS200 Memory Map (continued)

eMIOS200[n] Base Address	Description
0x00C	Disable Channel (EMIOSUCDIS)
0x00F	
0x01F	Reserved
0x020	Channel 0 to Channel 7
0x11F	
0x120	Channel 8 to Channel 15
0x21F	
0x220	Channel 16 to Channel 23
0x31F	
0x320	Channel 24 to Channel 31
0x41F	
0x420	Reserved
0xFFF	

42.3.1.1 Unified channel memory map

Addresses of Unified Channel registers are specified as offsets from the channel's base address, otherwise the eMIOS200 base address is used as reference.

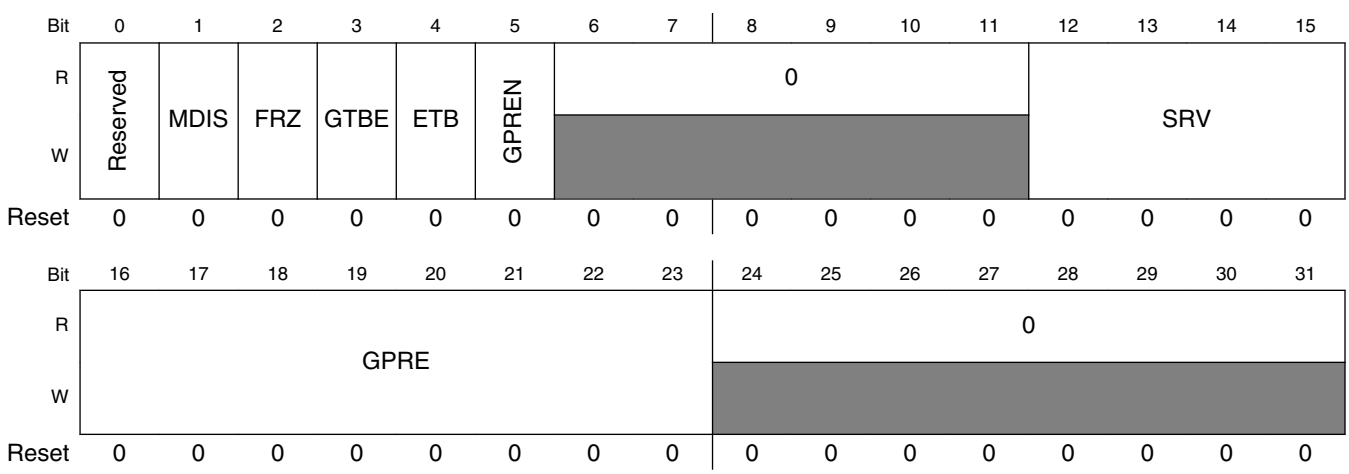
The following table describes the Unified Channel memory map.

Table 42-3. Unified channel memory map

UC[n] Base Address	Description
UC[n]_BASE + 0x000	A register (EMIOSA[n])
UC[n]_BASE + 0x004	B register (EMIOSB[n])
UC[n]_BASE + 0x008	Counter register (EMIOSCNT[n])
UC[n]_BASE + 0x00C	Control register (EMIOSC[n])
UC[n]_BASE + 0x010	Status register (EMIOSS[n])
UC[n]_BASE + 0x014	Alternate A register (EMIOSALTA[n])
UC[n]_BASE + 0x018	Control 2 register (EMIOSC2[n])
UC[n]_BASE + 0x01C to UC[n]_BASE + 0x01F	Reserved

42.4 Control Memory Map and Registers

All control registers are 32 bits wide. This document illustrates the eMIOS200 with 24 Unified Channels and 24-bit wide data registers.



eMIOS memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	eMIOS Module Configuration Register (eMIOS_MCR)	32	R/W	0000_0000h	42.4.1/1242
4	eMIOS Global FLAG Register (eMIOS_GFLAG)	32	R	0000_0000h	42.4.2/1244
8	eMIOS Output Update Disable register (eMIOS_OUDIS)	32	R/W	0000_0000h	42.4.3/1244
C	eMIOS Disable Channel register (eMIOS_UCDIS)	32	R/W	0000_0000h	42.4.4/1245

42.4.1 eMIOS Module Configuration Register (eMIOS_MCR)

The MCR register contains Global Control bits for the eMIOS200 block.

Address: 0h base + 0h offset = 0h

eMIOS_MCR field descriptions

Field	Description
0 Reserved	Reserved. This field is reserved. Only write this field with the reset value.

Table continues on the next page...

eMIOS_MCR field descriptions (continued)

Field	Description
1 MDIS	Module Disable bit. Puts the eMIOS200 into low power mode. The MDIS bit stops the clock of the block, except the access to registers EMIOSMCR, EMIOSOUDIS and EMIOSUCDIS. 0 Clock is running 1 Enter low power mode
2 FRZ	Freeze bit. This bit enables the eMIOS200 to freeze the registers of the Unified Channels when Debug Mode is requested at MCU level. Each Unified Channel should have FREN bit set in order to enter freeze state. While in Freeze state, the eMIOS200 continues to operate to allow the MCU access to the Unified Channels registers. The Unified Channel will remain frozen until the FRZ bit is written to zero or the MCU exits Debug mode or the Unified Channel FREN bit is cleared. 0 Exit freeze state 1 Stops Unified Channels operation when in Debug mode and the FREN bit is set in the EMIOSC[n] register
3 GTBE	Global Time Base Enable bit. The GTBE bit is used to export a Global Time Base Enable from the module and provide a method to start time bases of several blocks simultaneously. **NOTE:** The Global Time Base Enable input pin controls the internal counters. When asserted, Internal counters are enabled. When negated, Internal counters disabled. 0 Global Time Base Enable Out signal negated 1 Global Time Base Enable Out signal asserted
4 ETB	External Time Base bit The ETB bit selects the time base source that drives counter bus[A]. 0 Counter bus[A] assigned to Unified Channel. 1 Counter bus[A] assigned to STAC.
5 GPREN	Global Prescaler Enable bit. The GPREN bit enables the prescaler counter. 0 Prescaler disabled (no clock) and prescaler counter is cleared 1 Prescaler enabled
6–11 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
12–15 SRV	Server Time Slot bits. The SRV bits select the address of a specific STAC server to which the STAC is assigned.
16–23 GPRE	Global Prescaler bits. The GPRE[0:7] bits select the clock divider value for the global prescaler, as shown in the following table. GPRE values and corresponding divide ratio values are: 00000000 1

Table continues on the next page...

eMIOS_MCR field descriptions (continued)

Field	Description
	00000001 2 00000010 3 00000011 4 ------- - 11111110 255 11111111 256
24–31 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.

42.4.2 eMIOS Global FLAG Register (eMIOS_GFLAG)

GFLAG is a read-only register that groups the FLAG bits from all channels. Each bit relates to one channel.

Address: 0h base + 4h offset = 4h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0								F23_F0																							
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

eMIOS_GFLAG field descriptions

Field	Description
0–7 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
8–31 F23_F0	Channel [n] mirrored FLAG bit. For Unified Channels these bits are mirrors of the FLAG bits in the EMIOSS[n] register.

42.4.3 eMIOS Output Update Disable register (eMIOS_OUDIS)

Address: 0h base + 8h offset = 8h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0								OU23_OU0																							
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

eMIOS_OUDIS field descriptions

Field	Description
0–7 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
8–31 OU23_OU0	Channel [n] Output Update Disable bit. When running MC, MCB or an output mode, values are written to registers A2 and B2. OU[n] bits are used to disable transfers from registers A2 to A1 and B2 to B1. Each bit controls one channel. 0 Transfer enabled. Depending on the operation mode, transfer may occur immediately or in the next period. Unless stated otherwise, transfer occurs immediately. 1 Transfers disabled.

42.4.4 eMIOS Disable Channel register (eMIOS_UCDIS)

NOTE

See the Configuration information for the reset value of this register.

Address: 0h base + Ch offset = Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0								CHDIS23_CHDIS0																							
W

eMIOS_A*n* field descriptions

Field	Description
0–7 Reserved	Reserved. This field is reserved.

Table continues on the next page...

eMIOS_A*n* field descriptions (continued)

Field	Description
	This read-only field is reserved and always has the value 0.
8–31 A	Depending on the mode of operation, internal registers A1[0:23] or A2[0:23], used for matches and captures, can be assigned to address EMIOS_An. Both A1 and A2 are cleared by reset. The table in the EMIOS_Bn register description summarizes the EMIOS_An writing and reading accesses for all operation modes. Values not listed are reserved. For more information, see the “UC Modes of Operation” section.

42.5.2 eMIOS UC B register n (eMIOS_B*n*)

Depending on the mode of operation, internal registers B1[0:23] or B2[0:23] can be assigned to address EMIOS_Bn. Both B1 and B2 are cleared by reset. The table below summarizes the EMIOS_Bn writing and reading accesses for all operation modes. Values not listed are reserved. For more information see the “UC Modes of Operation” section.

Depending on the channel configuration, it may have an EMIOS_B register or not. EMIOS_B register is required for the following modes: DAOC, IPM, IPWM, OPWM, OPWMB, OPWFM, OPWMT, OPWFMB, OPWMC, OPWMCB, MC, MCB, PEA, PEC, WPTA.

The following table summarizes the EMIOS_An, EMIOS_Bn, and EMIOS_ALTAn writing and reading accesses for all operation modes. Values not listed are reserved. For more information, see the “UC Modes of Operation” section.

Table 42-13. EMIOS_An, EMIOS_Bn and EMIOS_ALTAn values assignment

Operation mode	Register access					
	Write	Read	Write	Read	Alt write	Alt read
GPIO	A1, A2	A1	B1, B2	B1	A2	A2
SAIC[1, 1]	–	A2	B2	B2	–	–

Table 42-13. EMIOS_An, EMIOS_Bn and EMIOS_ALTAn values assignment (continued)

Operation mode	Register access					
	Write	Read	Write	Read	Alt write	Alt read
OPWMT	A2	A1	B2	B1	A2	A2
MCB[1]	A2	A1	B2	B1	–	–
OPWFMB	A2	A1	B2	B1	–	–
OPWMCB	A2	A1	B2	B1	–	–
OPWMB	A2	A1	B2	B1	–	–

1. In these modes, the register EMIOS_Bn is not used, but B2 can be accessed.

Address: 0h base + 124h offset + (32d × i), where i=0d to 15d

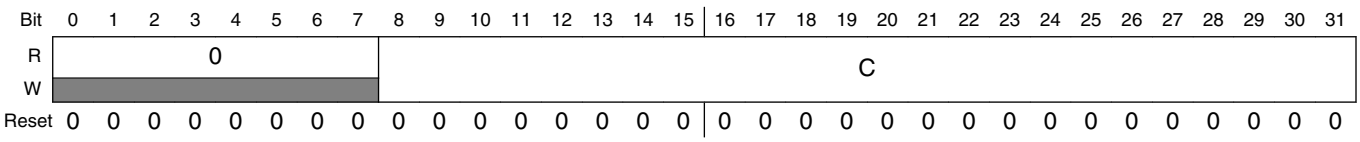
eMIOS_B*n* field descriptions

Field	Description
0–7 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
8–31 B	See text above register figure.

1. In these modes, the register EMIOS_Bn is not used, but B2 can be accessed.

42.5.3 eMIOS CNT register n (eMIOS_CNT*n*)

When GPIO mode is selected or the channel is frozen, the EMIOS_CNTn register is read/write. For all others modes, the EMIOS_CNTn is a read-only register. When entering some operation modes, this register is automatically cleared (refer to the “UC Modes of Operation” section for details).



EMIOS_CNTn register is required for the following modes:

- OPWFM
- OPWFMB
- OPWMC
- OPWMCB
- PEA
- PEC
- WPTA

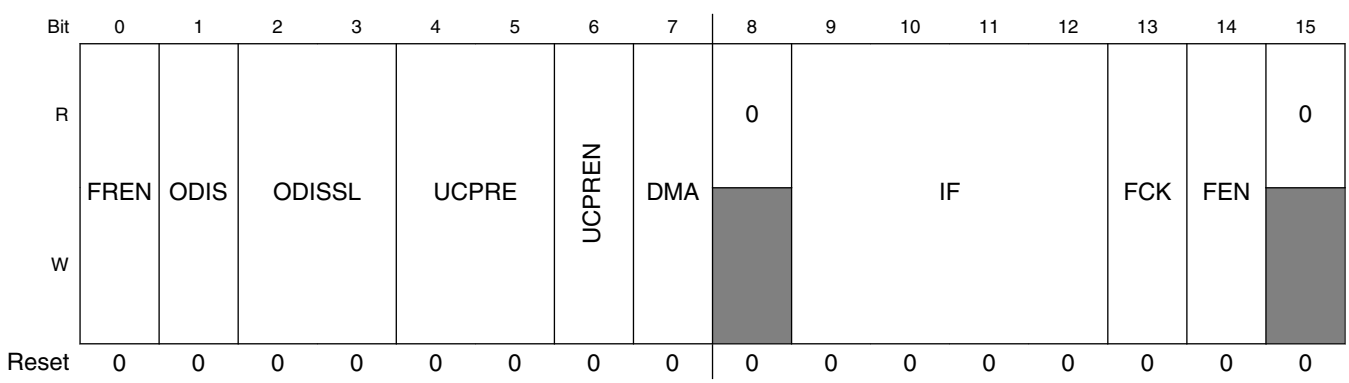
- QDEC
- MC
- MCB

For other modes, the internal counter is not used. Therefore, depending on the modes available in a channel, the internal counter may be absent.

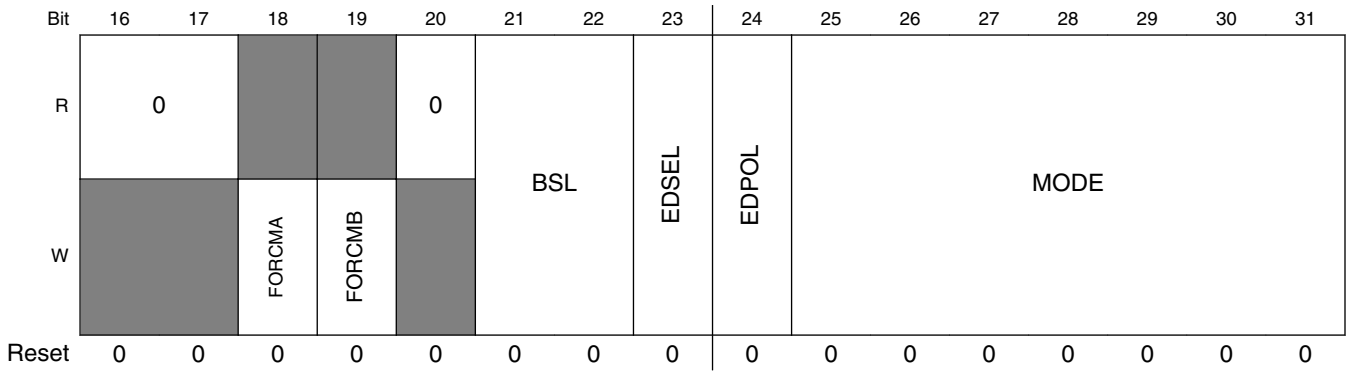
Address: 0h base + 128h offset + (32d × i), where i=0d to 15d

eMIOS_CNT*n* field descriptions

Field	Description
0–7 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
8–31 C	The C field contains the value of the internal counter.



42.5.4 eMIOS UC Control register n (eMIOS_C*n*)



The UC Control register gathers several read/write control bits affecting the UC operation conditions.

NOTE

This register does not include a FORCMB bit for Channel Types A and C.

Address: 0h base + 12Ch offset + (32d × i), where i=0d to 15d

eMIOS_C*n* field descriptions

Field	Description
0 FREN	Freeze Enable bit. The FREN bit, if set and validated by FRZ bit in EMIOS_MCR register allows the channel to enter freeze state, freezing all registers values when in debug mode and allowing the MCU to perform debug functions. 0 Normal operation 1 Freeze UC registers values
1 ODIS	Output Disable bit. The ODIS bit allows disabling the output pin when running any of the output modes with the exception of GPIO mode. 0 The output pin operates normally 1 If the selected Output Disable Input signal is asserted, the output pin goes to EDPOL for OPWFMB and OPWMB modes and to the complement of EDPOL for other output modes, but the Unified Channel continues to operate normally, i.e., it continues to produce FLAG and matches. When the selected Output Disable Input signal is negated, the output pin operates normally.
2–3 ODISSL	Output Disable select bits. The ODISSL[0:1] bits select one of the four output disable input signals, as shown in the following table. **Table 42-23. UC ODISSL selection** ODISSL[0:1] → input signal 00 → Output Disable Input 0 01 → Output Disable Input 1 10 → Output Disable Input 2 11 → Output Disable Input 3
4–5 UCPRE	Prescaler bits. The UCPRE[0:1] bits select the clock divider value for the internal prescaler of Unified Channel, as shown in the following table. **Table 42-22. UC Internal Prescaler clock divider** UCPRE[0:1] → Divide ratio 00 → 1

Field	Description
14 FEN	FLAG Enable bit. The FEN bit allows the Unified Channel FLAG bit to generate an interrupt signal or a DMA request signal (the type of signal to be generated is defined by the DMA bit). 0 Disable (FLAG does not generate an interrupt request) 1 Enable (FLAG generates an interrupt request)
15–17 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
18 FORCMA	Force Match A bit. For output modes, the FORCMA bit is equivalent to a successful comparison on comparator A (except that the FLAG bit is not set). This bit is cleared by reset and is always read as zero. This bit is valid for every output operation mode which uses comparator A, otherwise it has no effect. For input modes, the FORCMA bit is not used and writing to it has no effect. 0 Has no effect. 1 Force a match at comparator A
19 FORCMB	Force Match B bit. For output modes, the FORCMB bit is equivalent to a successful comparison on comparator B (except that the FLAG bit is not set). This bit is cleared by reset and is always read as zero. This bit is valid for every output operation mode which uses comparator B, otherwise it has no effect. 0 Has not effect 1 Force a match at comparator B
20 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
21–22 BSL	Bus Select bits. The BSL[0:1] bits are used to select either one of the counter buses or the internal counter to be used by the Unified Channel , as shown in the following tables.

Table 42-20. UC BSL bits

BSL[0:1]	Selected bus[1]
00	All channels: counter bus[A]
01	Channels 0 to 7: counter bus[B]
	Channels 8 to 15: counter bus[C]
	Channels 16 to 23: counter bus[D]
	Channels 24 to 31: counter bus[E]
10	Reserved
11	All channels: internal counter

1. Not all devices support all counter buses. See the Device Configuration chapter for details.

23 EDSEL	Edge Selection bit.

Table continues on the next page...

eMIOS_C*n* field descriptions (continued)

Field	Description
	For input modes, the EDSEL bit selects whether the internal counter is triggered by both edges of a pulse or just by a single edge as defined by the EDPOL bit . When not shown in the mode of operation description, this bit has no effect. 0 – Single edge triggering defined by the EDPOL bit 1 – Both edges triggering{mts_ipi_slv_saic} For GPIO in mode, the EDSEL bit selects if a FLAG can be generated. 0 – A FLAG is generated as defined by the EDPOL bit 1 – No FLAG is generated For SAOC mode, the EDSEL bit selects the behavior of the output flip-flop at each match. 0 – The EDPOL value is transferred to the output flip-flop 1 – The output flip-flop is toggled
24 EDPOL	Edge Polarity bit. For input modes (except QDEC mode), the EDPOL bit asserts which edge triggers either the internal counter or an input capture or a FLAG . When not shown in the mode of operation description, this bit has no effect. 0 – Trigger on a falling edge 1 – Trigger on a rising edge **NOTE:** UC[n-1] EDPOL bit selects which edge clocks the internal counter of UC[n] **NOTE:** In order to operate properly, EDPOL bit must contain the same value in UC[n] and UC[n-1] For output modes, the EDPOL bit is used to select the logic level on the output pin . 0 – A match on comparator A clears the output flip-flop, while a match on comparator B sets it 1 – A match on comparator A sets the output flip-flop, while a match on comparator B clears it
25–31 MODE	Mode selection bits. The MODE bits select the mode of operation of the Unified Channel, as shown in the following table. Values not listed are reserved. **NOTE:** If a reserved value is written to the mode bit field, the results are unpredictable.

Table 42-19. UC MODE bits

MODE[0:6]	Mode of operation[1]
0000000	General purpose Input/Output mode (input)
0000001	General purpose Input/Output mode (output)
0000010	Single Action Input Capture
0000011	Single Action Output Compare
0000100	Input Pulse Width Measurement

1100001 through 1111111	Reserved

1. Not all modes of operation are supported. See the configuration information for details.
2. b = adjust parameters for the mode of operation. Refer to “UC Modes of Operation” section for details.

1. Filter latency (the difference in time between the input and the response) is 3 clock edges.
2. The input signal is synchronized before arriving to the digital filter.
3. Not all devices support all counter buses. See the Device Configuration chapter for details.

4. Not all modes of operation are supported. See the configuration information for details.
5. b = adjust parameters for the mode of operation. Refer to “UC Modes of Operation” section for details.

42.5.5 eMIOS UC Status register n (eMIOS_S*n*)

The UC Status register EMIOS_Sn gathers bits reflecting the status of the UC input/ output signals and the overflow condition of the internal counter.

Address: 0h base + 130h offset + (32d × i), where i=0d to 15d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	OVR	0														
W	w1c															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	OVFL	0												UCIN	UCOUT	FLAG
W	w1c															w1c
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	*	0	0

* Notes:
- UCIN field: Reset value is undefined.

eMIOS_S*n* field descriptions

Field	Description
0 OVR	Overrun bit. The OVR bit indicates that FLAG generation occurred when the FLAG bit was already set . The OVR bit can be cleared either by clearing the FLAG bit or by writing a 1 to the OVR bit. 0 Overrun has not occurred 1 Overrun has occurred

Table continues on the next page...

eMIOS_S*n* field descriptions (continued)

Field	Description
1–15 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
16 OVFL	Overflow bit. The OVFL bit indicates that an overflow has occurred in the internal counter. The OVFL bit must be cleared by software writing a 1 to it. 0 No overflow 1 An overflow had occurred
17–28 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
29 UCIN	Unified Channel Input pin bit. The UCIN bit reflects the input pin state after being filtered and synchronized.
30 UCOUT	Unified Channel Output pin bit. The UCOUT bit reflects the output pin state .
31 FLAG	FLAG bit. The FLAG bit is set when an input capture or a match event in the comparators occurred. The FLAG bit must be cleared by writing a 1 to it. 0 FLAG cleared 1 FLAG set event has occurred

42.5.6 eMIOS Alternate Address register n (eMIOS_ALTA*n*)

The eMIOS_ALTAn register provides an alternate address to access A2 channel registers in restricted modes (GPIO, PEC, WPTA, OPWMT)only. In modes where the function of eMIOS_ALTAn register is not specified, any write access is ignored and any read access returns unspecified data. If eMIOS_An register is used along with eMIOS_ALTAn, both A1 and A2 registers can be accessed in these modes. The table in the eMIOS_Bn register's description summarizes the EMIOS_ALTAn writing and reading accesses for all EMIOS_ALTAn operation modes. See the “General purpose Input/Output mode (GPIO) Mode” section, the “Pulse/Edge Counting (PEC) Mode” section, the “Windowed Programmable Time Accumulation (WPTA) Mode” section, and the “Output Pulse Width Modulation with Trigger (OPWMT) Mode” section for a more detailed description of the use of eMIOS_ALTAn register.

Address: 0h base + 134h offset + (32d × i), where i=0d to 15d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

8–31 ALTA	See text above register figure.

42.6 Functional Description

The eMIOS200 provides independent channels (Unified) that can be configured and accessed by a host MCU. Up to five time bases can be shared by the channels.

The eMIOS200 module is based on a multi-bus timer architecture in which several timer channels are used to drive counter buses that are shared among the channels. Up to five timebases can be shared by the channels through five counter buses (counter bus A or F, B, C, D and E) and each channel can generate its own timebase. There are five counter buses in the module: one global counter bus, shared by all channels and selectable among

time bases A or F, and four local counter buses (B, C, D, and E), each one dedicated to a slice of 8 channels. Counter bus A is referred to as the global counter buse. Counter buses B, C, D, and E are the local counter buses.

The eMIOS200 counter buses are driven by channels in specific locations. Global counter bus A is driven by the channel in channel slot [23].. Counter buses B, C, D, and E are driven by channels in slots 0, 8, 16, and 24, respectively. Counter bus A or F drives all channels. Counter bus B drives channels in slots from 0 through 7. Counter bus C drives channels in slots from 8 through 15. Counter bus D drives channels in slots from 16 through 23. Counter bus E drives channels from 24 through 31.

The eMIOS200 block is reset asynchronously. All registers are cleared on reset.

The following figure shows an eMIOS200 block configured with a mix of Unified Channels. In this configuration example, each one of the channels can be driven by the respective local bus—B for the [7:0] slice and D for the [23:16] slice—or by the global counter bus A. Note that there are Unified Channels with no external pin associated. These channels are used to trigger internal SoC signals such as interrupt requests or DMA transfer requests. Since the channel flags are also connected to the block top-level pins, they can be used as trigger signals for other blocks at chip level.

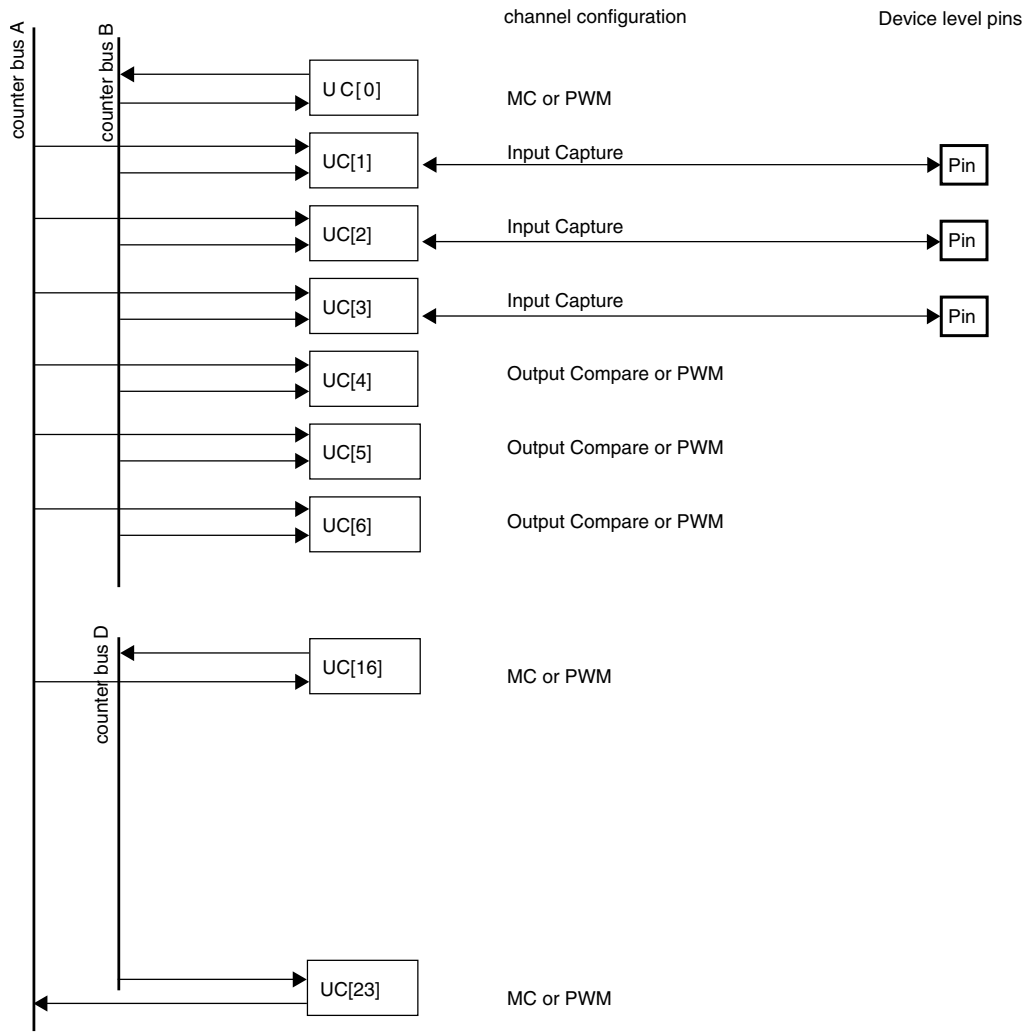

Figure 42-108. eMIOS200 example configuration using Unified Channels

42.6.1 Unified Channel (UC)

Figure 42-109 shows the Unified Channel block diagram. Each Unified Channel consists of the following:

- A counter bus selector, which selects the timebase to be used by the channel for all timing functions
- A programmable clock prescaler
- Two double-buffered data registers, A and B, that allow up to two input capture and/or output compare events to occur before software intervention is needed
- Two comparators (equal only), A and B, that compare the selected counter bus with the value in the data registers

- An internal counter, which can be used as a local time base or to count input events
- Programmable input filter, which ensures that only valid pin transitions are received by channel
- Programmable input edge detector, which detects the rising, falling, or either edge
- An output flip-flop, which holds the logic level to be applied to the output pin
- eMIOS200 Status and Control register
- An Output Disable Input selector, which selects the Output Disable Input signal that will be used as output disable

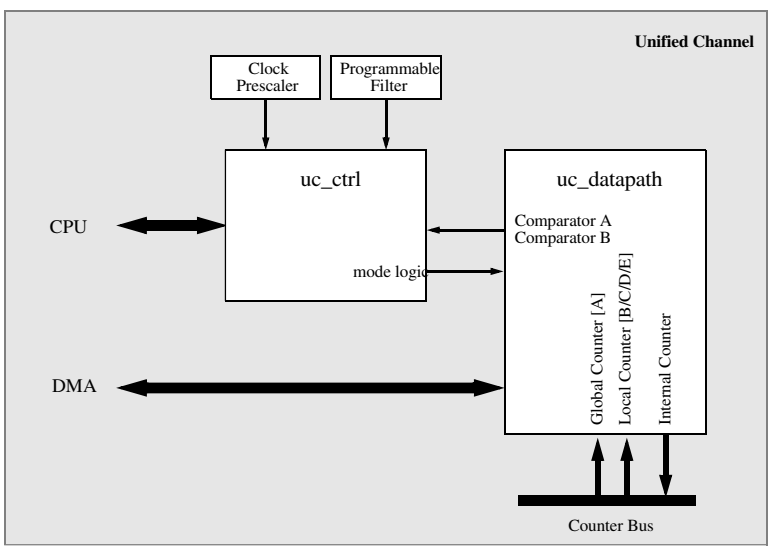

Figure 42-109. Unified Channel block diagram

Figure 42-110 shows both the Unified Channel control and datapath block diagrams. The control sub-block is responsible for the generation of signals to control the multiplexers in the datapath sub-block. Each mode is implemented by a dedicated logic independent from others modes, thus allowing to optimize the logic by disabling the mode and therefore its associated logic. Targeting the logic optimization, a set of registers is shared by the modes thus providing sequential events to be stored.

The datapath block provides the channel A and B registers, the internal timebase and comparators. Multiplexers select the input of comparators and data for the registers inputs, thus configuring the datapath to implement the channel modes. The outputs of the A and B comparators are connected to the uc_ctrl control block.

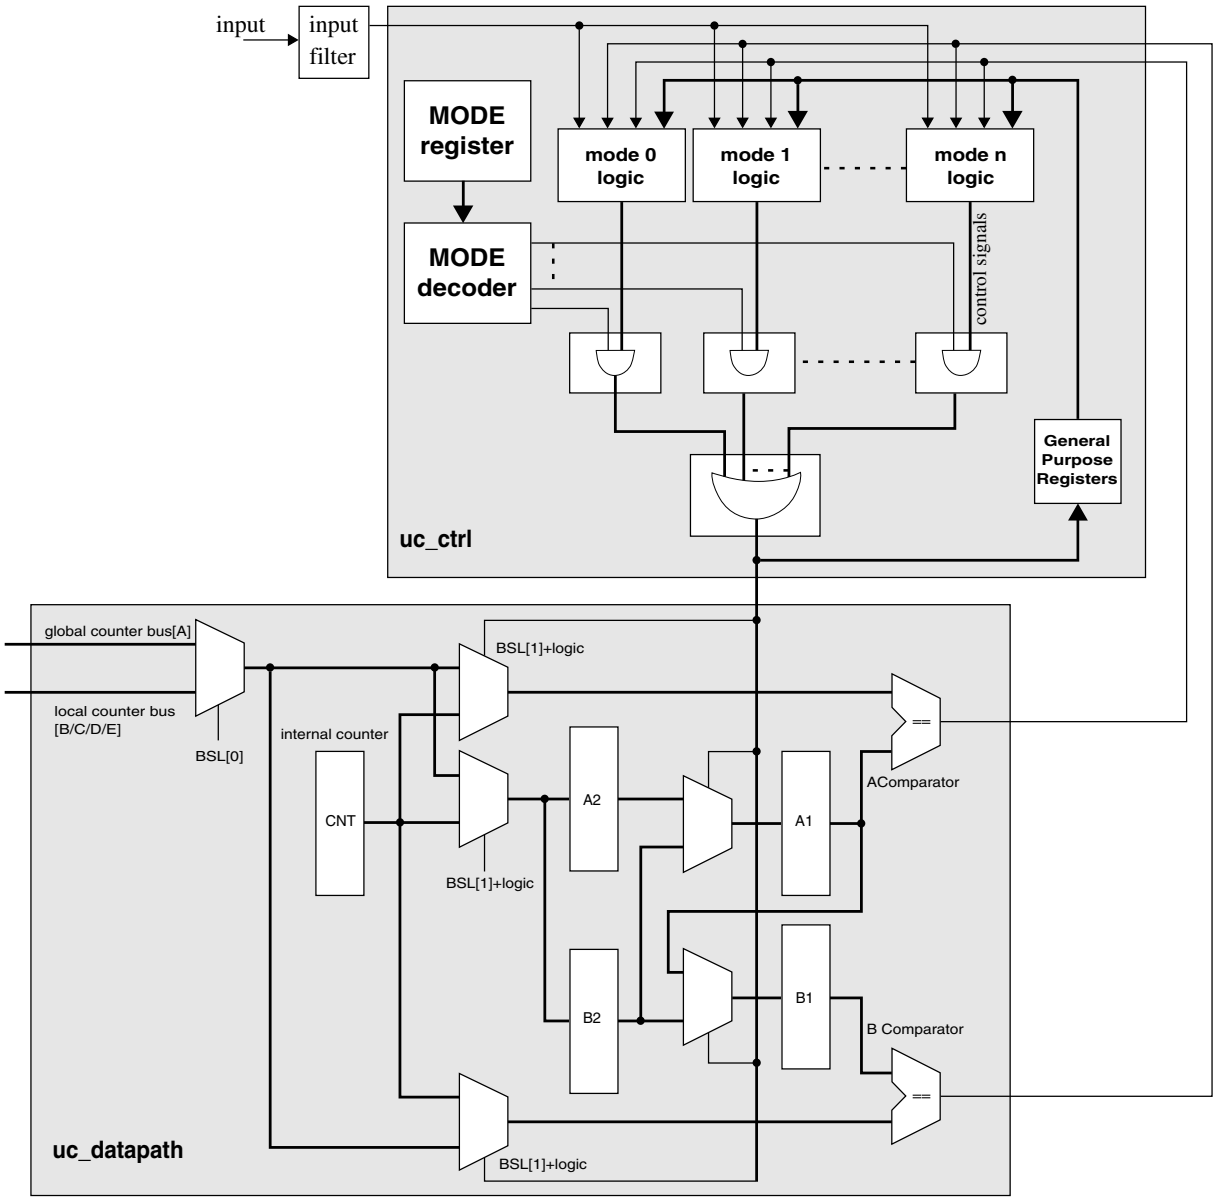

Figure 42-110. Unified Channel control and datapath block diagrams

42.6.1.1 Unified Channel modes of operation

The mode of operation of the Unified Channel is determined by the mode select bits MODE[0:6] in the EMIOS_C_n register.

When entering an output mode (except for GPIO mode), the output flip-flop is set to the disabled state according to EMIOSCn[ODIS].

As the internal counter, EMIOSCNTn, runs in all modes (except for GPIO mode) and can be used as a timebase if the resource is not used in the current mode.

In order to provide smooth waveform generation even when A and B registers are immediately changed, it is available with the MCB, OPWFMB, OPWMB and OPWFMB modes. In these modes, A and B registers are double buffered. They are presented in separate sections because there are several basic differences between these and each corresponding nonbuffered mode.

42.6.1.1.1 General-Purpose Input/Output (GPIO) mode

In GPIO mode, all input capture and output compare functions of the Unified Channel are disabled, and the internal counter (EMIOSCNTn register) is cleared and disabled. All control bits remain accessible. In order to prepare the UC for a new operation mode, writing to registers EMIOSAn or EMIOSBn stores the same value in registers A1/A2 or B1/B2, respectively. Writing to the EMIOSALTAn register stores a value only in register A2.

MODE[6] bit selects between input (MODE[6] = 0) and output (MODE[6] = 1) modes.

When changing MODE[0:6], the application software must first enter GPIO mode to reset the Unified Channel's internal functions properly. Failure to do this could lead to invalid and unexpected output compare or input capture results or the FLAGs being set incorrectly.

In GPIO input mode (MODE[0:6] = 0000000), FLAG generation is determined according to EDPOL and EDSEL bits and the input pin status can be determined by reading the UCIN bit.

In GPIO output mode (MODE[0:6] = 0000001), the Unified Channel is used as a single output port pin and the value of the EDPOL bit is permanently transferred to the output flip-flop.

42.6.1.1.2 Single Action Input Capture (SAIC) Mode

In SAIC mode (MODE[0:6]=0000010), when a triggering event occurs on the input pin, the value on the selected time base is captured into register A2. The FLAG bit is set along with the capture event to indicate that an input capture has occurred. Register EMIOSA[n] returns the value of register A2. As soon as the SAIC mode is entered coming out from GPIO mode the channel is ready to capture events. The events are captured as soon as they occur thus reading register A always returns the value of the latest captured event. Subsequent captures are enabled with no need of further reads from EMIOSA[n] register. The FLAG is set at any time a new event is captured.

The input capture is triggered by a rising, falling or either edges in the input pin, as configured by EDPOL and EDSEL bits in EMIOSC[n] register.

Figure 42-111 and Figure 42-112 show how the Unified Channel can be used for input capture.

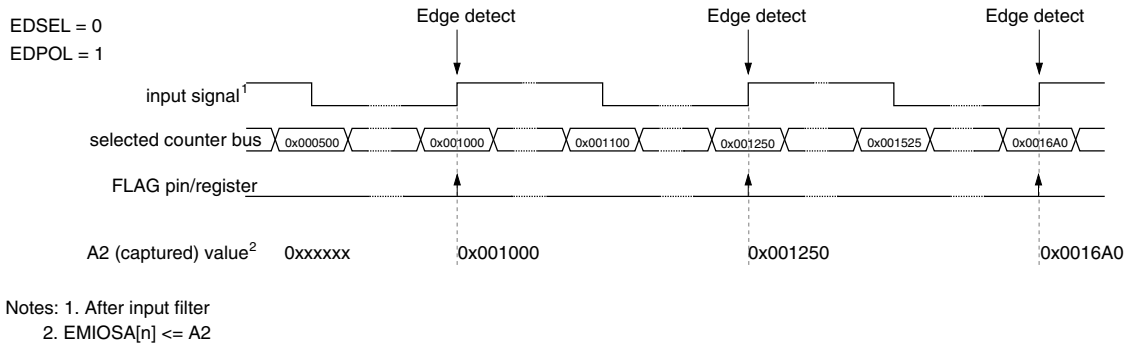

Figure 42-111. Single Action Input Capture with rising edge triggering example

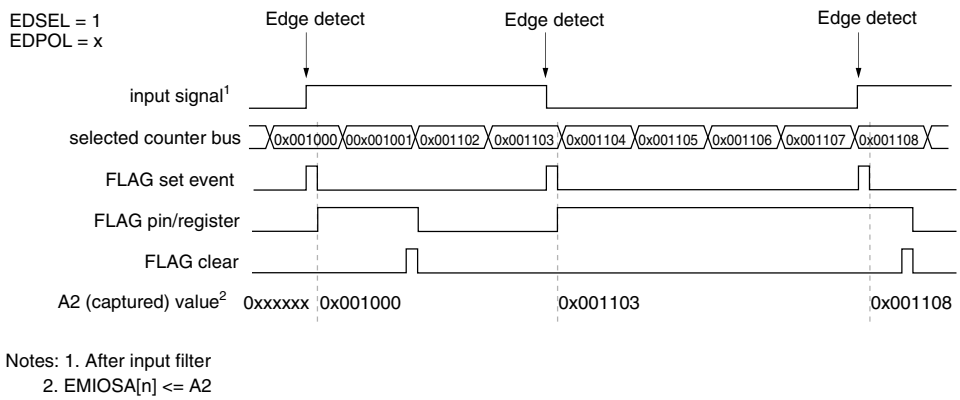

Figure 42-112. Single Action Input Capture with both edges triggering example

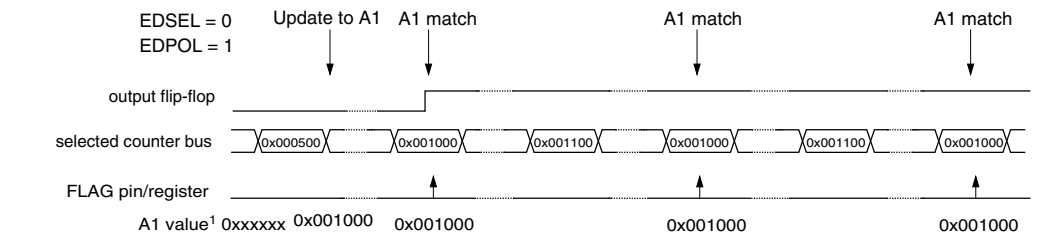
42.6.1.1.3 Single Action Output Compare (SAOC) Mode

In SAOC mode (MODE[0:6]=0000011) a match value is loaded in register A2 and then immediately transferred to register A1 to be compared with the selected time base. When a match occurs, the EDSEL bit selects whether the output flip-flop is toggled or the value in EDPOL is transferred to it. Along with the match the FLAG bit is set to indicate that the output compare match has occurred. Writing to register EMIOSA[n] stores the value in register A2 and reading to register EMIOSA[n] returns the value of register A1.

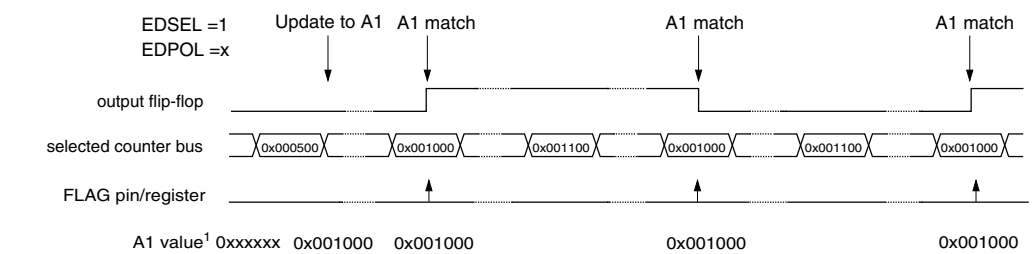
An output compare match can be simulated in software by setting the FORCMA bit in EMIOSC[n] register. In this case, the FLAG bit is not set.



When SAOC mode is entered coming out from GPIO mode, the output flip-flop is set to the complement of the EDPOL bit in the EMIOSC[n] register.

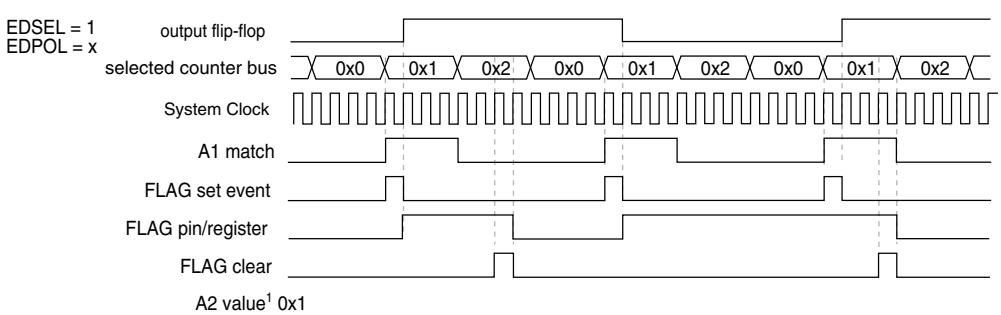
Counter bus can be either internal or external and is selected through BSL[0:1] bits.

Figure 42-113 and Figure 42-114 show how the Unified Channel can be used to perform a single output compare with EDPOL value being transferred to the output flip-flop and toggling the output flip-flop at each match, respectively. Note that once in SAOC mode the matches are enabled thus the desired match value on register A1 must be written before the mode is entered. A1 register can be updated at any time thus modifying the match value which will reflect in the output signal generated by the channel. Subsequent matches are enabled with no need of further writes to EMIOSA[n] register. The FLAG is set at the same time a match occurs (see Figure 42-115).



Note

The channel internal counter in SAOC mode is free-running. It starts counting as soon as the SAOC mode is entered.



Notes: 1. EMIOSA[n] = A2
A2 = A1 according to OU[n] bit

Figure 42-113. SAOC example with EDPOL value being transferred to the output flip-flop

Notes: 1. EMIOSA[n] = A2
A2 = A1 according to OU[n] bit

Figure 42-114. SAOC example toggling the output flip-flop

Note: 1. EMIOSA[n] <= A2

Figure 42-115. SAOC example with flag behavior

42.6.1.1.4 Input Pulse Width Measurement (IPWM) Mode

The IPWM mode (MODE[0:6]=0000100) allows the measurement of the width of a positive or negative pulse by capturing the leading edge on register B1 and the trailing edge on register A2. Successive captures are done on consecutive edges of opposite polarity. The leading edge sensitivity (i.e., pulse polarity) is selected by EDPOL bit in the EMIOSC[n] register. Registers EMIOSA[n] and EMIOSB[n] return the values in register A2 and B1, respectively.

The capture function of register A2 remains disabled until the first leading edge triggers the first input capture on register B2. When this leading edge is detected, the count value of the selected time base is latched into register B2; the FLAG bit is not set. When the trailing edge is detected, the count value of the selected time base is latched into register A2 and, at the same time, the FLAG bit is set and the content of register B2 is transferred to register B1 and to register A1.

If subsequent input capture events occur while the corresponding FLAG bit is set, registers A2, B1 and A1 will be updated with the latest captured values and the FLAG will remain set. Registers EMIOSA[n] and EMIOSB[n] return the value in registers A2 and B1, respectively.

In order to guarantee coherent access, reading EMIOSA[n] forces B1 be updated with the content of register A1. At the same time transfers between B2 and B1 are disabled until the next read of EMIOSB[n] register. Reading EMIOSB[n] register forces B1 be updated with A1 register content and re-enables transfers from B2 to B1, to take effect at the next trailing edge capture. Transfers from B2 to A1 are not blocked at any time.

The input pulse width is calculated by subtracting the value in B1 from A2.

The following figure shows how the Unified Channel can be used for input pulse width measurement.

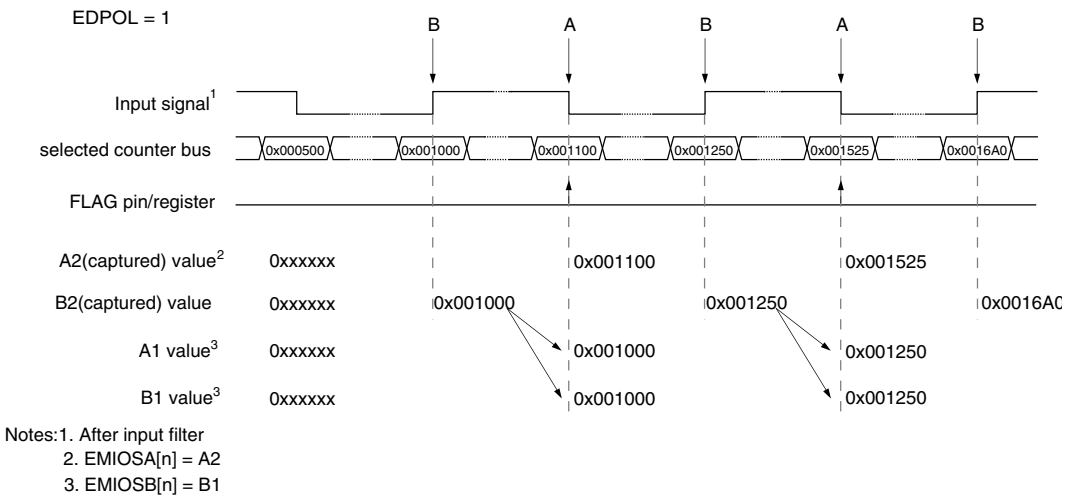


Figure 42-116. Input Pulse Width Measurement example

The following figure shows the A1 and B1 updates when EMIOSA[n] and EMIOSB[n] register reads occur. Note that A1 register has always coherent data related to A2 register. Note also that when EMIOSA[n] read is performed B1 register is loaded with A1 register content. This guarantee that the data in register B1 has always the coherent data related to the last EMIOSA[n] read. The B1 register updates remains locked until EMIOSB[n] read occurs. If EMIOSA[n] read is performed B1 is updated with A1 register content even if B1 update is locked by a previous EMIOSA[n] read operation.

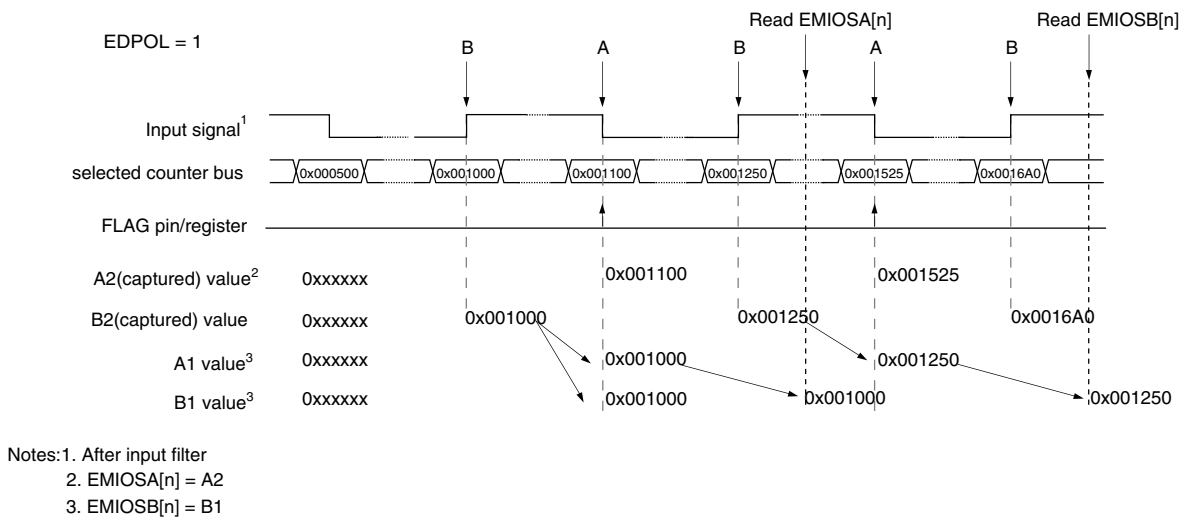

Figure 42-117. B1 and A1 updates at EMIOSA[n] and EMIOSB[n] reads

Reading EMIOS_A_n followed by EMIOS_B_n always provides coherent data. If coherent data is not required for any reason, the sequence of reads should be inverted, therefore EMIOSB[n] should be read prior to EMIOSA[n] register. Note that even in this case B1 register updates will be blocked after EMIOSA[n] read, thus a second EMIOSB[n] is required in order to release B1 register updates.

42.6.1.1.5 Input Period Measurement (IPM) Mode

The IPM mode (MODE[0:6]=0000101) allows the measurement of the period of an input signal by capturing two consecutive rising edges or two consecutive falling edges. Successive input captures are done on consecutive edges of the same polarity. The edge polarity is defined by the EDPOL bit in the EMIOSC[n] register.

Note

The input signal must have at least four system clock cycles period in order to be properly captured by the synchronization logic at the channel input even if the input filter is in by-pass mode.

When the first edge of selected polarity is detected, the selected time base is latched into the registers A2 and B2, and the data previously held in register B2 is transferred to register B1. On this first capture the FLAG line is not set, and the values in registers B1 is meaningless. On the second and subsequent captures, the FLAG line is set and data in register B2 is transferred to register B1.

When the second edge of the same polarity is detected, the counter bus value is latched into registers A2 and B2, the data previously held in register B2 is transferred to data register B1 and to register A1. The FLAG bit is set to indicate the start and end points of a complete period have been captured. This sequence of events is repeated for each subsequent capture. Registers EMIOSA[n] and EMIOSB[n] return the values in register A2 and B1, respectively.

In order to allow coherent data, reading EMIOSA[n] forces A1 content be transferred to B1 register and disables transfers between B2 and B1. These transfers are disabled until the next read of the EMIOSB[n] register. Reading EMIOSB[n] register forces A1 content to be transferred to B1 and re-enables transfers from B2 to B1, to take effect at the next edge capture.

The input pulse period is calculated by subtracting the value in B1 from A2.

The following figure shows how the Unified Channel can be used for input period measurement.

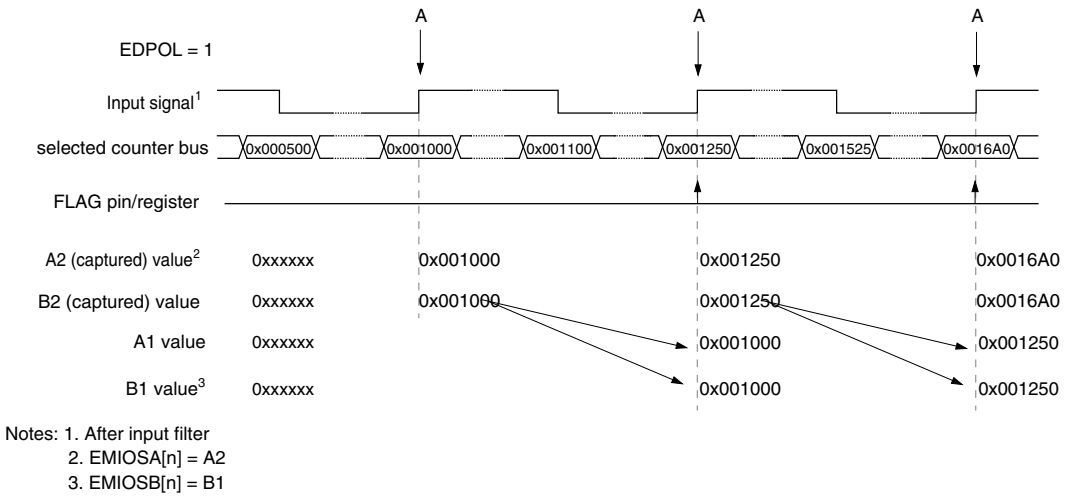

Figure 42-118. Input Period Measurement example

Figure 42-119 describes the A1 and B1 register updates when EMIOSA[n] and EMIOSB[n] read operations are performed. When EMIOSA[n] read occurs the content of A1 is transferred to B1 thus providing coherent data in A2 and B1 registers. Transfers from B2 to B1 are then blocked until EMIOSB[n] is read. After EMIOSB[n] is read, register A1 content is transferred to register B1 and the transfers from B2 to B1 are re-enabled to occur at the transfer edges, which is the leading edge in the following example figure.

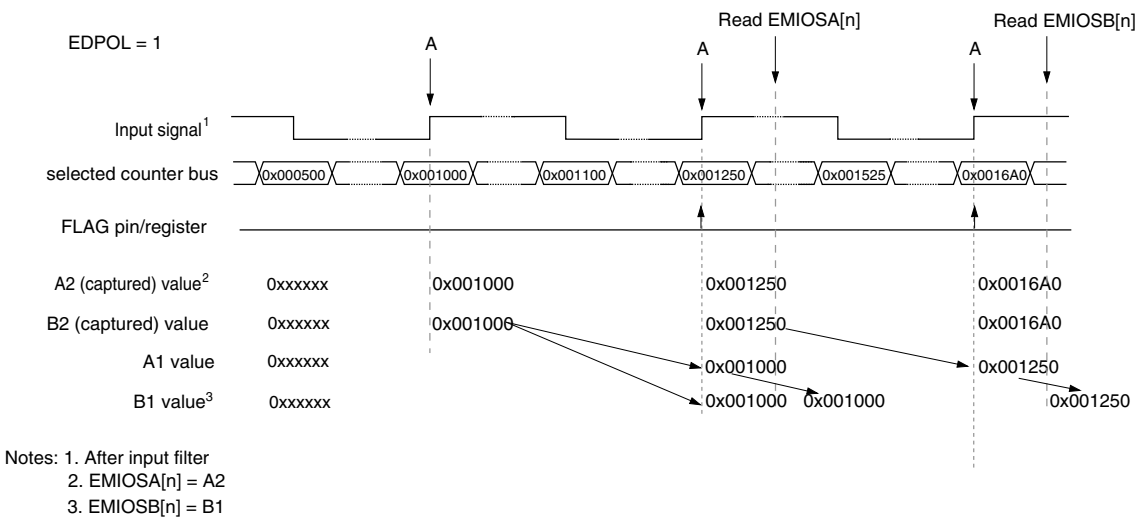

Figure 42-119. A1 and B1 updates at EMIOSA[n] and EMIOSB[n] reads

42.6.1.1.6 Double Action Output Compare (DAOC) Mode

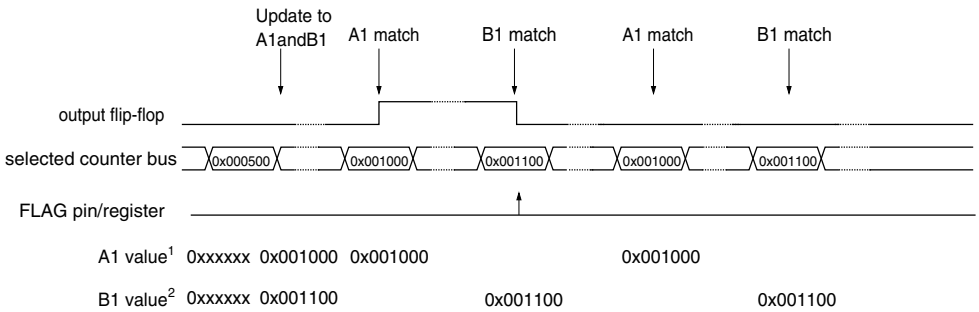
In the DAOC mode, the leading and trailing edges of the variable pulse width output are generated by matches occurring on comparators A and B. There is no restriction concerning the order in which A and B matches occur.

When the DAOC mode is entered, coming out from GPIO mode both comparators are disabled and the output flip-flop is set to the complement of the EDPOL bit in the EMIOSC[n] register.

Data written to A2 and B2 are transferred to A1 and B1, respectively, on the next system clock cycle if OU[n] bit of EMIOSOUDIS register is cleared (see Figure 42-146). The transfer is blocked if OU[n] bit is set. Comparator A is enabled only after the transfer to A1 register occurs and is disabled on the next A match. Comparator B is enabled only after the transfer to B1 register occurs and is disabled on the next B match. Comparators A and B are enabled and disabled independently.

The output flip-flop is set to the value of EDPOL when a match occurs on comparator A and to the complement of EDPOL when a match occurs on comparator B.

MODE[6] controls if the FLAG is set on both matches (MODE[0:6]=0000111) or just on the B match (MODE[0:6]=0000110). FLAG bit assertion depends on comparator enabling.

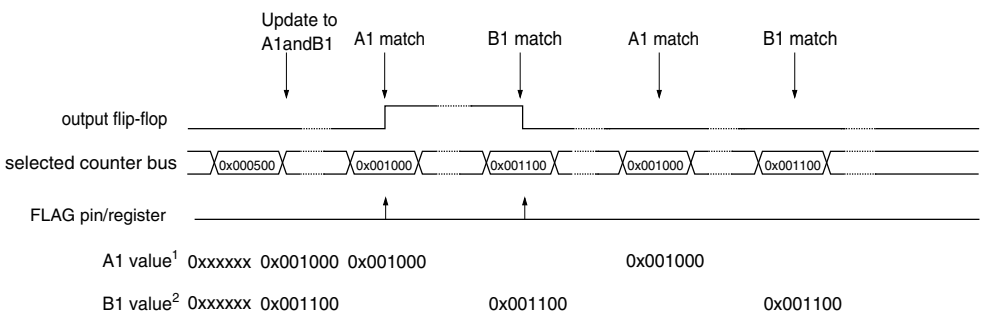


If subsequent enabled output compares occur on registers A1 and B1, pulses will continue to be generated, regardless of the state of the FLAG bit.

At any time, the FORCMA and FORCMB bits allow the software to force the output flip-flop to the level corresponding to a comparison event in comparator A or B, respectively. Note that the FLAG bit is not affected by these forced operations.

Note

If both registers (A1 and B1) are loaded with the same value, the B match prevails concerning the output pin state (output flip-flop is set to the complement of EDPOL), the FLAG bit is set and both comparators are disabled.



The following two tables show how the Unified Channel can be used to generate a single output pulse with FLAG bit being set on the second match or on both matches, respectively.

Notes:1. EMIOSA[n] = A1 (when reading)
2. EMIOSB[n] = B1 (when reading)

A2 = A1 according to OU[n] bit
B2 = B1 according to OU[n] bit

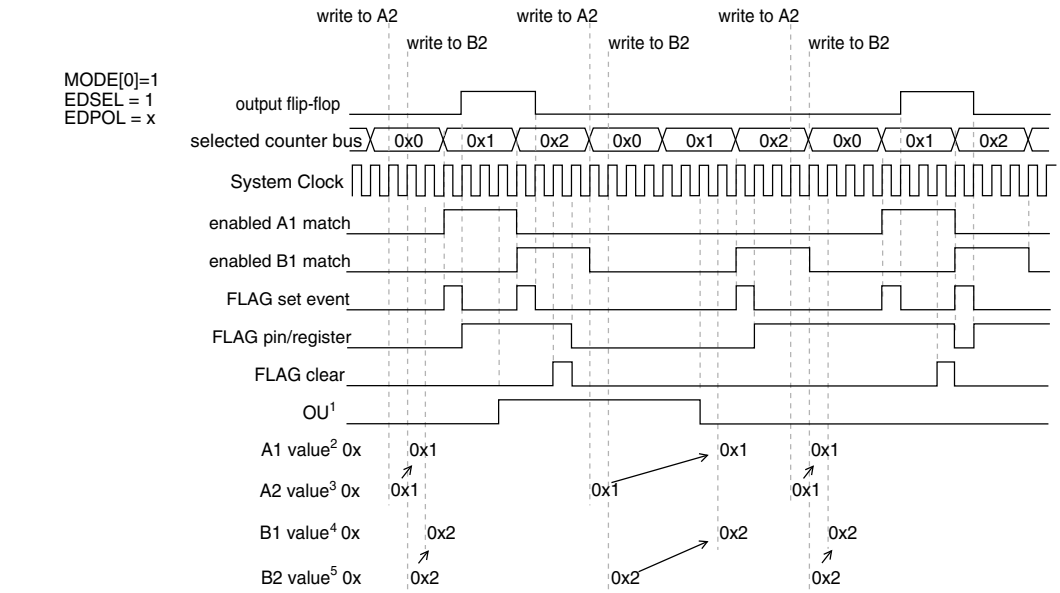


Figure 42-120. Double Action Output Compare with FLAG set on the second match, MODE[0] bit is 0

Notes:1. EMIOSA[n] = A1 (when reading)
2. EMIOSB[n] = B1 (when reading)

A2 = A1 according to OU[n] bit
B2 = B1 according to OU[n] bit

Figure 42-121. Double Action Output Compare with FLAG set on both matches, MODE[0] bit is 1

Note: 1. OU[n] bit of EMIOSOUDIS register
2. EMIOSA[n] = A1 (when reading)
3. EMIOSA[n] = A2 (when writing)
4. EMIOSB[n] = B1 (when reading)
5. EMIOSB[n] = B2 (when writing)

Figure 42-122. DAOC with transfer disabling example

42.6.1.1.7 Pulse/Edge Accumulation (PEA) Mode

The PEA mode returns the time taken to detect a desired number of input events. MODE[6] bit selects between continuous or single shot operation.

After writing to register A1, the internal counter is cleared on the first input event, ready to start counting input events and the selected timebase is latched into register B2. On the match between the internal counter and register A1, a counter bus capture is triggered to register A2 and B2. The data previously held in register B2 is transferred to register B1 and the FLAG bit is set to indicate that an event has occurred. The desired time interval can be determined by subtracting register B1 from A2. Registers EMIOSA[n] and EMIOSB[n] return the values in register A2 and B1, respectively.

As part of the coherency mechanism, reading EMIOSA[n] disables transfers from B2 to B1. These transfers are disabled until the next read of the EMIOS_B_n register. Reading the EMIOSB[n] register re-enables transfers from B2 to B1, to take effect at the next transfer event, as described above. [2]

In order to have coherent data in continuous mode of operation the following steps should be performed, assuming FLAG is initially cleared:

2. If B1 was not updated due to B2 to B1 transfer being disabled after reading register EMIOS_A_n, further EMIOS_A_n] and EMIOS_B_n reads will not return coherent data until a new bus capture is triggered to registers A2 and B2. This capture event is indicated by the channel FLAG being asserted. If enabled, the FLAG also generates an interrupt.

1. Wait for FLAG assertion;
2. Read EMIOSA[n] register;
3. Read EMIOSB[n] register;
4. Clear FLAG bit;
5. Return to step 1.

Accumulation cycles may be lost if the read is not performed in a timely manner. Whenever Overrun bit is asserted it means that one or more cycles have been lost.

Triggering of the counter clock (input event) is done by a rising or falling edge or both edges on the input pin. The polarity of the triggering edge is selected by the EDSEL and EDPOL bits in EMIOS_C_n register.

For continuous operation mode (MODE[6] cleared, MODE[0:6]=0001000), the counter is cleared on the next input event after a FLAG generation and continues to operate as described above.

For single shot operation (MODE[6] set, MODE[0:6]=0001001), the counter is not cleared or incremented after a FLAG generation, until a new writing operation to register A is performed.

Figure 42-123 and Figure 42-124 show how the Unified Channel can be used for continuous and single shot pulse/edge accumulation mode.

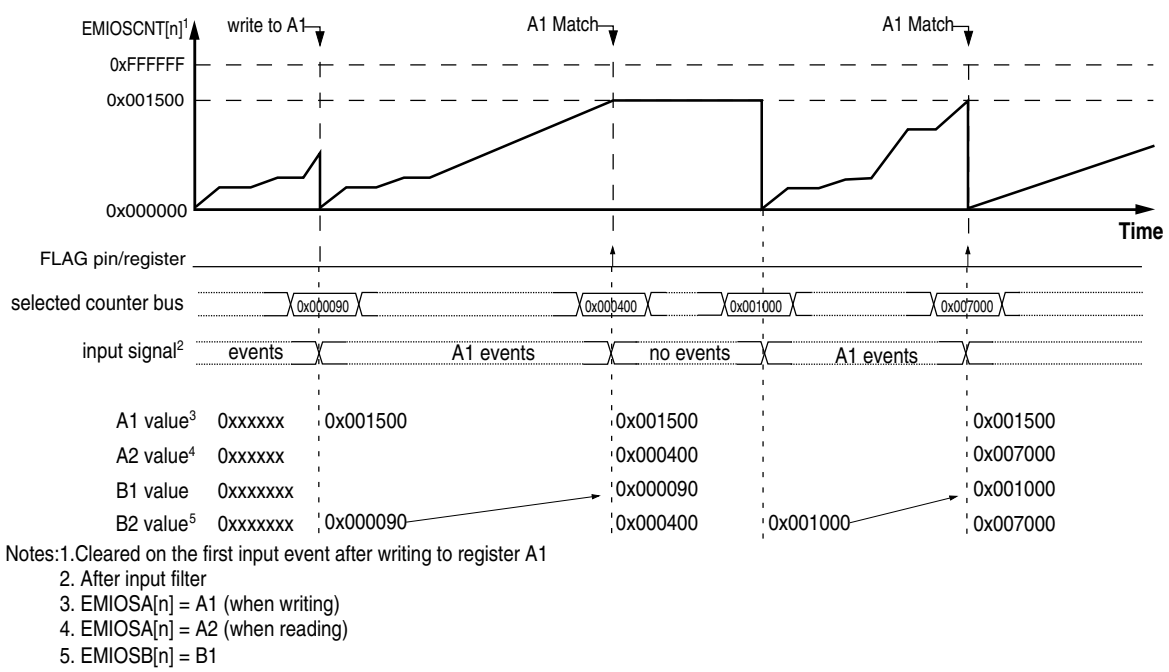

Figure 42-123. Pulse/Edge Accumulation continuous mode example (MODE[6] bit is 0b)

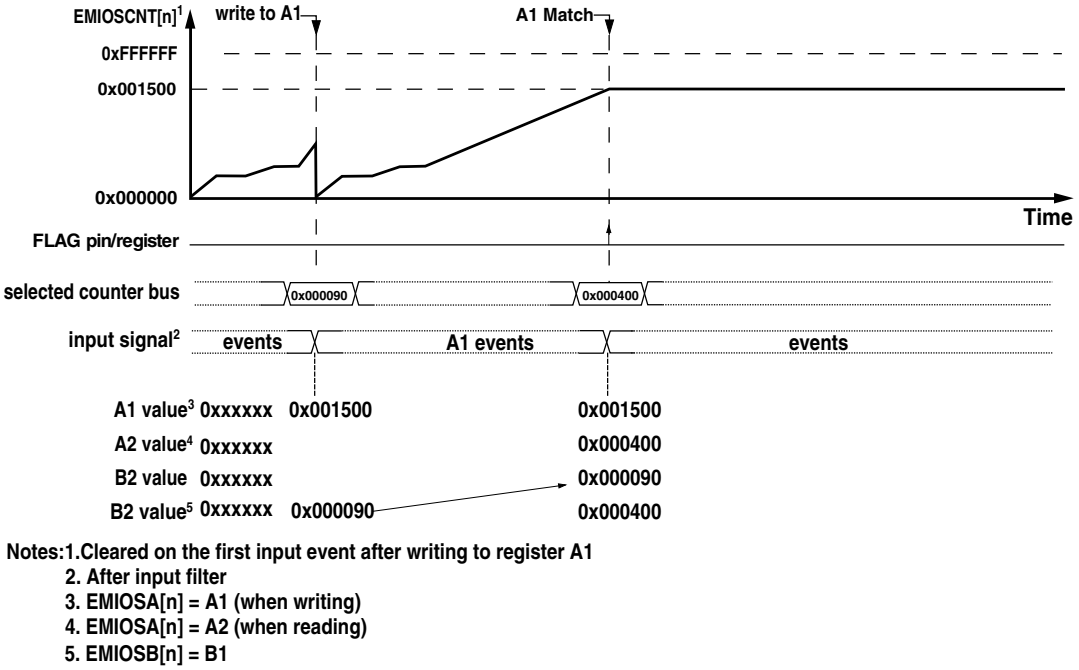

Figure 42-124. Pulse/Edge Accumulation single-shot mode example (MODE[6] bit is 1b)

42.6.1.1.8 Pulse/Edge Counting (PEC) Mode

The PEC mode returns the amount of pulses or edges detected on the input for a desired time window. MODE[6] bit selects between continuous or single shot operation.

Triggering of the internal counter is done by a rising or falling edge or both edges on the input signal. The polarity and the triggering edge is selected by EDSEL and EDPOL bits in EMIOSC[n] register.

Register A1 holds the start time and register B1 holds the stop time for the time window. After writing to register A1, when a match occur between comparator A and the selected timebase, the internal counter is cleared and it is ready to start counting input events. When the time base matches comparator B, the internal counter is disabled and its content is transferred to register A2. At the same time the FLAG bit is set. Reading registers EMIOSCNT[n] or A2 returns the amount of detected pulses.

For continuous operation (MODE[6] cleared, MODE[0:6]=0001010), the next match between comparator A and the selected time base clears the internal counter and counting is enabled again. In order to guarantee coherent measurements when reading EMIOSCNT[n] after the FLAG is set, the software must check if the time base value is out of the time interval defined by registers A1 and B1. Alternatively register A2 always holds the latest available measurement providing coherent data at any time after the first FLAG had occurred. This register is addressed by the alternate address EMIOSALTA[n].

For single shot operation (MODE[6] set, MODE[0:6]=0001011), the next match between comparator A and the selected time base has no effect, until a new write to register A is performed. The EMIOSCNT content is also transferred to register A2 when a match in the B comparator occurs.

Figure 42-125 and Figure 42-126 show how the Unified Channel can be used for continuous or single shot pulse/edge counting mode.

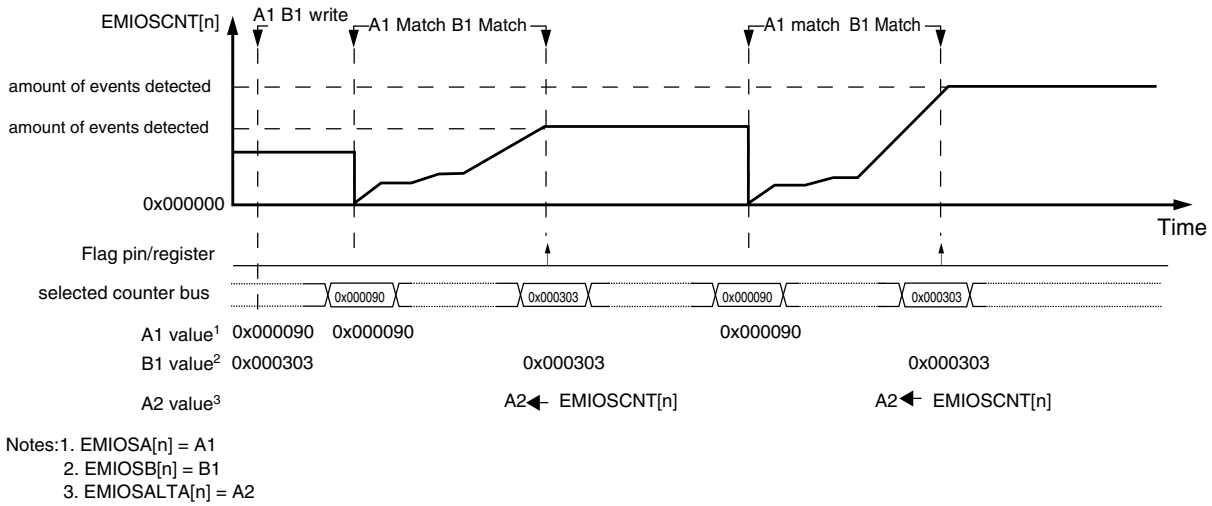

Figure 42-125. Pulse/Edge Counting continuous mode example

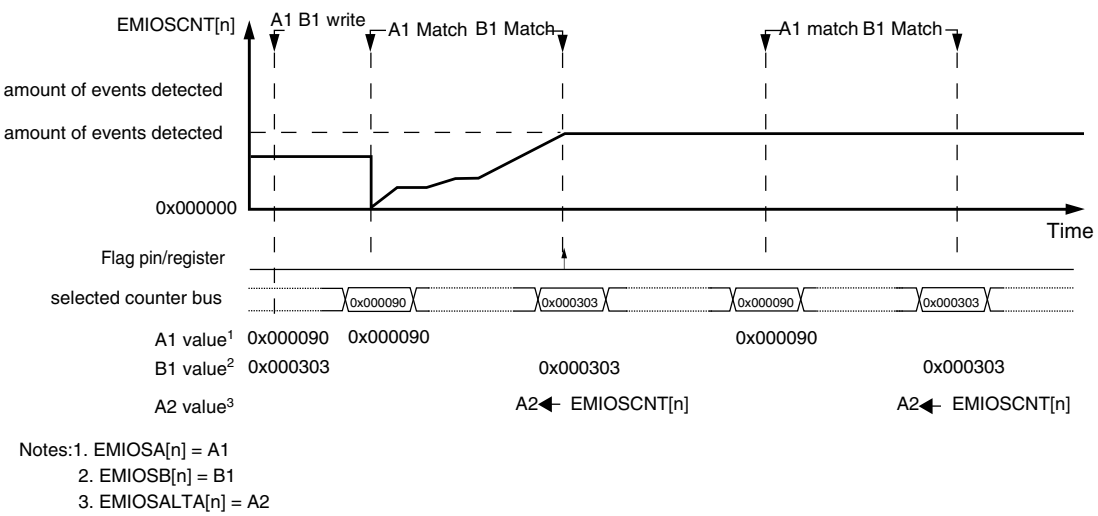

Figure 42-126. Pulse/Edge Counting single-shot mode example

42.6.1.1.9 Quadrature Decode (QDEC) Mode

Quadrature decode mode uses UC[n] operating in QDEC mode and the input programmable filter (IPF) from UC[n-1]. Note that UC[n-1] can be configured, at the same time, to an operation mode that does not use I/O pins, such as MC mode (modulus counter). The connection among the UCs is circular, i.e., when UC[0] is running in QDEC mode, the input programmable filter from UC[23] is being used, for the case of a 24-channel configuration.

This mode generates a FLAG every time the internal counter matches A1 register. The internal counter is automatically selected and is not cleared when entering this mode.

MODE[6] bit selects which type of encoder will be used: *count & direction* encoder or *phase_A and phase_B* encoders.

When operating with *count and direction* encoder (MODE[6] cleared), UC[n] input pin must be connected to the *direction* signal and UC[n-1] input pin must be connected to the *count* signal of the quadrature encoder. UC[n] EDPOL bit selects count direction according to *direction* signal and UC[n-1] EDPOL bit selects if the internal counter is clocked by the rising or falling edge of the *count* signal.

When operating with *phase_A and phase_B* encoder (MODE[6] set), UC[n] input pin must be connected to the *phase_A* signal and UC[n-1] input pin must be connected to the *phase_B* signal of the quadrature encoder. EDPOL bit selects the count direction according to the phase difference between *phase_A and phase_B* signals.

Figure 42-127 and Figure 42-128 show two Unified Channels configured to quadrature decode mode for *count & direction* encoder and *phase_A and phase_B* encoders, respectively.

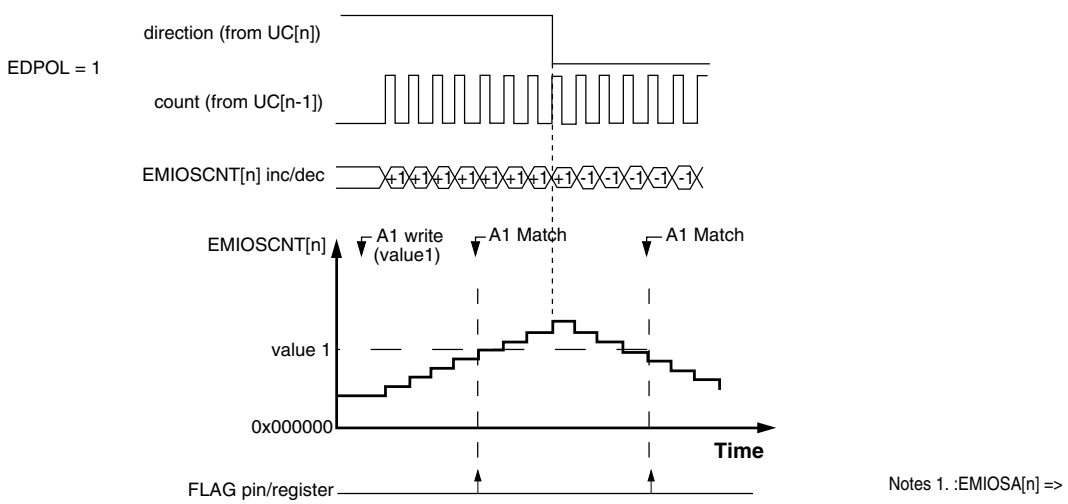

Figure 42-127. Quadrature Decode mode example with *count and direction* encoder

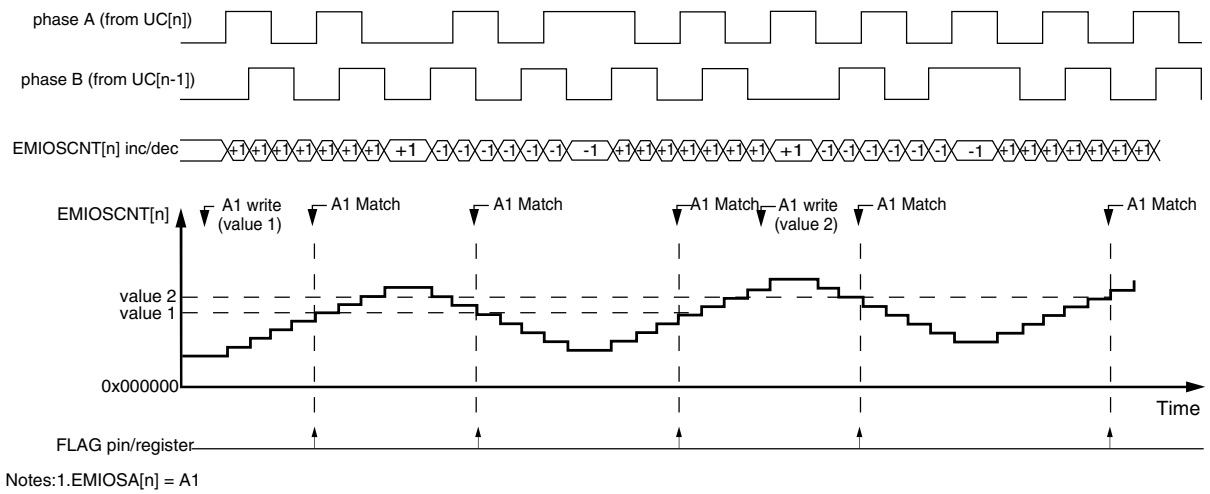

Figure 42-128. Quadrature Decode mode example with *phase_A and phase_B encoder*

42.6.1.1.10 Windowed Programmable Time Accumulation (WPTA) Mode

The WPTA mode (MODE[0:6]=0001110) accumulates the sum of the total high time or low time of an input signal over a programmable interval (time window).

The prescaler bits UCPRE[0:1] in EMIOSC[n] register define the increment rate of the internal counter.

Register A1 holds the start time and register B1 holds the stop time of the programmable time interval. When a match occurs between register A and the selected timebase, the internal counter is cleared and it is ready to start counting. The internal counter is used as a time accumulator, i.e., it counts up when the input signal has the same polarity of EDPOL bit in EMIOSC[n] register and does not count otherwise. When a match occurs in comparator B, the internal counter is disabled regardless of the input signal polarity and the FLAG bit is set. At the same time the content of EMIOSCNT[n] is transferred to register A2. Reading registers EMIOSCNT[n] or A2 returns the high or low time of the input signal.

Note that EMIOSCNT[n] is stable only outside the time window defined from A1 to B1 matches, otherwise its content reflects a count in progress and not the final value. Alternatively to EMIOSCNT register A2 returns the latest available measurement. Since this register is updated only at comparator B matches it always contains stable and up-to-date data. In this mode this register is accessible through the alternate register address EMIOSALTA[n].

The following figure shows how the Unified Channel can be used to accumulate high time.

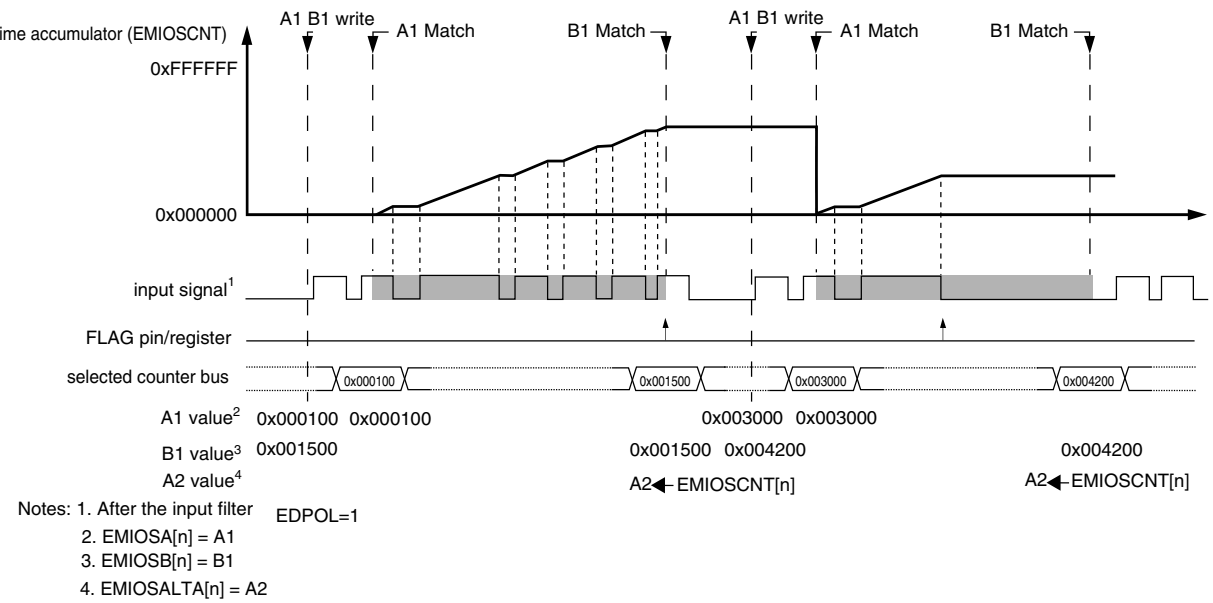

Figure 42-129. Windowed Programmable Time Accumulation example

42.6.1.1.11 Modulus Counter (MC) Mode

The MC mode can be used to provide a time base for a counter bus or as a general purpose timer.

MODE[6] bit selects internal or external clock source when cleared or set, respectively. When external clock is selected, the input signal pin is used as the source and the triggering polarity edge is selected by the EDPOL and EDSEL in the EMIOSC[n] register.

The internal counter counts up from the current value until it matches the value in register A1. Register B1 is cleared and is not accessible to the MCU. MODE[4] bit selects up mode or up/down mode, when cleared or set, respectively.

When in up count mode, a match between the internal counter and register A1 sets the FLAG and clears the internal counter. The timing of those events varies according to the MC mode setup as follows:

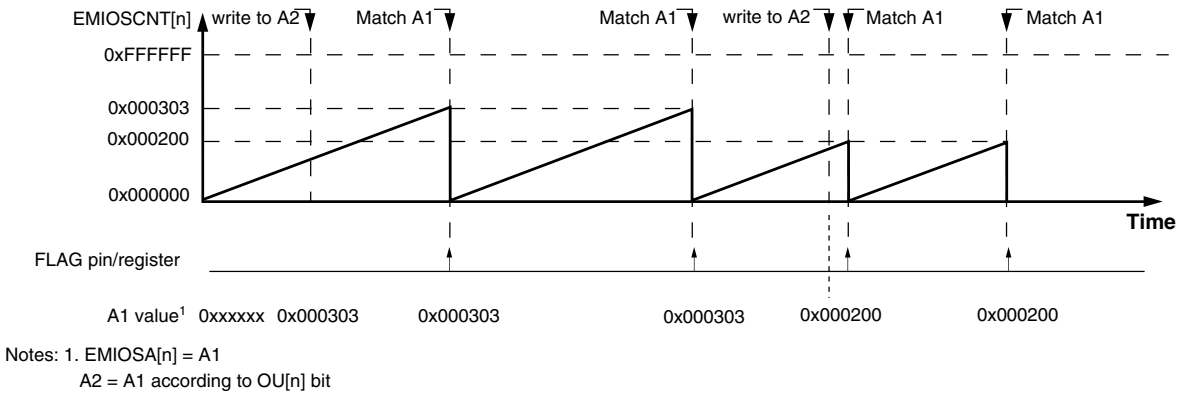
- Internal counter clearing on match start (MODE[0:6]=001000b)

- External clock is selected if MODE[0] is set. In this case the internal counter clears as soon as the match signal occurs. The channel FLAG is set at the same time the match occurs. Note that by having the internal counter cleared as soon as the match occurs and incremented at the next input event a shorter zero count is generated. See Figure 42-162 and Figure 42-163.
- Internal clock source is selected if MODE[0] is cleared. In this case the counter clears as soon as the match signal occurs. The channel FLAG is set at the same time the match occurs. At the next prescaler tick after the match the internal counter remains at zero and only resumes counting on the following tick. See Figure 42-162 and Figure 42-164.

- Internal counter clearing on match end (MODE[0:6]=001001b)
  - External clock is selected if MODE[0] is set. In this case the internal counter clears when the match signal is asserted and the input event occurs. The channel FLAG is set at the same time the counter is cleared. See Figure 42-162 and Figure 42-165.
  - Internal clock source is selected if MODE[0] is cleared. In this case the internal counter clears when the match signal is asserted and the prescaler tick occurs. The channel FLAG is set at the same time the counter is cleared. See Figure 42-162 and Figure 42-165.

Note

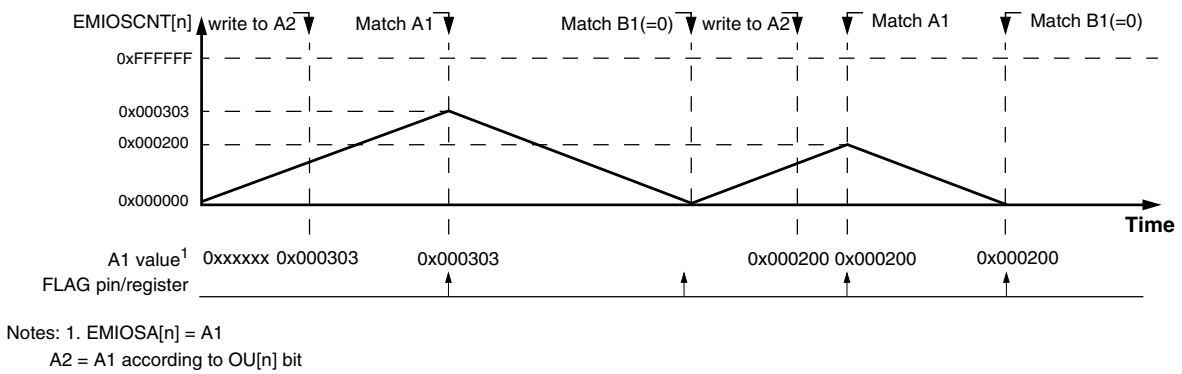
If internal clock source is selected and the prescaler of the internal counter is set to 1 the MC mode behaves the same way even in Clear on Match Start or Clear on Match End sub-modes.



When in up/down count mode (MODE[0:6]=00101bb), a match between the internal counter and register A1 sets the FLAG and changes the counter direction from increment to decrement. A match between register B1 and the internal counter changes the counter direction from decrement to increment and sets the FLAG only if MODE[5] bit is set.

Only values different than 0x0 must be written at A register. Loading 0x0 leads to unpredictable results.

Updates on register A or counter in MC mode may cause loss of match in the current cycle if the transfer occurs near the match. In this case, the counter may rollover and resume operation in the next cycle.



Register B2 has no effect in MC mode. Nevertheless, register B2 can be accessed for reads and writes by addressing EMIOSB.

The following two figures show how the Unified Channel can be used as modulus counter in up mode and up/down mode, respectively.

Notes: 1. EMIOSA[n] = A1
A2 = A1 according to OU[n] bit

Figure 42-130. Modulus Counter up mode example (MODE[4] bit is 0)

Notes: 1. EMIOSA[n] = A1
A2 = A1 according to OU[n] bit

Figure 42-131. Modulus Counter up/down mode example (MODE[4] bit is 1)

42.6.1.1.12 Modulus Counter Buffered (MCB) Mode

The MCB mode provides a time base which can be shared with other channels through the internal counter buses. Register A1 is double buffered thus allowing smooth transitions between cycles when changing A2 register value on the fly. Register A1 is updated at the cycle boundary, which is defined as when the internal counter transitions to 0x1.

The internal counter values operates within a range from 0x1 up to register A1 value. If when entering MCB mode coming out from GPIO mode the internal counter value is not within that range then the A match will not occur causing the channel internal counter to wrap at the maximum counter value which is 0xff_ffff for a 24-bit counter. After the counter wrap occurs it returns to 0x1 and resume normal MCB mode operation. Thus in order to avoid the counter wrap condition make sure its value is within the 0x1 to register A1 value range when the MCB mode is entered.

MODE[6] bit selects internal clock source if cleared or external if set. When external clock is selected the input channel pin is used as the channel clock source. The active edge of this clock is defined by EDPOL and EDSEL bits in the EMIOSC[n] channel register.

When entering in MCB mode, if up counter is selected by MODE[4]=0 (MODE[0:6]=101000b), the internal counter starts counting from its current value to up direction until A1 match occurs. The internal counter is set to 0x1 when its value matches A1 value and a clock tick occurs (either prescaled clock or input pin event).

If up/down counter is selected by setting MODE[4]=1, the counter changes direction at A1 match and counts down until it reaches the value 0x1. After it has reached 0x1 it is set to count in up direction again. Register B1 is used to generate a match in order to set the internal counter in up-count direction if up/down mode is selected. Register B1 cannot be changed while this mode is selected.

Note that differently from the MC mode, the MCB mode counts between 0x1 and A1 register value. Only values greater than 0x1 must be written at register A1. Loading values other than those leads to unpredictable results. The counter cycle period is equal to A1 value in up counter mode. If in up/down counter mode the period is defined by the expression: (2*A1)-2.

Figure 42-132 describes the counter cycle for several A1 values. Register A1 is loaded with A2 register value at the cycle boundary. Thus any value written to A2 register within cycle **n** will be updated to A1 at the next cycle boundary and therefore will be used on cycle **n+1**. The cycle boundary between cycle **n** and cycle **n+1** is defined as when the internal counter transitions from A1 value in cycle **n** to 0x1 in cycle **n+1** . Note that the FLAG is generated at the cycle boundary and has a synchronous operation, meaning that it is asserted one system clock cycle after the FLAG set event.

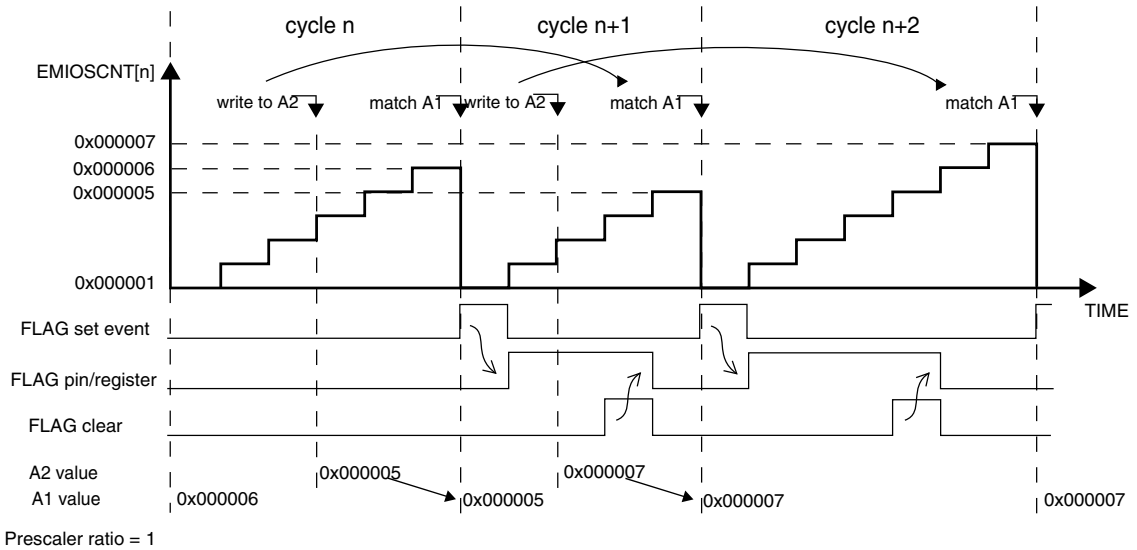


Figure 42-132. Modulus Counter Buffered (MCB) Up Count mode

Figure 42-133 describes the MCB in up/down counter mode (MODE[0:6]=10101bb). Register A1 is updated at the cycle boundary. If A2 is written in cycle **n**, this new value will be used in cycle **n+1** for A1 match. Flags are generated only at A1 match start if MODE[5] is 0. If MODE[5] is set to 1 flags are also generated at the cycle boundary.

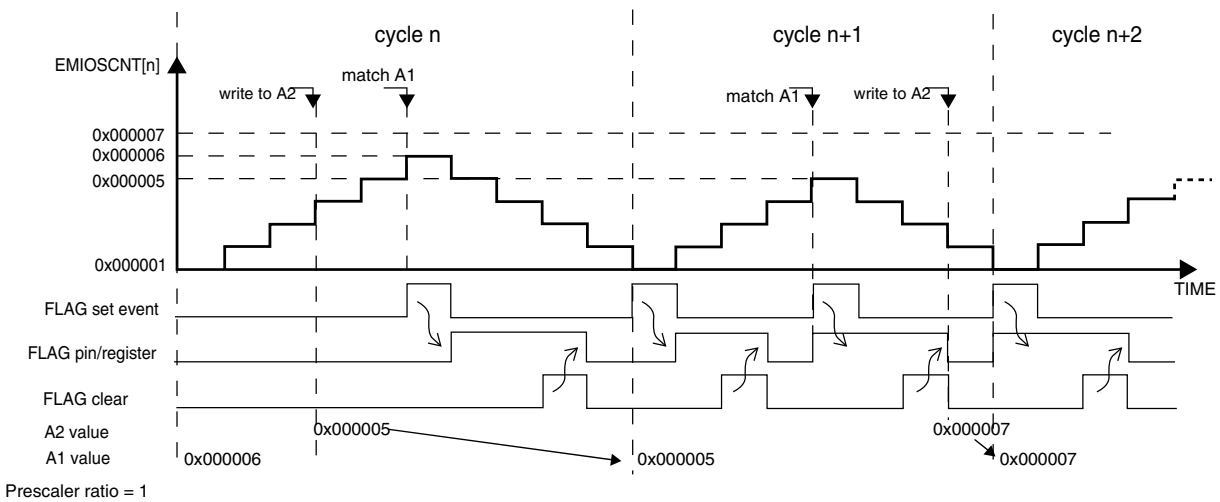

Figure 42-133. Modulus Counter Buffered (MCB) Up/Down Mode

The figure below describes in more detail, the register A1 update process in up counter mode. The A1 load signal is generated at the last system clock period of a counter cycle. Thus, A1 is updated with A2 value at the same time that the counter (EMIOSCNT[n]) is loaded with 0x1. The load signal pulse has the duration of one system clock period. If A2 is written within cycle **n** its value is available at A1 at the first clock of cycle **n+1** and the new value is used for match at cycle **n+1**. The update disable bits OU[n] of EMIOSOUDIS register can be used to control the update of this register, thus allowing to delay the A1 register update for synchronization purposes.

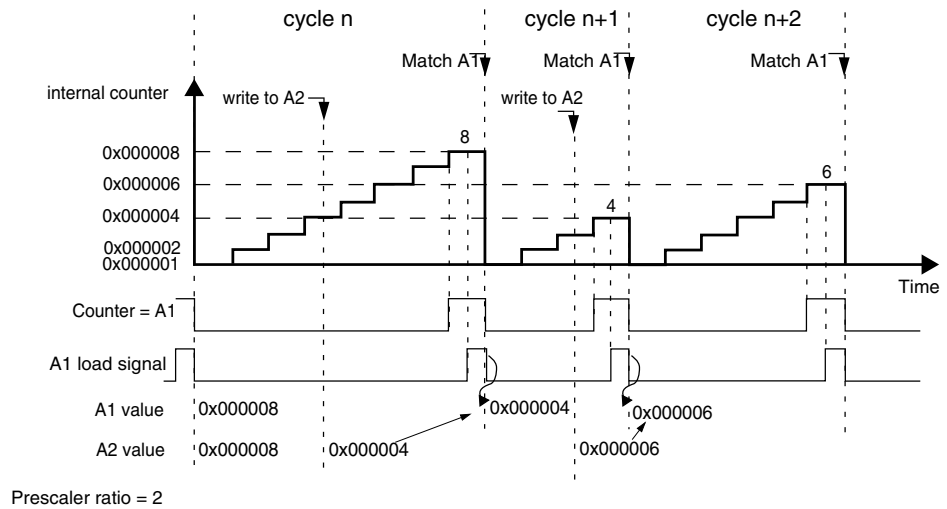

Figure 42-134. MCB Mode Register A1 Update in Up Counter Mode

The figure below describes the register A1 update in up/down counter mode. Note that A2 can be written at any time within cycle **n** in order to be used in cycle **n+1**. Thus A1 receives this new value at the next cycle boundary. Note that the update disable bits OU[n] of EMIOSOUDIS register can be used to disable the update of register A1.

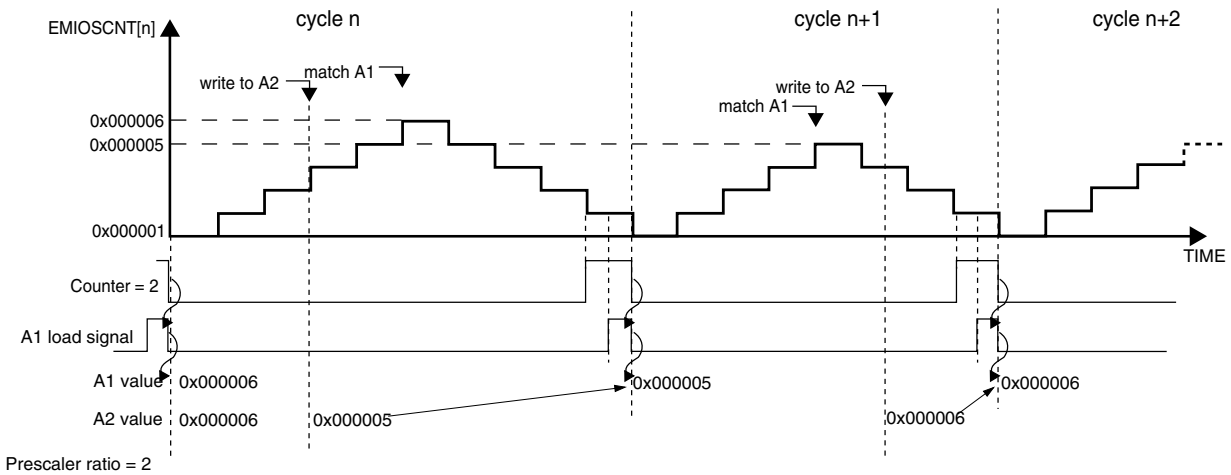

Figure 42-135. MCB Mode Register A1 Update in Up/Down Counter Mode

42.6.1.1.13 Output Pulse Width and Frequency Modulation (OPWFM) Mode

In this mode, duty cycle of output signal is the value defined in register A1 plus one and the period is the value defined in register B1 plus one. MODE[6] bit controls the transfer from register B2 to B1, which can be done either immediately (MODE[6] cleared, MODE[0:6]=00110b0), providing the fastest change in the duty cycle, or at every match of register A1 (MODE[6] set, MODE[0:6]=00110b1).

When OPWFM mode is entered, coming out from GPIO mode, the output flip-flop is set to the complement of the EDPOL bit in the EMIOSC[n] register.

The internal counter is automatically selected as a time base, therefore the BSL[0:1] bits in register EMIOSC[n] has no meaning. When a match on comparator A occurs, the output flip-flop is set to the value of the EDPOL bit. When a match occurs on comparator B, the output flip-flop is set to the complement of the EDPOL bit and the internal counter is cleared.

A FLAG can be generated at match B, when MODE[5] is cleared, or in both matches, when MODE[5] is set.

At any time, the FORCMA and FORCMB bits allow the software to force the output flip-flop to the level corresponding to a match on A or B respectively. Also, FORCMB clears the internal counter. Note that the FLAG bit is not set by the FORCMA or FORCMB operations.

If subsequent comparisons occur on comparators A and B, the PWFM pulses continue to be output, regardless of the state of the FLAG bit.

In order to achieve 100% duty cycle, both registers A1 and B1 must be set to the same value. When a simultaneous match occurs on comparators A and B, the output flip-flop is set to the value of EDPOL bit. 0% duty cycle is possible by writing 0x0 to register A. When a match occurs, the output flip-flop is set at every period to the complement of EDPOL bit. The transfer from register B2 to B1 is still controlled by MODE[6] bit.

Note

Writing 0x0 to A1 and B1 produces a duty cycle of 0%.

Figure 42-136 shows the Unified Channel running in OPWFM mode with immediate register update and Figure 42-137 shows the Unified Channel running in OPWFM mode with next period update.

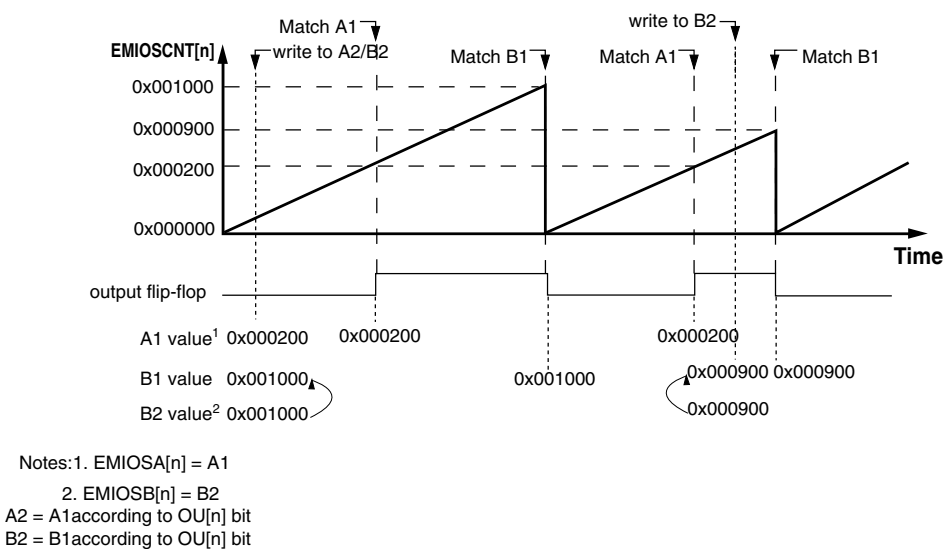

Figure 42-136. OPWFM with immediate update (MODE[6] bit is 0b)

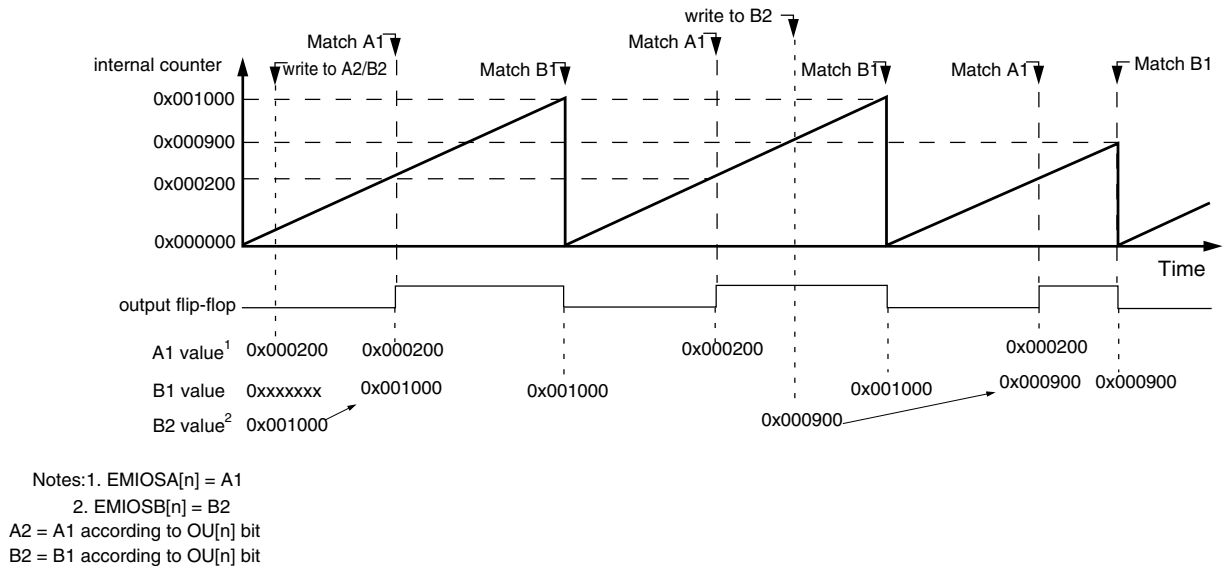

Figure 42-137. OPWFM with next period update (MODE[6] bit is 1b)

42.6.1.1.14 Output Pulse Width and Frequency Modulation Buffered (OPWFMB) Mode

This mode (MODE[0:6]=10110b0) provides waveforms with variable duty cycle and frequency. The internal channel counter is automatically selected as the time base when this mode is selected. Register A1 indicates the duty cycle and B1 register the frequency. Both registers A1 and B1 are double buffered to allow smooth signal generation when changing the registers values.. 0% and 100% duty cycles are supported.

At OPWFMB mode entry, the output flip-flop is set to the value of the EDPOL bit in the EMIOSC[n] register.

In order to provide smooth and consistent channel operation this mode differs substantially from the OPWFM mode. The main differences reside in the A1 and B1 registers update, on the delay from the A1 match to the output pin transition and on the range of the internal counter values which starts from 0x1 up to register B1 value.

When entering OPWFMB mode coming out of GPIO mode, the internal counter value is not within that range then the B match will not occur causing the channel internal counter to wrap at the maximum counter value which is 0xff_ffff for a 24-bit counter. After the counter wrap occurs it returns to 0x1 and resume normal OPWFMB mode operation. Thus in order to avoid the counter wrap condition make sure its value is within the 0x1 to B1 register value range when the OPWFMB mode is entered.

When a match on comparator A occurs the output register is set to the value of EDPOL. When a match on comparator B occurs the output register is set to the complement of EDPOL. B1 match also causes the internal counter to transition to 0x1, thus restarting the counter cycle.

Only values greater than 0x1 are allowed to be written to register B1. Loading values other than those leads to unpredictable results.

Figure 42-138 describes the operation of the OPWFMB mode regarding output pin transitions and A1/B1 registers match events. Note that the output pin transition occurs when the A1 or B1 match signal is deasserted which is indicated by the A1 match negedge detection signal. If register A1 is set to 0x4 the output pin transitions 4 counter periods after the cycle had started, plus one system clock cycle. Note that in the example shown in Figure 42-138 the internal counter prescaler has a ratio of two.

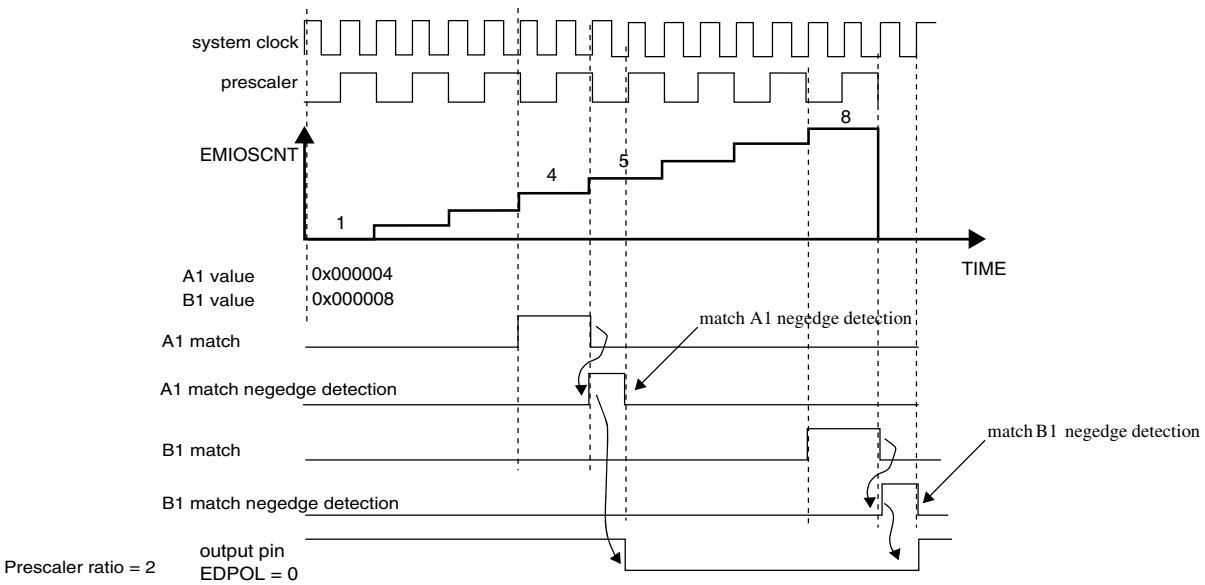

Figure 42-138. OPWFMB A1 and B1 match to Output Register Delay

Figure 42-139 describes the generated output signal if A1 is set to 0x0. Since the counter does not reach zero in this mode, the channel internal logic infers a match as if A1=0x1 with the difference that in this case, the posedge of the match signal is used to trigger the output pin transition instead of the negedge used when A1=0x1. Note that A1 posedge match signal from cycle **n+1** occurs at the same time as B1 negedge match signal from cycle **n** . This allows to use the A1 posedge match to mask the B1 negedge match when they occur at the same time. The result is that no transition occurs on the output flip-flop and a 0% duty cycle is generated.

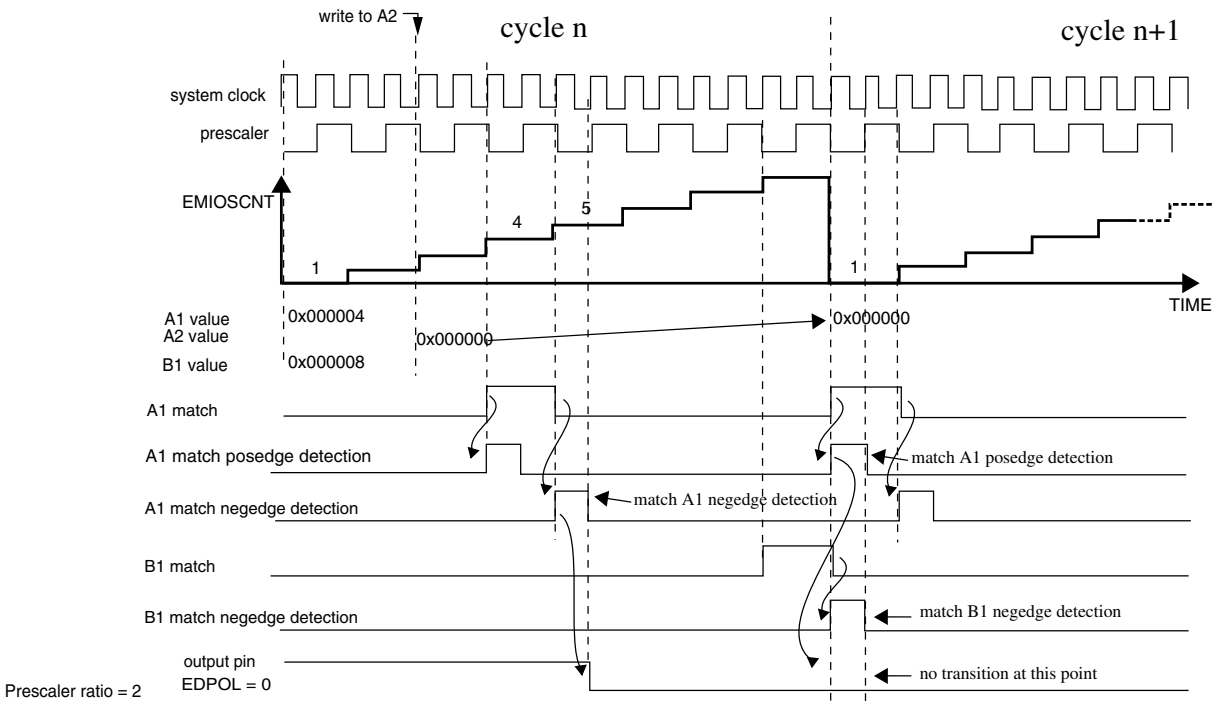

Figure 42-139. OPWFMB Mode with A1 = 0 (0% duty cycle)

Figure 42-140 describes the timing for the A1 and B1 registers load. The A1 and B1 load use the same signal which is generated at the last system clock period of a counter cycle. Thus, A1 and B1 are updated respectively with A2 and B2 values at the same time that the counter (EMIOSCNT[n]) is loaded with 0x1. This event is defined as the cycle boundary. The load signal pulse has the duration of one system clock period. If A2 and B2 are written within cycle **n** their values are available at A1 and B1, respectively, at the first clock of cycle **n+1** and the new values are used for matches at cycle **n+1**. The update disable bits OU[n] of EMIOSOUDIS register can be used to control the update of these registers, thus allowing to delay the A1 and B1 registers update for synchronization purposes.

In Figure 42-140, it is assumed that both the channel and global prescalers are set to 0x1 (each divide ratio is two), meaning that the channel internal counter transitions at every four system clock cycles. FLAGs can be generated only on B1 matches when MODE[5] is cleared, or on both A1 and B1 matches when MODE[5] is set. Since B1 flag occurs at the cycle boundary, this flag can be used to indicate that A2 or B2 data written on cycle **n** were loaded to A1 or B1, respectively, thus generating matches in cycle **n+1**. Note that the FLAG has a synchronous operation, meaning that it is asserted one system clock cycle after the FLAG set event.

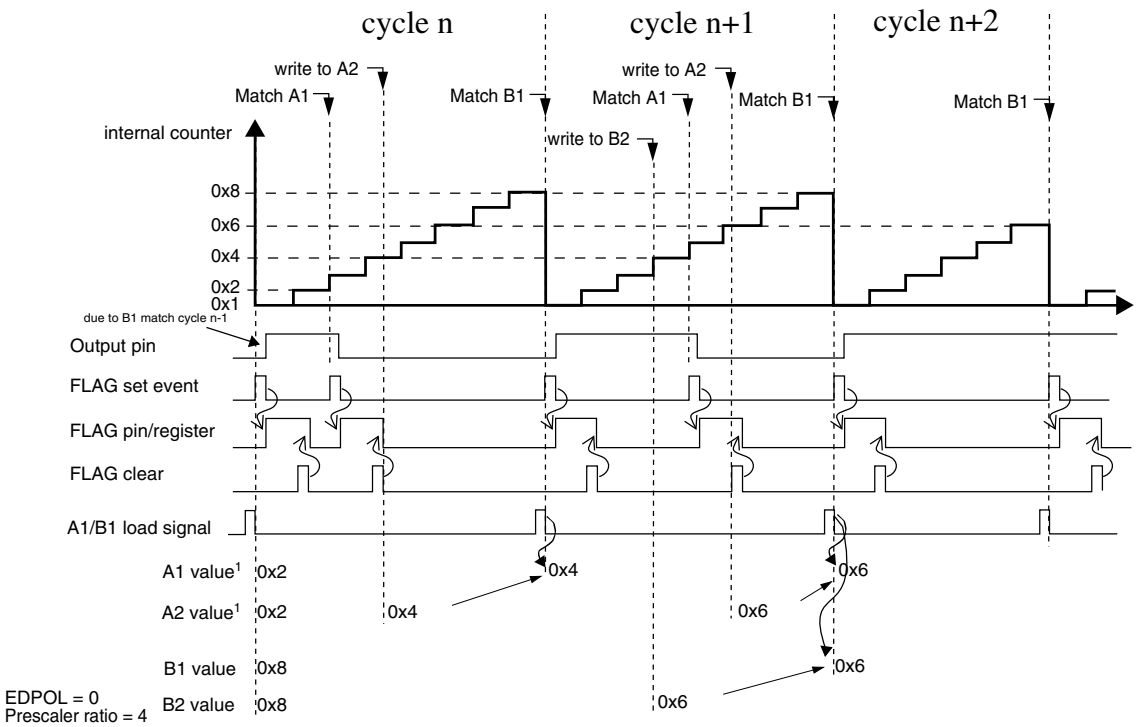

Figure 42-140. OPWFMB A1 and B1 Registers Update and Flags (MODE6] bit is 0b)

Figure 42-141 describes the operation of the Output Disable feature in OPWFMB mode. Differently from the OPWFM mode, the output disable forces the channel output flip-flop to EDPOL bit value. This functionality targets applications that use active high signals and a high to low transition at A1 match. In this case EDPOL should be set to 0. Note that both the channel and global prescalers are set to 0x0 (each divide ratio is one), meaning that the channel internal counter transitions at every system clock cycle.

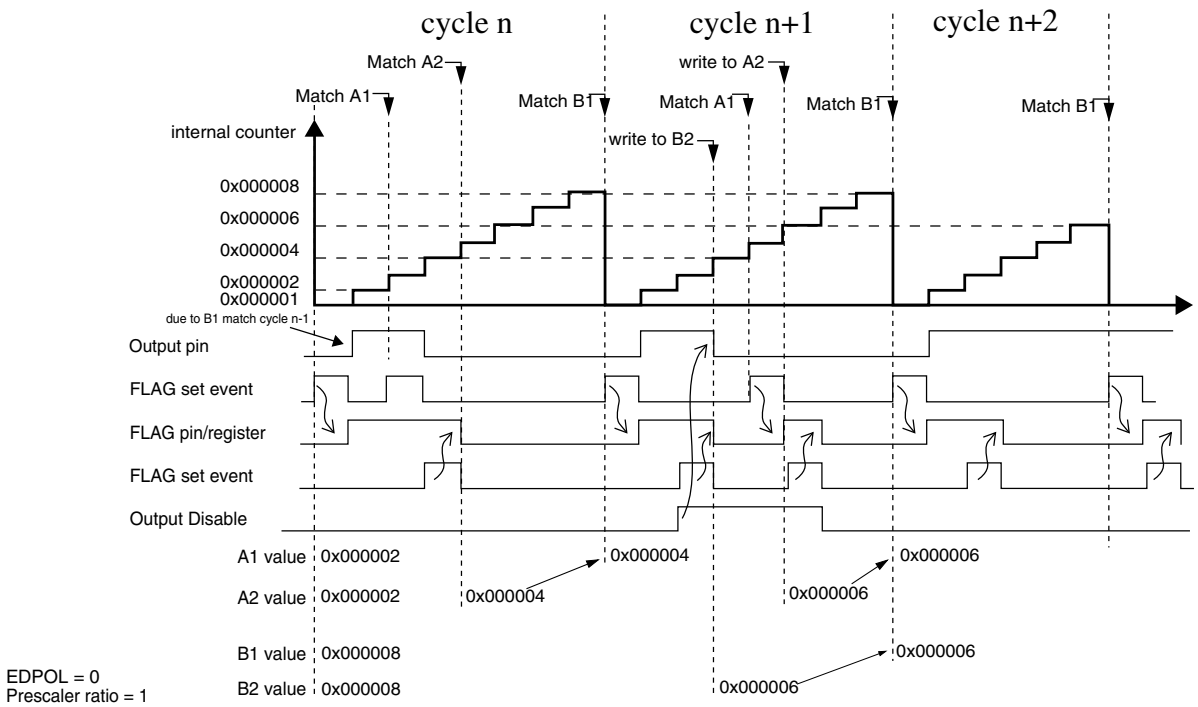

Figure 42-141. OPWFMB Mode with Active Output Disable (MODE[6] bit is 1b)

Note that the output disable has a synchronous operation, meaning that the assertion of the Output Disable input pin causes the channel output flip-flop to transition to EDPOL at the next system clock cycle. If the Output Disable input is deasserted the output pin transition at the following A1 or B1 match.

In Figure 42-141, it is assumed that the Output Disable input is enabled and selected for the Channel. Please, refer to UC Control Register (EMIOSCn) for a detailed description about the ODIS and ODISSL bits, respectively enable and selection of the Output Disable inputs.

The FORCMA and FORCMB bits allow the software to force the output flip-flop to the level corresponding to a match on comparators A or B respectively. Similarly to a B1 match FORCMB sets the internal counter to 0x1. The FLAG bit is not set by the FORCMA or FORCMB bits being asserted.

Figure 42-142 describes the generation of 100% and 0% duty cycle signals. It is assumed EDPOL =0 and the resultant prescaler value is 1. Initially, A1=0x8 and B1=0x8. In this case, B1 match has precedence over A1 match, thus the output flip-flop is set to the complement of EDPOL bit. This cycle corresponds to a 100% duty cycle signal. The same output signal can be generated for any A1 value greater or equal to B1.

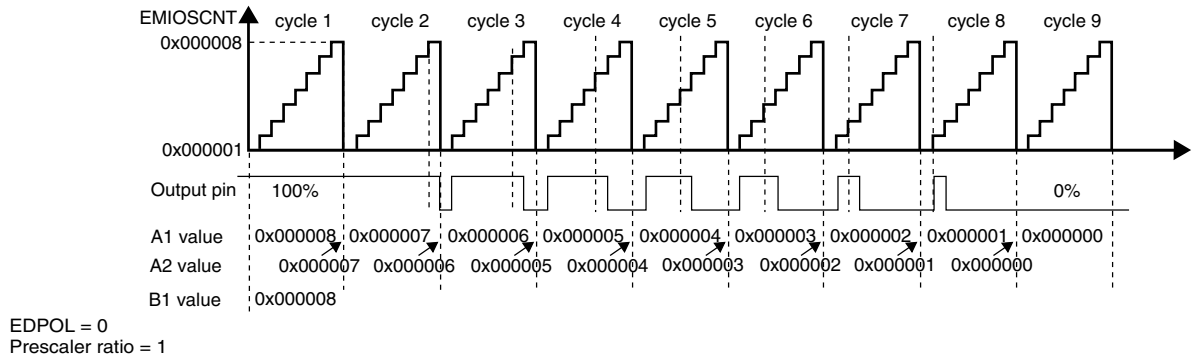

Figure 42-142. OPWFMB Mode from 100% to 0% Duty Cycle

A 0% duty cycle signal is generated if A1=0x0 as shown in Figure 42-142 cycle 9. In this case B1=0x8 match from cycle 8 occurs at the same time as the A1=0x0 match from cycle 9. Please, refer to Figure 42-139 for a description of the A1 and B1 match generation. In this case A1 match has precedence over B1 match and the output signal transitions to EDPOL.

42.6.1.1.15 Center Aligned Output Pulse Width Modulation with Dead Time Insertion (OPWMC) Mode

This operation mode generates a center aligned PWM with dead time insertion in the leading (MODE[0:6]=00111b1) or trailing edge (MODE[0:6]=00111b0).

The selected counter bus must be running an up/down time base, as shown in the 'Modulus Counter up/down mode example' figure. BSL[0:1] bits select the time base. Register A1 contains the ideal duty cycle for the PWM signal and is compared with the selected time base. Register B1 contains the dead time value and is compared with the internal counter. For a leading edge dead time insertion, the output PWM duty cycle is equal to the difference between register A1 and register B1, and for a trailing edge dead time insertion, the output PWM duty cycle is equal to the sum of register A1 and register B1. Mode[6] bit selects between trailing and leading dead time insertion, respectively.

Note

The internal counter may be running in the internal prescaler ratio, while the selected time base may be running in a different prescaler ratio. The output signal may produce an unexpected output if the dead time interval is greater than the duty cycle of the PWM signal.

When OPWMC mode is entered, coming out from GPIO mode, the output flip-flop is set to the complement of the EDPOL bit in the EMIOSC[n] register.

When operating with leading edge dead time insertion, the first match between A1 and the selected time base clears the internal counter and switches the selected time base to the internal counter. When a match occurs between register B1 and the selected time base, the output flip-flop is set to the value of the EDPOL bit and the time base is switched to the selected counter bus. In the next match between register A1 and the selected time base, the output flip-flop is set to the complement of the EDPOL bit. This sequence repeats continuously.

When operating with trailing edge dead time insertion, the first match between A1 and the selected time base sets the output flip-flop to the value of the EDPOL bit. In the next match between register A1 and the selected time base, the internal counter is cleared and the selected time base is switched to the internal counter. When a match occurs between register B1 and the selected time base, the output flip-flop is set to the complement of the EDPOL bit and the time base is switched to the selected counter bus. This sequence repeats continuously.

FLAG can be generated in the trailing edge of the output PWM signal when MODE[5] is cleared, or in both edges, when MODE[5] is set.

At any time, the FORCMA or FORCMB bits are equivalent to a successful comparison on comparator A or B with the exception that the FLAG bit is not set.

Note

When in freeze state, the FORCMA or FORCMB bits only allow the software to force the output flip-flop to the level corresponding of a match on A or B respectively.

If subsequent matches occur on comparators A and B, the PWM pulses continue to be generated, regardless of the state of the FLAG bit.

In order to achieve a duty cycle of 100%, both registers A1 and B1 must be set to the same value. When a simultaneous match occurs between the selected time base and registers A1 and B1, the output flip-flop is set to the value of EDPOL bit and the selected time base switches to the selected counter bus, allowing a new cycle to begin at any time, as previously described. 0% duty cycle is possible by writing 0x0 to register A. When a match occurs, the output flip-flop is set to the complement of EDPOL bit and the selected time base switches to the selected counter bus, allowing a new cycle to begin at any time, as previously described. In both cases, FLAG is generated regardless of MODE[6] bit.

Note

If A1 and B1 are set to the 0x0, a 0% duty cycle waveform is produced.

Figure 42-143 and Figure 42-144 show the Unified Channel running in OPWMC with leading and trailing dead time, respectively.

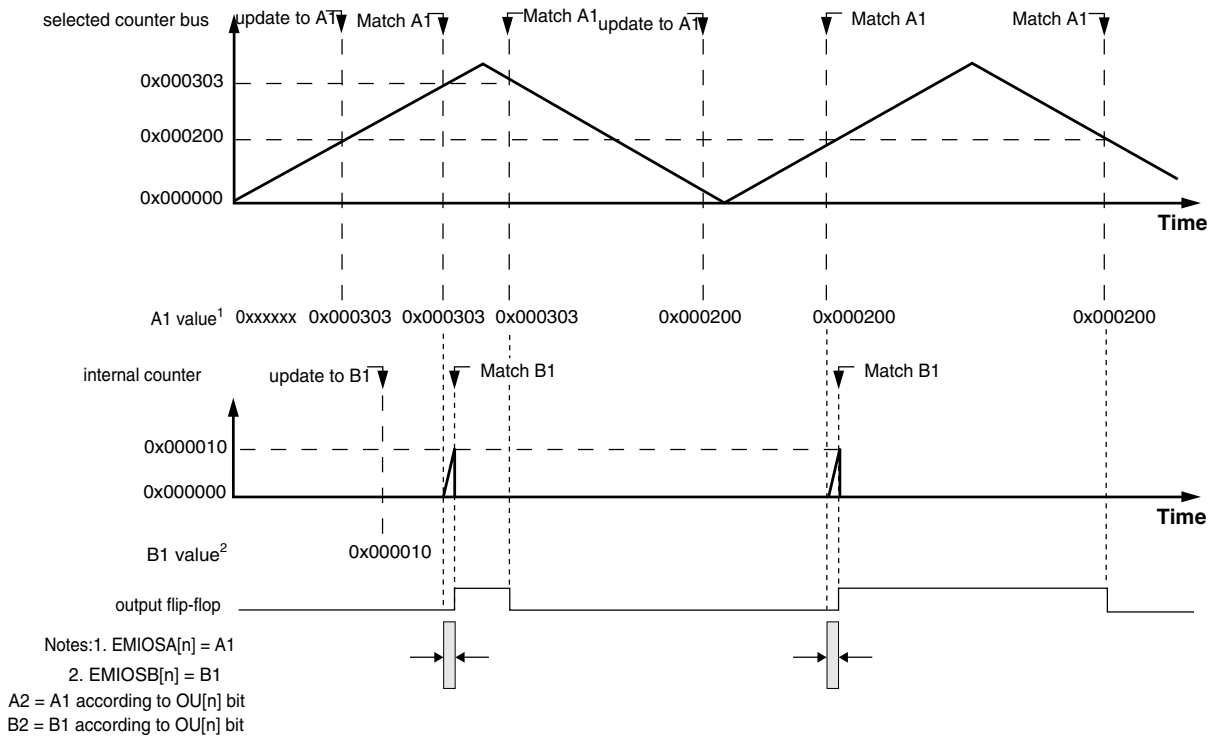

Figure 42-143. OPWMC with leading dead time insertion (MODE [6] bit is 1b)

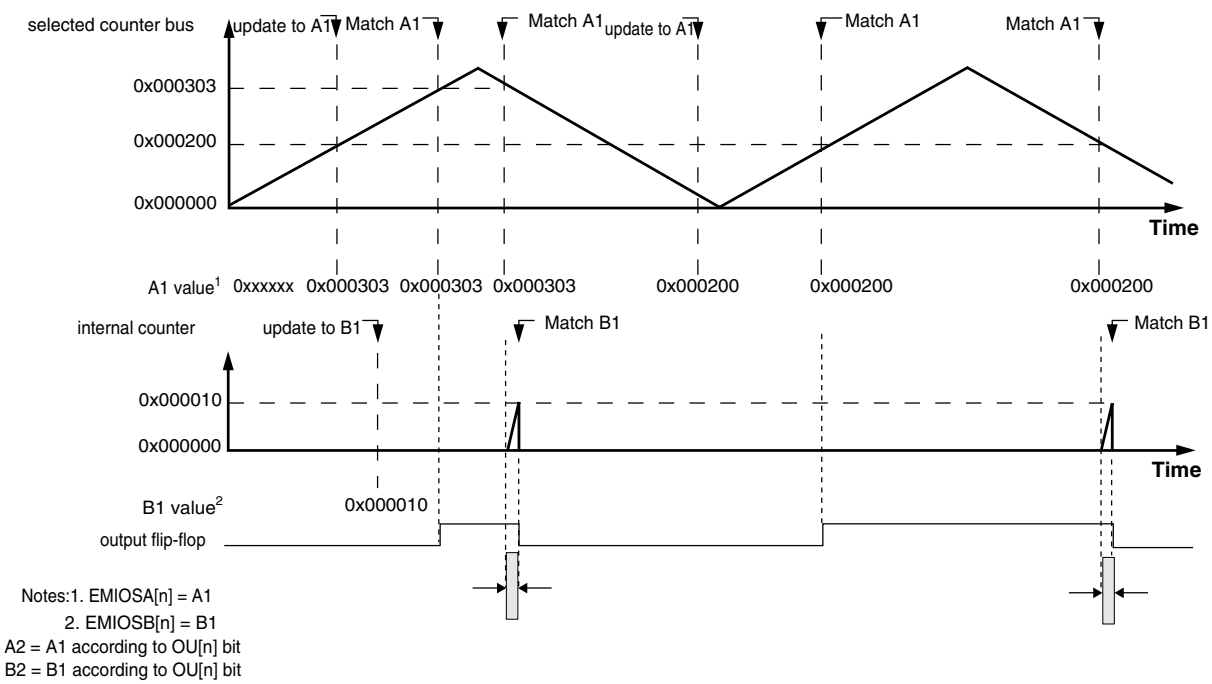

Figure 42-144. OPWMC with trailing dead time insertion (MODE [6] bit is 0b)

42.6.1.1.16 Center Aligned Output Pulse Width Modulation with Dead Time Insertion Buffered (OPWMCB) Mode

This operation mode generates a center aligned PWM with dead time insertion to the leading (MODE[0:6]=10111b1) or trailing edge (MODE[0:6]=10111b0). A1 and B1 registers are double buffered to allow smooth output signal generation when changing A2 or B2 registers values.

BSL[0:1] bits select the time base. The time base selected for a channel configured to OPWMCB mode should be a channel configured to MCB Up/Down mode, as shown in Figure 42-133 . It is recommended to start the MCB channel time base after the OPWMCB mode is entered in order to avoid missing A matches at the very first duty cycle.

Register A1 contains the ideal duty cycle for the PWM signal and is compared with the selected time base.

Register B1 contains the dead time value and is compared against the internal counter. For a leading edge dead time insertion, the output PWM duty cycle is equal to the difference between register A1 and register B1, and for a trailing edge dead time insertion, the output PWM duty cycle is equal to the sum of register A1 and register B1. Mode[6] bit selects between trailing and leading dead time insertion, respectively.

Note

The internal counter runs in the internal prescaler ratio, while the selected time base may be running in a different prescaler ratio.

When OPWMCB mode is entered, coming out from GPIO mode, the output flip-flop is set to the complement of the EDPOL bit in the EMIOSC[n] register.

The following basic steps summarize proper OPWMCB startup, assuming the channels are initially in GPIO mode:

1. *[global]* Disable Global Prescaler.
2. *[MCB channel]* Disable Channel Prescaler.
3. *[MCB channel]* Write 0x1 at internal counter.
4. *[MCB channel]* Set A register.
5. *[MCB channel]* Set channel to MCB Up mode.
6. *[MCB channel]* Set prescaler ratio.
7. *[MCB channel]* Enable Channel Prescaler.

8. *[OPWMCB channel]* Disable Channel Prescaler.
9. *[OPWMCB channel]* Set A register.
10. *[OPWMCB channel]* Set B register.
11. *[OPWMCB channel]* Select time base input through BSL[1:0] bits.
12. *[OPWMCB channel]* Enter OPWMCB mode.
13. *[OPWMCB channel]* Set prescaler ratio.
14. *[OPWMCB channel]* Enable Channel Prescaler.
15. *[global]* Enable Global Prescaler.

The following figure describes the load of A1 and B1 registers which occurs when the selected counter bus transitions from 0x2 to 0x1 . This event defines the cycle boundary. Note that values written to A2 or B2 within cycle **n** are loaded into A1 or B1 registers, respectively, and used to generate matches in cycle **n+1** .

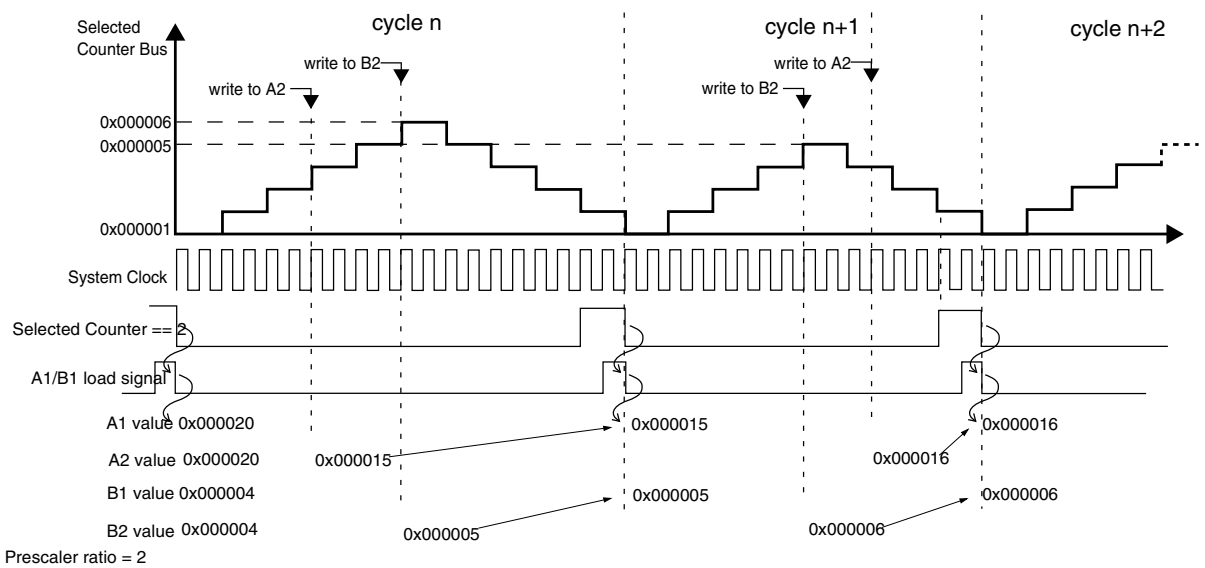

Figure 42-145. OPWMCB A1 and B1 registers load

The OU[n] bit of EMIOSOUDIS register can be used to disable the A1 and B1 updates, thus allowing to synchronize the load on these registers with the load of A1 or B1 registers in others channels. Note that using the update disable bit A1 and B1 registers can be updated at the same counter cycle thus allowing to change both registers at the same time.

In this mode, A1 matches always sets the internal counter to 0x1 . When operating with leading edge dead time insertion the first A1 match sets the internal counter to 0x1. When a match occurs between register B1 and the internal time base, the output flip-flop is set

to the value of the EDPOL bit. In the following match between register A1 and the selected time base, the output flip-flop is set to the complement of the EDPOL bit. This sequence repeats continuously. The internal counter should not reach 0x0 as consequence of a rollover. In order to avoid it, the user should not write to EMIOSB register a value greater than twice the difference between external count up limit and EMIOSA value.

The following figure shows two cycles of a Center Aligned PWM signal. Note that both A1 and B1 register values are changing within the same cycle which allows to vary at the same time the duty cycle and dead time values.

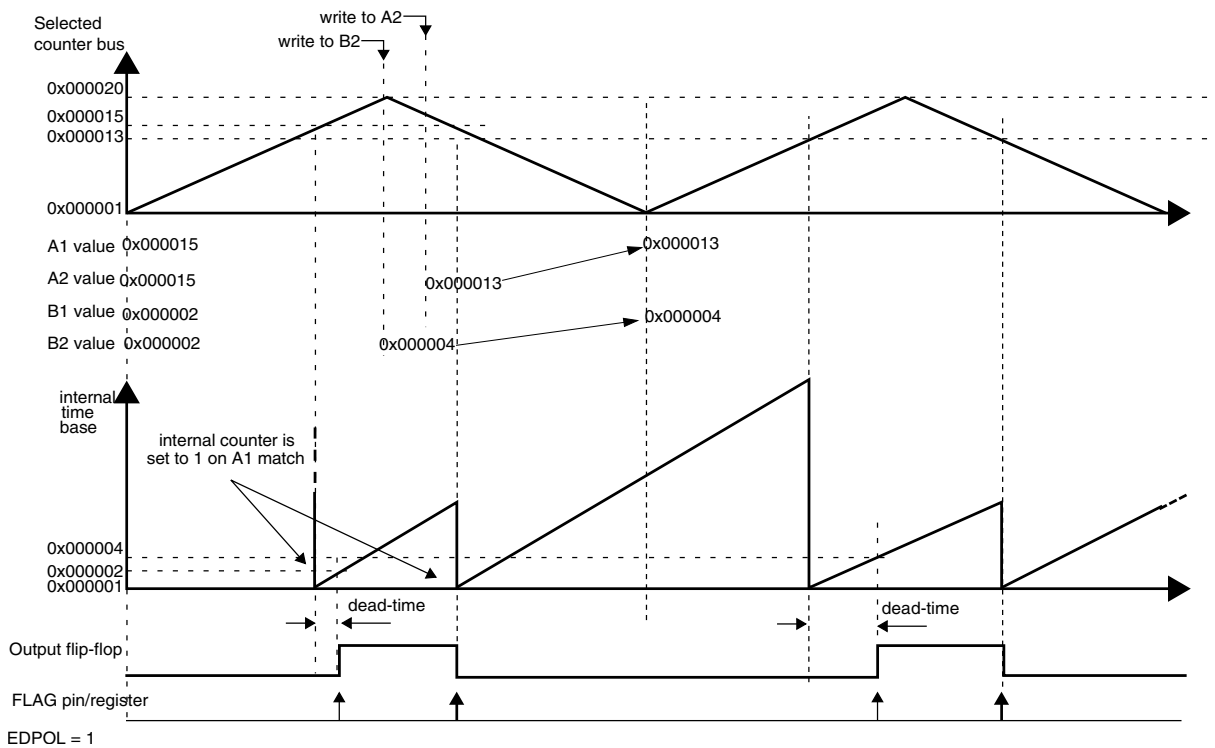

Figure 42-146. OPWMCB with Lead Dead Time Insertion

When operating with trailing edge dead time insertion, the first match between A1 and the selected time base sets the output flip-flop to the value of the EDPOL bit and sets the internal counter to 0x1. In the second match between register A1 and the selected time base, the internal counter is set to 0x1 and B1 matches are enabled. When the match between register B1 and the selected time base occurs the output flip-flop is set to the complement of the EDPOL bit. This sequence repeats continuously.

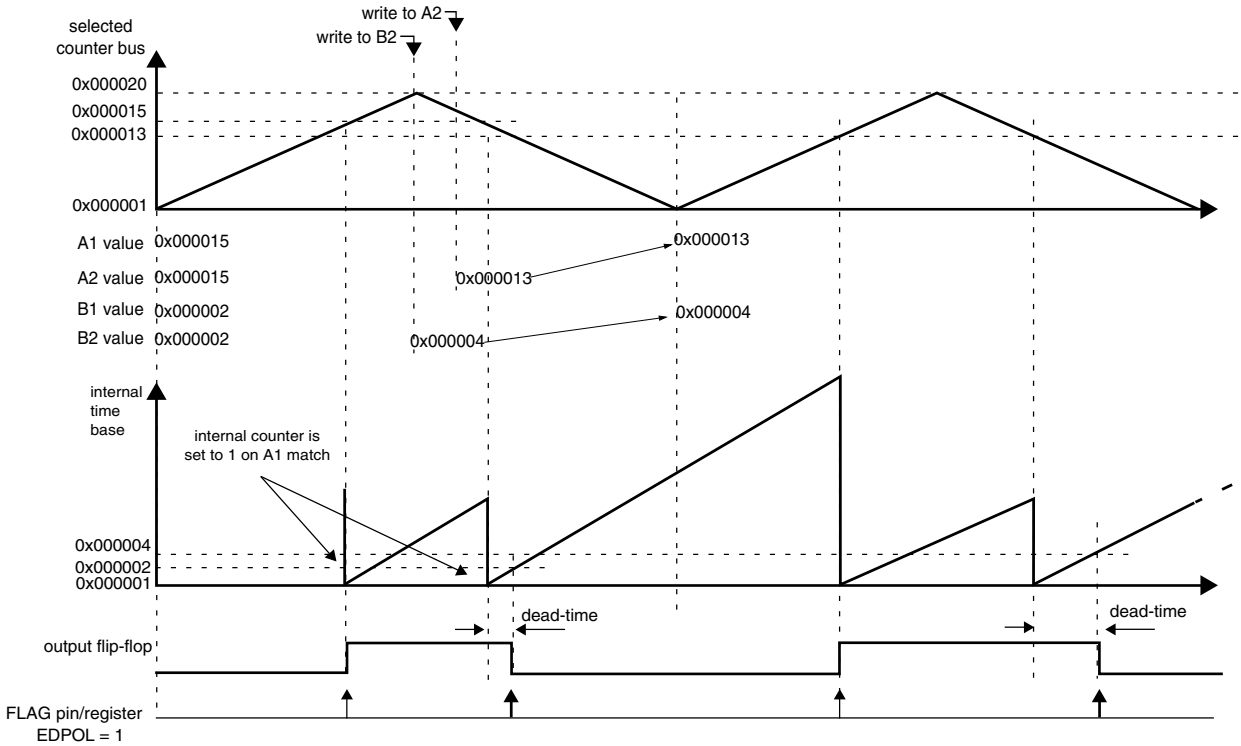

Figure 42-147. OPWMCB with Trail Dead Time Insertion

A FLAG can be generated in the trailing edge of the output PWM signal when MODE[5] is cleared, or in both edges, when MODE[5] is set. If subsequent matches occur on comparators A and B, the PWM pulses continue to be generated, regardless of the state of the FLAG bit.

Note

In OPWMCB mode FORCMA and FORCMB do not have the same behavior as a regular match. Instead they force the output flip-flop to constant value which depends upon the selected dead time insertion mode, lead or trail and the value of the EDPOL bit.

FORCMA has different behaviors depending upon the selected dead time insertion mode, lead or trail. In lead dead time insertion FORCMA force a transition in the output flip-flop to the opposite of EDPOL. In trail dead time insertion the output flip-flop is forced to the value of EDPOL bit.

If FORCMB bit is set, the output flip-flop value depends upon the selected dead time insertion mode. In lead dead time insertion FORCMB forces the output flip-flop to transition to EDPOL bit value. In trail dead time insertion the output flip-flop is forced to the opposite of EDPOL bit value.

Note

FORCMA bit set does not set the internal time-base to 0x1 as a regular A1 match.

The FLAG bit is not set either in case of a FORCMA or FORCMB or even if both forces are issued at the same time.

Note

FORCMA and FORCMB have the same behavior even in Freeze or normal mode regarding the output pin transition.

When *FORCMA* is issued along with *FORCMB* the output flip-flop is set to the opposite of EDPOL bit value. This is equivalent of saying that *FORCMA* has precedence over *FORCMB* when lead dead time insertion is selected and *FORCMB* has precedence over *FORCMA* when trail dead time insertion is selected.

A duty cycle from 0% to 100% can be generated by setting appropriate values to A1 and B1 registers relatively to the period of the external time base. Setting A1=0x1 generates a 100% duty cycle waveform. Assuming EDPOL is set to one and OPWMCB mode with trail dead time insertion, 100% duty cycle signals can be generated if B1 occurs at or after the cycle boundary (external counter = 1). If A1 is greater than the maximum value of the selected counter bus period, then a 0% duty cycle is produced, only if the pin starts the current cycle in the opposite of EDPOL value. In case of 100% duty cycle, the transition from EDPOL to the opposite of EDPOL may be obtained by forcing pin, using FORCMA and/or FORCMB.

Note

If A1 is set to 0x1 at OPWMCB entry the 100% duty cycle may not be obtained in the very first PWM cycle due to the pin condition at mode entry.

Only values different than 0x0 are allowed to be written to A1 register. If 0x0 is loaded to A1, the results are unpredictable.

Note

A special case occurs when A1 is set to (external counter bus period)/2, which is the maximum value of the external counter. In this case the output flip-flop is constantly set to the EDPOL bit value.

The internal channel logic prevents matches from one cycle to propagate to the next cycle. In trail dead time insertion B1 match from cycle **n** could eventually cross the cycle boundary and occur in cycle **n+1.** In this case B1 match is masked out and does not cause the output flip-flop to transition. Therefore matches in cycle **n+1** are not affected by the late B1 matches from cycle **n**.

The following figure shows a 100% duty cycle output signal generated by setting A1=0x4 and B1=0x3. In this case, the trailing edge is positioned at the boundary of cycle **n+1**, which is actually considered to belong to cycle **n+2** and therefore does not cause the output flip-flip to transition.

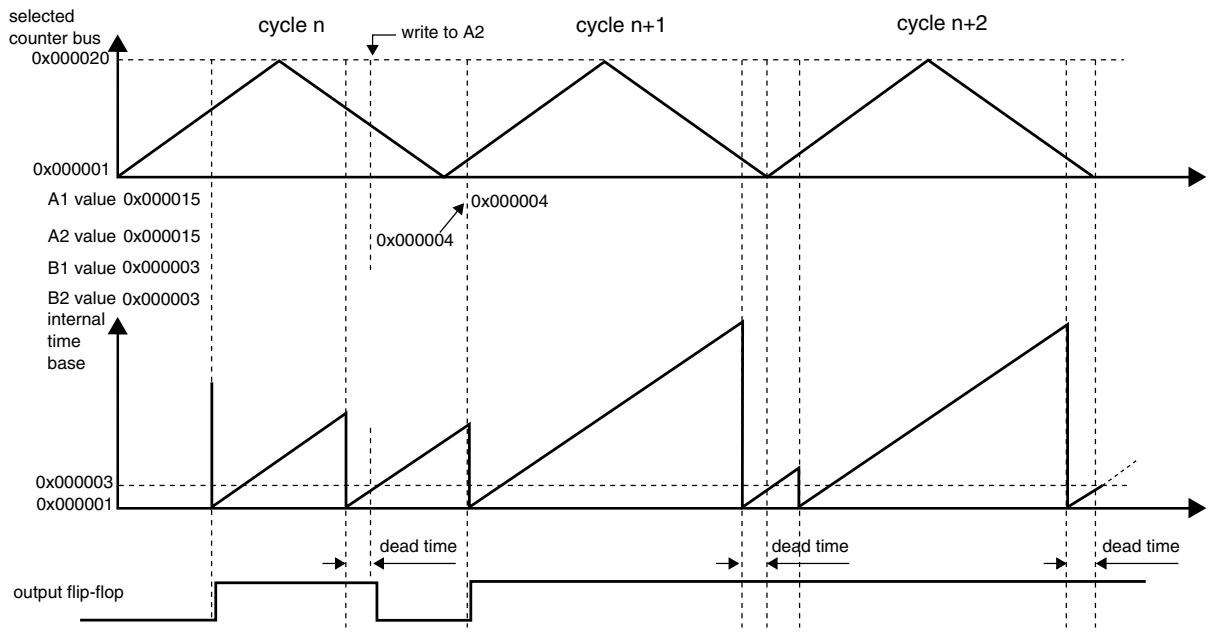

Figure 42-148. OPWMCB with 100% Duty Cycle (A1=4 and B1=3)

The output disable feature, if enabled, causes the output flip-flop to transition to the EDPOL inverted state. This feature allows an application to force the channel output pin to a "safe" state. The internal channel matches continue to occur even in this case, thus generating Flags. As soon as the output disable is deasserted, the channel output pin is again controlled by A1 and B1 matches. Note that this process is synchronous, meaning that the output channel pin transitions only on system clock edges.

It is important to notice that, such as in OPWMB and OPWFMB modes, the match signal used to set or clear the channel output flip-flop is generated on the deassertion of the channel combinational comparator output signal which compares the selected time base with A1 or B1 register values. Please refer to Figure 42-138, which describes the delay from matches to output flip-flop transition in OPWFMB mode. The operation of OPWMCB mode is similar to OPWFMB regarding matches and output pin transition.

42.6.1.1.17 Output Pulse Width Modulation (OPWM) Mode

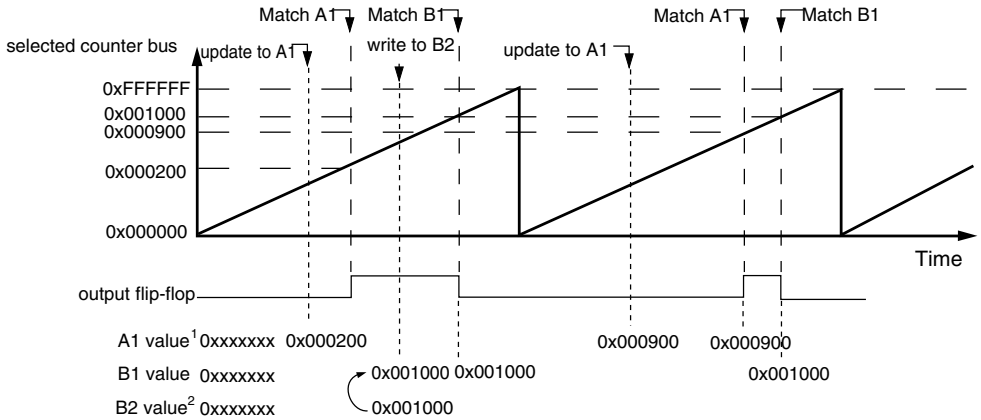
Registers A1 and B1 define the leading and trailing edges of the PWM output pulse, respectively. MODE[6] bit controls the transfer from register B2 to B1, which can be done either immediately (MODE[6] cleared, MODE[0:6]=01000b0), providing the fastest change in the duty cycle, or at every match of register A1 (MODE[6] set, MODE[0:6]=01000b1).

The value loaded in register A1 is compared with the value on the selected time base. When a match on comparator A occurs, the output flip-flop is set to the value of the EDPOL bit. When a match occurs on comparator B, the output flip-flop is set to the complement of the EDPOL bit.

A FLAG can be generated at match B, when MODE[5] is cleared, or in both matches, when MODE[5] is set.

At any time, the FORCMA and FORCMB bits allow the software to force the output flip-flop to the level corresponding to a match on A or B respectively. Note that FLAG bit is not set by the FORCMA and FORCMB operations.

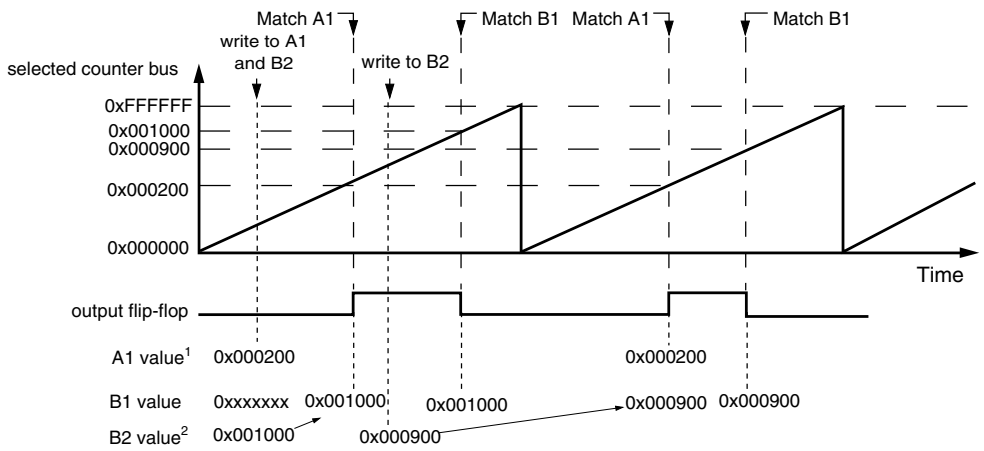
If subsequent matches occur on comparators A and B, the PWM pulses continue to be generated, regardless of the state of the FLAG bit.



At OPWM mode entry the output flip-flop is set to the complement of the EDPOL bit in the EMIOSC[n] register.

In order to achieve 100% duty cycle, both registers A1 and B1 must be set to the same value. When a simultaneous match on comparators A and B occur, the output flip-flop is set at every period to the value of EDPOL bit. 0% duty cycle is possible by writing 0x0 to register A. When a match occurs, the output flip-flop is set at every period to the complement of EDPOL bit. The transfer from register B2 to B1 is still controlled by the MODE[6] bit.

Note



If A1 and B1 are set to the 0x0, a 0% duty cycle waveform is produced.

Figure 42-149 and Figure 42-150 show the Unified Channel running in OPWM with immediate update and next period update, respectively.

Notes:1. EMIOSA[n] = A1
2. EMIOSB[n] = B2
A2 = A1 according to OU[n] bit
B2 = B1 according to OU[n] bit

Figure 42-149. PWM with immediate update (MODE[6] is 0b)

Notes:1. EMIOSA[n] = A1
2. EMIOSB[n] = B2
A2 =A1 and A2= A1 according to OU[n] bit

Figure 42-150. PWM with next period update (MODE[6] is 1b)

42.6.1.1.18 Output Pulse Width Modulation Buffered (OPWMB) Mode

OPWMB mode (MODE[0:6]=11000b0) is used to generate pulses with programmable leading and trailing edge placement. An external counter driven in MCB Up mode must be selected from one of the counter buses. A1 register value defines the first edge and B1 the second edge. The output signal polarity is defined by the EDPOL bit. If EDPOL is zero, a negative edge occurs when A1 matches the selected counter bus and a positive edge occurs when B1 matches the selected counter bus.

The A1 and B1 registers are double buffered and updated from A2 and B2, respectively, at the cycle boundary. The load operation is similar to the OPWFMB mode. Please refer to Figure 42-140 for more information about A1 and B1 registers update.

FLAG can be generated at B1 matches, when MODE[5] is cleared, or in both A1 and B1 matches, when MODE[5] is set. If subsequent matches occur on comparators A and B, the PWM pulses continue to be generated, regardless of the state of the FLAG bit.

FORCMA and FORCMB bits allow the software to force the output flip-flop to the level corresponding to a match on A1 or B1 respectively. The FLAG bit is not set by the FORCMA and FORCMB operations.

At OPWMB mode entry the output flip-flop is set to the value of the EDPOL bit in the EMIOSC[n] register.

Some rules applicable to the OPWMB mode are:

- B1 matches have precedence over A1 matches if they occur at the same time within the same counter cycle
- A1=0 match from cycle **n** has precedence over B1 match from cycle **n-1**
- A1 matches are masked out if they occur after B1 match within the same cycle
- Any value written to A2 or B2 on cycle **n** is loaded to A1 and B1 registers at the following cycle boundary (assuming OU[n] bit of EMIOSOUDIS register is not asserted). Thus the new values will be used for A1 and B1 matches in cycle **n+1**

The following figure describes the operation of the OPWMB mode regarding A1 and B1 matches and the transition of the channel output pin. In this example EDPOL is set to zero.

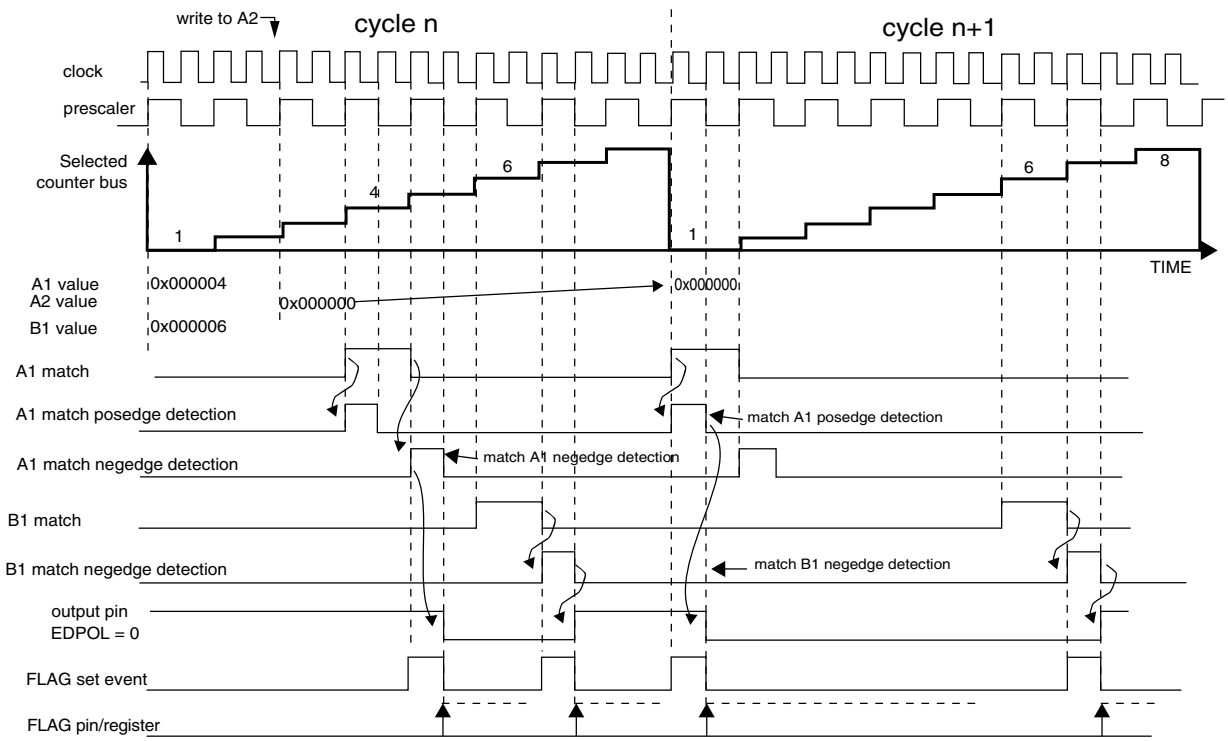


Figure 42-151. OPWMB Mode Matches and Flags

Note that the output pin transitions are based on the negedges of the A1 and B1 match signals. The figure above shows in cycle **n+1** the value of A1 register being set to zero. In this case the match posedge is used instead of the negedge to transition the output flip-flop.

The figure below describes the channel operation for 0% duty cycle. Note that the A1 match posedge signal occurs at the same time as the B1=0x8 negedge signal. In this case A1 match has precedence over B1 match, causing the output pin to remain at EDPOL bit value, thus generating a 0% duty cycle signal.

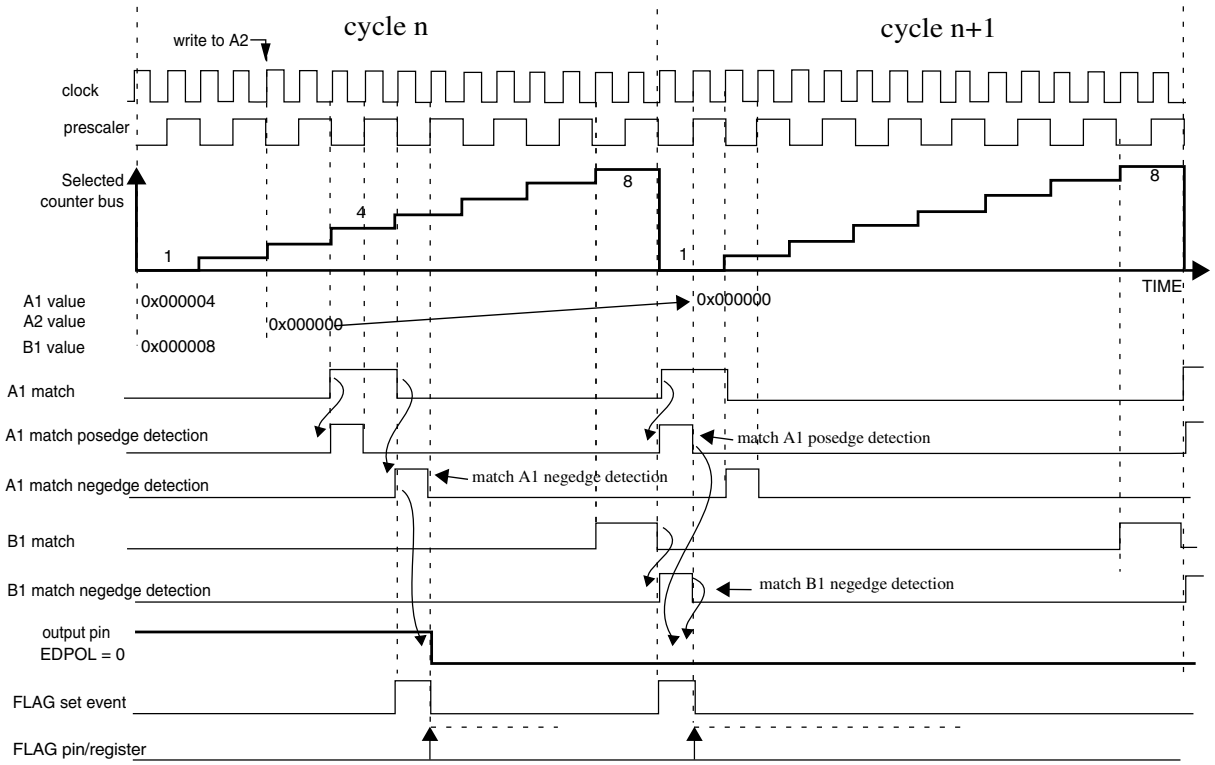

Figure 42-152. OPWMB Mode with 0% Duty Cycle

Figure 42-153 describes the operation of the OPWMB mode with the Output Disable signal being asserted. The Output Disable forces a transition in the output pin to the EDPOL bit value. After deasserted, the output disable allows the output pin to transition at the following A1 or B1 match. Note that the Output Disable does not modify the Flag bit behavior. Note that there is one system clock delay between the assertion of the output disable signal and the transition of the output pin to EDPOL.

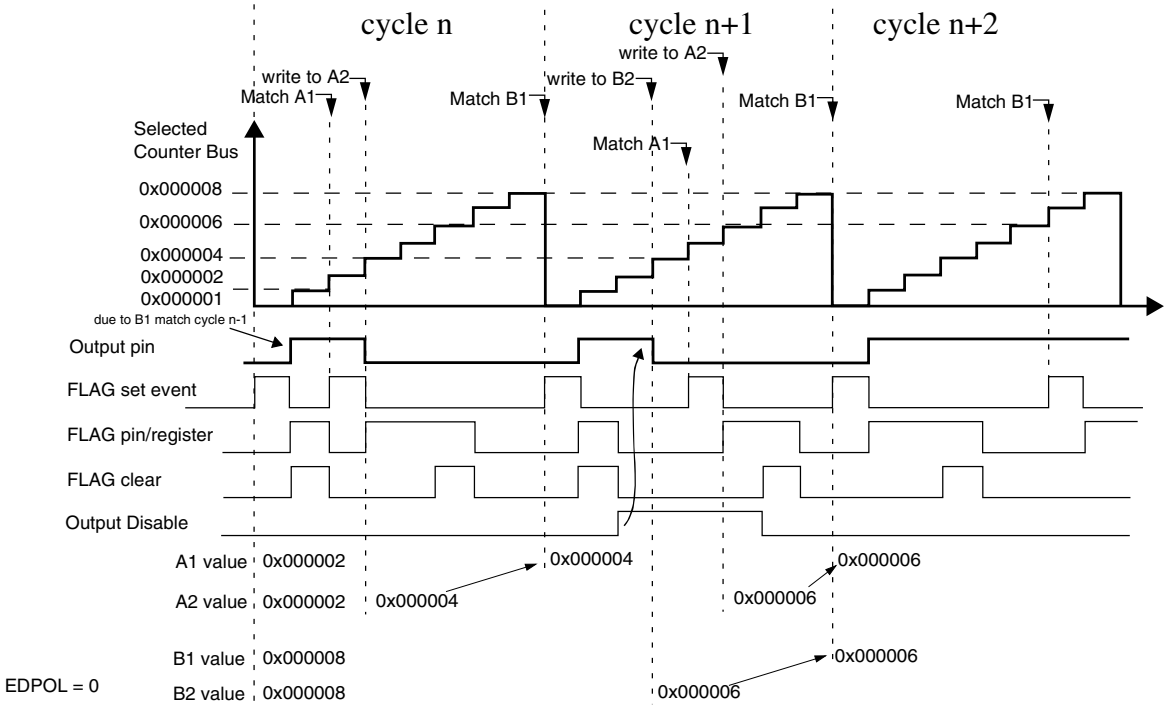

Figure 42-153. OPWMB Mode with Active Output Disable (MODE[6] bit is 1b)

Figure 42-154 shows a waveform changing from 100% to 0% duty cycle. EDPOL in this case is zero. In this example, B1 is programmed to the same value as the period of the external selected time base.

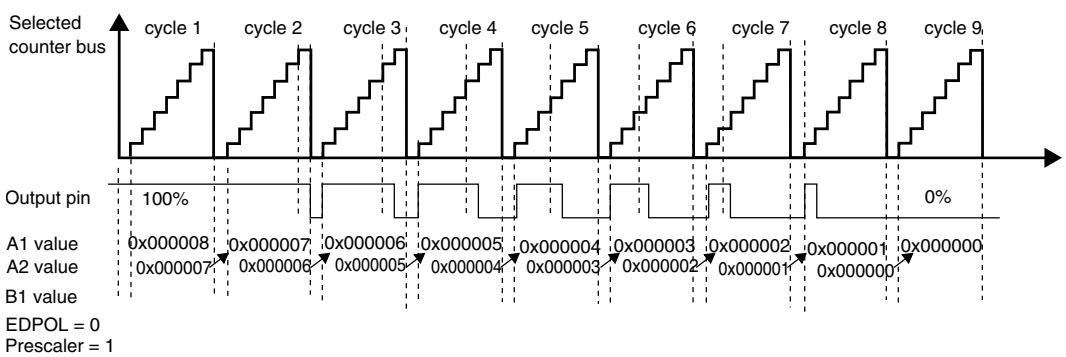

Figure 42-154. OPWMB Mode from 100% to 0% Duty Cycle

In Figure 42-154, if B1 is set to a value lower than 0x8, it is not possible to achieve 0% duty cycle by only changing A1 register value. Since B1 matches have precedence over A1 matches the output pin transitions to the opposite of EDPOL bit at B1 match. Note also that if B1 is set to 0x9, for instance, B1 match does not occur, thus a 0% duty cycle signal is generated.

42.6.1.1.19 Output Pulse Width Modulation with Trigger (OPWMT) Mode

OPWMT mode (MODE[0:6]=0100110) is intended to support the generation of Pulse Width Modulation signals where the period is not modified while the signal is being output, but where the duty cycle will be varied and must not create glitches. The mode is intended to be used in conjunction with other channels executing in the same mode and sharing a common timebase. It will support each channel with a fixed PWM leading edge position with respect to the other channels and the ability to generate a trigger signal at any point in the period that can be output from the module to initiate activity in other parts of the SoC such as starting ADC conversions.

An external counter driven in either MC Up or MCB Up mode must be selected from one of the counter buses.

Register A1 defines the leading edge of the PWM output pulse and as such the beginning of the PWM's period. This makes it possible to insure that the leading edge of multiple channels in OPWMT mode can occur at a specific time with respect to the other channels when using a shared timebase. This can allow the introduction of a fixed offset for each channel which can be particularly useful in the generation of lighting PWM control signals where it is desirable that edges are not coincident with each other to help eliminate noise generation. The value of register A1 represents the shift of the PWM channel with respect to the selected timebase. A1 can be configured with any value within the range of the selected time base. Note that registers loaded with 0x0 will not produce matches if the timebase is driven by a channel in MCB mode.

A1 is not buffered as the shift of a PWM channel must not be modified while the PWM signal is being generated. In case A1 is modified it is immediately updated and one PWM pulse could be lost.

EMIOSB[n] address gives access to B2 register for write and B1 register for read. Register B1 defines the trailing edge of the PWM output pulse and as such the duty cycle of the PWM signal. To synchronize B1 update with the PWM signal and so ensure a correct output pulse generation the transfer from B2 to B1 is done at every match of register A1. This behavior is the same as the OPWM mode with next period update.

EMIOSOUDIS register affects transfers between B2 and B1 only.

In order to account for the shift in the leading edge of the waveform defined by register A1 it will be necessary that the trailing edge, held in register B1, can roll over into the next period. This means that a match against the B1 register should not have to be qualified by a match in the A1 register. The impact of this would mean that incorrectly setting register B1 to a value less that register A1 will result in the output being held over a cycle boundary until the B1 value is encountered.

This mode provides a buffered update of the trailing edge by updating register B1 with register B2 contents only at a match of register A1.

The value loaded in register A1 is compared with the value on the selected time base. When a match on comparator A1 occurs, the output flip-flop is set to the value of the EDPOL bit. When a match occurs on comparator B, the output flip-flop is set to the complement of the EDPOL bit.

Note that the output pin and flag transitions are based on the posedges of the A1, B1 and A2 match signals. Please refer to Figure 42-151 in Output Pulse Width Modulation Buffered (OPWMB) Mode for details on match posedge.

Register A2 defines the generation of a trigger event within the PWM period and A2 should be configured with any value within the range of the selected time base, otherwise no trigger will be generated. A match on the comparator will generate the FLAG signal but it has no effect on the PWM output signal generation. The typical setup to obtain a trigger with FLAG is enabling DMA and driving the channel's ipd_done input high.

A2 is not buffered and therefore its update is immediate. If the channel is running when a change is made this could cause either the loss of one trigger event or the generation of two trigger events within the same period. Register A2 can be accessed by reading or writing the eMIOS200 UC Alternate A Register (eMIOS_ALTA) at UC[n] base address +0x14.

The FLAG signal is set only at match on the comparator with A2. A match on the comparator with A1 or B1 or B2 has no effect on FLAG.

At any time, the FORCMA and FORCMB bits allow the software to force the output flip-flop to the level corresponding to a match on A or B respectively. Any FORCMA and/or FORCMB has priority over any simultaneous match regarding to output pin transitions. Note that the load of B2 content on B1 register at an A match is not inhibited due to a simultaneous FORCMA/FORCMB assertion. If both FORCMA and FORCMB are asserted simultaneously the output pin goes to the opposite of EDPOL value such as if A1 and B1 registers had the same value. FORCMA assertion causes the transfer from register B2 to B1 such as a regular A match, regardless of FORCMB assertion.

If subsequent matches occur on comparators A1 and B, the PWM pulses continue to be generated, regardless of the state of the FLAG bit.

At OPWMT mode entry the output flip-flop is set to the complement of the EDPOL bit in the EMIOSC[n] register.

In order to achieve 0% duty cycle both registers A1 and B must be set to the same value. When a simultaneous match on comparators A and B occur, the output flip-flop is set at every period to the complement value of EDPOL.

In order to achieve 100% duty cycle the register B1 must be set to a value greater than maximum value of the selected time base. As a consequence if 100% duty cycle must be implemented the maximum counter value for the time base is 0xFFFFFE for a 24-bit counter and 0xFFFE for a 16-bit counter, respectively. When a match on comparator A1 occurs the output flip-flop is set at every period to the value of EDPOL bit. The transfer from register B2 to B1 is still triggered by the match at comparator A.

As with other eMIOS200 mode, the OPWMT mode will implement the Output Disable function. Setting the ODIS bit in the eMIOS200 UC Control Register (EMIOSC[n]) will enable the Output Disable function. If the selected Output Disable input signal is asserted for the channel, the output pin will go to the inverse of the EDPOL. The channel will continue to operate normally, although the output will be fixed. When the Output Disable input signal is negated, the output pin will return to operate as normal.

Figure 42-155 shows the Unified Channel running in OPWMT mode with Trigger Event Generation and duty cycle update on next period update.

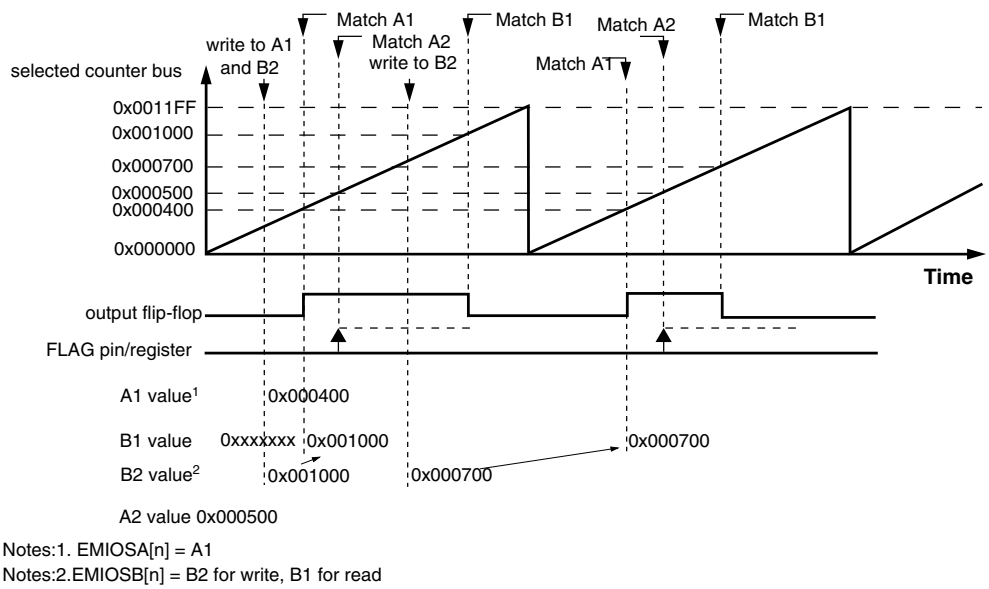

Figure 42-155. OPWMT example

Figure 42-156 shows the Unified Channel running in OPWMT mode with Trigger Event Generation and 0% duty.

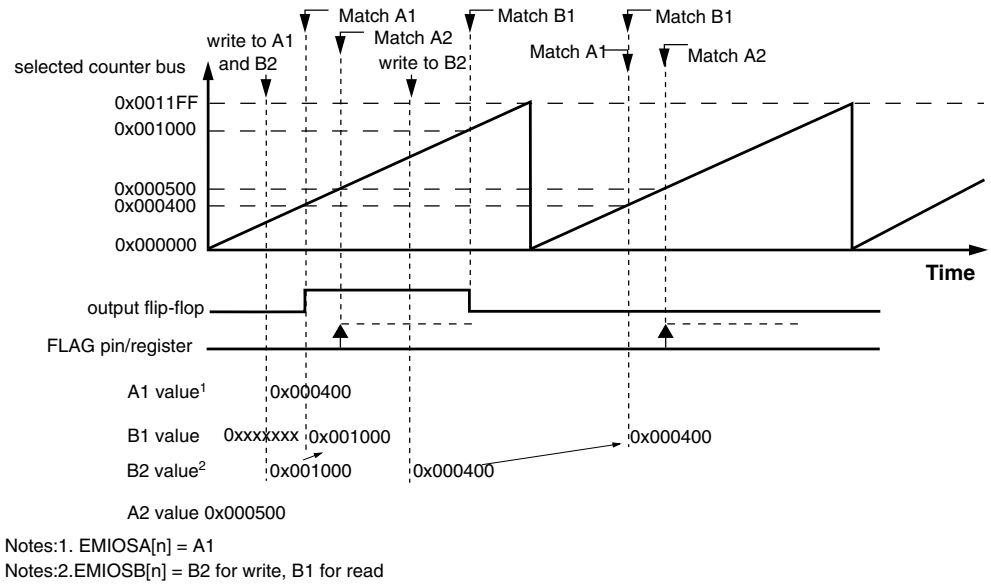

Figure 42-156. OPWMT with 0% Duty Cycle

Figure 42-157 shows the Unified Channel running in OPWMT mode with Trigger Event Generation and 100% duty cycle.

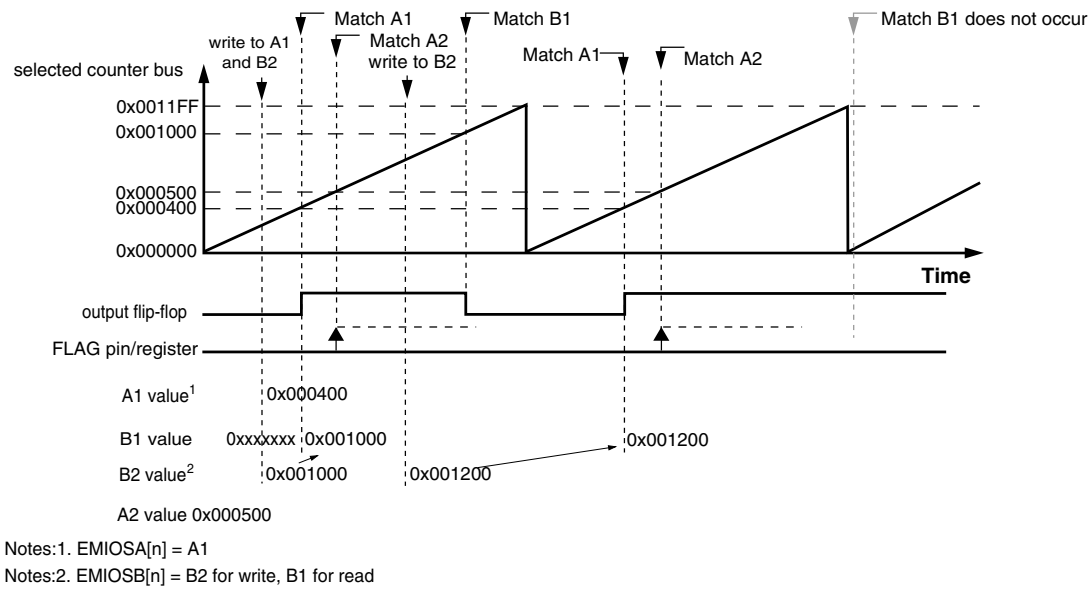

Figure 42-157. OPWMT with 100% Duty Cycle

42.6.1.2 Input Programmable Filter (IPF)

The IPF ensures that only valid input pin transitions are received by the Unified Channel edge detector. A block diagram of the IPF is shown in Figure 42-158.

The IPF is a 5-bit programmable up counter that is incremented by the selected clock source, according to bits IF[0:3] in EMIOSC[n] register.

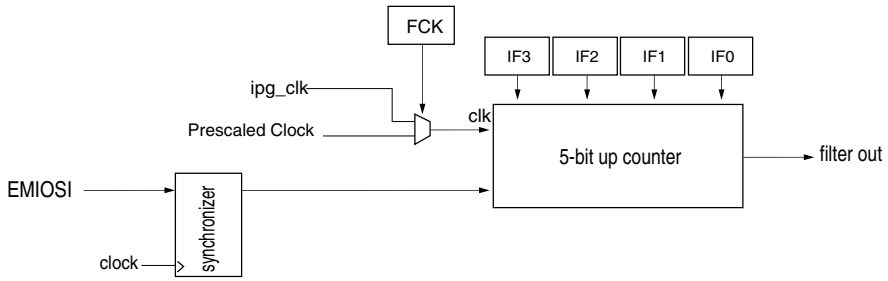

Figure 42-158. Input Programmable Filter Submodule Diagram

The input signal is synchronized by system clock . When a state change occurs in this signal, the 5-bit counter starts counting up. As long as the new state is stable on the pin, the counter remains incrementing. If a counter overflow occurs, the new pin value is validated. In this case, it is transmitted as a pulse edge to the edge detector. If the opposite edge appears on the pin before validation (overflow), the counter is reset. At the next pin transition, the counter starts counting again. Any pulse that is shorter than a full range of the masked counter is regarded as a glitch and it is not passed on to the edge detector. A timing diagram of the input filter is shown in Figure 42-159.

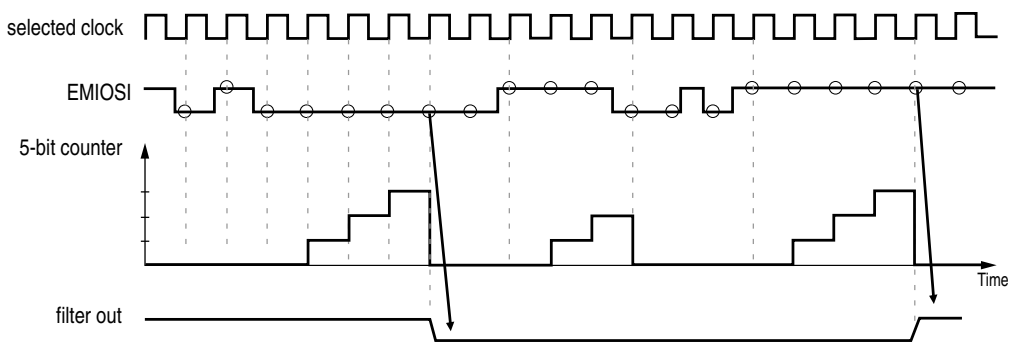

Figure 42-159. Input Programmable Filter Example (IF[0:3] is 0010b)

The filter is not disabled during either freeze state or negated GTBE input

42.6.1.3 Clock Prescaler (CP)

The CP divides the GCP output signal to generate a clock enable for the internal counter of the Unified Channels. The GCP output signal is prescaled by the value defined in the UCPRE[0:1] field description in the EMIOSC[n] register. The prescaler is enabled by setting the UCPREN bit in the EMIOSC[n] and can be stopped at any time by clearing this bit, thereby stopping the internal counter in the Unified Channel.

In order to ensure safe working and avoid glitches the following steps must be performed whenever any update in the prescaling rate is desired:

1. Write 0 at both GPREN bit in EMIOSMCR register and UCPREN bit in EMIOSC[n] register, thus disabling prescalers;
2. Write the desired value for prescaling rate at UCPRE[0:1] bits in EMIOSC[n] register;
3. Enable channel prescaler by writing 1 at UCPREN bit in EMIOSC[n] register;
4. Enable global prescaler by writing 1 at GPREN bit in EMIOSMCR register.

The prescaler is not disabled during either freeze state or negated GTBE input.

42.6.1.4 Effect of Freeze on the Unified Channel

When in debug mode, FRZ bit in the EMIOSMCR register and the FREN bit in the EMIOSC[n] are both set, the internal counter and Unified Channel capture and compare functions are halted. The UC is frozen in its current state.

During freeze, all registers are accessible. When the Unified Channel is operating in an output mode, the force match functions remain available, allowing the software to force the output to the desired level.

Note that for input modes, any input events that may occur while the channel is frozen are ignored.

When exiting debug mode or freeze enable bit is cleared (FRZ in the EMIOSMCR or FREN in the EMIOSC[n] register) the channel actions resume, but may be inconsistent until channel enters GPIO mode again.

42.6.2 IP Bus Interface Unit (BIU)

The BIU provides the interface between the Internal Interface Bus (IIB) and the Peripheral Bus, allowing communication among all submodules and this IP interface.

The BIU allows 8, 16 and 32 bits access. They are performed over a 32-bit data bus in a single cycle clock.

42.6.2.1 Effect of Freeze on the BIU

When the FRZ bit in the EMIOSMCR register is set and the module is in debug mode, the operation of BIU is not affected.

42.6.3 STAC Bus Client submodule

The STAC bus client provides one external time base, imported from the STAC bus, to the Unified Channels. Figure 42-160 provides a block diagram for the module.

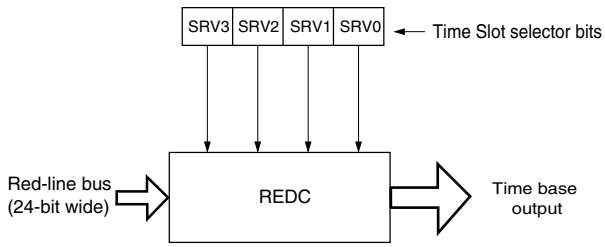

Figure 42-160. Block diagram

Bits SRV[0:3] in register EMIOSMCR selects the desired time slot of the STAC bus to be output. Figure 42-161 shows a timing diagram for the REDC.

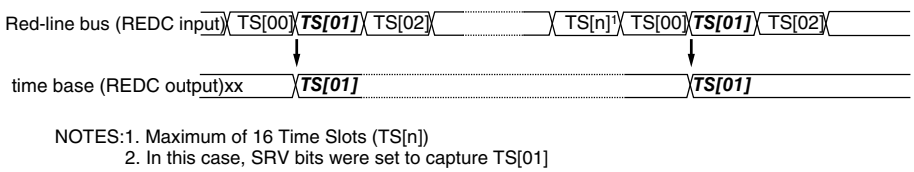

Figure 42-161. Timing diagram for the STAC bus and STAC output

Every time the selected time slot change, the STAC output is updated.

See the chip-specific eMIOS information for the STAC server IDs.

42.6.3.1 Effect of Freeze on the STAC bus

When the FRZ bit in the EMIOS_MCR register is set and the module is in debug mode, the operation of REDC submodule is not affected, i.e., there is no freeze function in this submodule.

42.6.4 Global Clock Prescaler Submodule (GCP)

The GCP divides the system clock to generate a clock for the CPs of the channels. The main clock signal is prescaled by the value defined in the Global Prescaler clock divider table within the eMIOS200 Module Configuration Register (EMIOSMCR) description

according to the GPRE[0:7] bits in EMIOSMCR register. The global prescaler is enabled by setting the GPREN bit in the EMIOSMCR register and can be stopped at any time by clearing this bit, thereby stopping the internal counters in all the channels.

In order to ensure safe working and avoid glitches the following steps must be performed whenever any update in the prescaling rate is desired:

1. Write 0 at GPREN bit in EMIOSMCR register, thus disabling global prescaler;
2. Write the desired value for prescaling rate at GPRE[0:7] bits in EMIOSMCR register;
3. Enable global prescaler by writing 1 at GPREN bit in EMIOSMCR register.

The prescaler is not disabled during either freeze state or negated GTBE input.

42.6.4.1 Effect of Freeze on the GCP

When the FRZ bit in the EMIOSMCR register is set and the module is in debug mode, the operation of GCP submodule is not affected, i.e., there is no freeze function in this submodule.

42.7 Initialization/Application Information

On resetting the eMIOS200, the Unified Channels enter GPIO input mode.

42.7.1 Considerations

Before changing an operating mode, the UC must be programmed to GPIO mode and EMIOSA[n] and EMIOSB[n] registers must be updated with the correct values for the next operating mode. Then the EMIOSC[n] register can be written with the new operating mode. If a UC is changed from one mode to another without performing this procedure, the first operation cycle of the selected time base can be random, i.e., matches can occur in random time if the contents of EMIOSA[n] or EMIOSB[n] were not updated with the correct value before the time base matches the previous contents of EMIOSA[n] or EMIOSB[n].

When interrupts are enabled, the software must clear the FLAG bits before exiting the interrupt service routine.

42.7.2 Application Information

Correlated output signals can be generated by all output operation modes. Bits OU[n] of eMIOS200_OUDIS register can be used to control the update of these output signals.

In order to guarantee that the internal counters of correlated channels are incremented in the same clock cycle, the internal prescalers must be set up before enabling the global prescaler. If the internal prescalers are set after enabling the global prescaler, the internal counters may increment in the same ratio, but at a different clock cycle.

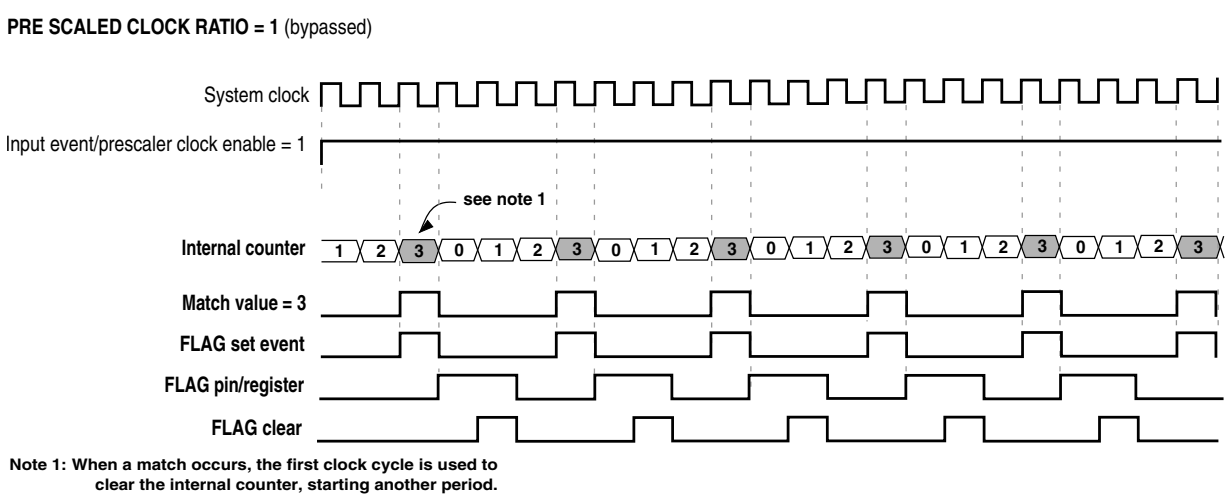
It is recommended to drive Output Disable Input signals with the emios_flag_out signals of some UCs running in SAIC mode. When an output disable condition happens, the software interrupt routine must service the output channels before servicing the channels running SAIC. This procedure avoid glitches in the output pins.

42.7.2.1 Time Base Generation

For MC and OPWFM with internal clock source operation modes, the internal counter rate can be modified by configuring the clock prescaler ratio. Figure 42-162 shows an example of a time base with prescaler ratio equal to one.

Note

MCB and OPWFMB modes have a different behavior.



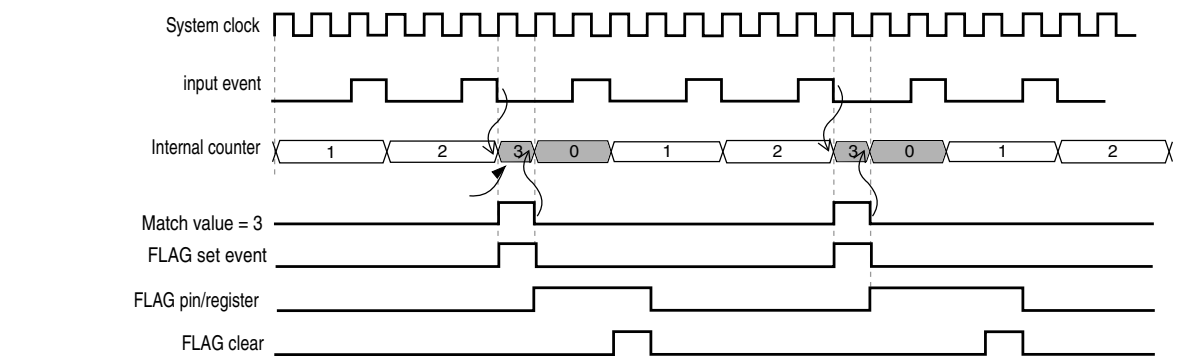


Figure 42-162. Time base period when running in the fastest prescaler ratio

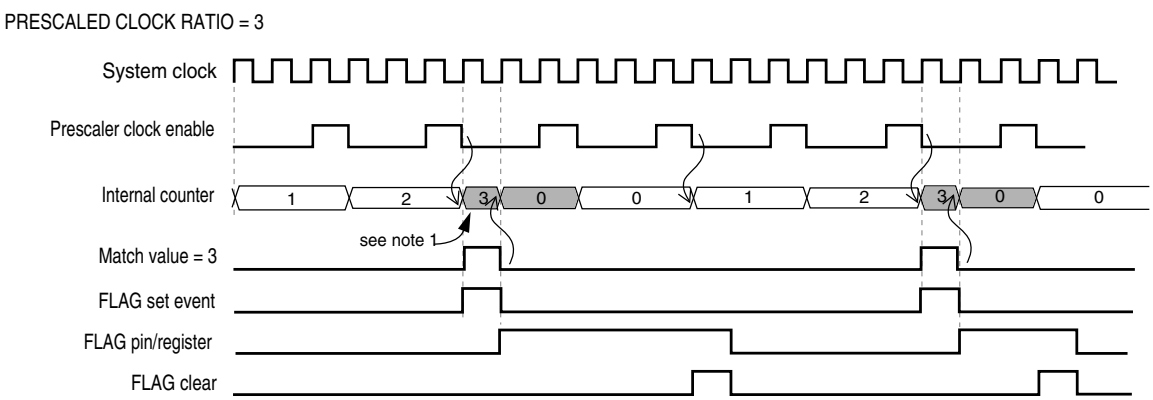
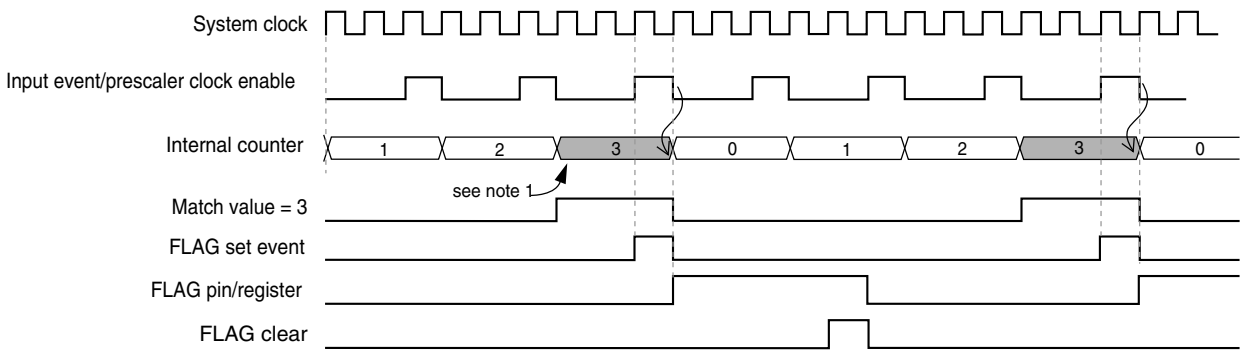
If the prescaler ratio is greater than one or external clock is selected, the counter may behave in one of four different ways depending on the channel mode:

- If MC mode and Clear on Match Start and External Clock source are selected the internal counter behaves as described in Figure 42-163 .
- If MC mode and Clear on Match Start and Internal Clock source are selected the internal counter behaves as described in Figure 42-164.
- If MC mode and Clear on Match End are selected the internal counter behaves as described in Figure 42-165.
- If OPWFM mode is selected the internal counter behaves as described in Figure 42-164. The internal counter clears at the start of the match signal, skips the next prescaled clock edge and then increments in the subsequent prescaled clock edge.



Note

MCB and OPWFMB modes have a different behavior.



Note 1: When a match occurs, the first system clock cycle is used to clear the internal counter, and at the next edge of prescaler clock enable the counter will start counting.

Figure 42-163. Time base generation with external clock and clear on match start

Note 1: When a match occurs, the first clock cycle is used to clear the internal counter, and only after a second edge of pre scaled clock the counter will start counting.

Figure 42-164. Time base generation with internal clock and clear on match start

Note 1: The match occurs only when the input event/prescaler clock enable is active. Then, the internal counter is immediately cleared.

Figure 42-165. Time base generation with clear on match end

42.7.2.2 Coherent Accesses

Reading the EMIOSA[n] register again in the same period of the last read of EMIOSB[n] register may lead to incoherent results. This will occur if the last read of EMIOSB[n] register occurred after a disabled B2 to B1 transfer.

42.7.2.3 Channel/Modes Initialization

The following basic steps summarize basic output mode startup, assuming the channels are initially in GPIO mode:

1. *[global]* Disable Global Prescaler.
2. *[timebase channel]* Disable Channel Prescaler.
3. *[timebase channel]* Write initial value at internal counter.
4. *[timebase channel]* Set A/B register.
5. *[timebase channel]* Set channel to MC(B) Up mode.
6. *[timebase channel]* Set prescaler ratio.
7. *[timebase channel]* Enable Channel Prescaler.
8. *[output channel]* Disable Channel Prescaler.
9. *[output channel]* Set A/B register.
10. *[output channel]* Select timebase input through BSL[1:0] bits.
11. *[output channel]* Enter output mode.

12. *[output channel]* Set prescaler ratio (same ratio as timebase channel).
13. *[output channel]* Enable Channel Prescaler.
14. *[global]* Enable Global Prescaler.
15. *[global]* Enable Global Time Base.

The timebase channel and the output channel may be the same for some applications such as in OPWFM(B) mode or whenever the output channel is intended to run the timebase itself.

At any time the flags can be configured.

Chapter 43
Enhanced Time Processing Unit (eTPU)

43.1 Enhanced Time Processing Unit (eTPU) chip-specific module information

43.1.1 Configuration

eTPU is an intelligent, semi-autonomous co-processor designed for timing control. Operating in parallel with the Host CPU, the eTPU processes instructions, real-time input events, performs output waveform generation, and accesses shared data without Host intervention. Consequently, for each timer event, the Host CPU setup and service times are minimized or eliminated.

The eTPU2+ is an enhanced version of the eTPU2 targeted at C55 devices.

43.1.2 Device-specific information

- Dual (64 channels, dual core) Engine
- Shared Code Memory (SCM) error detection, error correction
- Shared Data Memory (SDM) error detection, error correction
- Class 3 Nexus support
- GTBE is a logical OR with the eMIOS GTBE
- Channels used to trigger the ADC subsystem
- Channels used to enable the Reaction Module modulation
- Channels with DMA request
- Channel output buffers are controlled through SIUL2, and cannot be controlled with microcode.
- Six latency monitors in each of 2 engines.

43.1.3 Register reset values

Some eTPU registers on this device have a different reset value, which overrides the corresponding reset value that is shown in the body of the eTPU documentation, as shown in the following table.

Table 43-1. Reset value overrides

Register	Reset value override
eTPU System Configuration Registers_MCR	000B_0000h
eTPU System Configuration Registers_ECR_ENG1	5000_0000h
eTPU System Configuration Registers_ECR_ENG2	5000_0000h
Time Base Registers_TBCR_ENG1	2000_0000h
Time Base Registers_TBCR_ENG2	2000_0000h
Time Base Registers_STAC_ENG1	0000_0200h
Time Base Registers_STAC_ENG2	0100_0300h

43.1.4 Memory

The eTPU is a true Harvard architecture machine that implements separate code and data memories. The eTPU engines share the same code and data memories. To meet the safety goals, the memories have ECC.

Memory characteristics:

- Code memory 24k with ECC. The code memory can only be accessed with 32-bit accesses so only 7 bits of ECC are implemented. The module size is 6144 locations x 39-bits wide.
- Data memory 6k with ECC. The data memory can be accessed as bytes, and cycles for updating the ECC are not allowed, so 20 bits of ECC are implemented. The required module size is 1536 locations x 52 bits wide.

43.1.5 Clocking

The eTPU is clocked by the non-FM clock used for the peripherals.

The eTPU BIU can optionally run at double the clock speed of the other peripheral on the AIPS. Double clock speed can be used in cases where higher eTPU processing throughput is needed.

43.1.6 Debug

The eTPU implements Nexus class 3 debug, accessed through the same Nexus debug port pins used for core debug.

43.1.7 STAC bus

The eTPU timebases and angle counter can be exported to eMIOS through the STAC bus.

Table 43-2. STAC server ID

Engine	Timebase	Server ID
1	TCR1	0
1	TCR2	2
2	TCR1	1
2	TCR2	3

NOTE

If the STAC-bus Export/Import feature is used, the clock ratio of eTPU : eMIOS should be 1:1 or 2:1, such as the following:

- eTPU 100MHz : eMIOS 100MHz
- eTPU 200MHz : eMIOS 100MHz

This applies whether the STAC-bus Export/Import is used from eTPU to eMIOS or used between eTPUs.

43.1.8 Input connections

The channel inputs are connected to:

- External pins,
- SD ADC trigger outputs,
- BCTU trigger outputs, and the
- Input glitch filter.

Channels with more than 1 input source are connected through the IOMUX (see SIUL2 chapter).

The TCRCLK input is connected to the same input as channel 0.

43.1.9 Output connections

The channel outputs are connected to:
- External pins
- ADC triggers
- Decimation filters

43.2 Introduction

eTPU is an intelligent, semi-autonomous co-processor designed for timing control. Operating in parallel with the Host CPU, the eTPU processes instructions and real-time input events, performs output waveform generation, and accesses shared data without Host intervention. Consequently, for each timer event, the Host CPU setup and service times are minimized or eliminated.

High-level assembler, compiler and documentation allows customers to develop their own functions on the eTPU.

eTPU architecture aims at high resolution timing capabilities. From a system perspective, high resolution timing is limited by Host CPU overhead required for servicing timing tasks such as period measurement, pulse measurement, pulse width modulated waveform generation, etc. On the eTPU, high resolution timing is achieved by three main capabilities:

- Reduced latency: pin actions are immediate.
- Reduce or eliminate host interrupt service time.
- Double action channel capability reducing the channel request rate.

eTPU provides higher resolution than the Host CPU can achieve and creates no Host overhead for servicing timing tasks.

Latency is the interval from occurrence of an event to the start of event servicing. eTPU can service its own events without interrupting the Host. There are two types of timing events:

- Input pin transition.
- Selected Time Base match, i.e., a selected Time Base counter reached or exceeded a pre-programmed value.

Service time is the time spent servicing an event. In general, in microcontrollers the service time is constrained because the instruction set is not optimized for time function synthesis. The eTPU instruction set is optimized, so that time functions can be implemented with much fewer instructions than the Host CPU. Instructions execute faster, service time is reduced and program memory compacted.

Instructions executed by the eTPU are connected directly to the eTPU timing hardware and allow parallelism of hardware related actions.

43.2.1 Overview

The figure below shows a top-level eTPU block diagram. It displays a dual eTPU Engine configuration.

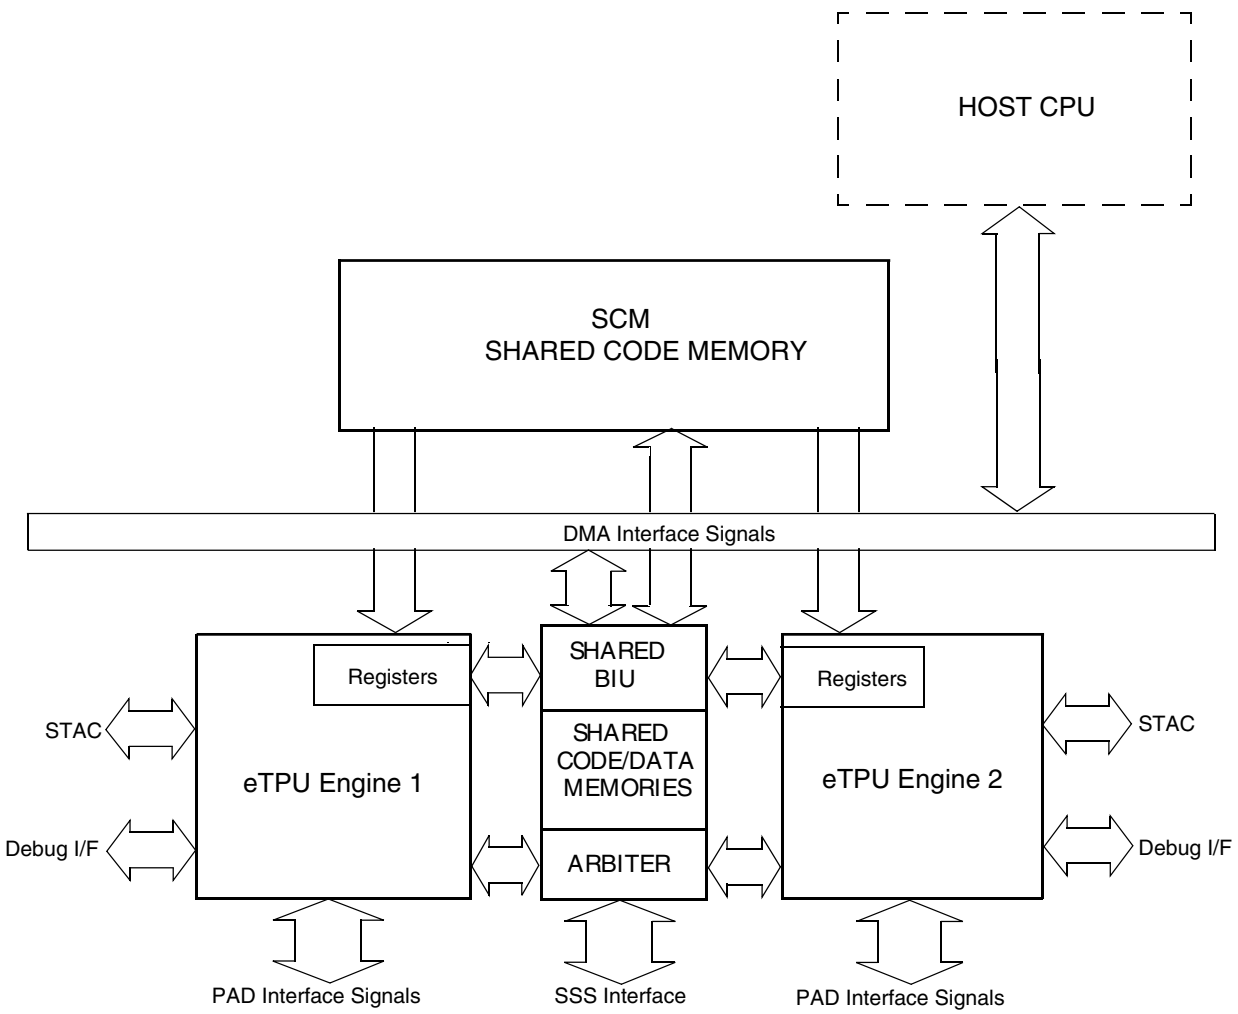


Figure 43-1. eTPU Block Diagram

eTPU Engine is responsible for processing input pin transitions and output pin waveform generation based on the **Time Bases**. Each eTPU Engine has its own microprocessor and dedicated hardware for processing signals on I/O pins and can also interface with external time bases through the STAC bus.

Both eTPU Engine CPUs, hereafter called **microengines**, fetch microinstructions from a **Shared Code Memory - SCM**.

Shared Data Memory - **SDM -** holds eTPU application parameters and work data. It is accessed by Host and both microengines.

Bus Interface Unit - BIU - allows Host to access eTPU registers, SCM and SDM.

Each I/O signal pair is associated with a dedicated **Channel**, which provides hardware for input signal processing and output signal generation, in relationship with selected Time Bases.

The eTPU, as a microprocessed subsystem, works much like a typical real-time system: it runs microengine code from instruction memory (SCM) to handle specific events, accessing data memory (SDM) for parameters, work data and application state info; events may originate from I/O Channels (due to pin transitions and/or time base matches), Host CPU requests or inter-channel requests; events that call for local eTPU processing activate the microengine by issuing a **Service Request**. The Service Request microcode may set an interrupt to the Host CPU. I/O channel events cannot directly interrupt the Host CPU.

Each Channel is associated with a **Function**, which defines its behavior: the Function is a software entity consisting, within the eTPU, of a set of microengine routines that attend to Service Requests. The Function routines are also responsible for Channel configuration. Function routines reside in SCM, which may contain several Functions. A Function may be assigned to several Channels, but a Channel can be associated with just one Function at a given moment. The association between Functions and Channels is defined by Host CPU, and is explained in detail in Functions and Threads.

eTPU hardware supplies resource sharing features that support concurrency:

- A hardware **Scheduler** dispatches the Service Request microengine routines based on a set of priorities defined by the Host CPU. Each Channel has its associated priority.
- A Service Request routine cannot be interrupted until it ends. This sequence of uninterrupted instruction execution is called a **Thread**.

- Channel-specific context (registers and flags) is automatically switched between the end of a Thread and the beginning of the next one.
- SDM arbitration, a dual-parameter coherency controller and semaphores can be used to ensure coherent access to eTPU data shared by both eTPU Engines and Host CPU.

43.2.1.1 eTPU Engine

Each eTPU Engine consists of all blocks that are duplicated in a dual eTPU configuration: two 24-bit time bases, 32 independent timer channels, a task scheduler, a microengine, and a Host interface. In addition, a 32-bit Shared Data Memory (SDM) is used for two eTPU Engines data storage and for passing information between the eTPU Engines and the Host CPU.

The following figure shows the block diagram for the eTPU Engine.

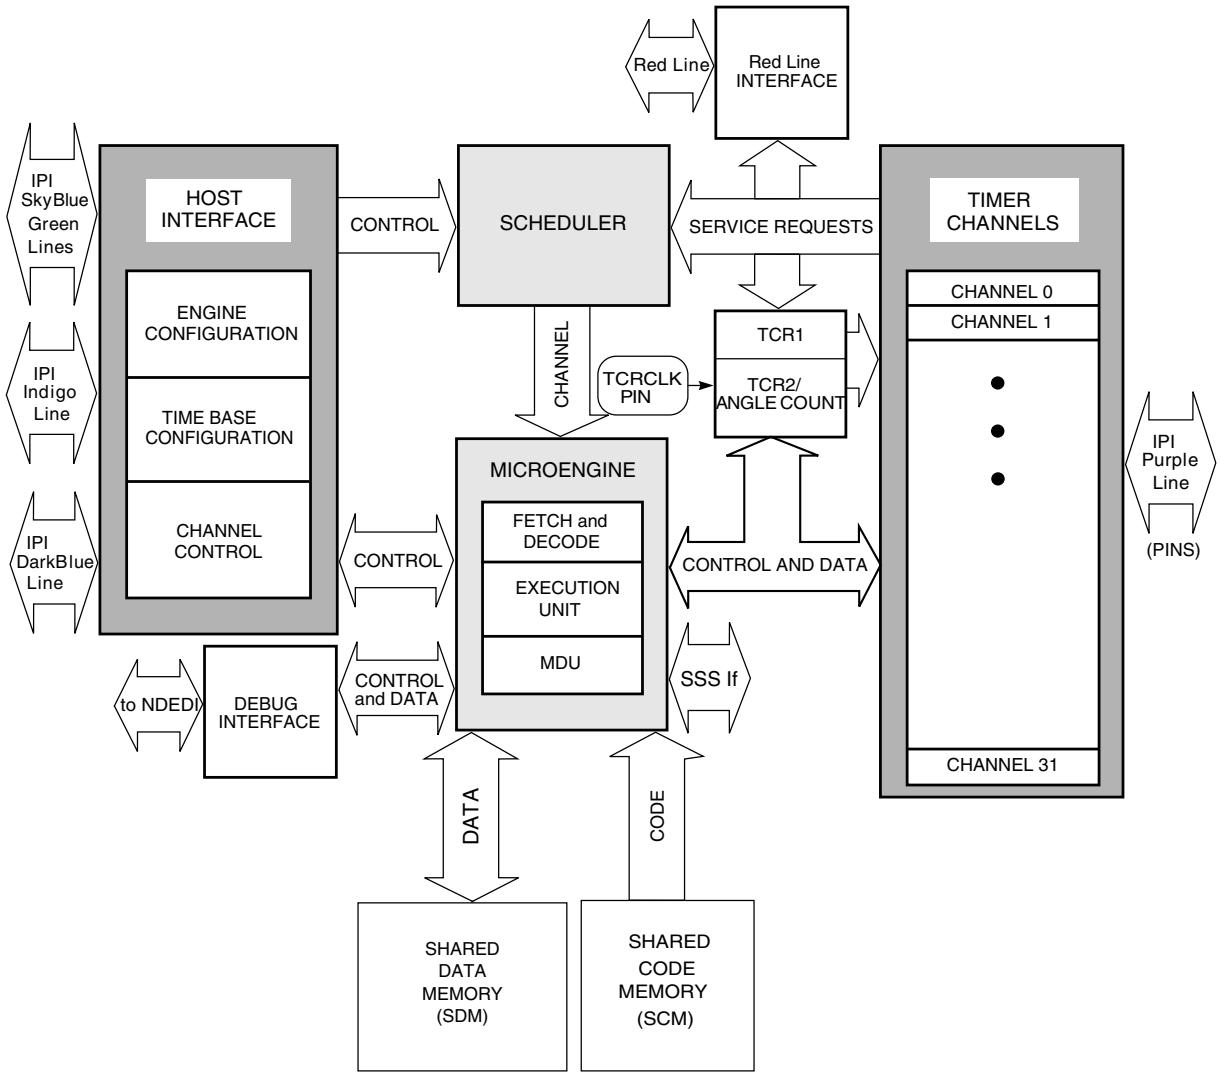

Figure 43-2. eTPU Engine Block Diagram

eTPU Engines 1 and 2 are sometimes called eTPU 1 and eTPU 2 for short throughout this chapter.

43.2.1.1.1 Time Bases

Two 24-bit counters TCR1 and TCR2 provide reference time bases for all match and input capture events. Prescalers for both time bases are controlled by the Host CPU through bit fields in the eTPU Engine configuration registers. The eTPU is able to export/import time to/from TCR1 or TCR2 in accordance to the STAC bus specification.

The clock for each of TCR1 and TCR2 clock can be independently derived from the eTPU clock or from an external input via the TCRCLK clock pin. In addition, the TCR2 timebase can be derived from special angle-clock hardware which enables implementing angle-based functions. This feature is added to support advanced angle based engine control applications.

For further details refer to Time Bases.

43.2.1.1.2 eTPU Timer Channels

Each eTPU Engine has 32 independent channels, each corresponding to an Input/Output signal pair. The channel time resolution is 24 bits, and are all identical.

Each channel consists of logic which supports two events and output controls. The event logic contains two 24-bit capture registers, two 24-bit match registers, greater-equal and equal-only comparators. Supporting two events enables many combinations of double action functions (for example the channel can handle two events with a single microcode service).

The channel configuration can be changed immediately by the microengine. Each channel can perform double capture, double match and other capture-match combinations. Channel modes available can do ordered or unordered match. Some modes are also provided that can block one match by the occurrence of the other. Service request can be generated on one or both of the match events.

Input signal can be separated from output signal in each channel. They can, optionally, be combined in a single I/O pin driver. An output buffer enable is controlled by the SIU (or SIUL). Digital filters are provided for the input signals, with distinct filtering modes available.

Each channel can use any time base or angle counter for either match or capture operation. For example, a match on TCR1 can capture the value of TCR2. The channels can request service from the microengine due to recognized pin transitions (input events) or timebase matches.

The eTPU channels also support the basic single-action operations found on TPU3 functionality with the exception that time resolution is 24-bits.

Channel configuration combinations:

- Single input capture, no match (TPU3 functionality)
- Single input capture with single match timeout (TPU3 functionality)
- Single input capture with double match timeout with several double match sub-modes
- Double input capture with single or double match timeout with several double match sub-modes
- Single output match (TPU3 functionality)

- Double output match with several double match sub-modes
- Input-dependent output generation

The double match functionality has various combinations for generation of service request and determining pin actions. For more details refer to Enhanced Channels.

In addition to the predefined channel configurations above, the user can also program its own channel configuration, defining how input captures, matches and service-requests are related.

43.2.1.1.3 Host Interface

The Host interface allows the Host CPU to control the operation of the eTPU. The Host CPU must initialize the eTPU by writing to the appropriate Host interface registers to assign a Function and priority to each channel. In addition, the Host writes to the Host Service Request and channel configuration registers to further define Function operation for each initialized channel. Refer to Host Interface for a detailed description.

When the SCM is implemented by RAM, the Host must first initialize it with the proper microcode program prior to enabling any eTPU Function, and then enable eTPU access (which also disables Host access).

43.2.1.1.4 Shared Data Memory - SDM

The SDM works as data RAM which can be accessed by the Host CPU and up to two eTPU Engines. This memory is used for information transfer between the Host CPU and the eTPU, as data storage for the eTPU microcode program or for communication between the two eTPU Engines. SDM width is 32 bits, and is accessible by the Host as byte, 16-bit or 32-bit wide. eTPU can access it as full 32-bits, lower 24-bits or upper byte (8-bit).

The host can also access the SDM space mirrored in other area with Parameter Sign Extension (PSE). Parameter Sign Extension accesses differ from the usual host accesses to the original SDM area as follows:

- Writes are effective only to the lower 3 bytes of a word: the word's most significant byte is kept unaltered in SDM.
- Reads return the lower 3 bytes of a word sign-extended to 32 bits, i.e.: the most significant bit of the word's 2nd most significant byte is copied in all 8 bits of the most significant read byte.

Each eTPU channel can be associated with a variable number of parameters located in the SDM, according to its selected Function. In addition, the SDM can be fully shared between two eTPU Engines, enabling direct communication between them.

High flexibility of the SDM utilization is achieved as follows:

- Each channel has a programmable base address pointing to the address of its first parameter with two parameter granularity. This way the SDM can be partitioned according to the actual function needs.
- The microcode can access the first 128 parameters of the selected channel in channel relative access mode.
- Each Engine can access all the SDM address space in indirect addressing mode. Blocks of data are easily transferred using stack operation.
- Absolute addressing mode can access the first 256 parameters (TPU3 functionality), implementing a shared pool of parameters holding global variables.

In the Host address space each parameter occupies four bytes. eTPU usage of the upper byte is achieved by having a 32-bit P register which can access the upper byte, the lower 24 bits or all the 32 bits. The microcode can switch between access sizes at any time.

Each Function may require a different number of parameters. During the eTPU initialization the Host has to program channel base addresses, allocating proper parameters for each channel according to its selected Function.

43.2.1.1.5 Shared Subsystem Area

The Shared Subsystem (SSS) area is a memory map region used by both the host and the eTPU to access registers of the reaction channel, giving the user the option to control them by the host, the eTPU code, or a combination of both.

43.2.1.1.6 Scheduler

Out of reset, all channels are disabled. The Host CPU makes a channel active by assigning it one of three priorities: high, middle, or low. The Scheduler determines the order in which channels are serviced based on channel number and assigned priority. The priority mechanism, implemented in hardware, ensures that all requesting channels are serviced. For additional details refer to Scheduler.

43.2.1.1.7 Microengine

eTPU microengine is a simple RISC implementation which performs each instruction in a microcycle of two eTPU clocks, while prefetching the next instruction through an instruction pipeline. Instruction execution time is constant unless it gets wait states from the SDM arbitration. Two eTPU Engines share code memory without having any performance degradation by interleaving their accesses (the Shared Code Memory has one-clock access time).

Instruction width is 32 bits. The microengine instruction set provides basic arithmetic and logic operations, flow control (jumps and subroutine calls), SDM access, and Channel configuration and control. The instruction formats are defined in such a way that allow particular combinations of two or three of these operations with unconflicting resources to be executed in parallel in the same microcycle.

Microengine has also an independent Multiply/Divide/MAC unit that performs these complex operations in parallel with other microengine instructions.

Channel functionality is tightly integrated to the instruction set through Channel Control operations and conditional Branch operations, which support jumps/calls on Channel-specific conditions. This allows quick and terse Channel configuration and control code, contributing to reduced service time.

Detailed description can be found in Microengine.

43.2.1.1.8 Dual eTPU Engine System

A typical eTPU implementation includes two eTPU Engines sharing SDM and the same code in SCM.

The two eTPU Engines share the Bus Interface Unit (BIU) and the data memory (SDM) which enable Host-eTPU and eTPU Engine-Engine communication. The shared BIU includes coherency logic which supports dual parameter (8 bytes) coherency in transfers between Host and eTPU, using a temporary parameter area within the SDM. More details on this can be found on Parameter Sharing and Coherency.

43.2.2 Features

The following sections show eTPU features and enhancements.

43.2.2.1 eTPU Feature Summary

The eTPU includes these distinctive features:

- up to 32 channels for each eTPU Engine, each channel is associated with an Input/ Output signal pair.
  - enhanced input digital filters on the input pins for improved noise immunity. The eTPU digital filter can use 2 samples, 3 samples or work in continuous mode.
  - identical, orthogonal channels, except for channel 0: each channel can perform any time function. Each time function can be assigned to more than one channel at a given time, so each signal can have any functionality. Channel 0 has the same capabilities of the others, but can also work with special Angle Counter logic (see below).
  - Link Service Request allows activation of a Channel function by request of another channel, even between eTPU Engines.
  - Host Service Request allows activation of a Channel function by Host CPU request
  - each channel has an event mechanism which supports single and double action functionality in various combinations. It includes two 24-bit capture registers, two 24-bit match registers, 24-bit greater-equal and equal-only comparators.
- Two independent 24-bit time bases for channel synchronization:
  - first time base clocked by eTPU clock with programmable prescaler division from 1 to 512 (in steps of 2), or by output of second time base prescaler.
  - first time base can also be clocked by external signal with programmable prescaler division of 1 to 256.
  - second time base clocked by external signal with programmable prescaler division from 1 to 64.
  - second time base external clock source can be replaced by eTPU clock divided by 8.
  - both time bases can be exported or imported via Shared Time and Counter bus.
  - second time base counter can work as an Angle counter, enabling angle based applications to match angle instead of time.
  - second time base can also be used as a pulse accumulator gated by external signal.
- Event-Triggered RISC processor (microengine):
  - 3 stage pipeline implementation (fetch, decoding and execution), with separate instruction memory - SCM - and data memory - SDM (Harvard architecture)

- fixed-length instruction execution in one microcycle of two eTPU clocks
- interleaved SCM access in dual eTPU Engine avoids contention in time for instruction memory
- SCM address space of up to 16K positions (64 Kbytes) (see chip-specific eTPU information)
- SDM with interleaved access in dual eTPU Engine avoids contention for data memory
- SDM address space (both Engines) of up to 8 Kbytes (see chip-specific eTPU information)
- instruction set with embedded Channel support, including specialized Channel control subinstructions and conditional branching on Channel-specific flags.
- channel-oriented addressing: channel-bound address mode with Host configured Channel Base Address allows channel data isolation, independent of microengine application code.
- channel-bound data address space of up to 128 32-bit parameters (512 bytes)
- global parameter address mode allows access to common Channel data of up to 256 32-bit parameters (1024 bytes)
- support for indirect and stacked data access schemes.
- parallel execution of: data access, ALU, Channel control and flow control subinstructions in selected combinations.
- 32-bit microengine registers and 24-bit resolution ALU, with 1 microcycle addition and subtraction, absolute value, bitwise logical operations on 24-bit, 16-bit, or byte operands; single bit manipulation, shift and rotate operations, sign extension and conditional execution.
- additional 24-bit Multiply/MAC/Divide unit which supports all signed/unsigned Multiply/MAC combinations, and unsigned 24-bit Divide. The MAC/Divide unit works in parallel with the regular microcode commands.

- Resource sharing features support channel sharing of channel registers, memory and microengine time:
  - hardware Scheduler works as a "task management" unit, dispatching event service routines by predefined, Host-configured priority.

- automatic Channel context switch when a "task switch" occurs, i.e., one Function Thread ends and another begins to service a request from other Channel: Channel-specific registers, flags and parameter base address are automatically loaded for the next serviced channel.
- individual channel priority setting in 3 levels: high, middle and low.
- Scheduler priority scheme allows calculation of worst case latency for event servicing and ensures servicing all channels by preventing permanent blockage.
- SDM shared between Host CPU and both eTPU Engines, supporting communication either between Channels and Host or inter-channel.
- hardware implementation of 4 Semaphores supports resource sharing between both eTPU Engines.
- Hardware semaphores directly supported by the microengine instruction set.
- dual parameter coherency hardware support allows atomic (to host) access to 2 parameters by microengine(s) in back-to-back accesses.
- coherent dual-parameter controller allows atomic (to microengines) accesses to 2 parameters by the host.

- Development support features:
  - Nexus class 3 debug support (optional, associated with the eTPU-Nexus Block NDEDI).
  - Software breakpoints.
  - Debug interface supporting single-step execution, forced microinstruction execution, Hardware breakpoints and watchpoints on several conditions.
- Safety support features:
  - SCM (code memory) continuous signature-check built-in self test (MISC - Multiple Input Signature Calculator), runs concurrently with eTPU normal operation.
  - See eTPU Plus Enhancements over eTPU) for additional safety features.

43.2.2.2 eTPU Enhancements over TPU3

- 32 orthogonal channels with enhanced functionality. Full support for double action with double match and double transition sub-mode combinations.

- Input and Output features separated in channel logic and microinstructions, allowing input and output signals to be processed separately or combined.
- Increased time resolution and execution unit to 24 bits.
- Increased linear code memory, shared by two eTPU Engines, configurable up to 16K positions (64 KB).
- Increased SDM address range (8 KB each Engine) and width (32 bits per parameter). The SDM can be dynamically allocated to support variable number of parameters for each channel. Each channel can have access to at least 256 parameters.
- The SDM is fully shared by two eTPU Engines (SDM), supporting direct inter-engine communication with the help of hardware semaphores.
- Enhanced arithmetic operations, including add/subtract with carry, absolute value, multiple shift and rotate, conditional execution with variable operand widths.
- Enhanced logic operations, including bitwise operations (and, or, xor) and bit manipulation, with conditional execution. Support for read-modify-write of any bit in the SDM.
- Hardware for Multiply/MAC/Divide, running in parallel to execution of other operations. The 24-bit divide result is available after 13 other unrelated instructions. Multiplication supports any data width of both operands (8, 16 or 24 bits), signed or unsigned. A 24x24 Multiply/MAC result is available after four other unrelated instructions. A 24x8 Multiply/MAC result is available after one other unrelated instruction.
- Supports export/import of time bases from other sources through the real time bus (STAC - Shared Time and Counter bus). This internal bus is used for sharing real time data between multiple peripherals.
- Contains angle clock hardware, supported by microcode, which can provide a 24-bit angle bus instead of time bus. This feature enables the eTPU to run angle based engine control applications.
- More interrupt types. Each eTPU channel can generate a data transfer request interrupt, in addition to regular interrupts, and one global exception interrupt. Data Transfer requests can be used either as interrupt sources or DMA requests. This feature takes advantage of DMA peripherals which off-load the Host. Interrupt Overflow status is also provided.
- Improved visibility to the Host (pin states, time bases, serviced channel).

- An edge case of priority inversion on TPU3 Scheduler was resolved.
- Supports channel link requests between eTPU Engines.

43.2.2.3 eTPU Plus Enhancements over eTPU

eTPU Plus features include the enhancements below in addition to all eTPU features

- TCR1, channel logic and digital filters (both channel and TCRCLK) now have an option to run at divisions of full eTPU clock speed, besides eTPU clock / 2 (see T2/T4 Channel Timing).
- Channels support unordered transitions: transition B can now be detected before transition A. Related to this enhancement, TDLA and TDLB can now be independently negated by microcode (see Channel Mode Logic and Event Flags)
- Channel logic can now work on full eTPU clock, allowing faster response with slow clocks (see T2/T4 Channel Timing).
- Added a new User Programmable Channel Mode: the blocking, enabling, service request and capture characteristics of this channel mode can be programmed via microcode (see General Channel Registers).
- Microinstructions now provide an option to issue Interrupt and Data Transfer requests selected by CHAN. They can also be requested simultaneously at the same instruction (see Channel Interrupt and Data Transfer Requests).
- Channel Flags 0 and 1 can now be tested for branching, besides selecting the entry point (see Branch Operations).
- Channel digital filters can be bypassed, and can be clocked by full eTPU clock (see Bypass Mode).

Backward compatibility is maintained so that all legacy object code (both Host and microcode) runs on eTPU Plus without modification.

43.2.2.4 eTPU2 enhancements over eTPU Plus

eTPU2 features include the enhancements below in addition to all eTPU Plus enhancements and eTPU features.

- Scheduler priority-passing mechanism can now be disabled (see Priority Passing Disabling).
- New Watchdog mechanism kills threads over a programmable timeout (see Watchdog).

- New counter allows microengine load information collection for performance analysis (see Idle Counter).
- Channels 1 and 2 (besides channel 0) can now be selected to control the EAC (see the TBCR_ENG1 and TBCR_ENG2 eTPU Time Base Configuration Registers).
- Timebase prescalers are now reset when the GTBE input is negated, guaranteeing synchronization with eMIOS in all cases (see GTBE - Global Time Base Enable).
- New MISC flag indicates when an SCM signature calculation round is completed. This allows measuring of the average MISC scan period in a real application situation (see the eTPU Module Configuration Register - MCR).
- New channel TCCEA flag allows continuous capture even after TDLA is set, making it fully compatible with TPU behavior (see TCCEA - Transition Continuous Capture Enable).
- New branch condition PRSS tells the pin state at the time when a channel (match or transition) service request occurred (see Pin Control Registers).
- MRLEA/B can now be negated independently by microcode (see Disable Matches).
- New Engine Relative address mode allows a function to access SDM address space common to one engine, but distinct between engines (see Engine Relative Addressing Mode under SDM Addressing Modes).
- Memory error support for Code (SCM) and Data (SDM) memories: error detection, correction, and hardware-assisted soft-error fixing (see Memory Error Support).
- Sharing of microengine and host accesses to subsystem modules (for instance, the Reaction Module), allowing their control by the eTPU, the host, or both (see Shared Subsystems Support).

Backward compatibility is maintained so legacy object code (both Host and microcode) runs on eTPU2 without modification.

43.2.2.5 eTPU2 Plus enhancements over eTPU2

eTPU2 Plus features include the enhancements listed below in addition to all eTPU features, eTPU Plus enhancements and eTPU2 enhancements.

- New Latency Monitor allows latency measurements, either for individual channels or channels combined in a single priority (High, Medium or Low).
- Watchdog can now be configured to disable thread forced ending and channel blocking, allowing it to monitor thread lengths with no interference on the application.

- EAC Angle Tick Generator can now be clocked by the TCR2 prescaler output, as an alternative to the TCR1 clock.
- EAC now supports up to 7 missing teeth on hardware.

Backward compatibility is maintained so legacy object code (both Host and microcode) runs on eTPU2 Plus without modification.

43.2.3 Modes of Operation

eTPU can be seen as capable of working in the following modes:

- **User Configuration Mode**

  User has the ability to program the eTPU Cores with User Time Functions, having access to the Shared Code Memory (SCM).

- **User Mode**

  User does not access the eTPU Shared Code Memory:

  - Use of predefined eTPU Functions
  - No need for eTPU Core programming ability

- **Debug Mode**

  User debugs eTPU code, accessing special Trace/Debug features via Nexus interface:

  - hardware breakpoint/watchpoint setting
  - access to internal registers
  - single-step execution
  - forced instruction execution
  - software breakpoint insertion and removal.

- **Module Disable Mode**

  eTPU Engine clocks are stopped through a register write to ETPUECR bit MDIS, saving power. Input sampling stops. eTPU Engines can be in Module Disable Mode independently. Module Disable Mode stops only the Engine clock, so that the Shared BIU, and Global Channel registers can be accessed, and interrupts and DMAs can be cleared and enabled/disabled. An Engine only enters Module Disable Mode when any currently running thread is finished (see Functions and Threads).

- **Stop Mode**

Stop Mode is entered when eTPU answers device stop request assertion with stop acknowledge. The definition of which clocks are stopped is made at the MCU level, which defines whether or not registers can be accessed, interrupts and DMA requests cleared.

These modes are loosely selected: there is no unique register field or signals to choose between them. Some features of one mode can be used with features of other mode(s). More on this subject can be found on eTPU Mode Selection below.

Note

Throughout this chapter, an engine is said to be "stopped" if it is either in Module Disable mode or Stop mode.

43.2.3.1 eTPU Mode Selection

User and User Configuration are the production operating modes, and differ from each other only in access to SCM. User programmability is only possible with a RAM SCM.

On chips where the SCM is implemented as a RAM, it can either be accessed directly from IP-Bus for code loading, or for software breakpoint setting . On chips with a ROM SCM, an internal SCM Emulation RAM may be used, depending on the specific MCU implementation, to replace ROM SCM for test or debug purposes. SCM Emulation RAM is selected in a MCU-specific way. For more details, see .

Debug Mode is characterized by the use of the debug interface features. Specifically, Nexus blocks provide Nexus class 3 debug features. For more information on debug features, refer to Development Support Features.

Module Disable Mode is entered by setting ETPUECR register bit MDIS. eTPU Engines can be individually stopped going into Module Disable Mode (there is one ETPUECR register for each Engine). Each engine can leave Module Disable Mode by writing MDIS=0 (which can only be done if VIS=0).

Stop Mode is activated by IP-Bus (device stop request). In this case, the eTPU waits for both eTPU Engines to enter in stop mode, and then asserts the stop acknowledge line. eTPU leaves Stop Mode when device stop request is negated, but only if VIS=0. If device stop request is negated and VIS=1, eTPU will leave Stop Mode as soon as VIS=0.

Note

An Engine can stay in Module Disable mode when it leaves Stop Mode if its bit MDIS=1, even if the other leaves it.

43.3 Detailed Signal Descriptions

Detailed signal descriptions are presented in the following sections.

43.3.1 eTPU Channel Output Signals

Each channel output signal is associated with a channel. The microcode may affect the logic level of an output signal[1] by implementing one of two actions:

- Specify the logic level output to the signal when there is a match or a transition.
- Immediately force a logic level.

The output signal may also be forced to a logic level, independently of the output value from the channel logic, by one of the four (each Engine) output disable input signals (see eTPU Channel Output Disable Signals).

The output buffer enable signals are not used.

43.3.2 eTPU Channel Input Signals

Each channel input signal is associated with a channel. The microcode can directly control the effect of the transition edge. Each channel can be programmed to sense a transition when a rising and/or falling edge is detected. The channel logic can also process two transition events, and relate these events to each other and to other programmed timer events. The edge sensitivities of the two transition events are configured independently by microcode. For further information refer to Enhanced Channels and Transition Detection and Pin Action Control.

Each channel input signal has an associated synchronizer made of two flip-flops sampling the signal on every other eTPU clock[2], followed by a digital filter. This digital filter can work in three sub-modes, whose purpose is to filter out noise pulses that have width less then a programmed value of eTPU clocks, preventing these transitions from being input to the transition detect logic. The synchronizer and digital filter are guaranteed to pass pulses that are greater than a programmed value. All channel input filters in one Engine work on the same mode and sampling clock. For more information on channel input

1. Note that the minimum pulse width is one microcycle (two eTPU clocks), and slow pads may not be able to transfer it on time. For generation of very short pulses the eTPU pads have to be programmed by the system integration for fast operation mode with the voltage levels defined for fast pad operation in the MCU technology.
2. Sampled on the T4 microcycle phase, see Microcycle and I/O Timing.

filters, refer to Enhanced Digital Filter - EDF . In one of the Angle Modes, the output of the digital filter of channel 0 is replaced by the output of TCRCLK signal digital filter (see EAC - eTPU Angle Counter).

43.3.3 Time Base Clock Signal — TCRCLK

TCRCLK is an input signal used to control the Time Bases TCR1 and TCR2. There is one independent TCRCLK input for each Engine. For pulse accumulator operations TCRCLK can be used as a gate for a counter based on the eTPU clock divided by eight. For Angle operations TCRCLK can be used to get the tooth transition indications in Angle Mode. Further details can be found on Time Bases and EAC - eTPU Angle Counter.

Like the channel input signals, the TCRCLK signal has an associated synchronizer followed by a digital filter. This digital filter can work in two sub-modes, whose purpose is to filter out noise pulses that have width less then a programmed value of eTPU clocks, preventing these transitions from being input to the transition detect logic. The synchronizer and digital filter are guaranteed to pass pulses that are greater than a programmed value. The clock and operation sub-mode of the TCRCLK filter is configured independently of the other channel input filters, through the field TCRCF in register ETPUTBCR. For more information on filter sub-modes, refer to TCRCLK Digital Filter. In one of the Angle Modes, the output of the digital filter of channel 0 is replaced with the output of TCRCLK signal digital filter (see EAC - eTPU Angle Counter).

43.3.4 eTPU Channel Output Disable Signals

Each of these 4 input signals are used to force the outputs of a group of 8 channels to an inactive level. When an ODIS input is active, all the channels in its group of 8 that have their bits ODIS=1 in ETPUCxCR register have their outputs forced to the opposite of the value specified in bit OPOL of the same register. Therefore, channels can be individually selected to be affected by the output disable signals, as well as their disabling forced polarity (see 'Pin State Input/Output Logic' figure in Pin Control Registers).

See the chip-specific eTPU information for details on the output channel disable group definition.

In a Dual-engine eTPU there are 8 output disable signals for the 64 channels.

43.4 Memory Map/Register Definition

The guideline for the description of all bits and fields throughout the“Memory Map/ Register Definition” section is to provide only a brief explanation (without examples or method of use) of the features, since it will be used mainly as a reference for the reader that is studying the “Functional Description" section, where those features are explained in detail.

43.5 Memory Map

The eTPU System simplified memory map is shown in Table 43-3. Each of the register areas shown may have their own reserved address areas.

Table 43-4 shows a detailed memory map. Offsets are relative to the eTPU Base address, which is MCU-dependent.

See the chip-specific eTPU information about accessing eTPU registers in chip-level Stop mode.

SCM unused area is decoded and returns a fixed opcode, determined by the register ETPUSCMOFFDATAR.

eTPU_SCR_MCR field descriptions

Field	Description
0 GEC	Global Exception Clear. This write-only bit negates global exception request and clears global exception status bits SDMERR, SSAERR, SCMERR, WDTO1/2, MGE1/2, ILF1/2, LTO1/2, and SCMMISF. GEC works the same way with either one or both Engines in Module Disable Mode. 0 Keep Global Exception request and status bits SDMERR, SCMERR, WDTO1/2, ILF1/2, MGE1/2, LTO1/2, and SCMMISF as is. 1 Negate Global Exception, clear status bits SDMERR, SCMERR, WDTO1/2, ILF1/2, MGE1/2, LTO1/2, and SCMMISF.
1 SDMERR	SDM Read Error This flag indicates that an SDM non-correctable read error occurred on a microengine or host (including CDC) read, generating a Global Exception. This bit is cleared by writing 1 to GEC. 0 No Global Exception pending because of SDM read error. 1 Global Exception requested by SDM read error is pending.
2 WDTO1	Watchdog 1 Timeout. Flag WDTO1 indicates that a Watchdog Timeout occurred in engine 1, generating a Global Exception. This bit is cleared by writing 1 to GEC. 0 No Global Exception pending because of Watchdog timeout. 1 Global Exception requested by Watchdog timeout.
3 WDTO2	Watchdog 2 Timeout. Flag WDTO2 indicates that a Watchdog Timeout occurred in engine 2, generating a Global Exception. This bit is cleared by writing 1 to GEC. 0 No Global Exception pending because of Watchdog timeout. 1 Global Exception requested by Watchdog timeout.
4 MGE1	Microcode Global Exception Engine 1. This bit indicates that a global exception was asserted by microcode executed on engine 1. The determination of the reason why the global exception was asserted is application dependent: it can be coded in an SDM status parameter, for instance. This bit is cleared by writing 1 to GEC. 0 No microcode-requested global exception pending. 1 Global exception requested by microcode is pending.
5 MGE2	Microcode Global Exception Engine 2. This bit indicates that a global exception was asserted by microcode executed on engine 2. The determination of the reason why the global exception was asserted is application dependent: it can be coded in an SDM status parameter, for instance. This bit is cleared by writing 1 to GEC. 0 No microcode-requested global exception pending. 1 Global exception requested by microcode is pending.
6 ILF1	Illegal Instruction Flag for Engine 1. The ILFA1 flag is set by the microengine to indicate that an illegal instruction was decoded in Engine 1. This bit is cleared by host writing 1 to GEC. See Illegal Instructions for more details.

Table continues on the next page...

eTPU_SCR_MCR field descriptions (continued)

Field	Description
	0 Illegal Instruction not detected. 1 Illegal Instruction detected by Engine 1.
7 ILF2	Illegal Instruction Flag for Engine 2. The ILFA2 flag is set by the microengine to indicate that an illegal instruction was decoded in Engine 2. This bit is cleared by host writing 1 to GEC. See Illegal Instructions for more details. 0 Illegal Instruction not detected. 1 Illegal Instruction detected by Engine 2.
8 Reserved	Reserved. This field is reserved.
9 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
10 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
11–15 SCMSIZE	SCM Size = 64 Kbytes. This read-only field holds the number of 2 KB SCM Blocks minus 1. See Register Reset Values in Configuration information.
16 LTO1	Latency Timeout for Engine 1. The LTO1 flag indicates the latency measured by the Latency Monitor of Engine 1 surpassed the specified maximum. See Latency Monitor for details. This bit is cleared by writing 1 to GEC. 0 No latency timeout detected by Engine 1’s Latency Monitor. 1 Latency timeout detected by Engine 1's Latency Monitors.
17 LTO2	Latency Timeout for Engine 2. The LTO2 flag indicates the latency measured by the Latency Monitor of Engine 2 surpassed the specified maximum. See Latency Monitor for details. This bit is cleared by writing 1 to GEC. 0 No latency timeout detected by Engine 2’s Latency Monitor. 1 Latency timeout detected by Engine 2's Latency Monitors.
18–19 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
20 SCMMISC	SCM MISC Complete flag. Flag SCMMISC indicates that MISC has completed the evaluation of the SCM signature since reset or since the last time it was cleared. SCMMISC is cleared by writing 1 to it, and is not cleared when MISC is disabled (SCMMISEN=0). SCMMISC asserts at the end of the SCM memory scan, either if the signature matches or not.

Table continues on the next page...

eTPU_SCR_MCR field descriptions (continued)

Field	Description
	0 MISC has not yet completed an SCM signature calculation and compare since the last time SCMMISC was cleared. 1 MISC completed at least one SCM signature calculation and compare since the last time SCMMISC was cleared.
21 SCMMISF	SCM MISC Flag. The SCMMISF bit is set by the SCM MISC (Multiple Input Signature Calculator) logic to indicate that the calculated signature does not match the expected value, at the end of a MISC iteration. See SCM Test - Multiple Input Signature Calculator for more details. This bit is cleared when Global Exception is cleared by writing 1 to GEC. 0 Signature mismatch not detected. 1 MISC has read entire SCM array and the expected signature in ETPUMISCCMPR does not match the value calculated.
22 SCMMISEN	SCM MISC Enable. The SCMMISEN bit is used for enabling/disabling the operation of the MISC logic. SCMMISEN is readable and writable at any time. The MISC logic will only operate when this bit is set to 1. When the bit is reset, the MISC address counter is set to the initial SCM address. When enabled, the MISC will continuously cycle through the SCM addresses, reading each and calculating a CRC. In order to save power, the MISC can be disabled by clearing the SCMMISEN bit. See SCM Test - Multiple Input Signature Calculator for more details. SCMMISEN resets automatically when MISC logic detects an error, i.e., when SCMMISF transitions from 0 to 1, disabling the MISC operation. 0 MISC operation disabled. The MISC logic is reset to its initial state. 1 MISC operation enabled.
23 SCMERR	SCM Read Error. This flag indicates that an SCM non-correctable read error occurred on a host or microengine (including MISC) read, generating a Global Exception. This bit is cleared by writing 1 to GEC. 0 No Global Exception pending because of SCM read error. 1 Global Exception requested by SCM read error is pending.
24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25 VIS	SCM Visibility Bit. VIS bit turns SCM visible to the IP-Bus and resets MISC state (but SCMMISEN keeps its value). This bit is write protected when any of the Engines is not halted or stopped. When VIS=1, the MDIS bits in the eTPU Memory Error Support registers are write protected. 0 SCM is not visible to the slave bus. Accessing SCM address space issues a bus error, writes are protected and reads are meaningless. 1 SCM is visible to the slave bus. MISC state is reset.
26–30 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

eTPU_SCR_MCR field descriptions (continued)

Field	Description
31 GTBE	Global Time Base Enable. GTBE enables time bases in both Engines, allowing them to be started synchronously. **NOTE:** Global Time Base Enable action may also depend on other blocks, as explained in GTBE - Global Time Base Enable. **NOTE:** When GTBE is turned off with Angle Mode enabled, the EAC must be reinitialized before GTBE is turned on again. The EAC reinitialization procedure is described in Restarting Angle Logic. 0 Time bases in both Engines are disabled to run. 1 Time bases in both Engines are enabled to run.

43.6.2 eTPU Coherent Dual-Parameter Controller Register (eTPU_SCR_CDCR)

ETPUCDCR configures and controls dual-parameter coherent transfers. For more information, see Coherent Dual-parameter Controller - CDC.

Address: 0h base + 4h offset = 4h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R W	STS	CTBASE							PBBASE							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	PWIDTH	PARM0							WR	PARM1						
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

eTPU_SCR_CDCR field descriptions

Field	Description
0 STS	Start Bit. This bit is set by the host in order to start the data transfer between the parameter buffer pointed by PBBASE and the target addresses selected by the concatenation of fields CTBASE and PARM0/1. The host receives wait-states until the data transfer is complete, when this bit is reset by the coherency logic (see Coherent Dual-parameter Controller - CDC). Therefore, host always reads STS as 0.

Table continues on the next page...

eTPU_SCR_CDCR field descriptions (continued)

Field	Description
	0 Write does not start a coherent transfer. 1 Write starts a coherent transfer.
1–5 CTBASE	Channel Transfer Base. This field concatenates with fields PARM0 and PARM1 to determine the absolute word offset (from the SDM base) of the parameters to be transferred: Parameter 0 word address = {CTBASE, PARM0} + SDM base word address. Parameter 1 word address = {CTBASE, PARM1} + SDM base word address.
6–15 PBBASE	Parameter Buffer Base Address. This field points to the base address of the parameter buffer location, with granularity of 2 parameters (8 bytes). The host (byte) address of the first parameter in the buffer is PBBASE * 8 + SDM Base Byte Address. The microengine absolute (word) address of the first parameter in the buffer is PBBASE * 2.
16 PWIDTH	Parameter Width Selection. This bit selects the width of the parameters to be transferred between the PB and the target address. 0 Transfer 24-bit parameters. The upper byte remains unchanged in the destination address. 1 Transfer 32-bit parameters. All 32 bits of the parameters are written in the destination address.
17–23 PARM0	Channel Parameter number 0. The PARM0 and PARM1 fields in concatenation with CTBASE determine the word address offset (from the SDM base) of the parameters that are destination or source (defined by WR) of the coherent transfer. The word SDM address offset of the parameters are {CTBASE, PARM0/1}. **NOTE:** PARM0 and PARM1 allow non-contiguous parameters to be transferred coherently. The parameter pointed by {CTBASE, PARM0} is the first transferred.
24 WR	Read/Write selection. This bit selects the direction of the coherent data transfer. 0 Read operation. Data transfer is from the selected SDM address to the PB. 1 Write operation. Data transfer is from the PB to the selected SDM address.
25–31 PARM1	Channel Parameter number 1. The PARM0 and PARM1 fields in concatenation with CTBASE determine the word address offset (from the SDM base) of the parameters that are destination or source (defined by WR) of the coherent transfer. The word SDM address offset of the parameters are {CTBASE, PARM0/1}. **NOTE:** PARM0 and PARM1 allow non-contiguous parameters to be transferred coherently. The parameter pointed by {CTBASE, PARM0} is the first transferred.

43.6.3 eTPU MISC Compare Register (eTPU_SCR_MISCCMPR)

ETPUMISCCMPR holds the 32-bit signature expected from the whole SCM array. This register must be written by the host with the 32-bit word to be compared against the calculated signature at the end of the MISC cycle. This register is global to both eTPU Engines. For more detail, see SCM Test - Multiple Input Signature Calculator.

Address: 0h base + Ch offset = Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

eTPU_SCR_MISCCMPR field descriptions

Field	Description
0–31 ETPUMISCCMP	Expected Multiple Input Signature Register value. For details, see SCM Test - Multiple Input Signature Calculator.

43.6.4 eTPU SCM Off-range Data Register (eTPU_SCR_SCMOFFDATAR)

ETPUSCMOFFDATAR holds the 32-bit value returned when SCM array is accessed at non-implemented addresses, either by the Host or by the microengine. This register can be written by the host with the 32-bit instruction to be executed by the microengine to recover from runaway code. This register is global to both eTPU Engines. For more detail see SCM Off-range Data.

Address: 0h base + 10h offset = 10h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	ETPUSCMOFFDATAR

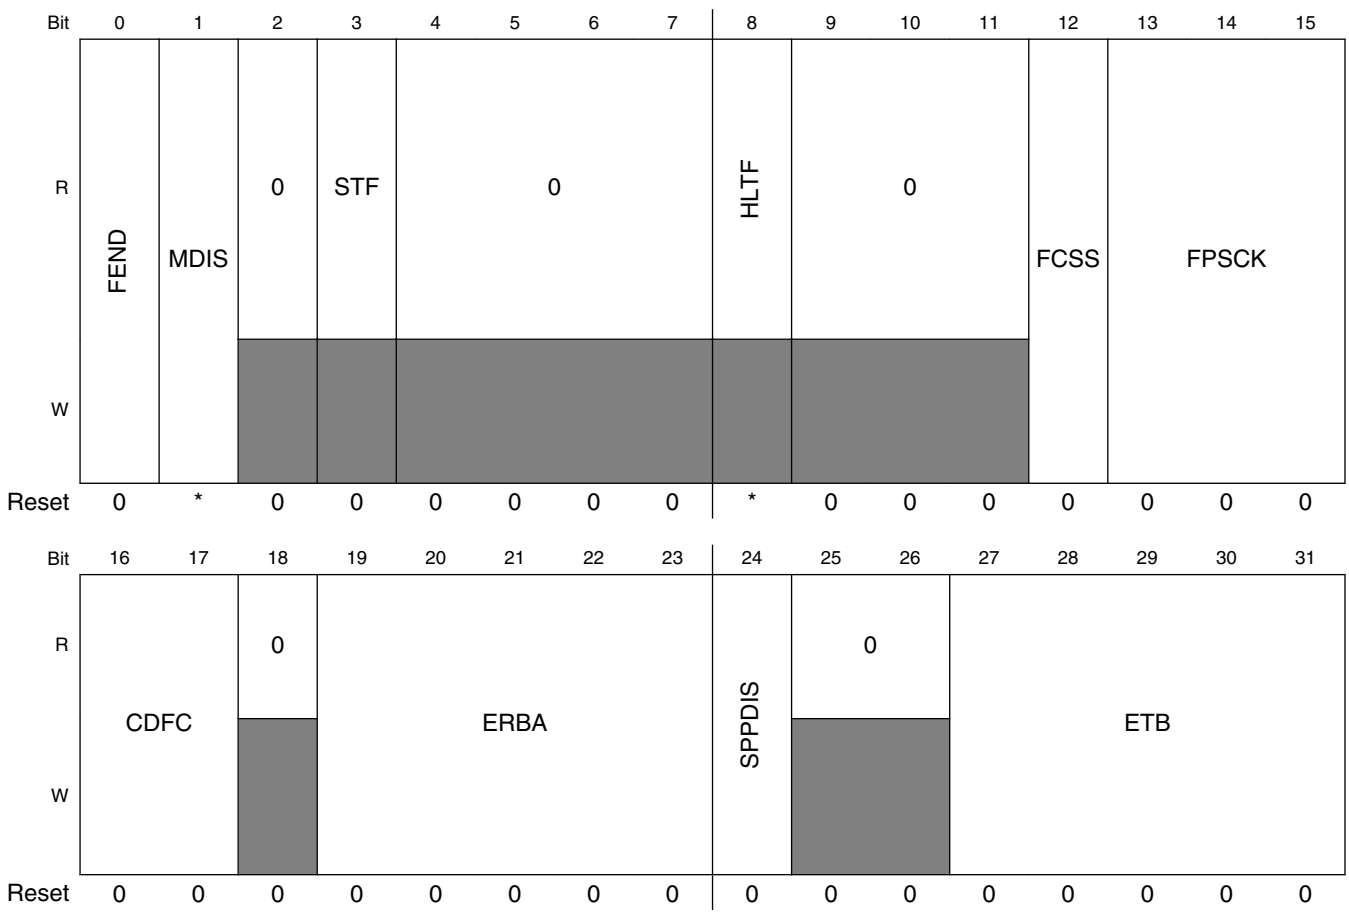
eTPU_SCR_SCMOFFDATAR field descriptions

Field	Description
0–31 ETPUSCMOFFDATAR	SCM Off-range read data value. See SCM Off-range Data.



43.6.5 eTPU Engine 1 Configuration Register (eTPU_SCR_ECR_ENG1)

Each engine has its own ETPUECR register. ETPUECR holds configuration and status fields that are programmed independently in each engine.

NOTE

See Register Reset Values in Configuration information.

Address: 0h base + 14h offset = 14h

* Notes:

- HLTF field: HLTF field reset value is 1 if, after a reset, the eTPU Nexus debug support is on and a breakpoint request is asserted. Otherwise the reset value is 0.
- MDIS field: Reset value is 1.

eTPU_SCR_ECR_ENG1 field descriptions

Field	Description
0 FEND	Force End. FEND assertion terminates any current running thread as if an END instruction have been executed (see Ending Current Thread - END).

Table continues on the next page...

eTPU_SCR_ECR_ENG1 field descriptions (continued)

Field	Description
	This bit is self-negating when the thread ends. **NOTE:** Only on rare occasions (e.g., during a long stall, see Microengine Stall) FEND can be read as 1, because it negates as soon as the end begins execution. Writing FEND = 1 is ignored and FEND stays 0 when the microengine is in TST, halted, stopped, or idle (no thread executing). 0 Normal operation. 1 Ends any ongoing thread.
1 MDIS	Module Disable Bit. When MDIS is set, the Engine shuts down its internal clocks, going into Module Disable Mode. TCR1 and TCR2 cease to increment, and input sampling stops. The Engine asserts the stop flag (STF) bit to indicate that it has stopped. However, the BIU continues to run, and the Host can access all registers except for the channel registers (see channel registers starting with eTPU Channel n Configuration Register for Engine 1 (eTPU_CCCR_C*n*CR_ENG1)) **NOTE:** The Timebase registers can still be read with MDIS=1, but writes are ineffective and a Bus Error is issued. Global Channel Registers and SDM can be accessed normally. After MDIS is set, even before STF asserts, data read from the channel registers is not meaningful and writes are ineffective, issuing a Bus Error. When the MDIS bit is asserted while the microcode is executing, the eTPU will stop when the thread is complete. Stop completes on the next eTPU clock after the stop condition is valid. **NOTE:** Once MDIS is switched from 1 to 0 or vice versa, it must not write a different value until STF changes accordingly. The MDIS bit is write-protected when VIS=1. See Register Reset Values in Configuration information. 0 eTPU Engine runs. 1 Commands Engine to stop its clocks.
2 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
3 STF	Stop Flag Bit. Each Engine asserts its stop flag (STF) to indicate that it has stopped. Only then the host can assume that the Engine has actually stopped. The eTPU system is fully stopped when the STF bits of both eTPU Engines are asserted. In case of a stop request, the eTPU responds by acknowledging stop only after both eTPU 1 and eTPU 2 have been stopped. Engine only stops when any ongoing thread is complete also in this case. Summarizing Engine stop conditions, which STF reflects: STF_1 := (after stop completed) MDIS_1 | device stop request. STF_2 := (after stop completed) MDIS_2 | device stop request. STF_1 and STF_2 mean STF bit from engine 1 and STF bit from engine 2, respectively. See Register Reset Values in Configuration information.

Table continues on the next page...

eTPU_SCR_ECR_ENG1 field descriptions (continued)

Field	Description
	0 Engine is operating. 1 Engine has stopped (after the local MDIS bit has been asserted, or after the IP-Bus stop line has been asserted).
4–7 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
8 HLTF	Halt Mode Flag. If eTPU Engine entered halt state, this flag is asserted. The flag remains asserted while the microengine is in halt state, even during a single-step or forced instruction execution. See Development Support Features for further details about entering Halt Mode. 0 eTPU Engine is not halted. 1 eTPU Engine is halted.
9–11 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
12 FCSS	Filter Clock Source Selection Speeds up the filter clock source before the prescaler, allowing more input capture resolution at minimum prescaling. **NOTE:** FCSS=1 also makes the channel work on T2/T4 timing mode (see T2/T4 Channel Timing). 0 Use eTPU clock / 2 as EDF clock source before prescaler. 1 Use eTPU clock as EDF clock source before prescaler
13–15 FPSCK	Filter Prescaler Clock Control. FPSCK controls the prescaling of the clocks used in digital filters for the channel input signals and TCRCLK input, as shown in the table below. Filtering can be controlled independently by each engine, but all input digital filters in the same engine have same clock prescaling. For more details, see Filter Clock Prescaler. A new value written to FPSCK only becomes effective when the filter prescaler finishes the current count.

Table 43-13. Filter prescaler clock control

Filter control	Sample on system clock divided by:	
	FCSS = 0	FCSS = 1
000	2	1
001	4	2
010	8	4
011	16	8
100	32	16
101	64	32
110	128	64
111	256	128

Table continues on the next page...

eTPU_SCR_ECR_ENG1 field descriptions (continued)

Field	Description
16–17 CDFC	Channel Digital Filter Control. These bits select a digital filtering mode for the channels when configured as inputs for improved noise immunity (refer to the table below). The eTPU has three digital filtering modes for the channels which provide programmable trade-off between signal latency and noise immunity (see Enhanced Digital Filter - EDF). Changing CDFC during eTPU normal input channel operation is not recommended since it changes the behavior of the transition detection logic while executing its operation.
18 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
19–23 ERBA	Engine Relative Base Address. This field value is concatenated with the AID instruction field in engine relative address mode to form the SDM address (see the “Engine Relative Addressing Mode" section under SDM Addressing Modes).
24 SPPDIS	Schedule Priority Passing Disable. SPPDIS is used to disable the priority passing mechanism of the microengine scheduler (see the “Primary Scheme - Priority Among Channels on Different Levels" section under Channel Priority Schemes). **NOTE:** SPPDIS bit must not be changed while any channel is enabled. 0 Scheduler priority passing mechanism enabled. 1 Scheduler priority passing mechanism disabled.
25–26 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
27–31 ETB	Entry Table Base.

Table 43-12. Channel digital filter control

CDFC	Selected digital filter
00	TPU2/3 Two Sample Mode: Using the filter clock which is the system clock divided by (2, 4, 8,..., 256) as a sampling clock (selected by FPSCK field in ETPUECR), comparing two consecutive samples which agree with each other sets the input signal state. This is the default reset state.
01	eTPU bypass mode: the input signal is taken unfiltered, also making the channels work on T2/T4 timing mode.[1]
10	eTPU Three Sample Mode: Similar to the TPU2/3 two sample mode, but comparing three consecutive samples which agree with each other sets the input signal state.
11	eTPU Continuous Mode: Signal need to be stable for the whole filter clock period. This mode compares all the values at the rate of eTPU clock (FCSS=1) or eTPU clock divided by two (FCSS=0), between two consecutive filter clock pulses. Signal needs to be continuously stable for the entire period. If all the values agree with each other, input signal state is updated.

1. See T2/T4 Channel Timing.

Table continues on the next page...

eTPU_SCR_ECR_ENG1 field descriptions (continued)

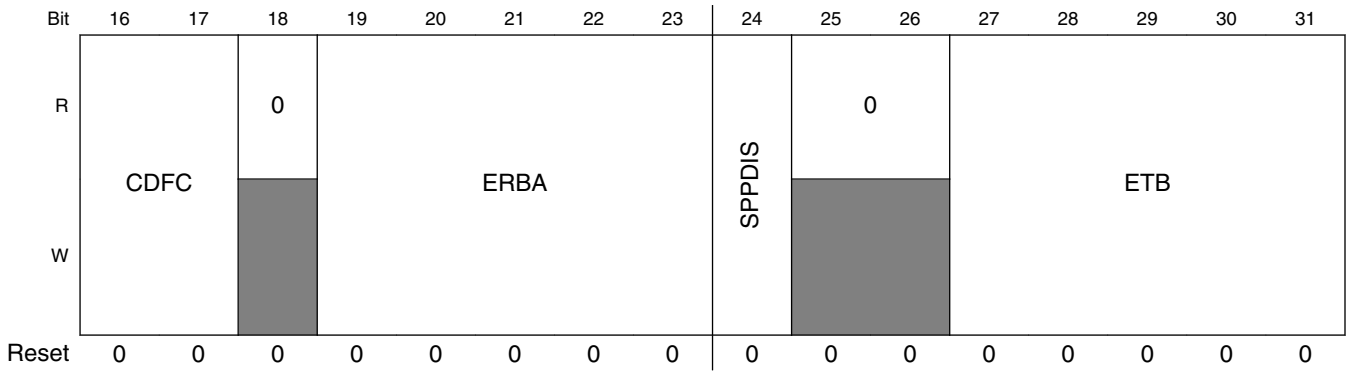
Field	Description
	The field determines the location of the microcode entry table for the eTPU functions in SCM (see Entry Points). The following table shows the entry table base address options.

Table 43-11. Entry table base address options

ETB	Entry Table Base Address for CPU Host Address (byte format)	Entry Table Base Address for Microcode Address (word format)
00000	0x000	0x000
00001	0x800	0x200
00010	0x1000	0x400
--------	----------	---------
11110	0xF000	0x3C00
11111	0xF800	0x3E00

3. See T2/T4 Channel Timing.

43.6.6 eTPU Engine 2 Configuration Register (eTPU_SCR_ECR_ENG2)



Each engine has its own ETPUECR register. ETPUECR holds configuration and status fields that are programmed independently in each engine.

NOTE

See Register Reset Values in Configuration information.

Address: 0h base + 18h offset = 18h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

W																
Reset	0	*	0	0	0	0	0	0	*	0	0	0	0	0	0	0

* Notes:
- HLTF field: HLTF field reset value is 1 if, after a reset, the eTPU Nexus debug support is on and a breakpoint request is asserted. Otherwise the reset value is 0.
- MDIS field: Reset value is 1.

eTPU_SCR_ECR_ENG2 field descriptions

Field	Description
0 FEND	Force End. FEND assertion terminates any current running thread as if an END instruction have been executed (see Ending Current Thread - END). This bit is self-negating when the thread ends. **NOTE:** Only on rare occasions (e.g., during a long stall, see Microengine Stall) FEND can be read as 1, because it negates as soon as the end begins execution. Writing FEND = 1 is ignored and FEND stays 0 when the microengine is in TST, halted, stopped, or idle (no thread executing). 0 Normal operation. 1 Ends any ongoing thread.
1 MDIS	Module Disable Bit. When MDIS is set, the Engine shuts down its internal clocks, going into Module Disable Mode. TCR1 and TCR2 cease to increment, and input sampling stops. The Engine asserts the stop flag (STF) bit to indicate that it has stopped. However, the BIU continues to run, and the Host can access all registers except for the channel registers (see channel registers starting with eTPU Channel Configuration-Control registers) **NOTE:** The Timebase registers can still be read with MDIS=1, but writes are ineffective and a Bus Error is issued. Global Channel Registers and SDM can be accessed normally. After MDIS is set, even before STF asserts, data read from the channel registers is not meaningful and writes are ineffective, issuing a Bus Error. When the MDIS bit is asserted while the microcode is executing, the eTPU will stop when the thread is complete. Stop completes on the next eTPU clock after the stop condition is valid. **NOTE:** Once MDIS is switched from 1 to 0 or vice versa, it must not write a different value until STF changes accordingly. The MDIS bit is write-protected when VIS=1. See Register Reset Values in Configuration information.

Table continues on the next page...

eTPU_SCR_ECR_ENG2 field descriptions (continued)

Field	Description
	0 eTPU Engine runs. 1 Commands Engine to stop its clocks.
2 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
3 STF	Stop Flag Bit. Each Engine asserts its stop flag (STF) to indicate that it has stopped. Only then the host can assume that the Engine has actually stopped. The eTPU system is fully stopped when the STF bits of both eTPU Engines are asserted. In case of IP-Bus stop, the eTPU system responds by acknowledging stop only after both eTPU 1 and eTPU 2 have been stopped. Engine only stops when any ongoing thread is complete also in this case. Summarizing Engine stop conditions, which STF reflects: STF_1 := (after stop completed) MDIS_1 | device stop request. STF_2 := (after stop completed) MDIS_2 | device stop request. STF_1 and STF_2 mean STF bit from engine 1 and STF bit from engine 2, respectively. See Register Reset Values in Configuration information. 0 Engine is operating. 1 Engine has stopped (after the local MDIS bit has been asserted, or after the IP-Bus stop line has been asserted).
4–7 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
8 HLTF	Halt Mode Flag. If eTPU Engine entered halt state, this flag is asserted. The flag remains asserted while the microengine is in halt state, even during a single-step or forced instruction execution. See Development Support Features for further details about entering Halt Mode. 0 eTPU Engine is not halted. 1 eTPU Engine is halted.
9–11 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
12 FCSS	Filter Clock Source Selection Speeds up the filter clock source before the prescaler, allowing more input capture resolution at minimum prescaling. **NOTE:** FCSS=1 also makes the channel work on T2/T4 timing mode (see T2/T4 Channel Timing). 0 Use eTPU clock / 2 as EDF clock source before prescaler. 1 Use eTPU clock as EDF clock source before prescaler
13–15 FPSCK	Filter Prescaler Clock Control.

eTPU_SCR_ECR_ENG2 field descriptions (continued)

Field	Description
19–23 ERBA	Engine Relative Base Address. This field value is concatenated with the AID instruction field in engine relative address mode to form the SDM address (see the “Engine Relative Addressing Mode" section under SDM Addressing Modes).
24 SPPDIS	Schedule Priority Passing Disable. SPPDIS is used to disable the priority passing mechanism of the microengine scheduler (see the “Primary Scheme - Priority Among Channels on Different Levels" section under Channel Priority Schemes). **NOTE:** SPPDIS bit must not be changed while any channel is enabled. 0 Scheduler priority passing mechanism enabled. 1 Scheduler priority passing mechanism disabled.
25–26 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
27–31 ETB	Entry Table Base. The field determines the location of the microcode entry table for the eTPU functions in SCM (see Entry Points). The following table shows the entry table base address options.

Table 43-15. Entry table base address options

ETB	Entry Table Base Address for CPU Host Address (byte format)	Entry Table Base Address for Microcode Address (word format)
00000	0x000	0x000
00001	0x800	0x200
00010	0x1000	0x400
--------	----------	---------
11110	0xF000	0x3C00
11111	0xF800	0x3E00

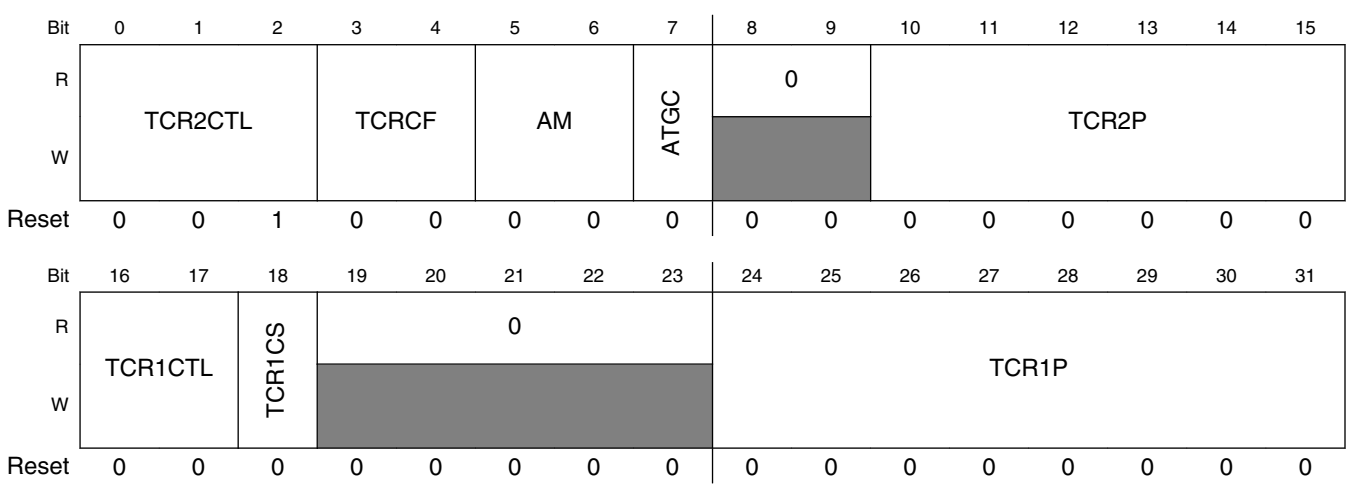
3. See T2/T4 Channel Timing.

43.7 Timebase memory map and registers

Time Base registers allows configuration and visibility of internally-generated time bases TCR1 and TCR2. There is one of each of these registers for each eTPU Engine.

NOTE

Writes to this register issue bus error and are ineffective when MDIS=1. Reads are always allowed.



eTPU_TBR memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page

Reset	0	0	0	0	*	*	*	*	0	0	0	0	0	0	0	0

* Notes:
- SERVER_ID2 field: See the chip-specific eTPU information for the reset value.
- SERVER_ID1 field: See the chip-specific eTPU information for the reset value.

eTPU_TBR_STAC_ENG2 field descriptions

Field	Description
0 REN1	TCR1 Resource Client/Server Operation Enable Bit. This bit enables Client/Server operation to eTPU STAC resources. REN1 enables TCR1 STAC bus operations. 0 Server/Client Operation for TCR1 is disabled. 1 Server/Client Operation for TCR1 is enabled.
1 RSC1	TCR1 Resource Server/Client Assignment Bits. This bit selects the eTPU data resource assignment to be used as Servers or Clients. For Server mode, MCU-dependent value determines the unique server address assigned to each TCR. See the chip-specific

Table continues on the next page...

eTPU_TBR_STAC_ENG2 field descriptions (continued)

Field	Description
	eTPU information for the STAC server IDs. For a Client mode, the SRV1 field determines the Server address to which the Client listens. **NOTE:** Resource identifies any parameter that changes along the time and can be exported / imported from other device. In eTPU context, a resource can be TCR1 or TCR2 (either Time or Angle values). **NOTE:** When TCR1 or TCR2 is configured as a STAC Bus Client (REN2 = 1, RSC2 = 0) the eTPU Angle Clock hardware cannot be used. **NOTE:** RSC1 must not be changed when the REN1 bit is asserted. 0 TCR1 Client operation. 1 TCR1 Server operation.
2–3 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
4–7 SERVER_ID1	STAC ID 1. STAC Server ID= 1 (read-only MCU-dependent values; see the chip-specific eTPU information for the STAC server IDs) used for TCR1 when STAC servers are used.
8–11 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
12–15 SRV1	TCR1 Resource Server. This bit selects the address of the specific STAC Server to which the local TCR1 listens when configured as a STAC Client. SRV1 selects the STAC Server of TCR1.
16 REN2	TCR2 Resource Client/Server Operation Enable Bit. This bit enables Client/Server operation to eTPU STAC resources. REN2 enables TCR2 STAC bus operations. 0 Server/Client Operation for resource 2 is disabled. 1 Server/Client Operation for resource 2 is enabled.
17 RSC2	TCR2 Resource Server/Client Assignment Bits. **NOTE:** Resource identifies any parameter that changes along the time and can be exported / imported from other device. In eTPU context, a resource can be TCR1 or TCR2 (either Time or Angle values). 0 Resource Client operation. 1 Resource Server operation.
18–19 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
20–23 SERVER_ID2	STAC ID 2.

Table continues on the next page...

eTPU_TBR_STAC_ENG2 field descriptions (continued)

Field	Description
	STAC Server ID= 3 (read-only MCU-dependent values; see the chip-specific eTPU information for the STAC server IDs) used for TCR2 when when STAC servers are used.
24–27 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
28–31 SRV2	TCR2 Resource Server. This bit selects the address of the specific STAC Server to which the local TCR2 listens when configured as a STAC Client. SRV2 selects the Red Line STAC Server of TCR2.

43.8 Engine memory map and registers

This section gathers registers that are engine-related, other than ETPUECR (see ECR_ENG1 and ECR_ENG2 registers).

eTPU_ER memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
60	eTPU Watchdog Timer Register for Engine 1 (eTPU_ER_WDTR_ENG1)	32	R/W	0000_0000h	43.8.1/1377
68	eTPU Idle Register for Engine 1 (eTPU_ER_IDLER_ENG1)	32	R/W	Undefined	43.8.2/1379
70	eTPU Watchdog Timer Register for Engine 2 (eTPU_ER_WDTR_ENG2)	32	R/W	0000_0000h	43.8.3/1380
78	eTPU Idle Register for Engine 2 (eTPU_ER_IDLER_ENG2)	32	R/W	Undefined	43.8.4/1381

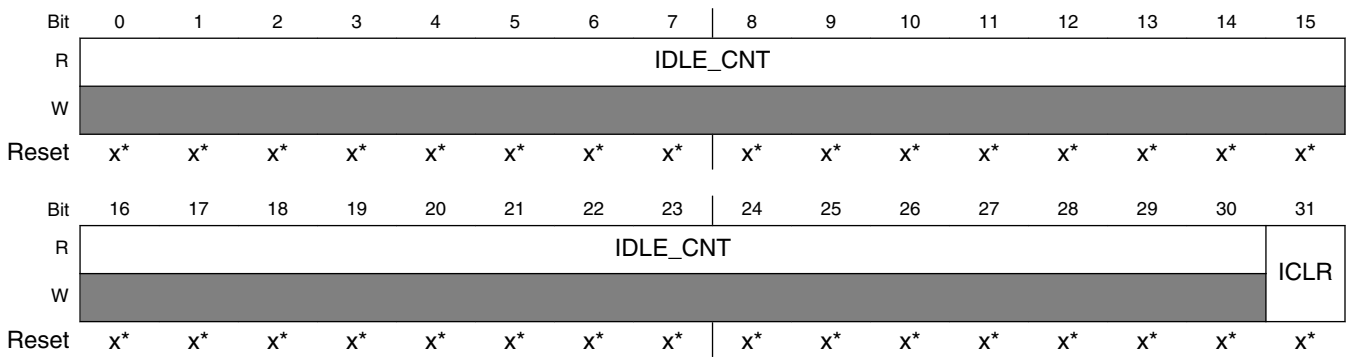
43.8.1 eTPU Watchdog Timer Register for Engine 1 (eTPU_ER_WDTR_ENG1)

This register configures the watchdog timer for the engine.

Address: 0h base + 60h offset = 60h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	WDM		0	WMO	0											
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	WDCNT															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0



eTPU_ER_WDTR_ENG1 field descriptions

Field	Description
0–1 WDM	Watchdog Mode. WDM selects the Watchdog operation mode. For more information on the Watchdog operation, see Watchdog). **NOTE:** Before a new mode is configured, all conditions below must apply: 1. All channels must be disabled (ETPUCnCR field CPR=00. 2. No thread must be executing (register ETPUCSSR reads 0). 3. The watchdog must be disabled (WDM=00). 00 Disabled 01 Reserved 10 Thread length 11 Busy length
2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3 WMO	Watchdog Monitor Operation. This bit enables the monitor operation of the watchdog, inhibiting the thread ending and channel disabling in case of a timeout. The Global Exception occurs on a watchdog timeout, independently of WMO. **NOTE:** The ETPUWDSR bits WDSn, the ETPUMCR bits WDTO1/2, and the Global Exception always asserts in case of a watchdog timeout, independently of WMO. 0 Force the end of the running thread and disable the service channel in case of a timeout. 1 Do not force the end of the running thread, nor disable the service channel in case of a timeout.
4–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 WDCNT	Watchdog Count. This field indicates the maximum number of microcycles allowed for a thread (in thread length mode) or a sequence of threads (in busy length mode) before the current running thread is forced to end. For more information on Watchdog operation, see Watchdog. **NOTE:** The TST microcycles are also counted by the watchdog. **NOTE:** Fields WDCNT and WMO must not be changed when the watchdog is enabled.

43.8.2 eTPU Idle Register for Engine 1 (eTPU_ER_IDLER_ENG1)

This register counts the microcycles in which the microengine is idle (see Idle Counter

Address: 0h base + 68h offset = 68h

* Notes:
- x = Undefined at reset.

eTPU_ER_IDLER_ENG1 field descriptions

Field	Description
0–30 IDLE_CNT	Idle Count. This is a freerunning count of the number of idle microcycles in the microengine. For more information on idle counter operation, see Idle Counter. **NOTE:** When the register is read, the ICLR bit is concatenated with the IDLE_CNT field (as the LSB) to form a 32-bit value.
31 ICLR	Idle Clear. Writing a 1 to this bit clears the IDLE_CNT field. **NOTE:** When the register is read, the ICLR bit is concatenated with the IDLE_CNT field (as the LSB) to form a 32-bit value. 0 Do not clear the IDLE_CNT field. 1 Clear the IDLE_CNT field.

43.8.3 eTPU Watchdog Timer Register for Engine 2 (eTPU_ER_WDTR_ENG2)

This register configures the watchdog timer for the engine.

Address: 0h base + 70h offset = 70h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	WDM		0	WMO	0											
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	WDCNT															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

eTPU_ER_WDTR_ENG2 field descriptions

Field	Description
0–1 WDM	Watchdog Mode. WDM selects the Watchdog operation mode. For more information on the Watchdog operation, see Watchdog. **NOTE:** Before a new mode is configured, all conditions below must apply: 1. All channels must be disabled (ETPUCnCR field CPR=00. 2. No thread must be executing (register ETPUCSSR reads 0). 3. The watchdog must be disabled (WDM=00). 00 Disabled 01 Reserved 10 Thread length 11 Busy length
2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3 WMO	Watchdog Monitor Operation. This bit enables the monitor operation of the watchdog, inhibiting the thread ending and channel disabling in case of a timeout. The Global Exception occurs on a watchdog timeout, independently of WMO. **NOTE:** The ETPUWDSR bits WDSn, the ETPUMCR bits WDTO1/2, and the Global Exception always assert in case of a watchdog timeout, independently of WMO. 0 Force the end of the running thread and disable the service channel in case of a timeout. 1 Do not force the end of the running thread, nor disable the service channel in case of a timeout.
4–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 WDCNT	Watchdog Count.

Table continues on the next page...

eTPU_ER_WDTR_ENG2 field descriptions (continued)

Field	Description
	This field indicates the maximum number of microcycles allowed for a thread (in thread length mode) or a sequence of threads (in busy length mode) before the current running thread is forced to end.For more information on Watchdog operation, see Watchdog. **NOTE:** The TST microcycles are also counted by the watchdog. **NOTE:** Fields WDCNT and WMO must not be changed when the watchdog is enabled.

43.8.4 eTPU Idle Register for Engine 2 (eTPU_ER_IDLER_ENG2)

This register counts the microcycles in which the microengine is idle (see Idle Counter).

Address: 0h base + 78h offset = 78h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	IDLE_CNT

Field	Description
	This read-only field holds the value of the greatest latency measured, in microcycles, since reset or the latest clear. When the value is greater than the maximum specified in the ETPULMnCR field MAXLAT and MAXLAT value is not zero, a Global Exception is issued and the ETPUMCR bit LTO1 (engine 1) or LTO2 (engine 2) is set. See the Latency Monitor section for the detailed latency measurement description. **NOTE:** When read, the LATENCY field is concatenated with the LTC bit (LSB) to form a 16-bit value. **NOTE:** Any latency measured above 0xFFFF is captured as 0xFFFF into the LATENCY+LTC field.
31 LTC	Latency measurement clear. Writing a 1 to the LTC bit clears the LATENCY field. **NOTE:** When read, the LATENCY field is concatenated with the LTC bit (LSB) to form a 16-bit value. **NOTE:** The LATENCY value is not automatically cleared when the Latency Monitor is disabled. 0 Keep the LATENCY field value. 1 Clear the LATENCY field value.

43.10 Memory Error Support memory map and registers

eTPU_MESR memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
100	eTPU Memory Error Control Register (eTPU_MESR_MECR)	32	R/W	0000_0000h	43.10.1/ 1389
104	eTPU Data Error Injection Address Register (eTPU_MESR_DEIAR)	32	R/W	0000_0000h	43.10.2/ 1392
108	eTPU Data Error Injection Data Pattern Register (eTPU_MESR_DEIDPR)	32	R/W	0000_0000h	43.10.3/ 1393

43.10.1 eTPU Memory Error Control Register (eTPU_MESR_MECR)

This register gathers control bits of both SCM and SDM error detection and correction support.

Address: 0h base + 100h offset = 100h

eTPU_MESR_MECR field descriptions

Field	Description
0 FME	Field Modification Enable. Negation of this bit disables the modification of all fields in the register, except MECIE, DRDIS, CRDIS and FME itself: Write accesses do not cause a bus error, regardless of FME state. 0 Fields cannot be modified during a write access, except MECIE, DRDIS, CRDIS and FME. 1 All fields can be modified during a write access.
1–14 Reserved	Reserved.

Table continues on the next page...

eTPU_MESR_MECR field descriptions (continued)

Field	Description
	This field is reserved. This read-only field is reserved and always has the value 0.
15 MECIE	Memory Error Correction Interrupt Enable. This bit enables the Memory Error Correction Interrupt (see Interrupt Types and Sources). 0 Memory Error Correction Interrupt disabled. 1 Memory Error Correction Interrupt enabled.
16 HDEIE	Host Data Error Injection Enable This bit enables error injection into the SDM host read path, including CDC transfers. The eTPU Data Error Injection Address Register (eTPU_MESR_DEIAR) register specifies the address where the error is injected, while registers eTPU Data Error Injection Data Pattern Register (eTPU_MESR_DEIDPR) and eTPU Data Error Injection Parity Pattern Register (eTPU_MESR_DEIPPR) define the bit flips on data and parity, respectively. **NOTE:** Data error injection is also performed when data error detection is disabled (DEDD=1). 0 SDM error injection disabled for host reads. 1 SDM error injection enabled for host reads.
17 MDEIE	Microengine(s) Data Error Injection Enable. This bit enables error injection into the SDM microengine read path. The eTPU Data Error Injection Address Register (eTPU_MESR_DEIAR) register specifies the address where the error is injected, while registers eTPU Data Error Injection Data Pattern Register (eTPU_MESR_DEIDPR) and eTPU Data Error Injection Parity Pattern Register (eTPU_MESR_DEIPPR) define the bit flips on data and parity, respectively. **NOTE:** Data error injection is also performed when data error detection is disabled (DEDD=1). 0 SDM error injection disabled for microengine reads. 1 SDM error injection enabled for microengine reads.
18–20 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
21 DTEND	Thread End on Data Non-correctable Error. This bit controls the behavior of the microengine when a non-correctable data error occurs. For more details, see “Memory Error Support” Memory Error Support. **NOTE:** DTEND must only be changed when the engine is stopped or halted, or when all channels are disabled. 0 Thread continues on non-correctable data read access by the microengine. 1 Thread ends on non-correctable data read access by the microengine.
22 DRDIS	Data Error Report Disable. This bit disables the sampling of SDM error address, data and syndrome into the registers eTPU Memory Error Support Registers, and eTPU Data Error Report Syndrome Register (eTPU_MESR_DERSR). It does not, however, disable the setting of eTPU Memory Error Status Register (eTPU_MESR_MESR) bits DCERR and DNCERR.

Table continues on the next page...

eTPU_MESR_MECR field descriptions (continued)

Field	Description
	NOTE: To guarantee coherent reading of registers ETPUDERAR, ETPUDERDR, ETPUDERSR, DRDIS must be asserted beforehand if SDM concurrent accesses can happen, by host or microengine. After the registers are read, DRDIS may be negated again to allow new samplings. 0 SDM error report sampling enabled. 1 SDM error report sampling disabled.
23 DEDD	Data Error Detection Disable. This bit disables SDM error detection. The disabled state turns ineffective any action due to error detection, including consequently error correction. 0 SDM error detection enabled. 1 SDM error detection disabled.
24 CEIE	Code Error Injection Enable. This bit enables error injection into the SCM read path, either on microengine accesses (see eTPU Module Configuration Register (eTPU_SCR_MCR) bit VIS=0) or host accesses (VIS = 1) The eTPU Code Error Injection Address Register (eTPU_MESR_CEIAR) register specifies the address where the error is injected, while registers eTPU Code Error Injection Data Pattern Register (eTPU_MESR_CEIDPR) and eTPU Code Error Injection Parity Pattern Register (eTPU_MESR_CEIPPR) define the bit flips on data and parity, respectively. **NOTE:** Code error injection is also performed when code error detection is disabled (CEDD=1). 0 SCM error injection disabled. 1 SCM error injection enabled.
25–28 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
29 CTEND	Thread End on Code Non-correctable Error. This bit controls the behavior of the microengine when a non-correctable code error occurs. For more details, see Memory Error Support. **NOTE:** CTEND must only be changed when the engine is stopped or halted, or when all channels are disabled. 0 Thread continues on instruction fetch non-correctable error. 1 Thread ends on instruction fetch non-correctable error.
30 CRDIS	Code Error Report Disable. This bit disables the sampling of SCM error address, data and syndrome into the registers eTPU Code Error Report Address Register (eTPU_MESR_CERAR), eTPU Code Error Report Data Register (eTPU_MESR_CERDR), and eTPU Code Error Report Syndrome Register (eTPU_MESR_CERSR). It does not, however, disable the setting of ETPUMESR bits CCERR and CNCERR (see eTPU Memory Error Status Register (eTPU_MESR_MESR)). **NOTE:** To guarantee coherent reading of registers ETPUCERAR, ETPUCERDR and ETPUCERSR, CRDIS must be asserted beforehand if SCM concurrent accesses can happen, by host or microengine. After the registers are read, CRDIS may be negated again to allow new samplings.

Table continues on the next page...

eTPU_MESR_MECR field descriptions (continued)

Field	Description
	0 SCM error report sampling enabled. 1 SCM error report sampling disabled.
31 CEDD	Code Error Detection Disable. This bit disables SCM error detection. The disabled state turns ineffective any action due to error detection, including consequently error correction. 0 SCM error detection enabled. 1 SCM error detection disabled.

43.10.2 eTPU Data Error Injection Address Register (eTPU_MESR_DEIAR)

This register holds the address where error is to be injected into the SDM read data path. The two least significant bits are 0 (read-only), so that the address is always word-aligned.

NOTE

This register must only be modified when ETPUMECR bits HDEIE and MDEIE are both negated.

Address: 0h base + 104h offset = 104h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0																INJ_ADDR														0

eTPU_MESR_DEIAR field descriptions

Field	Description
0–17 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
18–29 INJ_ADDR	Injection Address. INJ_ADDR holds the (word) address where an error is injected into the SDM read data path, as specified by registers ETPUDEIDPR eTPU Data Error Injection Data Pattern Register (eTPU_MESR_DEIDPR) and ETPUDEIPPR eTPU Data Error Injection Parity Pattern Register (eTPU_MESR_DEIPPR). For more information on error injection, see Error Injection.
30–31 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.

43.10.3 eTPU Data Error Injection Data Pattern Register (eTPU_MESR_DEIDPR)

This register is used to specify the bits in which error is injected into the SDM read data path.

NOTE

This register must only be modified when ETPUMECR bits HDEIE and MDEIE are both negated.

Address: 0h base + 108h offset = 108h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

eTPU_MESR_DEIDPR field descriptions

Field	Description
0–31 DFLIP	Data Flip bits. Each bit corresponds to a bit in the actual data read from the SDM address defined in the eTPU Data Error Injection Address Register (eTPU_MESR_DEIAR) register, specifying whether it should be inverted or not. The inversion only occurs if the SDM error injection is enabled by the eTPU Memory Error Control Register (eTPU_MESR_MECR) register bits HDEIE and/or MDEIE. For more information on error injection, see Error Injection. 0 Read data bit is not inverted. 1 Read data bit is inverted.

43.10.4 eTPU Data Error Injection Parity Pattern Register (eTPU_MESR_DEIPPR)

This register is used to specify the bits in which error is injected into the SDM read parity path.

NOTE

This register must only be modified when ETPUMECR bits HDEIE and MDEIE are both negated.

Address: 0h base + 10Ch offset = 10Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0			PFLIP_19_15					0			PFLIP_14_10					0			PFLIP_9_5					0			PFLIP_4_0			
W

eTPU_MESR_DEIPPR field descriptions

Field	Description
0–2 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
3–7 PFLIP_19_15	Parity Flip bits. Each bit corresponds to a bit in the actual parity read from the SDM address defined in the eTPU Data Error Injection Address Register (eTPU_MESR_DEIAR) register, specifying whether it should be inverted or not. The inversion only occurs if the SDM error injection is enabled by the eTPU Memory Error Control Register (eTPU_MESR_MECR) register bits HDEIE and/or MDEIE. Bits PFLIP[19:15] corresponds to the parity bits for the most significant byte, PFLIP[14:10] to the next most significant byte and so on until PFLIP[4:0] for the least significant byte. For more information on error injection, see Error Injection. 0 Parity data bit is not inverted. 1 Parity data bit is inverted.
8–10 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
11–15 PFLIP_14_10	Parity Flip bits. Each bit corresponds to a bit in the actual parity read from the SDM address defined in the eTPU Data Error Injection Address Register (eTPU_MESR_DEIAR) register, specifying whether it should be inverted or not. The inversion only occurs if the SDM error injection is enabled by the eTPU Memory Error Control Register (eTPU_MESR_MECR) register bits HDEIE and/or MDEIE. Bits PFLIP[19:15] corresponds to the parity bits for the most significant byte, PFLIP[14:10] to the next most significant byte and so on until PFLIP[4:0] for the least significant byte. For more information on error injection, see Error Injection. 0 Parity data bit is not inverted. 1 Parity data bit is inverted.
16–18 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
19–23 PFLIP_9_5	Parity Flip bits. Each bit corresponds to a bit in the actual parity read from the SDM address defined in the eTPU Data Error Injection Address Register (eTPU_MESR_DEIAR) register, specifying whether it should be inverted or not. The inversion only occurs if the SDM error injection is enabled by the eTPU Memory Error Control Register (eTPU_MESR_MECR) register bits HDEIE and/or MDEIE. Bits PFLIP[19:15] corresponds to the parity bits for the most significant byte, PFLIP[14:10] to the next most significant byte and so on until PFLIP[4:0] for the least significant byte. For more information on error injection, see Error Injection. 0 Parity data bit is not inverted. 1 Parity data bit is inverted.
24–26 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
27–31 PFLIP_4_0	Parity Flip bits.

Table continues on the next page...

eTPU_MESR_DEIPPR field descriptions (continued)

Field	Description
	Each bit corresponds to a bit in the actual parity read from the SDM address defined in the eTPU Data Error Injection Address Register (eTPU_MESR_DEIAR) register, specifying whether it should be inverted or not. The inversion only occurs if the SDM error injection is enabled by the eTPU Memory Error Control Register (eTPU_MESR_MECR) register bits HDEIE and/or MDEIE. Bits PFLIP[19:15] corresponds to the parity bits for the most significant byte, PFLIP[14:10] to the next most significant byte and so on until PFLIP[4:0] for the least significant byte. For more information on error injection, see Error Injection. 0 Parity data bit is not inverted. 1 Parity data bit is inverted.

43.10.5 eTPU Data Error Report Address Register (eTPU_MESR_DERAR)

This register holds the address where the last non-correctable error was detected from the SDM It also captures the address of the last correctable error detected, as long as the eTPU Memory Error Status Register (eTPU_MESR_MESR) bit DNCERR is 0. The two least significant bits are 0 (read-only), so that the address is always word-aligned.

Address: 0h base + 110h offset = 110h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	ERR_ACC		0	ERR_CHANNEL					0							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0		ERR_ADDR												0	
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

eTPU_MESR_DERAR field descriptions

Field	Description
0–1 ERR_ACC	Error Access Source Indication. This two-bit field indicates the source of the access when the error occurred. 00 Host - direct access 01 Engine 1 10 Engine 2 11 CDC
2 Reserved	Reserved.

Table continues on the next page...

eTPU_MESR_DERAR field descriptions (continued)

Field	Description
	This field is reserved. This read-only field is reserved and always has the value 0.
3–7 ERR_CHANNEL	Error Channel Access Indication. This field holds the number of the channel being serviced (not necessarily CHAN) when the error occurred. Its content is meaningful only when the field ERR_ACC indicates Engine 1 or Engine 2.
8–17 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
18–29 ERR_ADDR	Error Address. ERR_ADDR holds the (word) address where the last captured SDM read error was detected. The last captured error is a non-correctable one if eTPU Memory Error Status Register (eTPU_MESR_MESR) register bit DNCERR=1, or a correctable one if DNCERR=0 and DCERR=1. The field is meaningless if both DNCERR and DCERR are 0. For more information on error detection, see Memory Error Support.
30–31 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.

43.10.6 eTPU Data Error Report Data Register (eTPU_MESR_DERDR)

This register holds the data read with the last non-correctable error detected from the SDM. It also captures the data of the last correctable error read detection, as long as the eTPU Memory Error Status Register (eTPU_MESR_MESR) bit DNCERR is 0. In both cases, the data is captured after the error correction logic. The data is meaningless if both DNCERR and DCERR are 0. For more information on error detection, see Memory Error Support.

NOTE

Data is sampled before the error correction logic.

Address: 0h base + 114h offset = 114h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

eTPU_MESR_DERDR field descriptions

Field	Description
0–31 DATA	DATA.

eTPU_MESR_DERDR field descriptions (continued)

Field	Description
	NOTE: Individual data bytes are not meaningful when their respective BE bits in the eTPU Data Error Report Syndrome Register (eTPU_MESR_DERSR) register are not asserted.

43.10.7 eTPU Data Error Report Syndrome Register (eTPU_MESR_DERSR)

This register holds the syndrome read with the last non-correctable error detected from the SDM. It also captures the syndrome of the last correctable error read detection, as long as the eTPU Memory Error Control Register (eTPU_MESR_MECR) bit DNCERR is 0.

Address: 0h base + 118h offset = 118h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	BE3	0		SYND3					BE2	0		SYND2

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

eTPU_MESR_DERSR field descriptions

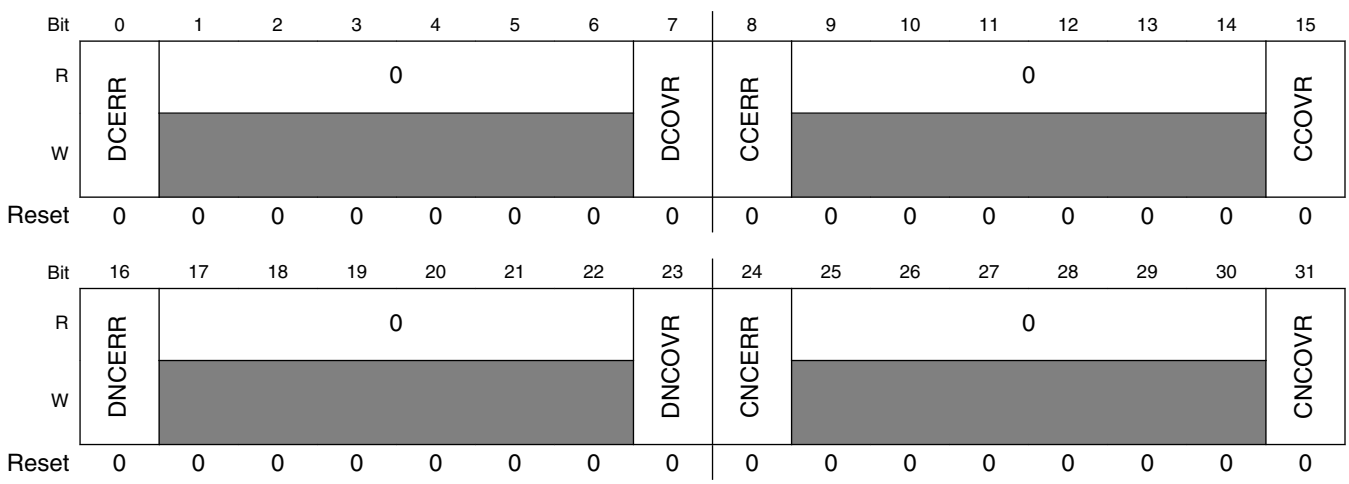
Field	Description
0 BE3	Byte Enable 3. Each BE bit corresponds to a report byte in a 32-bit aligned data word. BE3 corresponds to the most significant one. BE qualifies the error report for its respective byte. 0 Byte was not selected for read, therefore its respective error report fields are not meaningful. 1 Byte was selected for read, and the error report for the respective byte is meaningful.
1–2 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
3–7 SYND3	Error Syndrome 3. SYND3 holds the syndrome of an error detected in the SDM read data path, as defined in Error Correction Code (ECC) and Syndrome Definition. The field is meaningless if both eTPU Memory Error Status Register (eTPU_MESR_MESR) bits DNCERR and DCERR are 0. For more information on error detection, see Memory Error Support.

Table continues on the next page...

eTPU_MESR_DERSR field descriptions (continued)

Field	Description
	NOTE: Syndrome fields which have their respective BE bits negated are not meaningful.
8 BE2	Byte Enable 2. Each BE bit corresponds to a report byte in a 32-bit aligned data word. BE3 corresponds to the most significant one. BE qualifies the error report for its respective byte. 0 Byte was not selected for read, therefore its respective error report fields are not meaningful. 1 Byte was selected for read, and the error report for the respective byte is meaningful.
9–10 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
11–15 SYND2	Error Syndrome 2. SYND2 holds the syndrome of an error detected in the SDM read data path, as defined in the “Error Correction Code (ECC) and Syndrome Definition”section. The field is meaningless if both the eTPU Memory Error Status Register (eTPU_MESR_MESR) bit DNCERR and DCERR are 0. For more information on error detection, see Memory Error Support. **NOTE:** Syndrome fields which have their respective BE bits negated are not meaningful.
16 BE1	Byte Enable 1. Each BE bit corresponds to a report byte in a 32-bit aligned data word. BE3 corresponds to the most significant one. BE qualifies the error report for its respective byte. 0 Byte was not selected for read, therefore its respective error report fields are not meaningful. 1 Byte was selected for read, and the error report for the respective byte is meaningful.
17–18 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
19–23 SYND1	Error Syndrome 1. SYND1 holds the syndrome of an error detected in the SDM read data path, as defined in the “Error Correction Code (ECC) and Syndrome Definition”section. The field is meaningless if both the eTPU Memory Error Status Register (eTPU_MESR_MESR) bits DNCERR and DCERR are 0. For more information on error detection, see Memory Error Support. **NOTE:** Syndrome fields which have their respective BE bits negated are not meaningful.
24 BE0	Byte Enable 0. Each BE bit corresponds to a report byte in a 32-bit aligned data word. BE3 corresponds to the most significant one. BE qualifies the error report for its respective byte. 0 Byte was not selected for read, therefore its respective error report fields are not meaningful. 1 Byte was selected for read, and the error report for the respective byte is meaningful.
25–26 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
27–31 SYND0	Error Syndrome 0.

Table continues on the next page...



eTPU_MESR_DERSR field descriptions (continued)

Field	Description
	SYND0 holds the syndrome of an error detected in the SDM read data path, as defined in the “Error Correction Code (ECC) and Syndrome Definition”section. The field is meaningless if both the eTPU Memory Error Status Register (eTPU_MESR_MESR) bits DNCERR and DCERR are 0. For more information on error detection, see Memory Error Support. **NOTE:** Syndrome fields which have their respective BE bits negated are not meaningful.

43.10.8 eTPU Memory Error Status Register (eTPU_MESR_MESR)

This register gathers status bits of both SCM and SDM error detection and correction support.

Address: 0h base + 120h offset = 120h

eTPU_MESR_MESR field descriptions

Field	Description
0 DCERR	Data Correctable Error flag. When read: 0.....No SDM correctable error occurred. 1.....An SDM correctable error occurred. Writing 1 to this bit clears the DCERR status flag. DCERR asserts even if DNCERR is asserted beforehand, but in this case the address and data of the erroneous access is not captured (see the eTPU Memory Error Support registers and following sections). DCERR is cleared by writing a 1 to it. Assertion of this bit can also assert the Memory Error Correction Interrupt (see “Interrupt Types and Sources” Interrupt Types and Sources). **NOTE:** A correctable error is not considered for flagging if accompanied of a non-correctable one. Therefore, if both correctable and non-correctable data errors occur on the same access (in distinct bytes), the DNCERR flag asserts, but not the DCERR flag.

Table continues on the next page...

eTPU_MESR_MESR field descriptions (continued)

Field	Description
	0 Do not clear DCERR flag. 1 Clears DCERR flag
1–6 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
7 DCOVR	Data Correctable Overrun flag. Writing 1 to this bit clears the DCOVR status flag. 0 Data correctable error occurred while DCOVR = 1. 1 No data correctable error occurred while DCOVR = 1. DCOVR asserts when an SDM correctable error occurs and the DCERR flag is already asserted. Assertion of this bit causes no interrupt. **NOTE:** A correctable error is not considered for flagging if accompanied by a non-correctable one. Therefore, if both correctable and non-correctable data errors occur on the same access (in distinct bytes), the DCOVR does not assert, even if DCERR is asserted. The DNCOVR flag, on the other hand, asserts if DNCERR is asserted.
8 CCERR	Code Error flag. >When read: 0.....No SCM correctable error occurred. 1.....An SCM correctable error occurred. When written: 0.....Do not clear CCERR flag. 1.....Clears CCERR flag. The CCERR flag asserts even if CNCERR is asserted beforehand, but in this case the address and data of the erroneous access is not captured (see the eTPU Code Error Report Address Register (eTPU_MESR_CERAR) register and the following sections). CCERR is cleared by writing a 1 at the same position. Assertion of this bit can also assert the Memory Error Correction Interrupt (see Interrupt Types and Sources).
9–14 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
15 CCOVR	Code Correctable Overrun flag This bit asserts when an SCM correctable error occurs and the CCERR flag is already asserted. Assertion of this bit causes no interrupt. When read: 0.....No SCM correctable error overrun occurred. 1.....An SCM correctable error overrun occurred. Writing 1 to this bit clears the CCOVR status flag: 0 Do not clear CCOVR flag. 1 Clear CCOVR flag.

Table continues on the next page...

eTPU_MESR_MESR field descriptions (continued)

Field	Description
16 DNCERR	Data Non-Correctable Error flag DNCERR flags a non-correctable error. When read: 0.....No SDM non-correctable error occurred. 1.....An SDM non-correctable error occurred; registers eTPU Global Channel Registers are not updated by correctable error detections. DNCERR must be cleared (by writing a 1 to it) to allow correctable error updates to registers ETPUDERAR and ETPUDERDR. 0 Do not clear DNCERR flag. 1 Clear DNCERR flag.
17–22 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
23 DNCOVR	Data Non-Correctable Overrun flag. DNCOVR asserts when an SDM non-correctable error occurs and the DNCERR flag is already asserted. Assertion of this bit causes no interrupt. When read: 0.....No SDM non-correctable error overrun occurred. 1.....An SDM non-correctable error overrun occurred. DNCOVR is cleared by writing a 1 to it. 0 Do not clear DNCOVR flag. 1 Clear DNCOVR flag.
24 CNCERR	Code Non-Correctable Error flag CNCERR flags a non-correctable error: When read: 0.....An SCM non-correctable error occurred; the eTPU Global Channel Registers are not updated by correctable error detections. 1....an SCM non-correctable error occurred; registers ETPUCERAR and ETPUCERD are not updated by correctable error detections. CNCERR must be cleared to allow correctable error updates to registers ETPUCERAR and ETPUCERDR. CNCERR is cleared by writing a 1 to it. 0 Do not clear CNCERR flag. 1 Clear CNCERR flag.
25–30 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
31 CNCOVR	Code Non-Correctable Overrun flag.

Table continues on the next page...

eTPU_MESR_MESR field descriptions (continued)

Field	Description
	CNCOVR asserts when an SCM non-correctable error occurs and the CNCERR flag is already asserted. Assertion of this bit causes no interrupt. When read: 0.....an SCM non-correctable error overrun occurred. 1.....An SCM non-correctable error overrun occurred. When written: 0 Do not clear CNCOVR flag. 1 Clear CNCOVR flag.

43.10.9 eTPU Code Error Injection Address Register (eTPU_MESR_CEIAR)

This register holds the address where error is to be injected into the SCM read data path. The two least significant bits are 0 (read-only), so that the address is always word-aligned.

NOTE

This register must only be modified when eTPU Memory Error Control Register (eTPU_MESR_MECR) bit CEIE is negated.

Address: 0h base + 124h offset = 124h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

eTPU_MESR_CEIAR field descriptions

Field	Description
0–15 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
16–29 INJ_ADDR	Injection Address. INJ_ADDR holds the (word) address where an error is injected in the SCM read data path, as specified by registers eTPU Code Error Injection Data Pattern Register (eTPU_MESR_CEIDPR) and eTPU Code Error Injection Parity Pattern Register (eTPU_MESR_CEIPPR). For more information on error injection, see Error Injection.
30–31 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.

43.10.10 eTPU Code Error Injection Data Pattern Register (eTPU_MESR_CEIDPR)

This register is used to specify the bits in which error is injected into the SCM read data path.

NOTE

This register must only be modified when eTPU Memory Error Control Register (eTPU_MESR_MECR) bit CEIE is negated.

Address: 0h base + 128h offset = 128h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	DFLIP																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

eTPU_MESR_CEIDPR field descriptions

Field	Description
0–31 DFLIP	Data Flip bits. Each bit corresponds to a bit in the actual data read from the SCM address defined in the eTPU Code Error Injection Address Register (eTPU_MESR_CEIAR) register, specifying whether it should be inverted or not. The inversion only occurs if the SCM error injection is enabled by eTPU Memory Error Control Register (eTPU_MESR_MECR) register bit CEIE. For more information on error injection, see Error Injection. 0 Read data bit is not inverted. 1 Read data bit is inverted.

43.10.11 eTPU Code Error Injection Parity Pattern Register (eTPU_MESR_CEIPPR)

This register is used to specify the bits in which error is injected into the SCM read parity path.

NOTE

This register must only be modified when eTPU Memory Error Control Register (eTPU_MESR_MECR) bit CEIE is negated.

Address: 0h base + 12Ch offset = 12Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

eTPU_MESR_CEIPPR field descriptions

Field	Description
0–24 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
25–31 PFLIP	Parity Flip bits. Each bit corresponds to a bit in the actual parity/code read from the SCM address defined in the eTPU Code Error Injection Address Register (eTPU_MESR_CEIAR) register, specifying whether it should be inverted or not. The inversion only occurs if the SCM error injection is enabled by eTPU Memory Error Control Register (eTPU_MESR_MECR) bit CEIE. For more information on error injection, see Error Injection. 0 Parity data bit is not inverted. 1 Parity data bit is inverted.

43.10.12 eTPU Code Error Report Address Register (eTPU_MESR_CERAR)

This register holds the address where the last non-correctable error was detected from the SCM. It also captures the address of the last correctable error detected, as long as the eTPU Memory Error Control Register (eTPU_MESR_MECR) bit CNCERR is 0. The two least significant bits are 0 (read-only), so that the address is always word-aligned.

Address: 0h base + 130h offset = 130h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	ERR_ACC		0	ERR_CHANNEL					0							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R	ERR_ADDR														0	
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

eTPU_MESR_CERAR field descriptions

Field	Description
0–1 ERR_ACC	Error Access Source Indication. This two-bit field indicates the source of the access when the error occurred. 00 Host 01 Engine 1

Table continues on the next page...

eTPU_MESR_CERAR field descriptions (continued)

Field	Description
	10 Engine 2 11 MISC
2 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
3–7 ERR_CHANNEL	Error Channel Access Indication. This field holds the number of the channel being serviced (not necessarily CHAN) when the error occurred. Its content is meaningful only when the field ERR_ACC indicates Engine 1 or Engine 2.
8–15 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
16–29 ERR_ADDR	Error Address. ERR_ADDR holds the (word) address where the last captured SCM read error was detected. The last captured error is a non-correctable one if eTPU Memory Error Control Register (eTPU_MESR_MECR) register bit CNCERR = 1, or a correctable one if CNCERR = 0 and CCERR = 1. The field is meaningless if both CNCERR and CCERR are 0. For more information on error detection, see Memory Error Support.
30–31 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.

43.10.13 eTPU Code Error Report Data Register (eTPU_MESR_CERDR)

This register holds the data read with the last non-correctable error detected from the SCM. It also captures the data of the last correctable error read detection, as long as eTPU Memory Error Control Register (eTPU_MESR_MECR) bit CNCERR is 0. In both cases, the data is captured after the error correction logic. The data may be meaningless if both CNCERR and CCERR are 0. For more information on error detection, see Memory Error Support.

NOTE

CODE is sampled before the error correction logic.

Address: 0h base + 134h offset = 134h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

eTPU_MESR_CERSR field descriptions

Field	Description
0–24 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
25–31 SYND	Error Syndrome. SYND holds the syndrome of an error detected in the SCM read data path, as defined in Error Correction Code (ECC) and Syndrome Definition. The field is meaningless if both eTPU Memory Error Control Register (eTPU_MESR_MECR) bits CNCERR and CCERR are 0. For more information on error detection, see Memory Error Support.

43.10.15 eTPU Code Error Fix Register (eTPU_MESR_CEFR)

This register is used to fix single-bit error in a specified SCM position. The fix is done automatically, concurrently with code execution, by the MISC logic (see Error Fixing).

Address: 0h base + 13Ch offset = 13Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	CFIX_ADDR														0	
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

eTPU_MESR_CEFR field descriptions

Field	Description
0–1 CFIXM	Code Fix Mode. This field specifies the SCM MISC fix logic operation mode as shown in the table below. **NOTE:** The CFIXM field can only be changed to/from disabled mode. **Table 43-99. CFIXM - Code Fix Mode** Value / Mode / Description: 00 / Disabled / SCM error fix disabled. 01 / Reserved / Reserved value, must not be used. 10 / Reserved / Reserved value, must not be used. 11 / Automatic / The MISC logic rewrites the code word value read (already fixed by the error correction mechanism) into the same address whenever it finds a correctable error.
2–15 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
16–29 CFIX_ADDR	Code Fix Address. This field is used for hardware debug purposes. CFIX_ADDR may change its contents and must not be written in automatic mode. For more information on error detection and correction, see Memory Error Support.
30–31 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.

43.11 Global Channel memory map and registers

The registers in this section group, by type, the interrupt status and enable bits from all the channels. This organization eases management of all channels or groups of channels by a single interrupt handler routine. These bits, except the service and watchdog status, are mirrored in the individual channel registers, grouped by channel.

eTPU_GCR memory map

eTPU_GCR_CIOSR_ENG2 field descriptions

Field	Description
0–31 CIOSn	Channel n Interrupt Overflow Status When read: 0.....Indicates that no interrupt overflow occurred in the channel. 1.....Indicates that interrupt overflow occurred in the channel. When written: 0.....Keep status bit unaltered. 1.....Clear status bit.

43.11.7 eTPU Channel Data Transfer Request Overflow Status Register for Engine 1 (eTPU_GCR_CDTROSR_ENG1)

Data Transfer Request Overflow status (see the Interrupts and Data Transfer Requests section) from all channels are grouped in ETPUCDTROSR. These bits are mirrored from the Channel Status Control registers (see eTPU Channel n Status Control Register for Engine 1 (eTPU_CCCR_C*n*SCR_ENG1)) and the CPU must write 1 to clear a status bit.

Address: 0h base + 230h offset = 230h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

eTPU_GCR_CPSSR_ENG1 field descriptions

Field	Description
0–31 SRn	Pending Service Request n. Indicates a pending Service Request for channel n. Pending SR status is a logic OR of all service requests pending: if only HSR is active, SRn clears only at the end of the thread. SRn clear due to the other request sources is microcode dependent. **NOTE:** The pending service status bit for a channel is 1 when a Service Request is pending, even if the Channel is disabled (CPRn = 0). **NOTE:** There can be a delay of one clock between writing HSR greater than 0 in register ETPUCxHSRR of a channel and its respective bit being asserted in ETPUCPSSR. 0 No Service Request pending for channel n. 1 Pending Service Request for channel n.

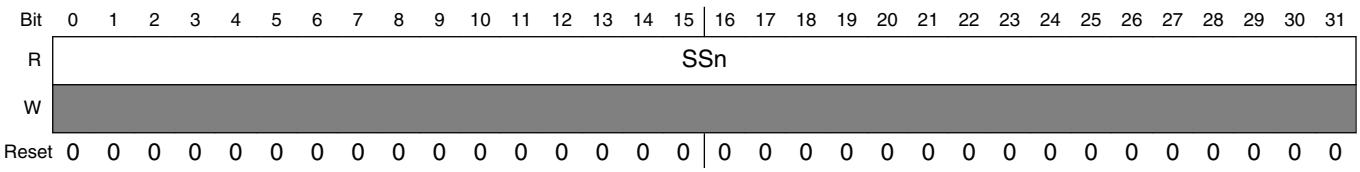
43.11.16 eTPU Channel Pending Service Status Register for Engine 2 (eTPU_GCR_CPSSR_ENG2)

ETPUCPSSR is a read-only register that holds the status of the pending Channel Service Requests (see the Functions and Threads section).

Address: 0h base + 284h offset = 284h

eTPU_GCR_CPSSR_ENG2 field descriptions

Field	Description
0–31 SRn	Pending Service Request n. Indicates a pending Service Request for channel n. Pending SR status is a logic OR of all service requests pending: if only HSR is active, SRn clears only at the end of the thread. SRn clear due to the other request sources is microcode dependent. **NOTE:** The pending service status bit for a channel is 1 when a Service Request is pending, even if the Channel is disabled (CPRn = 0). **NOTE:** There can be a delay of one clock between writing HSR greater than 0 in register ETPUCxHSRR of a channel and its respective bit being asserted in ETPUCPSSR. 0 No Service Request pending for channel n. 1 Pending Service Request for channel n.



43.11.17 eTPU Channel Service Status Register for Engine 1 (eTPU_GCR_CSSR_ENG1)

ETPUCSSR holds the current channel service status on whether it is being serviced or not (see the Functions and Threads section). Only one bit may be asserted in this register at a given time. When no channel is being serviced, the register read value is 0x0000_0000. ETPUCSSR is a read-only register. The register can be read during normal eTPU operation for monitoring the scheduler activity.

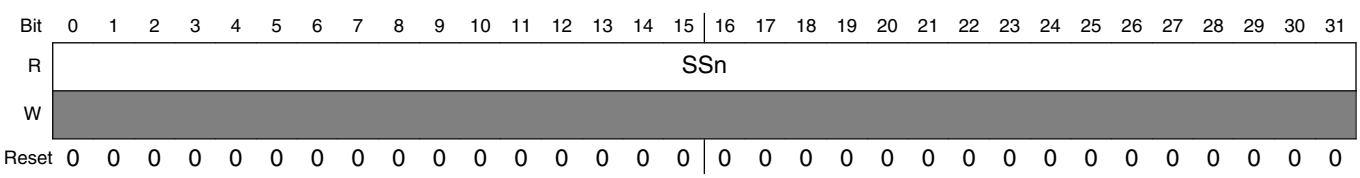
NOTE

Channel Service Status does not always reflect decoding of the CHAN register, since the latter can be changed by the service thread microcode.

Address: 0h base + 290h offset = 290h

eTPU_GCR_CSSR_ENG1 field descriptions

Field	Description
0–31 SSn	Service Status n. Indicates that channel n is currently being serviced. It is updated at the 1st microcycle of a Time Slot Transition (see Time Slot Transition), or when the microengine ends the thread. 0 Channel n is not currently being serviced. 1 channel n is currently being serviced.



43.11.18 eTPU Channel Service Status Register for Engine 2 (eTPU_GCR_CSSR_ENG2)

ETPUCSSR holds the current channel service status on whether it is being serviced or not (see the Functions and Threads section). Only one bit may be asserted in this register at a given time. When no channel is being serviced, the register read value is 0x0000_0000. ETPUCSSR is a read-only register. The register can be read during normal eTPU operation for monitoring the scheduler activity.

NOTE

Channel Service Status does not always reflect decoding of the CHAN register, since the latter can be changed by the service thread microcode.

Address: 0h base + 294h offset = 294h

eTPU_GCR_CSSR_ENG2 field descriptions

Field	Description
0–31 SSn	Service Status n. Indicates that channel n is currently being serviced. It is updated at the 1st microcycle of a Time Slot Transition (see Time Slot Transition), or when the microengine ends the thread.

eTPU_GCR_CSSR_ENG2 field descriptions (continued)

Field	Description
	0 Channel n is not currently being serviced. 1 channel n is currently being serviced.

43.12 Channel Configuration Control memory map and registers

Each channel has a group of 3 registers used to control, configure and check status of that channel as shown in the following table. This organization eases individual channel management.

Table 43-120. Channel Registers Structure

Channel Offset	Register Name
0x00	ETPUCnCR - eTPU Channel Configuration Register
0x04	ETPUCnSCR - eTPU Channel Status/Control Register
0x08	ETPUCnHSRR - eTPU Channel Host Service Request Register
0x0C	RESERVED

One contiguous area is used to map all channel registers of each eTPU engine as shown in the following table.

Table 43-121. Channel Registers Map

Offset	Registers Structure
0x400	eTPU 1 Channel 0 Registers Structure
0x410	eTPU 1 Channel 1 Registers Structure
0x420	eTPU 1 Channel 2 Registers Structure
0x430	-----
0x5E0	eTPU 1 Channel 30 Registers Structure
0x5F0	eTPU 1 Channel 31 Registers Structure
0x600	RESERVED
0x800	eTPU 2 Channel 0 Registers Structure
0x810	eTPU 2 Channel 1 Registers Structure
0x820	-----
0x9E0	eTPU 2 Channel 30 Registers Structure
0x9F0	eTPU 2 Channel 31 Registers Structure
0xA00	RESERVED

There are 64 structures defined, one for each available channel in the eTPU System (32 for each Engine). The base address for the structure presented can be calculated by using the following equation:

Channel_Register_Base = ETPU_Engine_Channel_Base + (channel_number * 0x10), where:

- ETPU_Engine_Channel_Base = ETPU_Base + 0x400 for Engine 1.
- ETPU_Engine_Channel_Base = ETPU_Base + 0x800 for Engine 2.

43.12.1 eTPU Channel n Configuration Register for Engine 1 (eTPU_CCCR_C*n*CR_ENG1)

ETPUCnCR gathers configurations set individually per channel.

Address: 0h base + 400h offset + (16d × i), where i=0d to 31d

eTPU_CCCR_C*n*CR_ENG1 field descriptions

Field	Description
0 CIE	Channel Interrupt Enable (see the eTPU Channel Interrupt Enable Register (ETPUCIER)). This bit is mirrored from eTPU Channel Interrupt Enable Register for Engine 2 (eTPU_GCR_CIER_ENG2). 0 Disable interrupt for this channel. 1 Enable interrupt for this channel.
1 DTRE	Channel Data Transfer Request Enable (see the “Channel Interrupt and Data Transfer Requests" section). This bit is mirrored from eTPU Channel Data Transfer Request Enable Register for Engine 2 (eTPU_GCR_CDTRER_ENG2). 0 Disable data transfer request for this channel. 1 Enable data transfer request for this channel.
2–3 CPR	Channel Priority. This field defines the priority level for the channel, used by the Hardware Scheduler (see the Scheduler section). 00 Disabled 01 Low 10 Middle 11 High

Table continues on the next page...

eTPU_CCCR_C*n*CR_ENG1 field descriptions (continued)

Field	Description
4 T4DIS	T4 channel action Disable. This bit forces the channel to work on T2 timing mode, regardless of the ETPUECR fields FCSS and CDFC (see eTPU Engine 2 Configuration Register (eTPU_SCR_ECR_ENG2)), or of the ETPUTBCR field TCR1CS (see eTPU Engine 2 Time Base Configuration Register (eTPU_TBR_TBCR_ENG2)). For more details see The Channel Timing Modes section. 0 Channel works either in T2 or T2/T4 timing modes, depending on ETPUTBCR field TCR1CS and ETPUECR fields FCSS and CDFC. 1 Channel works in T2 timing mode, regardless of ETPUTBCR field TCR1CS or ETPUECR fields FCSS and CDFC.
5 SSMAE	Shared Subsystem Microengine Access Enable. This bit enables the microengine access to the Shared Subsystem Area (see the Shared Subsystems Support section). When this bit is negated, DIOB address values pointing to the Shared Subsystem Area actually access SDM mirrors, in legacy mode. **NOTE:** SSMAE value must only be changed when the engine is either stopped or halted. 0 An SDM mirror is accessed when the Shared Subsystem Area is addressed by the microengine. 1 Enables microengine access to the Shared Subsystem Area.
6 ETPD	Entry Table Pin Direction. This bit selects which channel signal, input or output, is used in the Entry Point selection. The ETPD value has to be compatible with the function chosen for the channel, selected in the field CFS. For details about Entry Table and condition encoding schemes, refer to the “Entry Points” section. 0 Use PSTI for Entry Point selection. 1 Use PSTO for Entry Point selection.
7 ETCS	Entry Table Condition Select. This bit determines the channel condition encoding scheme that selects, according to channel conditions, the Entry Point to be taken in an Entry Table. ETCS value has to be compatible with the function chosen for the channel, selected in field CFS. Two condition encoding schemes are available. For details about Entry Table and condition encoding schemes, refer to the “Entry Points” section. 0 Select Standard Entry Table Condition encoding scheme. 1 Select Alternate Entry Table Condition encoding scheme.
8–10 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
11–15 CFS	Channel Function Select. This field defines the function to be performed by the channel (see the Functions and Threads section). The Function assigned to the channel has to be compatible with the channel condition encoding scheme, selected by field ETCS.
16 ODIS	Output Disable. This bit enables the channel to have its output forced to the value opposite to OPOL when the output disable input signal corresponding to the channel group that it belongs is active (see eTPU Channel Output Disable Signals and .

Table continues on the next page...

eTPU_CCCR_C*n*CR_ENG1 field descriptions (continued)

Field	Description
	0 Turns off the output disable feature for the channel. 1 Turns on the output disable feature for the channel.
17 OPOL	Output Polarity. Determines the output signal polarity. The activation of the output disable signal forces, when enabled by the ODIS bit, the channel output signal to the opposite of this polarity (see). 0 Output active low (output disable drives output to high). 1 output active high (output disable drives output to low).
18–20 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
21–31 CPBA	Channel n Parameter Base Address. The value of this field times 8 specifies the SDM parameter base host (byte) address for channel n (2-parameter granularity; see the SDM Organization section.) As seen by the Host, the channel parameter base (byte) address is (without parameter sign extension) ETPU_Base + 0x8000 + CPBA * 8 or (with parameter sign extension), ETPU_Base + 0xC000 + CPBA*8.

43.12.2 eTPU Channel n Status Control Register for Engine 1 (eTPU_CCCR_C*n*SCR_ENG1)

ETPUCnSCR gathers the interrupt status bits of the channel, and also the Function Mode definition (read-write). Bits CIS, CIOS and DTRS for each channel can be also accessed from ETPUCISR (see eTPU Channel Interrupt Status Register for Engine 1 (eTPU_GCR_CISR_ENG1)), ETPUCIOSR (see eTPU Channel Interrupt Overflow Status Register for Engine 1 (eTPU_GCR_CIOSR_ENG1)) and ETPUCDTRSR (see eTPU Channel Data Transfer Request Status Register for Engine 1 (eTPU_GCR_CDTRSR_ENG1)). Host must write 1 to clear a status bit.

Address: 0h base + 404h offset + (16d × i), where i=0d to 31d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

eTPU_CCCR_C*n*SCR_ENG1 field descriptions

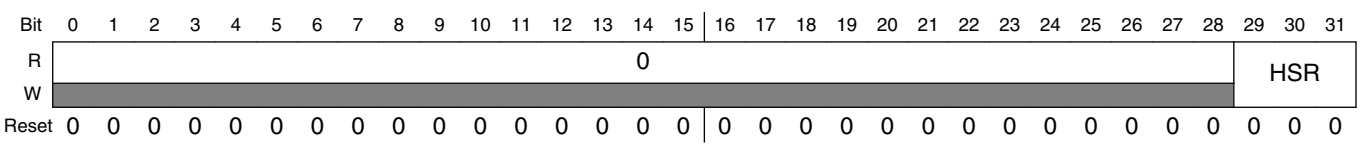
Field	Description
0 CIS	Channel Interrupt Status. These bits are mirrored in ETPUCISR. Also, see the Channel Interrupt and Data Transfer Requests section. When read: 0.....Channel has no pending interrupt to the Host CPU. 1.....Channel has a pending interrupt to the Host CPU. When written: 0.....Keep interrupt status bit unaltered.

Table continues on the next page...

eTPU_CCCR_C*n*SCR_ENG1 field descriptions (continued)

Field	Description
	1.....Clear interrupt status bit.
1 CIOS	Channel Interrupt Overflow Status. These bits are mirrored in eTPU Channel Interrupt Overflow Status Register for Engine 1 (eTPU_GCR_CIOSR_ENG1). Also, see the Interrupt and Data Request Overflow section. When read: 0.....Interrupt overflow negated for this channel. 1.....Interrupt overflow asserted for this channel. When written: 0.....Keep status bit unaltered. 1.....Clear status bit.
2–7 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
8 DTRS	Data Transfer Request Status. These bits are mirrored in eTPU Channel Data Transfer Request Status Register for Engine 1 (eTPU_GCR_CDTRSR_ENG1). Also, see the Channel Interrupt and Data Requests section. When read: 0.....Channel has no pending data transfer request. 1.....Channel has a pending data transfer request. When written: 0.....Keep status bit unaltered. 1.....Clear status bit.
9 DTROS	Data Transfer Request Overflow Status. These bits are mirrored in eTPU Channel Data Transfer Request Overflow Status Register for Engine 1 (eTPU_GCR_CDTROSR_ENG1). Also, see the Interrupt and Data Transfer Request Overflow section. When read: 0.....Data transfer request overflow negated for this channel. 1.....Data transfer request overflow asserted for this channel. When written: 0.....Keep status bit unaltered. 1.....Clear status bit.
10–15 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
16 IPS	Channel Input Pin State. This bit shows the current value of the filtered channel input signal state.
17 OPS	Channel Output Pin State.

Table continues on the next page...



eTPU_CCCR_C*n*SCR_ENG1 field descriptions (continued)

Field	Description
	This bit shows the current value driven in the channel output signal, including the effect of the external output disable feature (see eTPU Channel Output Disable Signals). If the channel input and output signals are connected to the same pad, OPS reflects the value driven to the pad (if OBE=1). This is not necessarily the actual pad value, which drives the value in the bit IPS.
18 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
19–29 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
30–31 FM	Channel Function Mode. Each function uses this field for a specific configuration. These bits can be tested by microengine code (see Conditional/Unconditional Branch). These bits are equivalent to the TPU/TPU2/TPU3 Host Sequence (HSQ) bits.

43.12.3 eTPU Channel n Host Service Request Register for Engine 1 (eTPU_CCCR_C*n*HSRR_ENG1)

ETPUCnHSRR is used by the Host to issue service requests to the channel.

Address: 0h base + 408h offset + (16d × i), where i=0d to 31d

eTPU_CCCR_C*n*HSRR_ENG1 field descriptions

Field	Description
0–28 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
29–31 HSR	Host Service Request This field is used by the Host CPU to request service to the channel (see the Host Service Requests section). HSR value turns to 000 automatically at the end of microengine service for that channel, but only if the thread started due to an HSR. Host should write HSR greater than 0 only when HSR=0. Writing HSR=000 withdraws a pending request if scheduler did not begin to resolve the Entry Point yet, but it does not abort the service thread from that point on. For more details, see the Entry Points and Host Service Requests sections.

Table continues on the next page...

43.13 Shared Subsystem Integration memory map and registers

Shared Subsystems Integration Registers configure aspects of how the shared modules interface with the eTPU. There is one integration register for each subsystem unit, which can be, depending on the specific subsystem, a whole IP module, a sub-module, or a channel within a module. For more details, Shared Subsystems Support.

eTPU_SSIR memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page

eTPU_SSIR_ETPUSSSIR*n* field descriptions

Field	Description
0–23 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
24–25 LENG	Link Engine. LENG specifies the engine that receives a Link Service Request when an interrupt is issued by the Shared Unit, or disables Shared Unit linking. The channel that receives the Link Service Request is specified in the LCHAN field. 00 Shared Unit Link Service Request disabled 01 Engine 1 receives Shared Unit Link Service Request 10 Engine 2 receives Shared Unit Link Service Request 11 Reserved
26 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
27–31 LCHAN	Link Channel. LCHAN specifies the channel linked when an interrupt is issued by the Shared Unit, if enabled in the LENG field. The field is meaningless if LENG disables Shared Unit linking. For more information on Link Service Requests, see Channel Link.

43.14 Functional Description

43.14.1 Functions and Threads

eTPU processing is event-driven, in the sense that eTPU microcode only runs to service a request from an event. Service Requests may result from the occurrence of any of the following events:

- Host CPU writing a non-zero value to the channel HSR (Host Service Request) field in ETPUCxHSR register.
- occurrence of a time base match, an input signal transition, or a specific combination of them (depending on the Channel Mode currently configured).
- a Link Service Request.

A given event is always associated to only one Channel:

- There is one HSR register field for each Channel
- Each signal is associated with only one Channel, which has its own Match registers and independent mode configuration.
- Each Link Service Request can have only one Channel as a target.

Service Request processing is done by a set of microengine routines. A set of related routines that implement a specific channel application is called a **Function** . One or more Functions reside on SCM, limited only by the SCM space available, size of microcode Functions and the number of entry points available. Each Engine can be controlled by up to 32 Functions at a time.

A Function can be assigned to several channels, but only one Function can be assigned to a given Channel at a time. This is defined by the Host through the Channel Configuration Registers (see Channel Configuration and Control registers).

The term **Thread** will be used hereafter to refer to a service routine of a Function, or its execution. A Thread is constructed of a specific number of microinstructions, typically the code necessary to calculate the next phase of waveform to be input to, or output from, a given channel. Once a Thread begins, its execution cannot be interrupted. A Thread normally finishes when an END microinstruction is executed.

A given Thread is selected and called by the Scheduler depending on the following:

- the type of event that generated the service request.
- the Function assigned to the target channel.

- target channel pin state.
- the state of the channel logic.
- the priority assigned to the target channel, relative to the priorities of other channels with pending service requests

The mechanism to select a thread based on the channel Function and type of event is described in the Entry Points.

The priority mechanism that determines the order of Thread execution amongst pending service requests is described in Scheduler.

43.14.1.1 Entry Points

43.14.1.1.1 Entry Table

Each Thread has its **Entry Point**, which contains the SCM address of its first instruction, besides other information. For a complete Entry Point description, see Entry Point Format.

Once the Scheduler chooses a channel among pending Service Requests, the Entry Point is taken from an **Entry Table**, based on the Function assigned for the channel and other conditions. Entry Table layout is shown in the following figure.

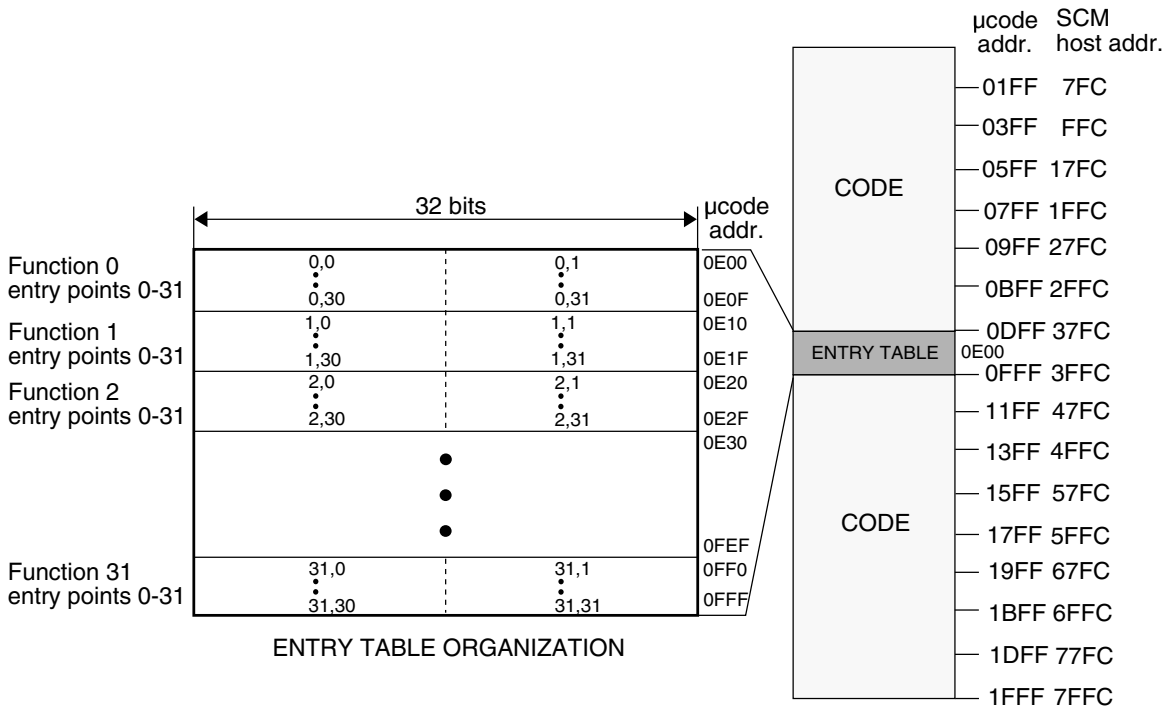

Figure 43-291. Entry Table

The Entry Table is organized by Functions. Each Function can have up to 32 Entry Points of 16 bits each, corresponding to 32 possible Threads per Function. Each Entry Point location in the table corresponds to a combination of events and channel states (see Entry Point Address Generation). A single Thread can be associated to more than one combination, having its Entry Point repeated in the table. Each 32-bit word in the Entry Table holds two Entry Points.

Note that the Entry Table can be placed in any SCM address multiple of the Entry Table size, determined by the field ETB in the register ETPUECR. However, it is recommended to place the Entry Table at the start of the SCM to get continuous code memory and to ease the eventual migration of the code from larger parts down to smaller ones without rearranging the binary image, but this is not a restriction. Unused Entry Points may be used for microcode, so this organization extends the microcode continuous area to the unused area of the Entry Table. For this purpose, Function numbers should be selected from 0 up to 31. If, for example, only 8 functions are implemented, only the Entry Table locations for Functions 0 to 7 are used, and the Entry Table locations for functions 8 to 31 can be used as microinstruction memory (adding extra continuous 1536 bytes for microprogram usage).

One way of implementing different sets of Functions is having more than one Entry Table, and configuring the eTPU with the appropriate one for the application by changing ETPUECR register field ETB. Note that the Engines can use different Entry Tables, with or without the same set of Functions.

43.14.1.1.2 Entry Point Address Generation

The Entry Point address within the Entry Table is determined by the Function assigned to the Channel, the state of the Channel, the type of event, and the condition encoding scheme. Together with the Entry Table base address, they form the Entry Point Address at the SCM, as shown in the following figure.

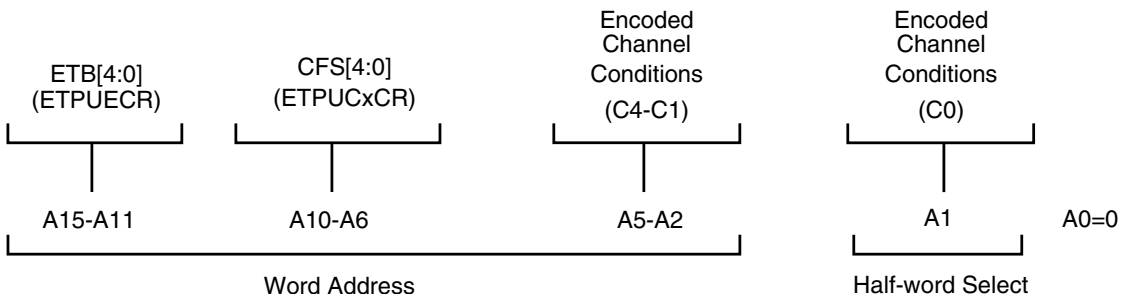

Figure 43-292. Entry Point Address (host address offset)

The type of event and channel state are coded in the Encoded Channel Conditions field C4-C0, according to one of two encoding schemes:

- Standard Entry Table Condition encoding scheme, shown in Table 43-332, which privileges Host Service Requests.
- Alternate Entry Table Condition encoding scheme, shown in Table 43-333, which focus on other events and state decoding.

The events that take part on condition encoding generate a Service Request, and have four origins:

1. Match Recognition (caused by greater/equal match, or equal-only, between the value TCR1/2 and the value stored in the channel match registers). eTPU channels support single and double match in various modes of match recognition; see Match Recognition.
2. Transition Detect Service Request (channel input signal transition detection of a selected edge). The eTPU channels support single and double transition, which together with the double match options provide various modes of transition detection; see Transition Detection and Time Base Capture.
3. Channel Linking Service Request (microcode writing the channel number to the LINK register). Link service request allows one channel to activate another (see Channel Link). Links may also come from Shared Subsystem units (see Shared Subsystems Support").

4. Host Service Request (Host writes a non-zero value to the HSR bits of the channel; see Host Service Requests).

Note

Even if a Transition or Match Service Request is inhibited (by channel mode/state or SRI), the Transition Detection and Match Recognition are taken into account for condition encoding. That is, the MRLA/B and TDLA/B flags are used, not their respective Service Requests.

Columns Host Request Bits, Link Request, MatchA/TransB, and MatchB/TransA determine the type of event. A non-zero value in these columns represents the recognition of the event, while "x" indicates that its recognition is irrelevant. Values 1 and 0 mean that event was recognized or not, respectively. Note that Match and Transition events may occur and not be recognized, and in this case it assumes value 0 for the condition encoding. The recognition of such an occurred event depends on the channel mode assigned and other conditions, as described in Enhanced Channels.

The **Host Service Request Bits** column refers to the value written by the Host CPU to the Host Service Request Register (ETPUCxHSRR) of the Channel being serviced. Note that the bits on this row are coded (3-bit representation). If the value of HSR is not zero, then the Host actually requested service.

The **Link Request** column refers to the occurrence of a Channel Link or SSS Link requests.

The **MatchA/TransB** column refers to the recognition of either a Match event specified by MatchA channel register or the detection of a channel input signal event specified by the IPACB configuration register (see Pin Control Registers).

The **MatchB/TransA** column refers to the recognition of either a Match event specified by MatchB channel register or the detection of a channel input signal event specified by the IPACA configuration register (see Pin Control Registers).

For the channel input signal, MatchA and MatchB provide double timeout conditions which depend on the channel mode programming (see Channel Modes). If the channel is used for output only, there are no transition detections, so the MatchB/TransA column represents only Match B, and MatchA/TransB column the Match A. In this case Match A and Match B are separated to give better state resolution in double match output functions. For more information about channel requests refer to Enhanced Channels.

Besides those events, the following channel state conditions help to determine the Entry Point:

1. Channel Flags 0 and 1: these are channel-internal flags (not in SDM) associated with a channel. Their values are set by microcode (see Channel Flags Operations).
2. Input Pin state or Output Flip Flop: the state (0 or 1) of the channel input signal after the Enhanced Filter (see Enhanced Digital Filter - EDF), or the state driven to the output signal. Which one (input or output) is used is selected by the ETPUCxCR bit ETPD.

The two Entry Table Condition encoding schemes combine events and state conditions differently, as detailed in the following sections.

43.14.1.1.3 Standard Condition Encoding Scheme

In this scheme, shown in the following table, all 7 HSR combinations are used and other event type columns are marked "x" when HSR is non-zero, indicating that Host Service Request has priority over any other type of event. However, when an HSR service thread is called (entry numbers 0 to 9), other events may also have been recognized, and it is microcode responsibility to check them.

When HSR is 0, i.e., Host did not issue a Service Request to the channel, the other event conditions, the input signal state and channel flags determine the Entry Point. Note that channel flag 1 does not influence the encoding in this scheme.

Table 43-332. Standard Channel Condition Encoding Scheme

No.	Encoded Channel Conditions [C4-C0]	Host Service Request Bits	Link Request	MatchA/ TransB	MatchB/ TransA	In/Output Pin State[1]	Channel Flag1	Channel Flag0

		Host Service Request						

1. The ETPUCxCR bit ETPD selects between input and output pin state.

43.14.1.1.4 Alternate Condition Encoding Scheme

This scheme is shown in the following table. Because the HSR bits cannot be tested by microcode, only three distinct Host Service Request can be used:

1. HSR=010 or 011, which are coded into the same Entry Points (0 to 3)
2. HSR=100,101 or 001, which are all coded into Entry Point 4
3. HSR=110 or 111, which are both coded into Entry Point 5

The remaining Entry Points use both channel flags for better state decoding, making this scheme better suited for Functions which need more states and/or faster state decoding, without needing many HSRs.

Table 43-333. Alternate Channel Condition Encoding Scheme

No.	Encoded Channel Conditions [C4-C0]	Host Service Request Bits	Link Request	MatchA/ TransB	MatchB/ TransA	In/Output Pin State[1]	Channel Flag1	Channel Flag0

		Host Service Request						

1. The ETPUCxCR bit ETPD selects between input and output pin state.

43.14.1.1.5 Entry Point Format

Entry Point information includes a Preload-Parameter selection field, a Match Enable field, and the first microcode address of the thread. The Entry Point format is illustrated in the following figure.

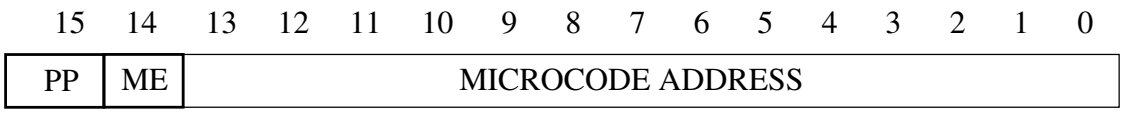

Figure 43-293. Entry Point Format

PP - Preload Parameter

PP indicates which pair of channel parameters are loaded into registers P and DIOB from the SDM prior to the execution of a thread. Preloading occurs during the time-slot transition period (see Time Slot Transition).

1 = microengine register P is preloaded from parameter 2 and DIOB from parameter 3.

0 = microengine register P is preloaded from parameter 0 and DIOB from parameter 1.

The parameter numbers are offsets from the channel parameter base address. For more info, see Parameter Access.

ME - Match Enable

ME specifies whether match event recognitions are enabled or disabled for the thread associated with the entry point during the thread execution. If they are disabled, a match recognition can only occur after channel service. For more details refer to Match Recognition.

1 = Matches are enabled during the thread.

0 = Matches are disabled during the thread.

The disabling of Match A/B recognition by MEF is dependent on IPACA/B configuration on the serviced channel (see Pin Control Registers). If IPACA=1xx, Match A is not disabled by ME=0. Likewise, IPACB=1xx overrides the effect of ME on Match B to "always on" If IPACA/B=0xx, Match A/B is disabled for two microcycles during TST (see Time Slot Transition) and is re-enabled when Entry Point is loaded, if

ME=1. Note that if the comparator is in equal-only mode and the time base reaches the value of the Match register during the time that recognition is disabled (beginning of TST, plus whole thread if ME=0), the match recognition is lost. If the comparator is in greater-equal mode, the match event may be recognized after the disabling period if it satisfies the "greater-than" condition.

MICROCODE ADDRESS - Starting Microcode Address

This field specifies the microcode address on which the thread is to begin execution.

43.14.1.2 Time Slot Transition

The Time Slot Transition period (also called TST for short) is the interval between the servicing of two channels, during which all Channel-specific context is loaded for the new serviced Channel. The primary tasks completed during this period include:

- Set MEF for the TST wait-states, if any.
- Reset MEF for the first two microcycles (after eventual wait-states).

- Update of the CHAN register with the number of the new channel to be serviced.
- Parallel update of ERTA and ERTB from CaptureA and CaptureB registers of the new serviced channel.
- Sampling of the branch conditions of the new channel to be serviced into the branch logic (this means flags TDLA/B, MRLA/B, LSR, FM[1], FM[0], and PSS). The branch conditions are coherent with the timebase capture values sampled into ERTA/B (if MRLA/B, TDLA/B are set at the same time of the sampling, either both old flag state and capture values are sampled, or both new values are sampled).
- Formation of the entry point address.
- Copy the ME bit in the Entry Point into MEF.
- Access to the entry point location and getting the first microinstruction address.
- Preload of two parameters from the SDM into P (32 bits) and DIOB (24 bits).
- Fetch the first instruction of the thread to be executed for the new channel.
- Preset the RAR register value (see RAR Register).

The preload operation is 32-bit wide for P and 24-bit wide for DIOB. The P register is loaded with all the 32-bit parameter. The DIOB register is loaded with the lower 24-bits of the parameter. The microcode can switch at any time to access the lower 24-bits, upper byte, or all the 32-bits of any parameter in the SDM. Preload of P-DIOB pair of parameters is atomic with respect to Host and CDC accesses, and so are coherent with their dual-parameter coherent transfers. For more details see Parameter Sharing and Coherency.

No instructions are executed at the Engine where the time slot transition period occurs, but the other Engine can execute normally. Match A/B is unconditionally disabled on the first two TST microcycles, if IPACA/B=0xx (respectively). During the rest of time slot transition, match recognition can be disabled or not, depending on IPACA/B field and ME. See Match Recognition .

Time Slot Transition takes a minimum of 3 microcycles (6 eTPU clocks), which may be extended due to SDM arbitration wait-states for the first preload access (see SDM Arbitration). When no wait-states are received (Figure 43-294), DIOB is preloaded twice, one for each PP value, and the correct value remains in DIOB when the Entry Point is loaded. Figure 43-295 and Figure 43-296 show the timing for one and two wait-states, respectively.

Registers B, C, D and SR are not altered by TST and keep their values from the previous thread. The values of registers A, MACL and MACH are not guaranteed at the thread start.

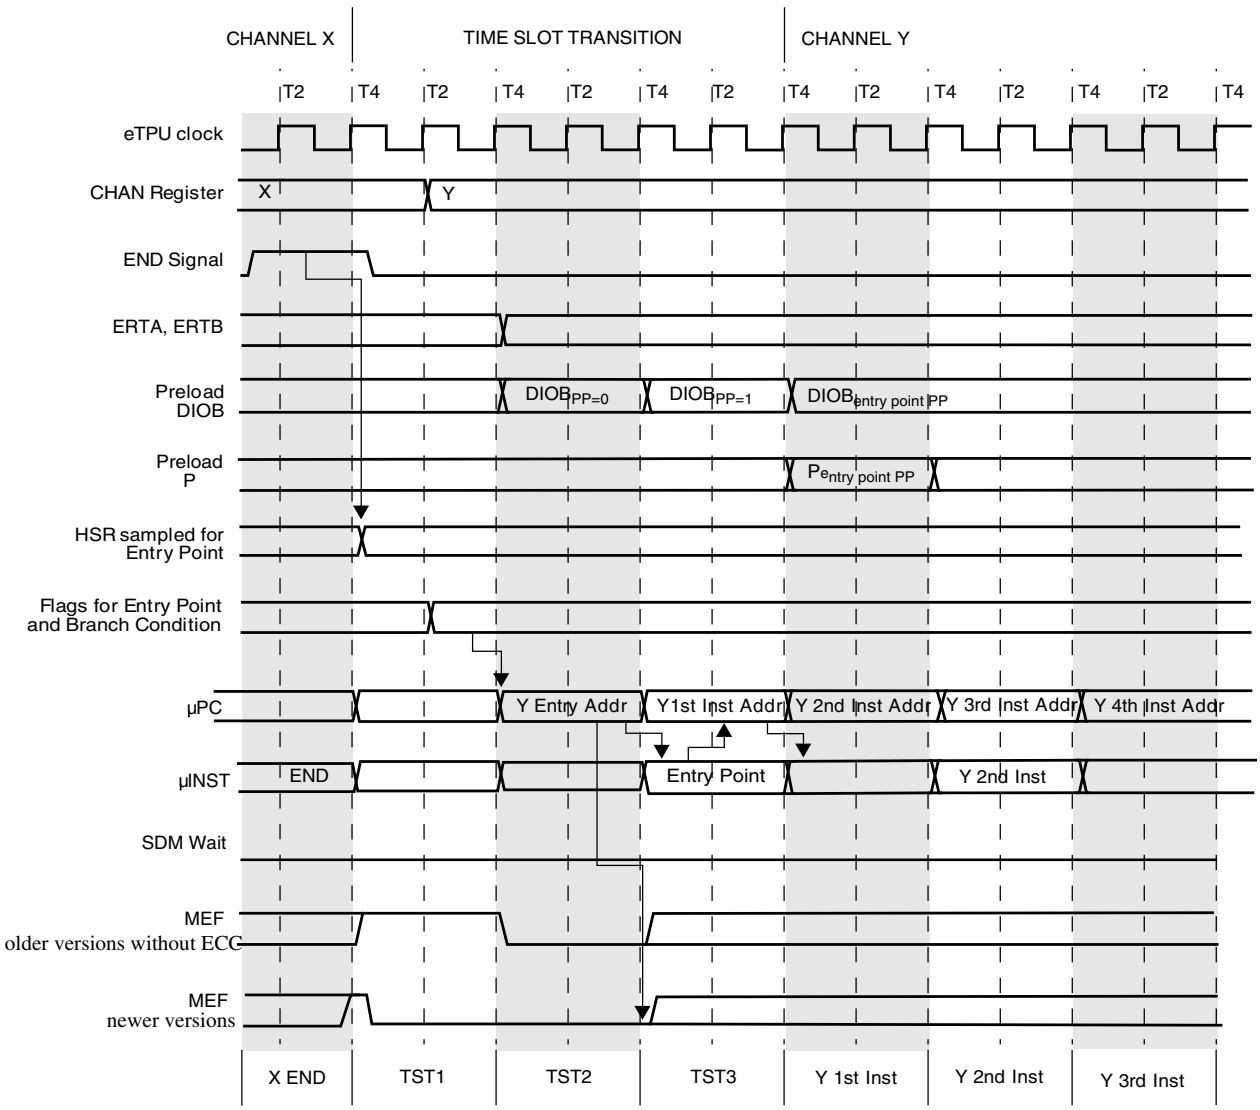

Figure 43-294. TST Timing - No Wait-states

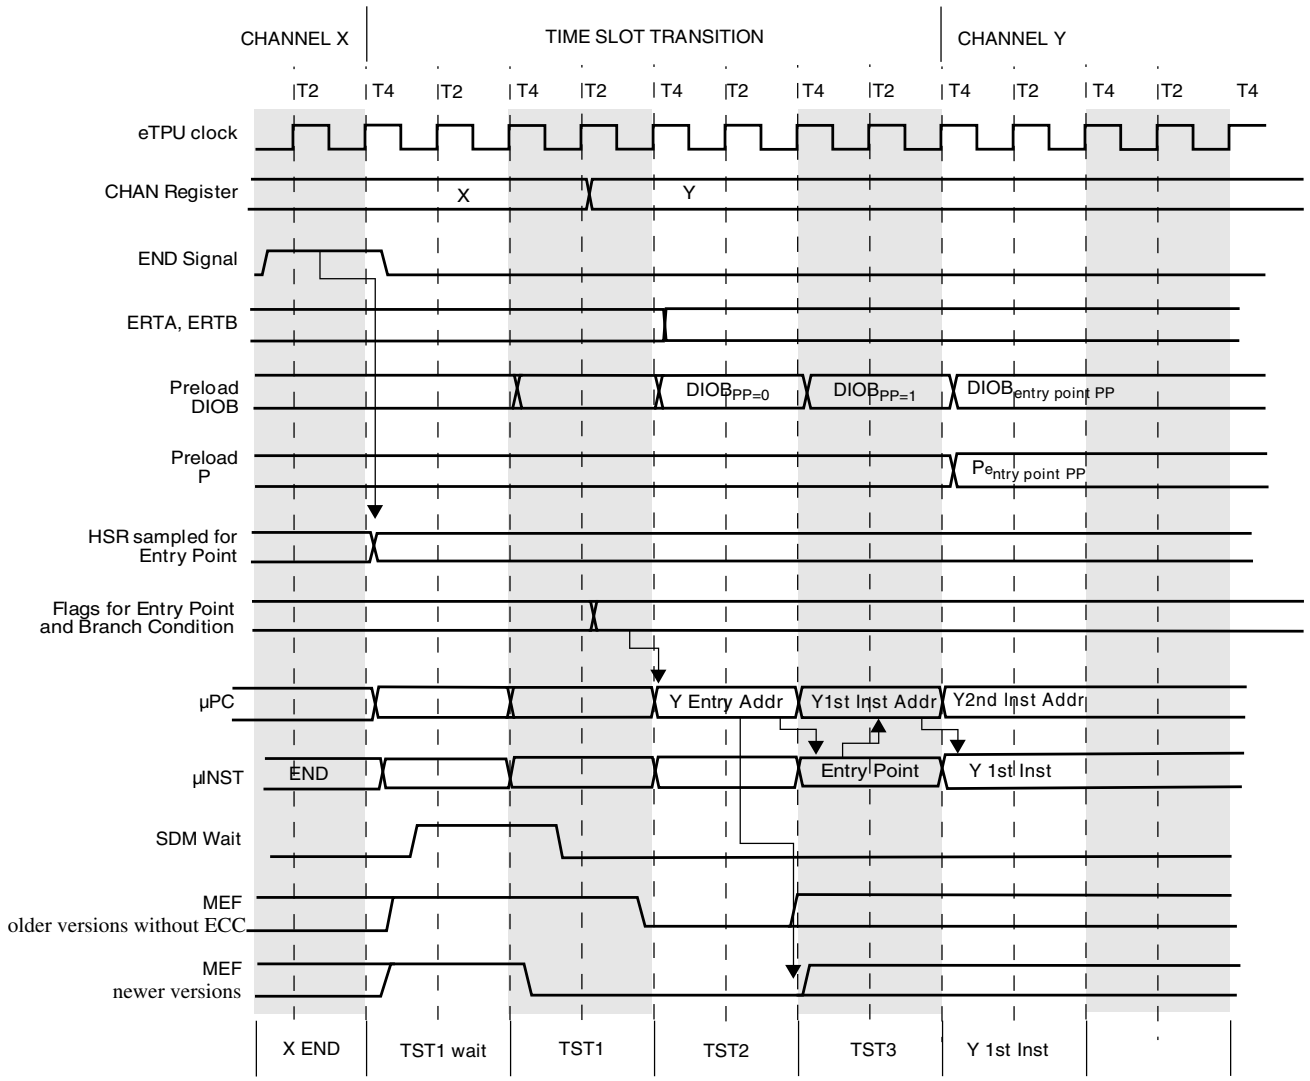

Figure 43-295. TST Timing - 1 Wait-State

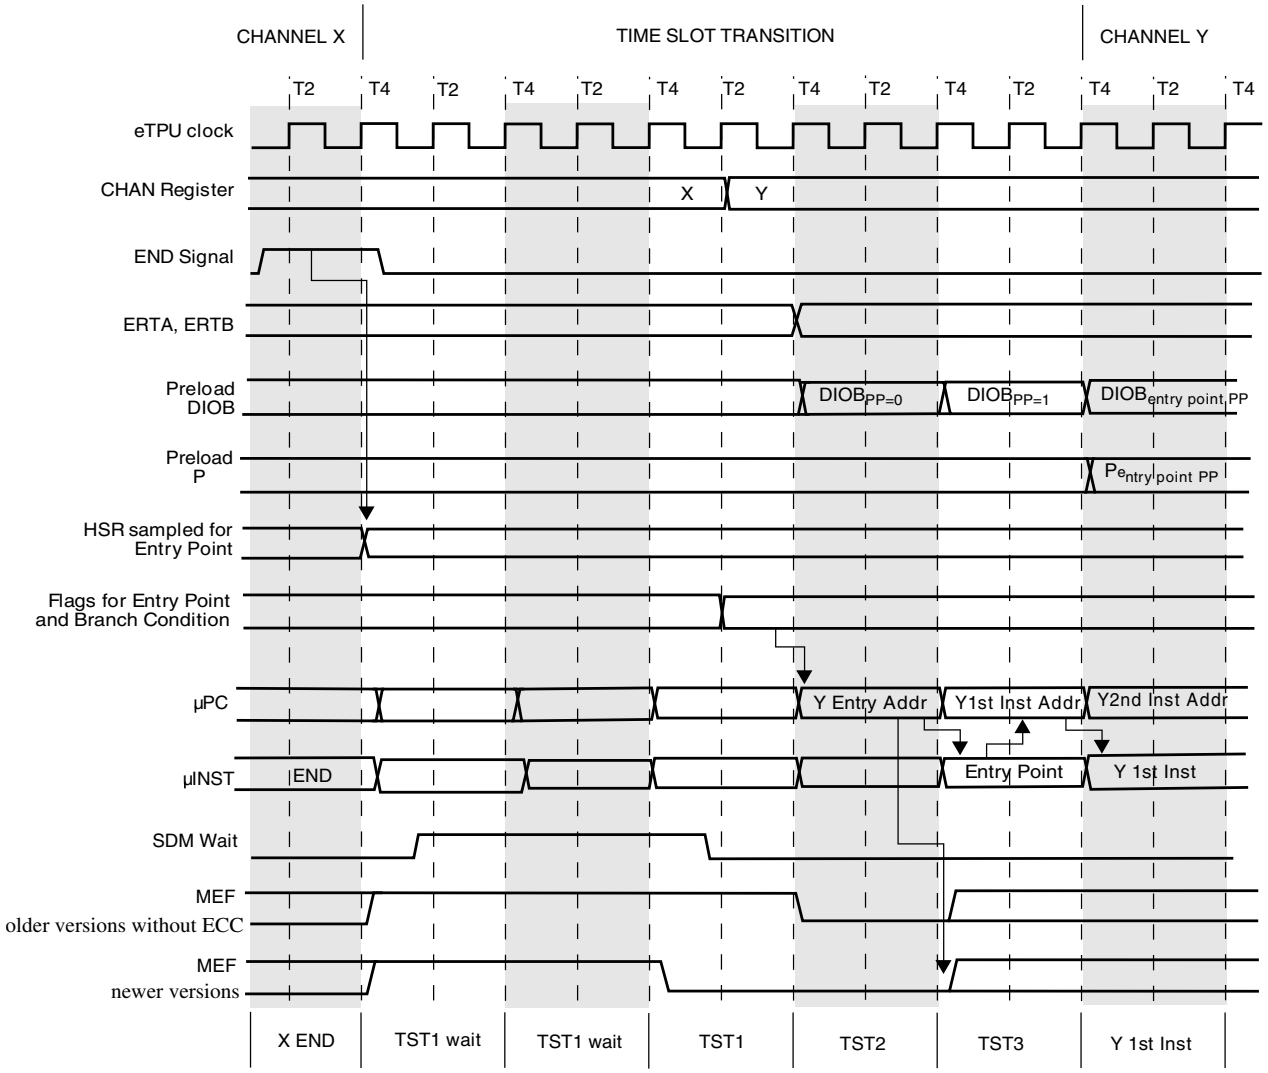

Figure 43-296. TST Timing - 2 Wait-states

For more information on Channel-specific registers and flags, refer to Enhanced Channels. For more information on P, ERTA/B and DIOB registers refer to Registers.

43.14.1.2.1 Thread Gap

The MEF timing has changed from previous eTPU/eTPU2 versions, now being reset for two microcycles from the start of TST. Therefore, two consecutive threads with ME=0 serving the same channel could block any match until the end of the second thread (see Figure 43-294). This could cause latency problems and also break compatibility with legacy code, so the thread transition logic was modified to introduce a one-microcycle gap between consecutive threads servicing the same channel, as shown in the following figure. During the gap MEF is set to one, regardless of the previous or the next entry point ME field. The thread gap is inserted only between threads serving the same channel.

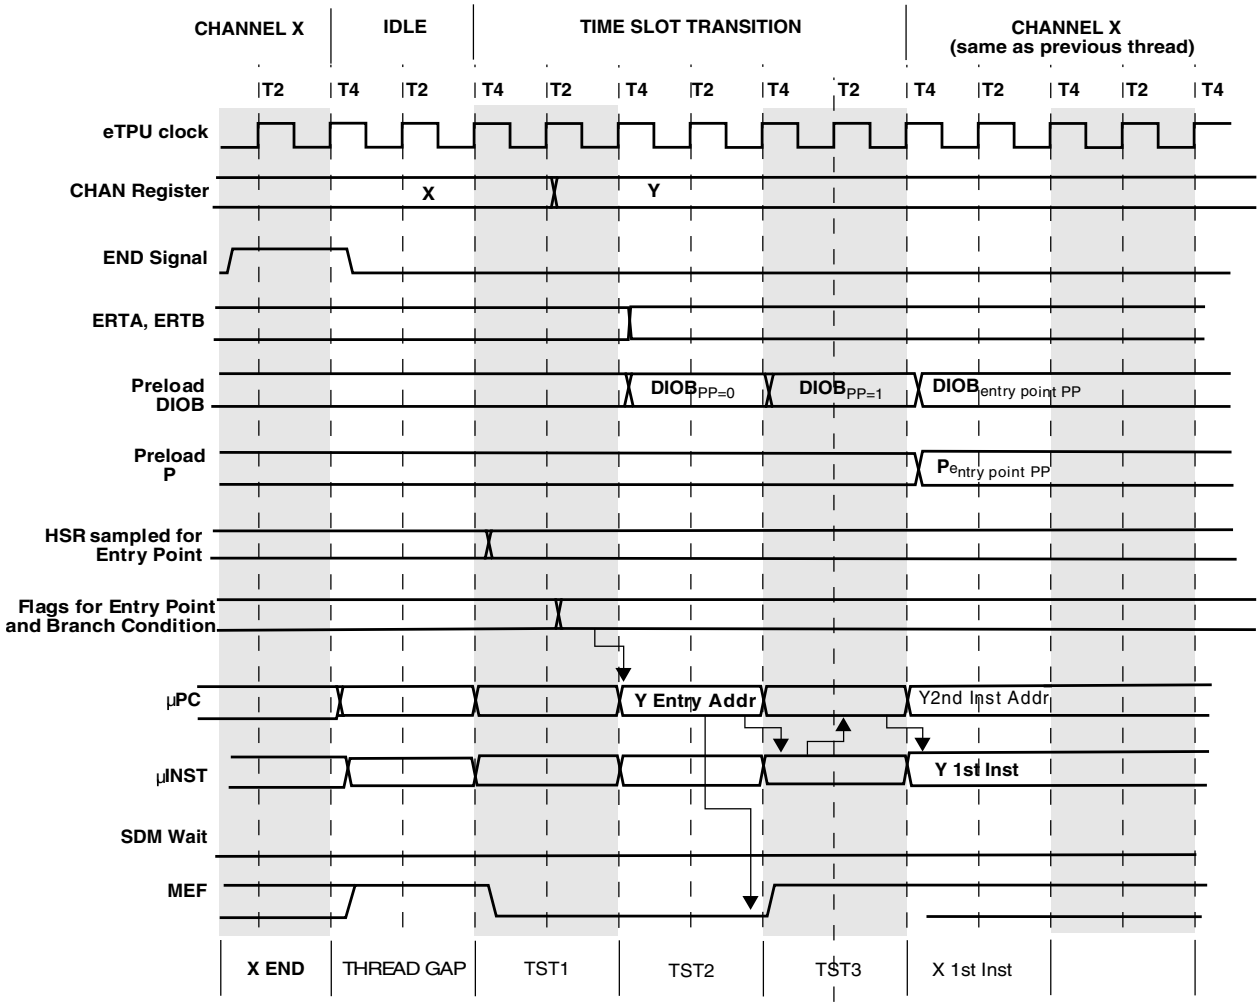

Figure 43-297. Thread Gap

43.14.1.3 Thread Ending

Threads can finish by either:

- an instruction with the END field active (see Ending Current Thread - END).
- a forced END by host writing to the ETPUECR bit FEND (see ETPUECR register).
- a forced END caused by Watchdog timeout (see Watchdog).
- a forced END caused by a non-correctable memory error (see Memory Error Support).

43.14.1.4 Watchdog

Each engine has a watchdog mechanism to prevent a thread or a sequence of threads from running too long, impacting the latency of the other channel services. The watchdog is configured through the register ETPUWDTR (see ETPUWDTR register). When the watchdog is enabled, an internal counter increments on each microcycle when a thread is executing. If the count is greater than the value specified in the ETPUWDTR field WDCNT and a thread is still executing, the watchdog:

1. if ETPUWDTR bit WMO is negated, forces an END of the thread, allowing other channels to be serviced
2. sets the WDS status bit of the serviced channel in the ETPUWDSR register (see ETPUWDSR register).
3. if ETPUWDTR bit WMO is negated, the channel is disabled, not initiating any thread until its WDS bit is cleared (its CPR field in ETPUCxCR is not changed, however).
4. issues a Global Exception and sets the ETPUMCR bit WDTO1 (engine 1) or WDTO2 (engine 2) (see ETPUMCR register, regardless of the WMO bit state.

If ETPUWDTR bit WMO is asserted, the watchdog can be used to monitor the execution time threshold of a thread or thread sequence without interfering with the eTPU code execution.

The watchdog can be configured in one of the following modes, defining how the internal watchdog count is reset:

- **Thread Length Mode**: the watchdog count is reset at the end of each thread.
- **Busy Length Mode**: the watchdog count is reset when the microengine goes idle. A sequence of threads, one right after another, keeps the count running. The counter is also reinitialized when a thread is forced to end, so that a new count begins if another TST initiates at the following microcycle.

The following applies to the watchdog mechanism:

- microcycles during TST and SDM access wait-states (on TST or instruction execution) are counted.
- if the watchdog count equals WDCNT in the last microinstruction (with SDM wait-states or not) of a thread servicing a channel, its WDS bit is not set.

- if the watchdog count expires (gets greater than WDCNT) during the TST, the thread is forced end on its first instruction.
- the watchdog count does not wrap, so that a thread (in thread length mode) or a thread sequence (in busy length mode) that lasts for more than the maximum value of WDCNT does get a forced end.

Note

Watchdog must not be enabled when the microengine enters halt mode.

The counter does not run when the engine is stopped, and resets when the watchdog is disabled.

43.14.2 Host Interface

43.14.2.1 System Configuration

System Configuration Registers are described in the System Configuration Registers section. Detailed explanation of the configured functionalities is found throughout Functional Description and a specification for the initial configuration sequence is found in Configuration Sequence.

43.14.2.2 Interrupts and Data Transfer Requests

43.14.2.2.1 Interrupt Types and Sources

Each one of the eTPU channels can be a source of two requests: **Channel Interrupt** request and **Data Transfer Request**.Channel Interrupts are targeted to a Host CPU. Data Transfer Requests may be targeted to a data transfer module (e.g., a DMA controller). Interrupt and Data Transfer registers are used by the Host to enable interrupts and data transfer requests, indicate their status and service them. Interrupt and Data Transfer requests have the same sets of registers and external signals, and are handled in the same way. They differ only by the fact that Data Transfer Requests are also cleared by the assertion of respective DMA completion acknowledge line .

Note

Interrupt and Data Transfer requests can be cleared even when Engines are in Module Disable Mode, through the Global Channel Registers, and also DMA completion for Data Transfer requests.

Channel Interrupts and Data Transfer Requests can only be issued by eTPU microcode, through one of the Channel Control instruction fields (see Channel Interrupt and Data Transfer Requests).

Both Channel Interrupt and Data Transfer requests can be individually enabled for each channel.

eTPU Interrupt and Data Transfer Registers are mirrored in two organizations: grouped by Channel and grouped by type (interrupt status, interrupt enable, data transfer status, data transfer enable). This allows either "channel-oriented" or "bundled channel" Host interrupt service schemes, or a combination of them. For a detailed description, refer to the Channel Register Layout and Global Channel Registers sections.

eTPU can also assert a **Global Exception** interrupt indicating a global illegal state. There are six possible sources for a Global Exception:

- Execution of an illegal instruction by the microengine (see Illegal Instructions). This Global Exception source is flagged by the bits ILF1 and ILF2 in register ETPUMCR.
- An SCM signature mismatch detected by the Multiple Input Signature Calculator - MISC. See SCM Test - Multiple Input Signature Calculator. This source is flagged by the bit SCMMISF in register ETPUMCR.
- Microcode request, through microinstruction field CIRC (see Channel Interrupt and Data Transfer Requests). This Global Exception source is flagged by bits MGE1(Engine 1) and MGE2(Engine 2) in register ETPUMCR. The cause of this illegal state is application-dependent. The microcode may write an error code into the SDM to indicate the cause of the exception, for instance.
- A Watchdog timeout, flagged by the ETPUMCR bits WDTO1 and WDTO2 (see Watchdog).
- An SDM or SCM non-correctable error on a microengine or host access, flagged by the ETPUMCR bits SDMERR and SCMERR, respectively (see Memory Error Support).
- The latency measured by any of either engine's Latency Monitors is greater than the specified maximum, flagged by ETPUMCR bits LTO1 (Engine 1) and LTO2 (Engine 2) (see Latency Monitor).

Global Exceptions cannot be directly disabled within eTPU, except by disabling its sources (Memory Error, SSS, MISC and microcode), and it is cleared by writing 1 to the GEC bit in ETPUMCR. Clearing Global Exception clears all Global Exception source status bits (ILF1, ILF2, SCMMISF, MGE1, MGE2, SCMERR, SDMERR). If GEC is written 1 at the same time any of the sources issues a Global Exception, both the interrupt and the status bit of that source remains asserted. The assertion of Global Exception by one of the sources above does not prevent the others from asserting it too, so any number of them, in any combination, can be flagged.

Note

There can be a race between the clear of a Global Exception and occurrence of a new set condition, such that the set happens just before the clear and cannot be sensed by the Host. Therefore, Global Exception cannot be used as a normal interrupt source. It should only be used for emergency procedures.

Memory Error Correction support (see Memory Error Support) has a distinct interrupt source, which can activate on any correctable error occurrence, either to SCM or SDM accesses, but does not activate on non-correctable errors (which assert Global Exception instead). Memory Error Correction interrupt assert when it is enabled through the ETPUMECR bit MECIE (see the ETPUMESR register) and either ETPUMESR bit DCERR or bit CCERR is asserted. The interrupt is negated when both DCERR and CCERR are negated, or MECIE is negated.

43.14.2.2.2 Interrupt and Data Transfer Request Overflow

If a Channel Interrupt was issued, its status bit is still set, and microcode issues another Channel Interrupt, the Interrupt Overflow status bit is set for that channel. Interrupt Overflow status can be checked by the Host in Channel Status register ETPUCxSCR bit CIOS (see the ETPUCnSCR register), mirrored in the ETPUCIOSR register. Interrupt Overflow status is not cleared automatically when Interrupt Status is cleared. The same mechanism and respective registers (ETPUCDTROSR) are available for Data Transfer Requests.

If interrupt is set and cleared at the same time, set prevails and overflow is not altered (keeps the same state as it was before, asserted or not).

Global Exception has no overflow status.

43.14.2.3 Parameter Access

43.14.2.3.1 Parameter Access Widths

From the Host side the SDM address space is mapped in bytes, and each 32-bit parameter occupies 4 contiguous, aligned bytes. The Host can read/write the SDM by 8-, 16-, or 32-bit accesses in aligned addresses.

In 32-bit access, Host can access all 32 bits or only the lower 24 bits with an automatic sign extension (see Parameter Sign Extension Area).

43.14.2.3.2 Parameter Addresses and Endianness

To access parameter number xxx, eTPU Microengine(s) would select address xxx. The Host would add *(xxx*4)* to the SDM base address to access the same parameter. For example, parameter 0x101 is seen by the Host in *(SDM base address +0x404)* . An example of SDM memory map is shown in Figure 43-298 . The Host can access the SDM with a 32-bit-wide bus cycle to a four-byte aligned address, 16-bit-wide bus cycle to a two-byte aligned address, or 8-bit wide bus cycle to any byte address.

The address of the 24-bit parameters and the most significant byte depends on the endianness of the MCU. For more details, see the Endianness.

43.14.2.3.3 Parameter Concurrency

Host accesses to parameters may occur in parallel with eTPU Microengine accesses. Readings taken from a group of parameters while they are being simultaneously updated may lack coherency. eTPU provides mechanisms to ensure parameter coherency in accesses from both Host side and Microengine side, including the use of a coherent dual-parameter transfer mechanism, described in detail on Parameter Sharing and Coherency.

43.14.2.3.4 Parameter Sign Extension Area

The SDM address space to the Host is mirrored in a Parameter Sign Extension - PSE - area (see Registers Memory Map). Accesses from the Host to the PSE area differ from accesses to the standard SDM address space as follows:

- **Writes**: the most significant byte of the parameters is not written, and the SDM retains the old byte value, regardless of the Host access size.
- **Reads**: the most significant bit of the 24-bit parameter (that is, the MSB of the second most significant 32-bit parameter byte) is repeated in the 8 most significant bits of the read value on all 32-bit reads and most significant 16- and 8-bit reads.

The same parameters written in the standard SDM address space are read from the PSE area with the same offsets, and vice-versa. See Table 43-426 for a reference of the address offsets in big and little endian machines.

This feature reliefs the Host from extending the signal of 24-bit eTPU parameters before calculations, and from read-modify-write accesses to modify 24-bit parameters at the SDM.

43.14.2.4 SDM Organization

The SDM internal partition for channel allocation is dynamic and programmed in the Channel Registers (see the ETPUCnCR register).

The Host application is responsible for allocating a different parameter base address to each channel during the initial eTPU configuration, and to allocate enough parameters for the selected Function, with no unintentional overlapping between parameters of different functions.

Besides channel parameters, global areas may have to be allocated for parameters that are shared by more than one channel, in one or both Engines. Also, temporary parameter areas should be reserved to be used by the coherent parameter transfer mechanisms described in Parameter Sharing and Coherency, if necessary. An SDM organization example is shown in the following figure.

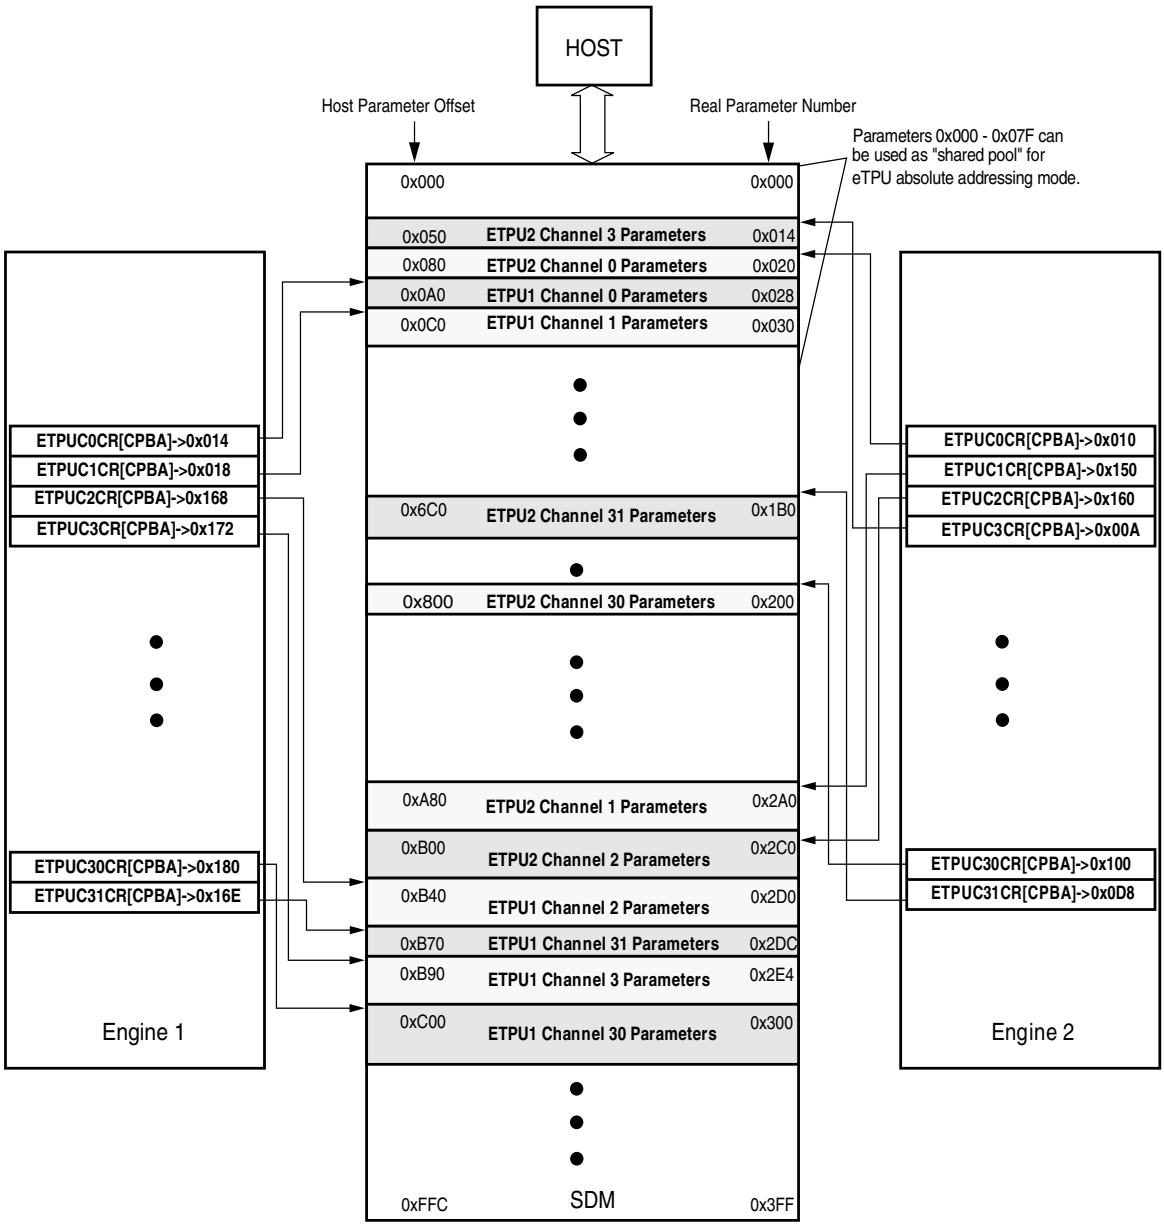

Figure 43-298. SDM Organization Example (4 KB)

Single-engine eTPU or dual eTPU system may require less parameters than the maximum number provided by the SDM. Since the SDM partition is fully dynamic, there is no limitation of fixed channel addresses, and the reduced array can be fully utilized.

43.14.2.5 Host Service Requests

Host CPU can request immediate service from a channel by writing a non-zero value to the Host Service Request register field - HSR (see the ETPUCnHSRR register). There is one HSR field for each channel, so that writing to it generates a Service Request to the respective channel only. A zero value in HSR means no Host Service Request is pending for the channel.

HSR value turns to 000 automatically at the end of microengine service for that channel, but only if the thread started due to an HSR.

The meaning of a non-zero HSR value depends on the Function assigned for the channel. These bits are part of the conditions which select the Function entry point, and cannot be tested by microcode. For more details, refer to Entry Points.

If Host writes HSR=000 when a thread for the same channel is already running, the thread runs until the end and is not aborted. If Host writes HSR>000 when an HSR thread for the same channel is already running, HSR value resets at the end of the thread, and no new HSR will be pending. If HSR is written before its value is resolved by the scheduler during TST, the entry point will obey the new HSR value, and if this new value is 000, no service thread is executed for the HSR.

The scheduling of HSRs is completely asynchronous with Host accesses, and there is no race-free manner to change an HSR value before service thread execution, so generally the safe way is: write HSR>0 only when HSR=0. Error recovery or emergency host procedures may require one to the safely abort service and reset channel state when an HSR is already pending or executing. In these cases, the procedure below should be followed:

1. Disable the channel, writing CPR=00 in register ETPUCxCR. That will prevent any pending HSR to be serviced.
2. Check if the channel is currently being serviced, reading its service status bit in register ETPUCSSR. If it is, wait for the time necessary to finish the service pending, or check again until HSR == 0, or channel service bit in ETPUCSSR is cleared.
3. Write HSR with the error recover value. This value should, possibly combined with other host-defined flags in SDM or FM bits, initiate a channel reset or error recovery procedure.
4. Re-enable the channel, writing CPR value > 0 in register ETPUCxCR.

43.14.2.6 SCM access

Only Host can access SCM as data. Depending on the specific device, SCM may be implemented as a RAM or ROM. This determines Host accesses to the SCM as shown below.

43.14.2.6.1 SCM RAM Implementations

When SCM is implemented as RAM, the Host may read or write to SCM by setting ETPUMCR bit VIS=1. If VIS=0 and Host tries to access SCM space, a bus error is issued, writes are ineffective and read data is meaningless. Both Engines must be stopped or halted to set VIS=1.

Note

It is necessary to turn VIS bit on to set software breakpoints (see Software Breakpoints).

43.14.2.6.2 SCM Low Power

SCM turns off its internal clocks when both Engines are stopped (ETPUECR bit STF asserted), VIS=0 at ETPUMCR, and MISC is not enabled

(SCMMISEN=0). The SCM clocks are automatically turned on if either one of the STF bits is negated or VIS turns to 1, or SCMMISEN turns to 1.

SCM clocks are not turned off if any of the Engines is not stopped, even if they are both halted.

The conditions for SCM Clocks and MISC activation are summarized in the following table.

Table 43-334. SCM Clocks and MISC activation

ETPUECR_1 STF	ETPUECR_2 STF	ETPUMCR VIS	ETPUMCR SCMMISEN	SCM Clocks	MISC
0	x	0[1, 1]	1	On	On
0	x	0[1]	0	On	off
x	0	0[1]	1	On	On
x	0	0[1]	0	On	off
1	1	0	0	off	off
1	1	0	1	On	On
1[2, 2]	1[2]	1	0	On	off
1[2]	1[2]	1	1	On	off[3]
0	0	x	0	On	off
0	0	x	1	On	On

1. VIS cannot be written 1 if ETPUECR_1 bit STF=0 or ETPUECR_2 bit STF=0, and both HLTF bits are 0.
2. If VIS=1, neither MDIS can be written 0 nor the Engine leaves Stop Mode, regardless of device stop request .
3. MISC resets and stays so when VIS=1, restarting automatically when VIS goes 0 if SCMMISEN=1.

43.14.2.6.3 SCM Off-range Data

When read accesses are made, either by the Host or by a microengine, to addresses above the limit corresponding to the SCMSIZE value in ETPUMCR, the value read comes from the register ETPUSCMOFFDATAR. The Host can program the register at initialization with an opcode value with operations that try to protect or recover the system from runaway code, for instance: terminate the thread, clear channel flags, disable match and transition service requests, issue an interrupt, jump to an error recovery procedure[11] . Writes to unimplemented addresses do not return error and can write on unspecified mirror addresses, so they should be avoided.

43.14.2.7 Bus Error Conditions

Follows a summary of the possible causes of bus errors on host accesses to the eTPU memory space:

- read or write access to the SCM with ETPUMCR bit VIS=0.
- read or write access to the channel registers with ETPUECR bits MDIS=1, or bit STF=1.
- write access to the Time Base Registers with ETPUECR bits MDIS=1, or bit STF=1.
- non-correctable errors in the SCM on reads of any size or writes less than 32-bits wide when ETPUMECR bit CEDD=0.
- non-correctable errors in the SDM on reads when ETPUMECR bit DEDD=0.
- accesses to the Shared Subsystem Area, when propagating a bus error issued by the attached subsystem.

11. Only part of these suggested operations can be parallelized in a single instruction, see Microinstruction formats.

43.14.3 Scheduler

Every Function is composed of one or more Threads. A Thread consists of a group of instructions that, once begins execution, cannot be interrupted by host or channel events. Each active channel intents to be serviced, being granted time for Thread execution. Since one microengine handles several channels operating concurrently, the Function threads must be executed serially.

The task of the Scheduler is to recognize and prioritize the channels needing service and to grant execution time to each channel. The time given to an individual Thread for execution or service is called a **Time Slot** . The duration of a time slot is determined by the number of instructions executed in the Thread plus SDM wait-states received, and varies in length.

At any time, an arbitrary number of channels can require service. To request service, channel logic, eTPU microcode or Host application notifies the Scheduler by issuing a Service Request.

43.14.3.1 Channel Enabling and Priority Assignment

Every channel is assigned one of three priority levels - high, middle, or low - by the Host CPU, through the Channel Configuration Register field CPR (see the ETPUCnCR register). These registers are also used to disable the channel, which is equivalent to assigning it a "null" priority. In this case, the Scheduler does not grant any of its Service Requests.

It is possible to change the channel priority level or disable it dynamically. If the Host disables a channel when it is currently being serviced, channel service thread will complete. This means that it is possible for the output level of a channel signal to change, or a Host interrupt occur, even after its priority register was written to "null". For instance, if an output transition is scheduled, the transition will occur even after the channel is disabled.

Service requests previously pending or that occur while a channel is disabled remain asserted while the channel is disabled, and are serviced if the channel is enabled again, in due time determined by the priority scheme and concurrent requests from other channels. Channels are disabled after reset, and it is recommended to configure a Host Service Request for initialization of a channel before that channel is enabled to active priority (see Initialization/Application Information).

43.14.3.2 Channel Priority Schemes

The Scheduler holds a Service Grant register with one bit for each channel. Once the Scheduler grants a time slot to channel, the Service Grant bit for that channel is asserted in the Service Grant register. When the Service Grant bit of a channel is set, the channel may request new service but is not serviced again before its Service Grant bit is cleared.

When all channels in a same priority level are serviced, their Service Grant bits are cleared at the end of the thread, one eTPU clock before the next serviced channel is calculated, according to the scheme below[12] :

- Clear all grant bits of priority High if all channels of that priority that are requesting have their grant bits in 1.
- Clear all grant bits of priority Medium if all channels of that priority that are requesting have their grant bits in 1.
- Clear all grant bits of priority Low if all channels of that priority that are requesting have their grant bits in 1.
- Clear all grant bits of disabled channels.

This scheme assures that no channel is left with its grant bit forever asserted (preventing it from being serviced again), even if the channel priorities are reassigned during the execution.

Priority level is determined based on the maximum latency desired for each channel. A channel having a Function that requires the most frequent or more immediate service should be allocated a high priority level.

The eTPU employs a **primary** and a **secondary priority scheme**. These two schemes ensure frequent servicing of high-demand Functions and ensure a minimum time allocation to all channels requesting service, regardless of their priority level. The primary scheme prioritizes requesting channels that have different priority levels; the secondary scheme prioritizes requesting channels that have the same priority level.

Initially, a channel requests service and is granted a time slot by the Scheduler: Service Grant bit is asserted. If only high-level channels constantly receive service first because of their priority level, middle- and low-level channels would only be serviced by default, i.e., if no high-level channels request service. To ensure that each priority level receives an opportunity for servicing, every time slot has a fixed priority level that the Scheduler honors first. Divided into sets of seven, time slots are numbered from one to seven. The figure below illustrates the numbered time slots in sets of seven (fields A and B) and

12. grant bits are also cleared in the next clock, when the service channel is chosen, or when the microengine is idle, using the same scheme.

identifies their assigned default priority level. The high level has more time slots than the middle and low levels. Out of every seven time slots available, four are assigned to honor high-level channels first, two are assigned to honor middle-level channels first, and one is assigned to honor low-level channels first. Only one request (in each Engine) is serviced per time slot. When no channel requests service and the microengine is idle the priority scheme is initialized to time slot one, to prevent priority inversion on the next request[13].

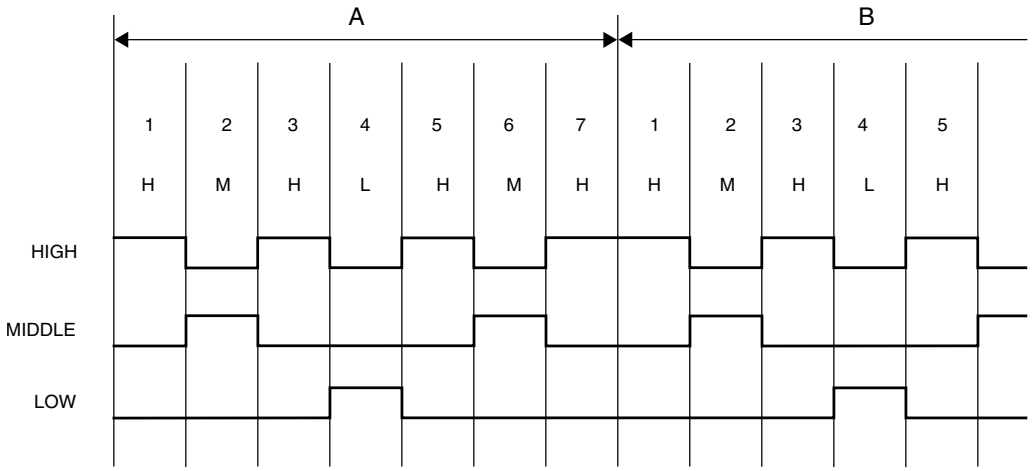

Figure 43-299. Time Slot Priority levels

43.14.3.2.1 Primary Scheme - Priority Among Channels on Different Levels

Although time slot priority assignment is fixed, the servicing priority is not. The primary scheme acknowledges the priority level assigned to a time slot, granting service first to a channel having the same priority. In Channel Priority Schemes, time slot one has a high-level assignment; therefore, a high-level channel requesting service is recognized first. However, if no high-level channel requests service, the Scheduler recognizes a requesting middle-level channel. If this level has no request, the Scheduler continues to the low-level. If no requests occur, the Scheduler truncates the seven state cycle and starts a new cycle at time slot one, waiting for the first request. Granting service to a different-level channel is called priority passing. The order of passing always gives the highest priority to the assigned level, and the second priority to the higher of the remaining requesting priority levels as shown in the following table.

13. Priority inversion would occur in the following situation: no channel is requesting service, and the current time slot is primarily assigned to a low-priority channel. If the Scheduler was not reset to time slot one and two channels requested service at the same time, one with high priority and the other with low priority, the channel to be serviced would be the low-priority channel.

Table 43-335. Priority Passing

Assigned Priority Level	Next Priority Level	Next Priority Level
High	Middle	Low
Middle	High	Low
Low	High	Middle

When priority is passed to another level, that level is serviced and the fixed-priority-level sequence is resumed with the next time slot.

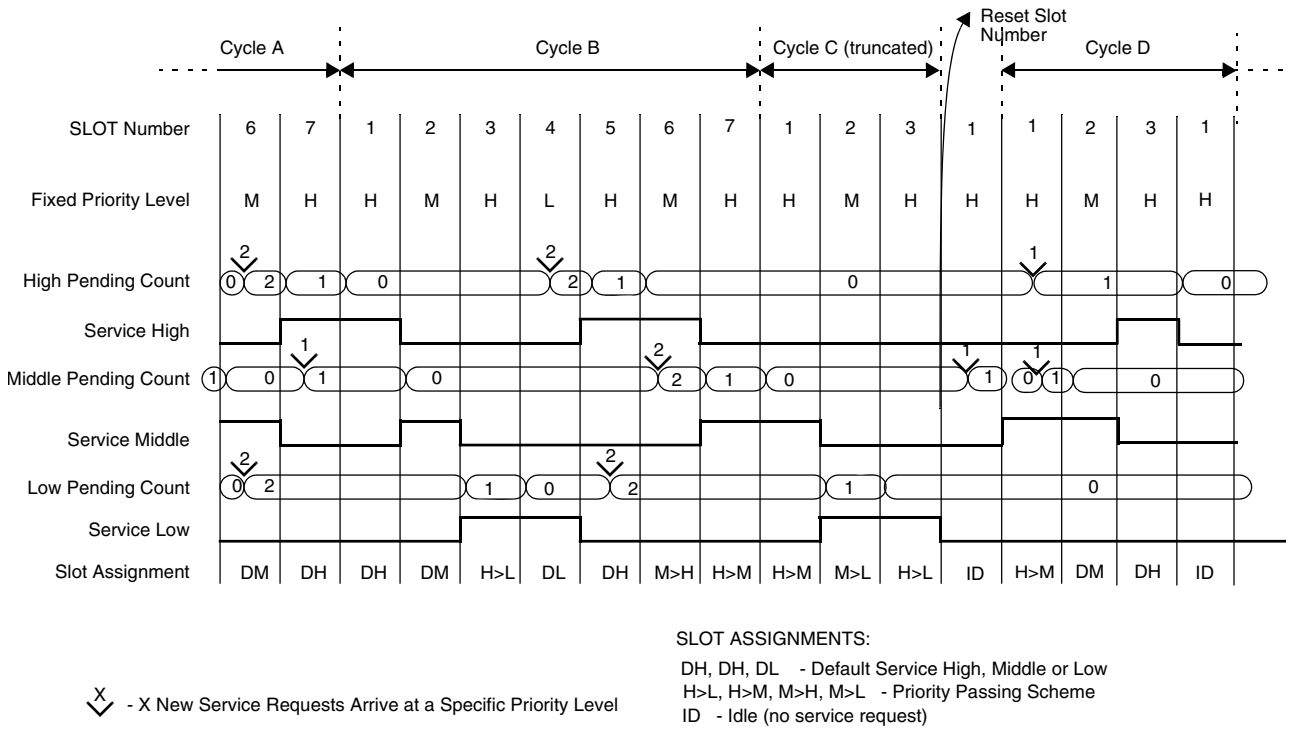

Figure 43-300. Priority Passing Example

Examples of priority passing are shown in the above figure. Each cycle contains seven time slots (or less if no service request exist). In cycle B, no high-level or middle-level service requests are present before time slot three which is assigned by default to high-level priority. Thus, time slot three is passed to the low level. In cycle B there are also no middle-level service requests before time slot six, so it passes the priority to a requesting high-level channel. During time slot six no more high level requests are left, but two new middle-level requests arrive, and there are also three low level pending service requests. Thus, time slot seven of cycle B and time slot one of cycle C are passed to the middle-level which is the next priority level after high. Time slots two and three of cycle C are passed to the low level which contains the three remaining channel service requests. At time slot three of cycle C the last low level request is serviced, and the Scheduler passes to idle state. At this point the cycle C is truncated and the Scheduler passes to time slot one of cycle D.

43.14.3.2.2 Priority Passing Disabling

The priority passing scheme allows a case where a high priority channel looses to a lower priority one right after another lower priority has been serviced, exemplified in the Cycle D on Figure 43-300. A middle priority channel wins time slot 1 due to priority passing from high to middle. While it is being serviced, two new service requests arrive, one high and one middle priority. The high priority request looses to the middle one on next time slot 2 by default priority assignment.

This priority inversion can be avoided by setting the ETPUECR register bit SPPDIS (see the ETPUECR register), which disables the priority passing mechanism. When priority passing is disabled, at the end of the thread the slot number is incremented until a time slot that matches the priority of one of the requesting channel(s). The time slot advance takes no extra clocks. If no channel requests service, the time slot counter stays at time slot 1. The priority selection scheme with disabled priority passing is summarized in the following table.

Table 43-336. Priority Passing Disabling

At the endof time slot	servici ng priority	if any request of priority	service it on time slot	else if any request of priority	service it on time slot	else if any request of priority	service it on time slot
1	High	Medium	2	High	3	Low	4
2	Medium	High	3	Low	4	Medium	6
3	High	Low	4	High	5	Medium	6
4	Low	High	5	Medium	6	Low	4
5	High	Medium	6	High	7	Low	4
6	Medium	High	7	Medium	2	Low	4
7	High	High	1	Medium	2	Low	4

An example of the priority passing disabling scheme is illustrated in the figure below. The sequence of service requests is the same as in the example of Figure 43-300, and although the time slot incrementing differs, the priorities granted are the same for cycle B. Cycle C has one of the low priority channels serviced before the second middle one. Cycle D, however, no longer has the priority inversion.

In cycle B, after the time slot 2 only a low priority request remains, so the time slot count advances directly to 4, which has a low priority assigned. Time slot keeps on 4 for the next service, as only a low priority request remains also, and only time slot 4 is assigned to low. Two high priority services contend for the next time slot 5 (assigned to High). The second high priority channel is serviced on the next time slot, jumped to 7 because there is no middle request, ending cycle B. Cycle C starts with time slot 2, as there are no high priority requests and two middle and two low ones. After the first middle service,

time slot count skips 3 assigned to high (no high requests), and services a low priority channel on time slot 4. It follows the same scheme until there are no other requests and cycle C is truncated, resetting the time slot counter to 1.

Cycle D begins with a middle request, jumping to time slot 2. During this service two requests arrive, one high and one middle. Unlike what happened with priority passing, the next serviced is the high priority channel, as the time slot increments to 3. The second middle priority channel request in cycle D is finally serviced next, on time slot 6.

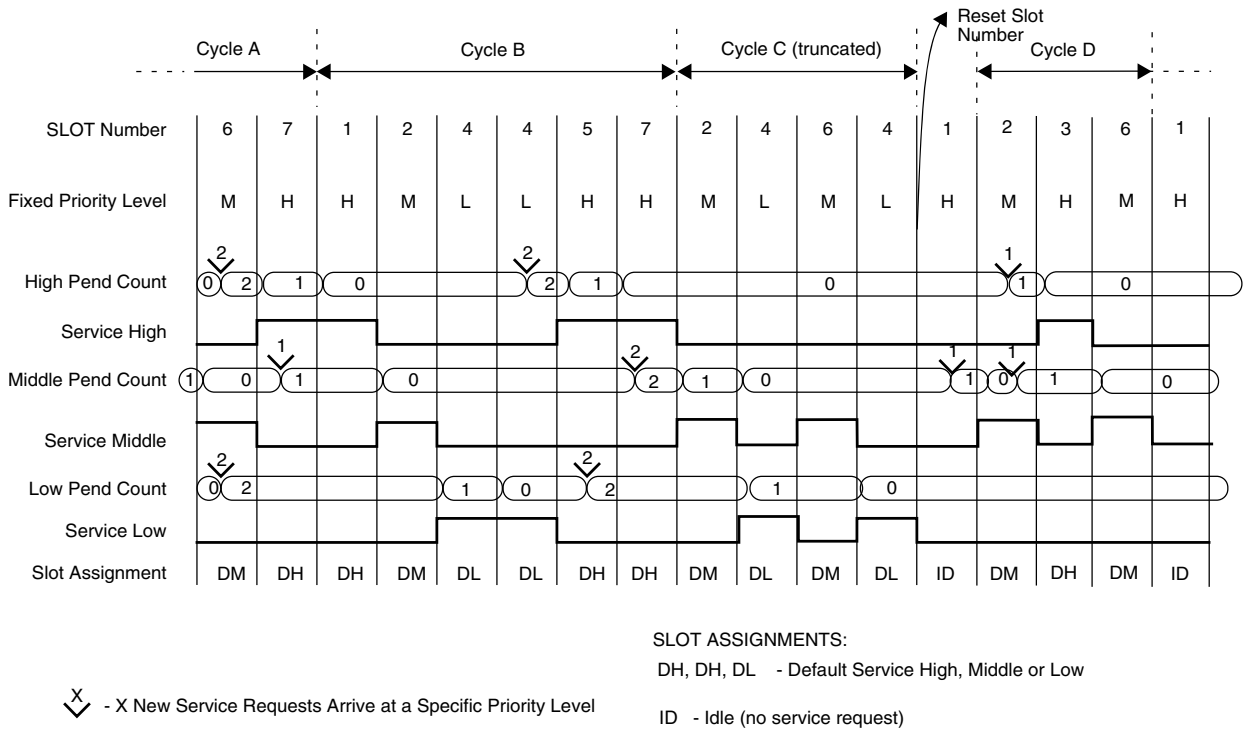

Figure 43-301. Priority Passing Disabling Example

43.14.3.2.3 Secondary Scheme - Priority Among Channels on the Same Level

Because channels can randomly request service, channels having the same priority level will inevitably request service simultaneously. A secondary scheme prioritizes these requests. The Scheduler services channels on each of the three priority levels, beginning with the lowest numbered channel on that level.

43.14.3.2.4 Priority Scheme Example

The overall priority scheme simultaneously incorporates both primary and secondary schemes. Combining both schemes in the following example conveys their correlation.

1. One high-priority and one low priority channels request service, while the Scheduler is in time slot one. Having its service request bit asserted, a single high-level channel is granted the time slot, which has high-level priority (primary scheme) and its service grant bit is asserted. At the end of the thread, the service grant bit is negated (no more requests of high priority level channels).
2. The Scheduler proceeds to time slot two, which has middle-level priority; however, no middle-level channel is requesting service. Priority is passed to the high level, but no high-level channel is requesting service; therefore, priority is passed again, and service is granted to the single requesting low-level channel. Once serviced, this channel's grant bit is negated (no more low-level requests).
3. The Scheduler resumes with the fixed-priority sequence on time slot three; however, no channels are requesting service. The Scheduler returns to time slot one, waiting for requests.
4. Two high-level and two middle-level channels simultaneously request service. Being in time slot one which is assigned high priority, the Scheduler finds the lowest numbered high-level channel (secondary scheme) and selects it for service. This channel's service grant bit is asserted.
5. The Scheduler continues to time slot two, which has middle priority (primary scheme), and allocates the slot to the lowest numbered middle-level channel requesting service (secondary scheme). The Scheduler notes the still unserviced middle-level channel and proceeds to time slot three.
6. Time slot three is allocated for high priority. The slot is allocated to the remaining unserviced high-priority channel, and the channel's service grant bit is asserted. The Scheduler checks again at the end of the thread. All service grant bits of high-level requested channels are asserted; therefore, all high-priority channels that requested have been allocated execution time. Under this condition, all service grant bits of the high-level serviced channels are negated. The Scheduler proceeds to time slot four.
7. Time slot four is allocated for low-priority channel; however, no low-level channel is requesting service. Priority is passed to the high level, but no high-level channel is requesting service; therefore, priority is passed again, and service is granted to the remaining middle-level channel which requests service. This channel's service grant bit is asserted. The Scheduler checks again at the end of the thread. All grant bits of middle-level requested channels are asserted; therefore, all middle-priority channels have been allocated execution time. Under this condition, all service grant bits of the middle-level serviced channels are negated. The Scheduler proceeds to time slot five. Meanwhile a low priority channel requests service.

8. Time slot five is allocated for high-priority channels, but there are no more requests from high-priority or middle priority channels. The single low-level channel which required service is granted time slot five. Once serviced, the channel's service grant bit is asserted. Next, the service grant bit is negated (no more requests of low priority level channels).
9. The Scheduler resumes with the fixed-priority sequence on time slot six; however, no channels are requesting service. The Scheduler returns to time slot one and waits for requests.

43.14.3.3 Time Slot Latency

Latency is the amount of time between a service request and the beginning of service on that channel. The following factors affect latency:

- Number of active channels
- Number of channels on a priority level
- Number of available time slots on a priority level
- Number of microcycles required to execute a thread of a Function
- Number of SDM accesses during execution of a Function thread
- eTPU clock frequency.

Each time slot may require a different number of microcycles, depending on the thread of a Function to be executed. This variation is shown in the figure below.

For more details on latency evaluation, see Estimating Worst Case Latency.

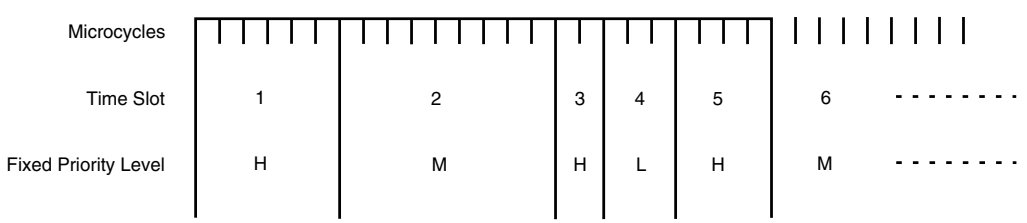

Figure 43-302. Time-Slot Variation

43.14.4 Parameter Sharing and Coherency

SDM can be concurrently accessed by Host and Microengines (two in a Dual eTPU Engine system). In general, there is no guaranteed order by which a group of parameters is accessed, which may lead to a lack of internal consistency if two or more related parameters are read when only part of them is updated.

eTPU provides mechanisms to guarantee parameter coherency. The most generic mechanisms for Host-eTPU coherency, suitable for any number of parameters, are:

- the use of Transfer Service Thread mechanism.
- the mailbox (or "software semaphore") mechanism.

These mechanisms, described in Multiple Parameter Coherency Methods, use microcode to transfer parameters from temporary buffers in SDM to their definitive locations (or vice-versa). These methods have the disadvantage of wasting processing and code memory resources.

eTPU also provides a **Coherent Dual-parameter Controller - CDC** - mechanism. It is used by Host to coherently transfer pairs of parameters from/to a parameter buffer located on SDM to/from the locations on SDM where parameters are accessed directly by the channels. Coherency is guaranteed by SDM access arbitration. Although limited to two parameters only, it has lower latency and wastes no microengine resources[14]. CDC usage is described in Coherent Dual-parameter Controller - CDC.

For parameters shared by both Engines, eTPU provides **Hardware Semaphores**. Coherency is assured given the semaphores are used to prevent concurrent access to the changing parameters. Microengine can request semaphores using specific microinstructions (see Semaphore Operations). Hardware Semaphores are described in detail in Hardware Semaphores.

Neither Host nor CDC have access to the hardware semaphores, but they can be combined with microcode transfer mechanisms if Host must coherently access parameters which are also shared by both Engines.

In order to ensure coherent access to a group of parameters by two or more contenders, **each contender must have atomic access** to the shared parameters. Atomicity conditions are discussed in Host Side Atomic Access and Microengine Side Atomic Accesses.

14. a microengine access to the SDM in the moment CDC is performing the transfer may suffer a maximum of two wait-states.

43.14.4.1 Host Side Atomic Access

Host side atomic accesses can be achieved by either of following ways:

- for one parameter, the SDM should be accessed by 32-bit-wide data transfers to ensure coherency
- for two parameters only, using the Coherent Dual Parameter Controller.
- indirectly, for any number of parameters, by requesting microcode to coherently access SDM in its behalf. The host side atomicity problem becomes, then, a microengine side atomicity problem. Some methods that use this approach to achieve coherency are described in Multiple Parameter Coherency Methods.

43.14.4.2 Microengine Side Atomic Accesses

43.14.4.2.1 Microengine Single Parameter Atomicity

SDM should be accessed by 32-bit-wide data transfers to ensure atomicity for 32-bit parameters. This applies either to Host-Microengine coherency or Microengine-Microengine coherency in a dual eTPU Engine system.

43.14.4.2.2 Microengine Dual Parameter Atomicity

Microengine has the ability to access two parameters coherently in back-to-back accesses, at random addresses: once it accesses SDM, it has priority over Host for another access in the next microcycle (see SDM Arbitration). Note that it applies **only to Microengine-Host** coherency. For Microengine-Microengine coherency in a dual eTPU Engine system, one must use Hardware Semaphores (see Hardware Semaphores).

Microengine dual back-to-back accesses are guaranteed to be atomic in relation to Host slave accesses or Coherent Dual-parameter Controller, regardless of semaphore usage: Host or CDC accesses cannot break-up a back-to-back Microengine access, neither Microengine can break a CDC transfer, due to the SDM arbitration mechanism described in SDM Arbitration.

Atomicity is not guaranteed if microengine enters halt state in the middle of a back-to-back access (see Microengine Halt State): Host can access SDM while microengine is halted in the middle of a back-to-back access.

43.14.4.2.3 Microengine Side Multiple Atomicity

Hardware Semaphores must be used for Microengine-Microengine coherency (more than 1 parameter) since two or more accesses from one Microengine are not atomic with respect to the other.

For multiple Microengine-Host coherency, the software methods described in Multiple Parameter Coherency Methods, or similar ones, must be used. Some of these methods rely on the fact that parameter access of a thread is atomic in relation to another thread in the same Engine, since a thread cannot be suspended (preempted).

For 1 parameter coherent access, or dual parameter coherency between only one Microengine and Host, the alternatives shown in previous sections apply.

43.14.4.3 Coherent Dual-parameter Controller - CDC

Dual-parameter coherency is supported by a Coherent Dual-parameter Controller hardware - CDC, which contends with microengine for SDM access. CDC atomically transfers, upon Host's command, two parameters from one area of the SDM to another. One area is a temporary (buffer) area, where the two parameters are directly read or written by the Host. This temporary area has to begin in an SDM address multiple of 2 words, and the two parameters must be sequential. The other area is the channel parameter area where the microcode normally accesses the parameters, usually with the channel relative address mode (see SDM Addressing Modes). In this area, the parameters transferred by CDC don't have to be sequential. A transfer from the temporary area to the channel area, when the Host sends data to the channel, is called a **write transfer**. Inversely, in a **read transfer** the parameters are copied from the channel area to the temporary area (channel to Host).

Coherency is guaranteed by the SDM access contention rules implemented in the SDM arbiter (see SDM Arbitration). CDC transfers are coherent in respect to the two Engines, so the target parameters in the channel area may be shared by channels on them both. During CDC operation, the Host may suffer from 3 up to 11 eTPU clocks wait states[15], and the Microengine(s) may suffer up to 2 microcycle wait-states[16] . CDC accesses are atomic with respect to Microengine(s) accesses to the SDM. Even when neither engine is in TST, CDC may suffer up to 4 eTPU clock internal wait-states from SDM arbiter, meaning 9 slave wait-states to Host, so that it does not break atomic back-to-back

15. The maximum number of Host wait states on CDC occurs when both microengines overlap their TSTs, delayed 3 eTPU clocks from each other.
16. One microcycle takes two eTPU clocks. Microengines get wait-states in multiples of microcycles, while Host and CDC wait-states are multiples of eTPU clocks.

accesses from microengine(s). CDC also cannot break TST preload accesses. Host can initiate CDC back-to-back transfers: there is no need of idle slave cycles between two transfers.

Note

SDM memory error detection and correction does not affect the number of wait-states to host due to CDC (see Memory Error Support).

CDC can be used to atomically fix SDM soft errors. For more details, see Error Fixing.

43.14.4.3.1 CDC Programming

The Coherent Dual-parameter Controller Register (see the ETPUCDCR register) is used to configure and initiate CDC transfers between the temporary area and channel parameter area. Host asserts STS bit in order to start the data transfer. CDC then contends for the SDM and starts the transfer. When the data transfer is complete, STS returns to 0. Host receives wait-states for writing STS=1 while CDC contends for SDM and during the transfer. The write access ends when CDC finishes the transfer. Host receives wait-states during the CDC transfer. If Host writes ETPUCDCR with STS=0 or does not write the STS byte, the CDC transfer does not occur. CDC programming can be summarized as follows:

1. if it is a write transfer, i.e., from Host to channel, write the two parameters into temporary area.
2. write ETPUCDCR with STS=1 and the remaining CDC programming parameters: parameter width (32 or 24 bits, field PWIDTH), transfer direction (read or write, field WR), temporary parameter area base address (field PBBASE), and the absolute addresses of the parameters to be transferred (concatenation of the fields CTBASE and PARM0/1).
3. if it is a read transfer, i.e., from channel to host, read the two parameters from the temporary area into Host memory/registers.

43.14.4.4 Hardware Semaphores

eTPU provides Hardware Semaphores accessible by the Microengine only. It is the responsibility of the application to ensure proper use of the semaphores (i.e., agree upon a specific semaphore and use it properly, to ensure coherency).

The eTPU microinstruction set has support for locking and freeing the semaphores, described in Semaphore Operations, and this is the only way to access them.

There are four semaphores available, which reduces the amount of collisions by assigning unrelated data transfers to different semaphores. Semaphores are used for parameters which can be shared by channels in different Engines, and for Engine-to-Engine synchronization. Semaphores are also the only way to ensure coherent access to parameters shared between the two Microengines.

Attempting to lock one semaphore (even not successfully) frees the other locked by the same Engine, ensuring one can lock just one semaphore at a time. That prevents deadlock conditions between the two Engines.

Microcode END command or Engine being in idle state (no thread executing) automatically releases all semaphores from one Engine side, even if a semaphore lock is done in parallel. However, it is recommended to write the microcode in a way which locks semaphores for the shortest required period, and frees them without waiting for the END command, to improve the performance of the other microengine. Semaphores are free after reset. An Engine can only free a sempaphore locked by itself.

Semaphore lock requests are always **non-blocking**, in the sense that they do not suspend the requester in case the semaphore is already locked. The semaphore status after the lock request - indicating if it was successfully locked or not - must be tested through the SMLCK microengine branch condition (see Branch Conditions).

43.14.4.5 SDM Arbitration

Up to four entities can access SDM:

- two Microengines (in a dual eTPU Engine system)
- the Coherent Dual-parameter Controller (CDC)
- the Host CPU (direct memory-mapped access)

The following rules specify the access priorities for contended access. They keep compatibility with the TPU3 dual parameter access atomicity, but only between the microengine and CDC (not Host accesses through slave bus).

1. Microengine accesses from the two eTPU Engines are interleaved between each other, but not with Host or CDC accesses;
2. The eTPU microengine(s) gives priority for SDM accesses to either the Host CPU or the CDC under any of the following conditions:

a. the microengine has completed accessing the second parameter in a back-to-back SDM access[17, 17].

b. the SDM was not accessed during the last arbitration slot for the microengine and the host does not loose the access to the other engine in the current arbitration slot[18, 18]

c. CDC is transferring data, after its first (read) access. Note that the CDC can be in middle of a data transfer of another pair of parameters, unrelated to the ones that microengine tries to access.

3. The eTPU microengine takes priority for SDM accesses under either of the following conditions:

a. the Host CPU or CDC has done a data transfer during the last access arbitration slot for the engine[18]. Also, the Host CPU does not hold a pending access against the other eTPU microengine.

b. the microengine is arbitrating for the access of its second parameter in a back-to-back access[1]. All pairs of back-to-back parameter accesses are coherent with respect to Host and CDC (not to the other microengine).

The direction (read or write) of any individual access by Host or microengine is irrelevant to the arbitration. The use of Normal or PSE SDM area by the Host is also irrelevant to the arbitration.

The first parameter preloading in a TST is considered first access by the arbiter, regardless of any access made at the END microinstruction of the previous thread, that is, the last access of a thread and the first preload are never considered a back-to-back access. On the other hand, the TST preload accesses are considered back-to-back and are, therefore, atomic with respect to Host or CDC.

Note

The Zero SDM operation (see Zero SDM Operation) is considered an SDM access for arbitration purposes both on writes and reads; the fact that read SDM data is discarded is irrelevant for arbitration.

17. if microengine tries to access the SDM in the following microcycles, the third and fourth consecutive accesses are considered the first and second of a new back-to-back dual access

18. The microengine access slot is between its own T4 and T2 edges (see Microcycle and I/O Timing).

43.14.5 Enhanced Channels

Enhanced Channels comprise hardware support for input digital signal processing and output signal generation. Each Channel is associated with one input and one output signal. Enhanced Channel logic is combined with Function microcode (and optionally Angle Mode logic) to implement Channel I/O functionality.

eTPU's Enhanced Channels are capable of **dual action**, meaning that each channel logic can handle two events at different times and/or cause two separated actions - these actions and events can be mutually dependent (with the first either blocking or enabling the other), or both independent, depending on the programmed **Channel Mode**.

Each Enhanced Channel contains event logic containing two **Event Register sets**, each set supporting one input and/or output action, the pair implementing dual action support. Each Event Register set contains two 24 bit registers: Match and Capture. The **Match register** holds the pending match value which is compared against one of the two time bases by an equal-only/greater-equal comparator. The **Capture register** captures one of the two time bases as a result of a Match or Transition detection. Service Requests are issued on particular combination of match and capture events, defined by the selected Channel Mode.

In the context of the eTPU channels, a **Match** is a comparison between a time base value and a channel Match register. If those two values are coincident, or the time base value is greater than the value of the Match register, a **Match Event occurs**. Depending on the channel mode of operation and current state of the channel logic, the match event may be recognized, i.e., change the state of the channel, or be ignored. A match event recognized by the channel logic is called a **Match Recognition**. Match Recognitions can cause, also depending on Channel Mode and current state, the channel to request service, configuring a **Match Service Request**.

eTPU uses two kinds of comparator to assert a Match Event: an **Equal comparator**, in which both the Match Register and the value of the selected time base must match exactly, and a **Greater-Equal comparator**. The Greater-Equal comparator considers any time base value between the range [N : N+0x800000-1] as a valid match against the value of N in the Match Register, even when the value N+0x800000-1 wraps around the point of origin (0x0). Refer to the following figure for an illustration of the matching values on a Greater-Equal comparator.

The second source of events for the eTPU channel is a **Transition** detected at the corresponding channel's input signal. Two distinct Transition detections can be programmed individually for each channel, allowing recognition of all possible combinations of edge detection. It is also possible to check the sampled state of an input

signal upon the occurrence of a Match: the sampling of the expected value is treated as a Transition, even if the input signal did not necessarily toggled at the time of the Match, or at any time at all.

Like Match Events, **Transitions Events** may or not be recognized by the channel logic. When they are, a **Transition Detection** occurs. As well as Match Recognitions, Transition Detections can issue a Channel Service Request, depending on Channel Mode and current state.

Transition Detections and Match Recognitions are sometimes simply called Transitions and Matches throughout this document, for short.

Input and output signals can be processed separately by the channel logic and microcode, and can also be combined such that Matches and Transitions are used to cause **output signal actions**. The output signals can also be directly controlled by microcode. Many event combinations are allowed for a channel, given the possibility of configuring pairs of matches and transitions for the dual action logic, where each event is able to block or enable the next one. There is a full set of Channel Modes described in Channel Modes, exploring all the capabilities mentioned here.

Each channel has its own set of registers and flags. They are selected, and made accessible to the Microengine, according to the value written into the microengine **CHAN Register** that points to the desired channel . Every time the CHAN register is written, even if with the same previous value, a channel is selected and its flags and registers are updated. For further detail, see the Channel Selection Register-CHAN topic in the General Channel Registers section .

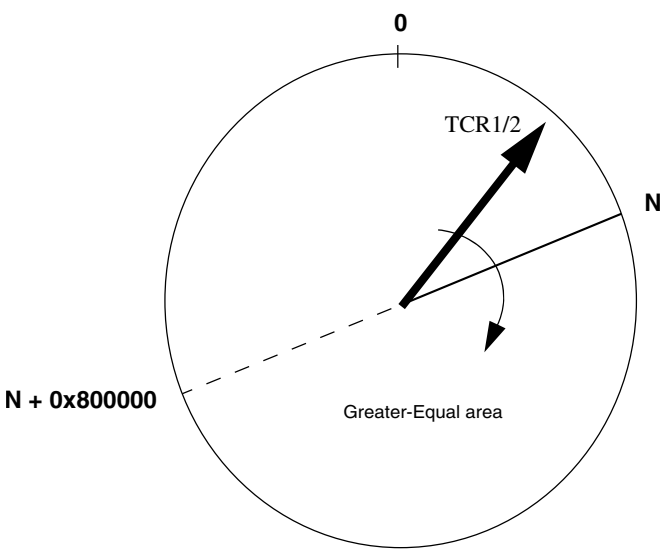

Figure 43-303. Greater-Equal Comparator

Beyond the request of services due to the signal and timing internal to each channel, one eTPU channel microcode can explicitly request service from another channel through the microengine **LINK Register**. A microcode write to the LINK Register asserts a service request to the channel whose number matches the contents of LINK. Refer to Channel Link for a complete description of this mechanism.

These service requests originated in the eTPU Enhanced Channels (either time base match, input signal transition, or link service request) result in a call to the corresponding channel service routine, which is the sequence of microinstructions that is called a **Thread**. For further detail, refer to Functions and Threads.

In addition to Event Logic, each Channel has an Output Buffer Enable signal, controlled by microcode, and an Enhanced Digital Filter, which eliminates spurious glitches on input pin signal. See the chip-specific eTPU information for how the Output Buffer Enable signal is controlled.

A high level diagram of Channel logic and registers is shown in the following figure.

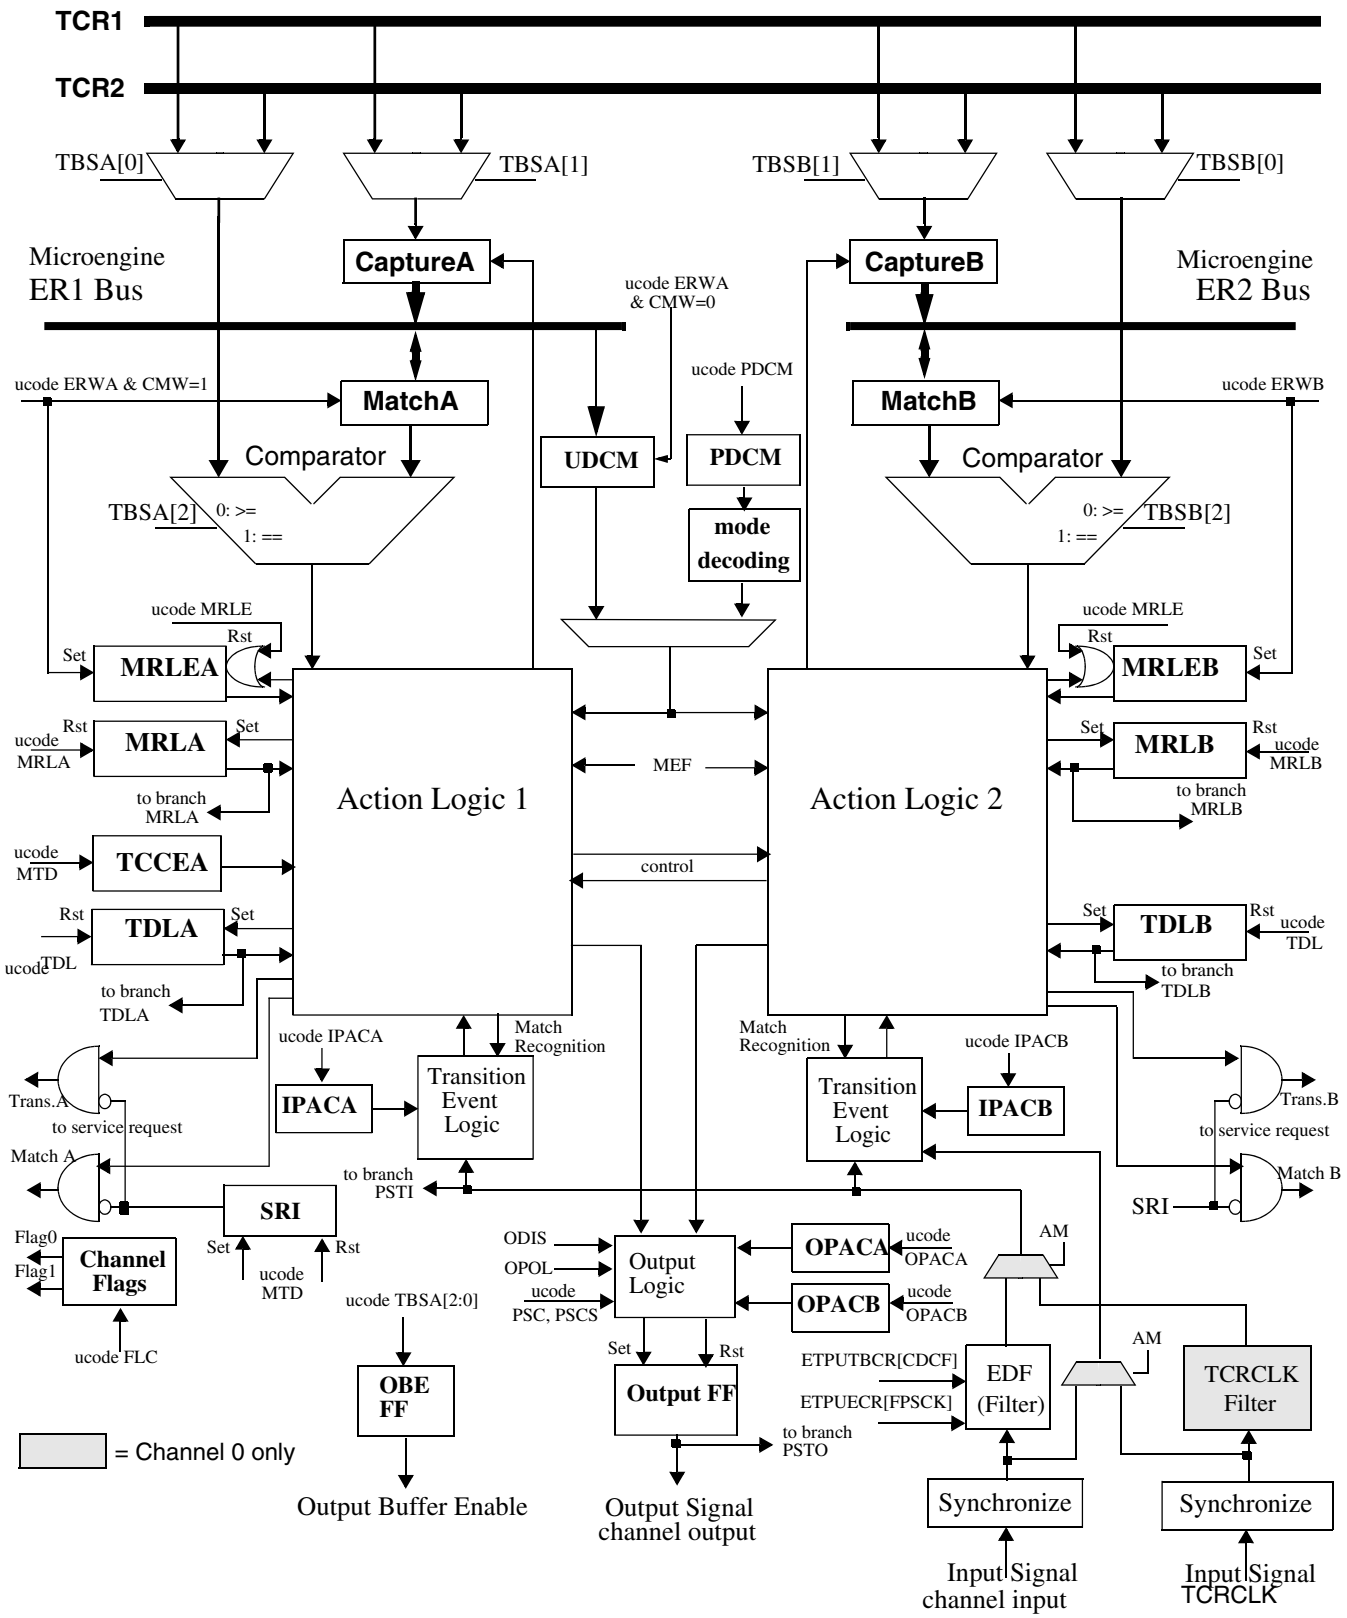

Figure 43-304. Channel Logic Block Diagram

43.14.5.1 Channel Registers and Flags

Channel configuration and control registers can be divided in the following groups:

- **Host Configuration and Control registers**, which define channel Function and parameter allocation in SDM, input signal filtering, manage Host interrupts, and are used for Host Service Requests; they can only be accessed by Host, except for the Function Mode bits which can be also tested by microcode.
- **Event Registers**, which can only be accessed by eTPU Microengine, through dedicated Channel Control microinstruction operations (see Channel Control and Configuration Microoperations); these registers are directly used to implement channel functionality, and include channel event status latches which can be directly tested by Microengine branch instructions.
- **Pin Control registers**, which basically define pin state and transition polarity (but not input signal filtering); they are accessible only by dedicated Channel Control microinstruction operations.
- **Link registers**, which implement the channel link mechanism that allows one channel to request service to another one; they are accessible only by microinstruction operations.
- **General Channel registers**: CHAN, SRI, Flag0/1, PDCM, UDCM.

Most of those registers are channel exclusive, i.e., there is one copy of them for each channel. Microcode can access registers from only one channel at a time. The Channel Selection (CHAN) register (see Channel Selection Register - CHAN), accessible only by microcode, defines the channel whose registers are being accessed, with exception of link register and function mode. CHAN register assumes the value of the channel to be serviced at the beginning of TST.

The Service Request Inhibit - SRI - register controls the generation of Service Requests on matches and transitions, also affecting channel logic behavior. For a full description see SRI - Match/Transition Service Request Inhibit Latch. Flag0/1 are used to select channel service threads based on channel software state. See Flag1,Flag0 - Channel "state resolution" flags for more details.

Host Configuration and Control registers are described in the Channel Configuration and Control registers section.

Time Base configuration is common to all channels, and described in Time Bases. Time Base selection for matches and captures, however, is individual to each channel, and is part of the Event Registers.

Link registers are described in Channel Link.

The following sections describe the Event Registers and Pin Control registers.

43.14.5.1.1 ER - Event Registers

Each channel contains two identical Event Register sets, named ERA and ERB, corresponding to the two actions supported. Each Event Register set contains:

- a 24-bit Match register (Match A or Match B), which holds a match value. This value is compared against the selected match time base (TCR1 or TCR2).
- a 24-bit Capture register (CaptureA or CaptureB), which samples the selected capture time base (TCR1 or TCR2)
- a Time Base Selection register (TBSA or TBSB)
- a Match Recognition status flag (or latch) (MRLA or MRLB)
- a Match Recognition Enable latch (MRLEA or MRLEB)
- a Transition Detection flag (or latch) (TDLA or TDLB)
- a Transition Continuous Capture enable (TCCEA only)

ERA and ERB are associated with the first and second events in double action modes, not necessarily in that order. The order of Match events associated with ERA and ERB depends on the programmed channel mode, the MatchA and MatchB values, and the timebases selected by TBSA and TBSB. Similarly, the order of Transition events associated with ERA and ERB depends on the programmed channel mode, and the transition detection selected by IPACA and IPACB.

These registers are directly or indirectly accessed by the microcode. TBSA and TBSB registers are defined in TBSA and TBSB - Time Base Selection Registers. The other registers are explained in Match Recognition and Transition Detection and Time Base Capture.

Access to the Event Registers is qualified by the channel currently selected by the microengine (i.e., the channel value currently in the CHAN register). During the channel transition period (automatic CHAN assignment), or whenever CHAN is written by microcode, Capture values of the new selected channel are sampled into Microengine registers ERTA and ERTB, therefore becoming visible to the microcode. At the same time, updated values of MRLA, MRLB, TDLA and TDLB are sampled into the branch logic, making the register values and the flags coherent with respect to each other and with the thread selected by the Scheduler.[19]

19. the thread selected is determined by the Entry Point which, in turn, is determined partially by the channel latches. See Entry Point Address Generation.

Note

The Function Mode bits are also sampled from the Host interface on Time Slot Transition, so that they remain constant to microengine even when Host changes them.

During service, the microcode can access updated values of the Event Registers of any channel by writing the channel number to CHAN. Writing CHAN with the same value (CHAN := CHAN) updates ERTA and ERTB with the new captured values, the branch logic with updated MRLA/B and TDLA/B flags. Writing CHAN with a different value does the same with the values from the newly selected channel.

Match values are also accessed through ERTA and ERTB Microengine registers, which are copied to/from the channel MatchA and MatchB registers by specific microinstruction operations.

Microcode writes to the flags and selections (MRLA/B, TDLA/B and TBSA/B) are immediately effective to the channel. The MRLA/B and TDLA/B branch conditions are also immediately reset when their correspondent flags are reset by microcode. Match registers are indirectly written by microcode through ERTA/B. MRLEA/B is unconditionally asserted when respective Match register is updated from ERTA/B, and its negation is immediate.

The following table summarizes Event Registers accesses.

Table 43-337. Event Registers microcode accesses

Register	Access Type	Sampled from channel	Update to channel	Microcode fields[1]	Reset value[2]
CaptureA, CaptureB	read through ERTA/B	to ERTA/B on CHAN assignment	no	T2ABD	n.a.
MatchA, MatchB	read and write through ERTA/B	to ERTA/B by microcode	from ERTA/B by microcode	ERWA, CMW, ERWB, T4ABS	n.a.
MRLEA, MRLEB	write to 0 (negate) directly; write to 1 (assert) upon MatchA/B update from ERTA/B	no	immediate	MRLE, ERWA, ERWB	0, 0
TBSA, TBSB	write only	no	immediate	TBSA, TBSB	000, 000
MRLA, MRLB	flag test on branch, write to 0 (negate) only	on CHAN assignment	immediate	BCC (test) MRLA, MRLB (reset)	0, 0
TDLA, TDLB	flag test on branch, write to 0 (negate) only	on CHAN assignment	immediate	BCC (test) TDL (reset)	0, 0
TCCEA	write only	no	immediate	MTD	0

1. see Microinstruction Set.
2. n.a. means that value of the register is undetermined after reset.

43.14.5.1.1.1 MatchA and MatchB Registers

MatchA and MatchB registers hold a match value to be compared against the selected channel time base. A match value can only be written into the Match register by microcode, through ERTA/B microengine registers (see Write Channel Match and UDCM Registers). Microcode can also read the Match register as a special T4ABS source operation, when T4ABS=0101, and the source for T4ABS is selected from the second register set. In this operation, MatchA/B registers are copied into ERTA/B registers (see Selecting Sources and Destination). For more information on time base matches, see Match Recognition.

43.14.5.1.1.2 CaptureA and CaptureB Registers

CaptureA and CaptureB registers capture the selected channel time base. CaptureA/B registers cannot be directly written or read by microcode. During the Time Slot Transition (TST) or during CHAN assignment, CaptureA/B registers are copied into ERTA/B microengine registers. For more information, see Transition Detection and Time Base Capture.

43.14.5.1.1.3 TBSA and TBSB - Time Base Selection Registers

TBSA/B are 3-bit registers which have the following effect on channel configuration:

- Selection of the timebase (TCR1 or TCR2) to be compared against the match values in MatchA and/or MatchB registers.
- Selection of the timebase (TCR1 or TCR2) to be captured in the CaptureA and/or CaptureB registers by a match or transition detection event.
- Selection of comparator mode to be used with MatchA and MatchB registers: equal-only or greater-equal.

After reset TBSA/B are 000. The following table shows values of TBSA and TBSB for configuration selection. Note that the time base selection for capture is independent of the time base selected for matches.

Table 43-338. TBSA/B Programming States

TBS bit	2	1	0
bit value	Comparator selection	Capture time base selection	Match time base selection
0	greater or equal	TCR1	TCR1
1	equal-only	TCR2	TCR2

TBSA/B are written through the microcode fields TBSA/B (see Comparator and Time Base Selection). Note that microcode field TBSA is also used to control the OBE pin control register (see Pin Control Registers), which is separate from the TBSA register.

43.14.5.1.1.4 MRLA/B - Match Recognition Latches

See MRLA/B - Match Recognition Latches.

43.14.5.1.1.5 MRLEA/B - Match Recognition Latch Enable

See MRLEA/B - Match Recognition Latch Enable.

43.14.5.1.1.6 TDLA/B - Transition Detection Latch

See TDLA/B - Transition Detect Latches.

43.14.5.1.1.7 TCCEA - Transition Continuous Capture Enable

See TCCEA - Transition Continuous Capture Enable.

43.14.5.1.2 Pin Control Registers

Pin Control Registers are replicated one per channel, accessed only by microcode and qualified by the CHAN register in the same way as Event Registers.

The following table lists Pin Control Registers, explained in following subsections, and their accesses.

Table 43-339. Pin Control Registers microcode accesses

Register	Access Type	Sampled from channel	Update to channel	Microcode fields[1]	Reset value
IPACA, IPACB	write only	no	immediate	IPACA, IPACB	000,000
OPACA, OPACB	write only	no	immediate	OPACA, OPACB	000,000
PSTI	flag test on branch	no	no	BCC	0

Table continues on the next page...

Table 43-339. Pin Control Registers microcode accesses (continued)

Register	Access Type	Sampled from channel	Update to channel	Microcode fields[1]	Reset value
PSTO	flag test on branch, write	no	immediate	BCC (test) PSC, PSCS (set)	0
OBE[2]	write only	no	immediate	TBSA values 1000,1001	0 (negated)
PSS	flag test on branch	on CHAN assignment	no	BCC	n.a.[3]
PRSS	flag test on branch	on CHAN assignment	no	BCC	n.a.[4]

1. see Microinstruction Set .
2. Although this register exists for code compatibility reasons, OBE functionality is not available on this chip.
3. PSS is PSTI or PSTO sampled on CHAN assignments and at thread start.
4. PRSS is PSTI sampled on channel service request.

43.14.5.1.2.1 IPACA,IPACB and OPACA,OPACB - Input and Output Pin Action Control Registers

These registers determine the transition detections and output pin actions which takes place due to match or transition events. Each field is three bit wide. After reset, the IPACA/B and OPACA/B registers are set to 000. IPACA and IPACB registers are mutually independent and have identical encoding, and so do OPACA and OPACB. The table below shows IPAC and OPAC encoding. Note that transition detections are independent from the output actions, but some options of output actions are triggered by transition detections. Output actions can also be triggered by Matches. For a detailed definition of Transition Detections, see Transition Detection and Time Base Capture.

IPACA/B define the Transition events treated by channel logic. Although the name "transition" is generically used for the transition detections, IPAC options 100 and 101 do not really detect transitions: they actually sample the state of the input signal at the occurrence of the corresponding Match (Match A used for IPACA, Match B used for IPACB).

Table 43-340. IPACA/B and OPACA/B Encoding

value	IPAC meaning	OPAC meaning
000	Do not detect transitions	Do not change output signal
001	Detect rising edge only	Match[1] sets output signal high
010	Detect falling edge only	Match[1] sets output signal low
011	Detect either edge	Match[1] toggles output signal
100	Detect input signal = 0 on Match[1, 1]	Transition sets output signal low
101	Detect input signal = 1 on Match[1]	Transition detection sets output signal high

Table continues on the next page...

Table 43-340. IPACA/B and OPACA/B Encoding (continued)

value	IPAC meaning	OPAC meaning
110	reserved	Transition detection toggles output signal
111	n.a.[2, 2]	n.a.[2]

1. Match A is used for IPACA/OPACA, and Match B for IPACB/OPACB.
2. On the microinstruction fields IPACA/B and OPACA/B this value is neutral, meaning that IPAC/OPAC register values are not changed.

43.14.5.1.2.2 Output Pin Control Logic and Pin State Output Register - PSTO

The output signal control logic uses OPACA/B, the Pre-defined Channel Mode (PDCM) and the User Defined Channel Mode (UDCM), and the microcode Pin State Control (PSC and PSCS) fields. It is responsible for setting the Pin State Output (PSTO) register to the specified logic value required by microcode, by input events, or by Match A and/or Match B events. The PSTO register stores the driven pin state determined by the Pin Control logic. The Output Buffer Enable signal, if used at MCU integration, must be set by microcode (using TBSA field) to make the pad propagate the PSTO register output to the actual pin.

PSTO register output also goes to the microengine branch logic, enabling branching on the driven pin state . PSTO is set to 0 on reset.

The PSC and PSCS microcode fields are used for setting the PSTO register to a fixed value, or to the value specified by the OPACA or OPACB microcode field, as shown in the following table

Table 43-341. PSC and PSCS encoding

PSC	Output Pin Action
00	Force pin state according to OPACA (PSCS=0) or OPACB (PSCS=1).
01	Force pin high.
10	Force pin low.
11	Do not change pin state.

For details refer to Channel Control and Configuration Microoperations.

On occurrence of match recognitions or transition detections, the pin control logic sets PSTO value according to the event number (Match A/Transition A or Match B/Transition B) and the contents of OPACA/IPACA or OPACB/IPACB registers. There are cases in which two match or transition events may occur at the same time, each of them trying to force a different pin action. The resolution of the selected match event which sets the

value depends on the Pre-defined Channel Mode (PDCM) register and the User Defined Channel Mode (UDCM). For details refer to Match/Transition Pin Action Conflict Resolution.

43.14.5.1.2.3 PSTI and PSS - Pin State Input and Pin Sampled State Registers

During the time slot transition period, or whenever the CHAN register is written by microcode, the filtered[20] input signal PSTI or output signal PSTO (selected by the ETPUCxCR bit ETPD) is sampled into the branch logic as the PSS flag (see Table 43-409). The microcode can then branch on either the currently driven (PSTO) or input (PSTI) pin state, or on sampled pin state (PSS, which is stable as long as CHAN does not change).

Note

If a transition occurs simultaneously (after the filter) with the CHAN assignment, PSS samples the new pin value. Therefore, if TDLA/B is cleared simultaneously with the assignment CHAN := CHAN, the occurrence of a transition at this very moment can still be tested with PSS.

43.14.5.1.2.4 PRSS - Pin Request Service Sample

Channel logic can, depending on its state and programmed mode, request service to the eTPU microengine (see Functions and Threads). When the channel logic issues a service request, the filtered input signal PSTI is sampled into an internal channel flag PRSS. There is one such PRSS flag for each channel (see Pin Control registers). Channel PRSS keeps its value until all its service request sources are cleared and until a new channel service request rises.

Note

Only channel service requests update PRSS: it is updated neither by host service requests (HSRs) nor by link service requests. Moreover, a channel service request updates PRSS even if the channel is disabled (its CPR set to 0, see the ETPUCnCR register).

The channel PRSS flag is sampled into the branch logic as the PRSS flag (see Table 43-409) during the time slot transition period, or whenever the CHAN register is written by microcode.

20. The filter can be bypassed.

43.14.5.1.3 General Channel Registers

These registers control other aspects of channel logic. Except for CHAN, they are unique per channel. The following table summarizes the registers and access options.

Table 43-342. General Channel registers microcode access

Register	Access Type	Sampled from channel	Update to channel	Microcode fields[1]	Reset value
CHAN	read/write	n.a.[2, 2]	n.a.[2]	T4ABS, T4BBS, T2ABD	defaults to serviced channel at thread start
PDCM	write only	no	immediate	PDCM	1100 (sm_st)
UDCM	write only	no	from ERTA by microcode	CMW, ERWA	parameter value defined at integration[3]
SRI	write only	no	immediate	MTD	1
Flag1,Flag0	branch flag test, write	no	immediate	BCC,FLC	0, 0

1. See Microinstruction Set.
2. CHAN is common to all channels in the Engine.
3. See the eTPU Integration Guide for parameter details and default value.

43.14.5.1.3.1 Channel Selection Register - CHAN

CHAN is the register that holds the number of the channel that qualifies the context of most Channel Registers, including Pin Control and ER accesses, and is common to all channels in a same Engine.

When a thread starts to be executed, the contents of CHAN register is automatically updated on Time Slot transition to the number of the channel to be serviced. Serviced channel is constant during channel servicing, but the selected channel can be changed any time by microengine writing into CHAN register.

Some microinstructions are affected by the serviced channel instead of CHAN. These are:

- Conditional branch using LSR (see LINK Register) or Function Mode (see the ETPUCnSCR register.
- Negate channel flag LSR, Interrupt CPU and Data Transfer Request (see Channel Interrupt and Data Transfer Requests).

When CHAN register is written, accesses are qualified by the new CHAN register value from the instruction following CHAN assignment on, except CaptureA/B sampling into ERTA/B and Match register writing from ERTA/B (see CHAN assignment, Read Match and ERWA/B).

Writing CHAN (including with the same value, CHAN:= CHAN) updates ERTA and ERTB with the new captured values, the branch logic with updated MRLA/B and TDLA/B flags.

The following table shows the commands, flags and registers selected by the CHAN register value.

Table 43-343. CHAN-selected features

Feature Used	Selected by CHAN
channel-relative SDM access	YES
Branch using PSS, PRSS, PSTI and PSTO channel flags.	YES
Branch using MRLA/B, TDLA/B, Flag0/1[1]	YES
Branch on all other conditions[2]	no
ERTA/B Value	YES
configure (selected) channel	YES
channel commands applied to: MRLA/B, TDLA/B, TBSA/B, IPACA/B,OPACA/B, PSC, PSCS, OBE, PDCM, MRLE, Flag0/1	YES
channel command: set/reset SRI	YES
channel command: write to Match registers (ERWA/B)	YES[3]
channel command: read Match registers into ERTA/B	YES
clear LSR	no
channel interrupts and data transfer requests (CIRC)	optionally

1. In TPU, these conditions retained the old values.
2. Refer to Branch Operations
3. If write Match (ERWA/B) occurs at the same time of a CHAN assignment, the channel which is target of the write is the one selected by the new CHAN value. See CHAN assignment, Read Match and ERWA/B.

43.14.5.1.3.2 PDCM - Predefined Channel Mode

PDCM determines the channel mode assigned to the channel. Channel mode defines much of the channel logic behavior, specially how matches blocks and enables transitions and vice-versa, as well as occurrence of time base captures and service requests based on matches and transitions. For a complete description see Channel Modes.

PDCM is a 4-bit register set by the microcode field of the same name (see Predefined Channel Modes), and cannot be read or tested in branch instructions. The table below relates the PDCM value with channel modes. The second column specifies the mnemonic used to reference the mode, introduced in Channel Modes Overview . There is one PDCM for each channel, initialized with 1100 on reset.

PDCM is also used to select the User Programmable Channel Mode. If this selection is made, the channel behavior is defined by the settings of the UDCM register (see UDCM - User Defined Channel Mode).

Table 43-344. PDCM encoding

PDCM	Channel mode
0000	em_b_st
0001	em_b_dt
0010	em_nb_st
0011	em_nb_dt
0100	m2_st
0101	m2_dt
0110	bm_st
0111	bm_dt
1000	m2_o_st
1001	m2_o_dt
1010	User Defined Channel Mode
1011	reserved
1100	sm_st[1]
1101	sm_dt
1110	sm_st_e
1111	n.a.[2]

1. This is the reset value, also compatible with TPU channel behavior.
2. This value is used as a neutral (do not change) value in the PDCM microinstruction field.

43.14.5.1.3.3 UDCM - User Defined Channel Mode

UDCM holds the control signals that define the channel logic behavior in terms of Match and Transition blocking and enabling, captures and service requests triggered by events. The register layout is defined in the figure below. The individual fields are defined in Channel Mode Logic and Event Flags. There is one UDCM register for each channel, which can be independently programmed.

UDCM can only be written into the Match register by microcode, through ERTA/B microengine registers (see Write Channel Match and UDCM Registers).

13	12	11	10	9	8	7	6	5	4	3	2	1	0
MSR		MCAP	M1ET	M1EM2	M1BM2	M2BM1	M2BT	T1BM1	T2BM1	TBM2	T1ET2	TSR	TCAP

Figure 43-305. UDCM Register

43.14.5.1.3.4 SRI - Match/Transition Service Request Inhibit Latch

SRI blocks channel service requests due to the assertion of MRLA/B and/or TDLA/B. SRI does not affect recognition of Link Service Requests or Host Service Requests, neither MRLA/B or TDLA/B microcode branch tests nor Entry Table selection[21] . SRI is asserted during reset and is controlled by microcode field MTD.

To unburden the microengine, SRI asserted configures a channel "dumb" regarding the servicing of match and capture channel service requests. Even with SRI=1, TDLA/B and MRLA/B can still be asserted, and the level specified by the OPAC (Output Pin Action Control) registers will be output to the pin.

43.14.5.1.3.5 Flag1,Flag0 - Channel "state resolution" flags

Each channel has a pair of flags, simply called Flag0 and Flag1, that can be set/reset by microcode through microinstruction field FLC. FLC sets/resets Flag0/1 of the channel selected by CHAN. These flags can be tested by microcode, and are also used to resolve the microcode entry point for the channel service (see Entry Points"). Flag0 and Flag1 are, so, typically used for fast state resolution. FLC microinstruction field also allows Flag1,Flag0 to be copied from selected bits of P register high byte, which is also meant to be used to hold application state. Flag0 and Flag1 are both zero out of reset.

43.14.5.2 Match Recognition

The match operation is performed every microcycle by comparing the channel MatchA and MatchB registers against the value of the TCR bus specified for each match. TCR1 or TCR2 bus is selected according to TBSA and TBSB fields. Both results have effect on the next clock cycle (see Microcycle and I/O Timing).

A Match A/B event is qualified by a set of match enabling conditions to the Match Recognition Registers MRLA/B. To recognize the match, the following match enabling conditions are required:

21. In TPU, SRI also blocked TDL and MDL branches and enabled any transition to capture time base.

- For IPACA/B=0xx, Match Enable Flag (MEF), qualified by the channel currently being serviced must be asserted. For IPACA/B =1xx, Match A/B is always enabled (even during Time Slot Transition - TST), regardless the state of the Match Enable Flag (MEF). See MEF - Match Enable Flag for the conditions of MEF assertion.
- Match Recognition Latch Enable 1/2 (MRLEA/B) is asserted. A match event recognition may only occur if its corresponding MRLEA/B bit is set, which only happens upon a write to a channel match register by the microcode, copied from ERTA/B. MRLEA/B is negated when the respective match occurs or, in some double match channel modes, when a match for the other Match register occurs. It ensures that the greater-equal comparison will not cause additional matches[22] .
- In selected modes (see Channel Modes), the particular conditions of MRL and TDL flags of the other event, i.e:
  - MRLA, TDLA enable or block MRLB;
  - MRLB, TDLB enable or block MRLA.
- The respective MRL is negated.
- In selected modes (see Channel Modes), the state of its respective TDL flag.

If the Match A and/or Match B conditions are met, the channel immediately forces the pin state if specified by the appropriate OPACA/B registers (Output Pin Action Control 1/2) and, in some cases, by IPACA/B registers. Refer to IPACA,IPACB and OPACA,OPACB - Input and Output Pin Action Control Registers.

If both Match A and Match B events occur at the same time, with conflicting pin actions, the priority over the pin action is mode dependent. For further details on pin action resolution refer to Match/Transition Pin Action Conflict Resolution.

43.14.5.2.1 MRLA/B - Match Recognition Latches

MRLA/B indicate the recognition of a match event detected by the comparator. They can be asserted either on T2 or T4 (see Microcycle and I/O Timing). Assertion of MRLA/B issues a match Service Request in specific channel modes, depending on previous events and state of SRI. After reset MRLA and MRLB are both negated.

22. Microcode can also negate MRLEA/B.

When MRLA or MRLB is asserted, it may change the output signal level according to the Input and Output Pin Action Control registers (refer to IPACA,IPACB and OPACA,OPACB - Input and Output Pin Action Control Registers). Assertion of MRLA/B causes a capture of one or two time bases, according to the selected mode capturing scheme (see Transition Detection and Time Base Capture)

A match recognition is self-blocking, regardless of Channel Mode: once MRLA (MRLB) has been asserted, it negates its associated MRLEA (MRLEB) register, preventing future match recognitions, until the associated match register is rewritten by microcode. The microcode has to enable new matches by updating the new match value in the MatchA (MatchB) register[23] . In addition, assertion of MRLA/B can block its twin MRLB/A, depending on the channel mode. In some double match blocking channel modes, Match A/B event blocks the occurrence of Match B/A in a "first win" scheme.

It is the transition from 0 to 1 in MRL that causes the Match actions, except the service request: apart from MRLEA/B negation(s) and service request, no action due to a Match occurs if MRL was already set to 1, even if the other MRL assert conditions are satisfied. However, if a Match and a microoperation negating its corresponding MRL occur at the same time, MRL negation by microcode overrides its assertion, but any dependable captures and pin action occurs anyway (if MRL was already negated before), and also the negation of MRLE(s) (the respective one and, in some channel modes, the other, regardless of MRL state before). Note that MRLE must have been set before (by writing a new Match value).

43.14.5.2.2 MEF - Match Enable Flag

MEF is a one-bit latch that is unique for all channels in an Engine.

MEF can selectively enable assertion of MRLA/B, depending on the IPACA/B field. For IPACA/B=0xx, MEF=1 enables assertion of MRLA/B for the scheduled channel during service. For IPACA/B=1xx, Match A/B is always enabled, regardless the state of the MEF, but it still depends on the other Match recognition conditions. Matches of channels not being serviced are never disabled by MEF.

MEF is not accessible by Microengine or Host. MEF is negated for two microcycles in the beginning of the time slot transition period. After two microcycles (plus wait-states) into TST, the ME bit in the entry point is copied to MEF to allow selective enabling of MRL for each thread (refer to Time Slot Transition). MEF is asserted unconditionally soon after a thread ends.

If a channel service needs to postpone a programmed match, MEF assures that microcode wins the race against match event after time slot transition (only for IPAC=0xx).

23. Before that, microcode should also negate MRLA (MRLB), otherwise an old match may be recognized by the scheduler and serviced as a new one

Note that a match event may be lost during the periods when MEF is negated only if:

- the match comparator is configured for "equal-only" behavior, and
- IPACA/B=0xx, and
- TCR increments at the rate of eTPU clock divided by 2 or faster.

When the comparator is configured as "greater-equal", the match event that occurred when MEF was negated may be recognized after MEF is asserted again, due to the "greater than" condition.

43.14.5.2.3 MRLEA/B - Match Recognition Latch Enable

MRLEA/B is negated upon the assertion of its respective MRLA/B. In blocking match channel modes it may also be negated together with the assertion of the twin MRLB/A. The MRLEA/B bits ensure that data captured due to the first match event will not be overwritten when MRLA/B is negated: due to greater-equal comparison, the match condition continues to be true, but should not cause another capture event.

In addition to negation by local match event, the microcode can negate both MRLEA and MRLEB, to block pending matches, and also MRLA/B, individually. This action will prevent future match events from the selected channel.

Writing the MatchA/B registers by microcode to schedule the next match values sets MRLEA and/or MRLEB and enables new matches. This setting overrides the MRLE negation conditions due to channel logic or microcode (see Channel Modes). By combining write to Match A/B with MRLEA/B negation microinstructions, the microcode can negate one MRLE while asserting the other.

Note

If the MRLE negation conditions continue after writing MatchA/B registers, the respective MRLE does not keep asserted. For instance, if MRL=1 and a match is programmed for a time value in the past during a thread with ME=1, then MRLE will be cleared soon after MatchA/B is written, even though a match does not occur (because MRL was already asserted, neither captures nor pin toggles occur).

When the match register is updated (with MRLE already asserted before) and field MRLA/B = 1 (no clear, see Clear Transition/Match Event Registers) and MRLA/B flag is zero, the eTPU behaves exactly as the TPU, that is: a match that comes concurrently with the rewrite of the match register, matching the old value, sets the MRL, as if the setting of

the MRLE due to match register write had precedence over its clear by the match at that moment. After this simultaneous operation, the MRLE value stays at 1, and the captured time base value, if any, reflects the match value.

When the match register is updated (with MRLE already asserted before) and field MRLA/B = 0 (clear MRL, see Clear Transition/Match Event Registers) and MRLA/B flag is zero, the match captures will occur, the MRLA/B flag will keep negated, and MRLE will stay asserted. Special care must be taken when a match is reprogrammed on a channel running at T2/T4 timing, please see the details in the “T2/T4 Channel Timing” section.

43.14.5.3 Transition Detection and Time Base Capture

Time Base Capture(s) occur when the value of a specified TCR is sampled into the CaptureA and/or CaptureB register. TBSA[1] and TBSB[1] select which TCR will be captured in CaptureA and CaptureB, respectively.

A capture event may occur due to either of the following events:

- the assertion condition of Match Recognition Latch (MRL), even if MRL is simultaneously negated by microcode
- the assertion condition of Transition Detection Latch (TDL), even if TDL is simultaneously negated by microcode.
- any Transition Event specified by IPACA if both the Transition Detection Latch TDLA and Transition Continuous Capture Enable TCCEA are asserted.

A capture event occurs together with the assertion of MRL or TDL either on T2 or T4 positive edges, and captures the time-base value that caused the match, even if TCR1/2 increments concurrently with the assertion (see Microcycle and I/O Timing)[24, 24] . MRLA/B and TDLA may, depending on the channel mode, inhibit the capture of the second event's TCR into CaptureA/B. As a general rule, values captured by signal transitions are not overwritten by values captured by match events.

When the enable bit TCCEA is asserted, captures due to Transition Events also occur after TDLA is asserted. Those captures happen on transition events specified by IPACA, and the TCR value is saved into CaptureA register only.

The capturing scheme is defined by the Channel Mode programmed at register PDCM, or at register UDCM when User Defined Channel Mode is selected . For more information on mode-dependent capture schemes refer to Channel Modes.

24. In TPU3, when TCR1 was counting at maximum rate of eTPU clock divided by 2, the next value was captured.

43.14.5.3.1 TDLA/B - Transition Detect Latches

TDLA/B indicate detection of specific transition occurrences on a channel input signal. TDLA and TDLB assertion causes service request in single and double transition predefined modes, respectively. TDLB assertion does not cause Service Request in single transition predefined modes, and TDLA assertion does not cause Service request in double transition predefined modes. In single transition channel predefined modes TDLB can be asserted on the second transition, but does not generate Service Request. Yet on predefined modes, TDLB assertion is enabled only if TDLA is asserted to detect an ordered input signal double transition. All the restrictions above, however, may be overridden by using the User Defined Channel Mode. The IPACA and IPACB registers indicate the programmed edges of the first and second detected transition, respectively.

The sampling of a determined value (0 or 1) on the input signal due the occurrence of a Match is also treated as a "transition", depending on IPACA/B programming (see IPACA,IPACB and OPACA,OPACB - Input and Output Pin Action Control Registers). When using a channel mode where the transition1 is initially blocked and IPACA is programmed to detect such "transitions", the occurrence of a Match A only unblocks the transition after the sampling. It means that the transition on the first Match (IPACA configurations 100 and 101) is not effective on predefined modes where Transition A is enabled by Match A (m2_st, m2_dt, m2_o_st and m2_o_dt) or user-defined modes with UDCM bit M1ET asserted . A Transition A can still happen after the Match A, however, if MatchA register is reprogrammed without clearing MRLA.

TDLA/B assertion conditions initiates a capture event of one or both selected TCR buses. TDLA or TDLB transition event generates a Service Request, depending on channel mode, previous events and the state of SRI. For more information on service request scheme refer to Entry Point Address Generation" and Channel Modes.

Assertion of TDLA/B occurs on either T2 or T4 positive edges. The capture event occurs on the same clock, and captures the time base value present when TDLA/B was asserted[1] . TDLA and TDLB are negated during reset and may also be negated independently by microcode. TDLA/B is reset by no way other than reset and microcode.

It is the transition from 0 to 1 in TDL that causes the Transition actions: even if TDL assert conditions are satisfied, no action due to a Transition occurs if TDL was already set to 1. However, if a Transition and a microoperation negating TDLs occur at the same time and TDL was already negated, TDL negation by microcode overrides its assertion, but any dependable captures and pin action occurs anyway.

43.14.5.3.2 TCCEA - Transition Continuous Capture Enable

TCCEA enables capture from transitions after the TDLA flag is set. TCCEA is negated on reset, so that a capture occurs only when TDLA asserts. TCCEA can be set and reset by microcode only, through the instruction field MTD (see Disable Match and Transition Service Requests). It can only be set together with inhibiting of the channel service requests (SRI = 1)[25].

When TCCEA is asserted, the transition events specified by IPACA that occur after TDLA is set also cause captures, into the CaptureA register only. However, output actions related to transition events are still blocked by TDLA.

43.14.5.4 Channel Modes

The Enhanced Channels support various modes of operation combining Match A/B recognition and transition detection events which set MRLA/B and TDLA/B. The channel mode is individually set for each channel by eTPU microcode, through the PDCM register (see PDCM - Predefined Channel Mode). The PDCM register selects among a set of 13 predefined channel modes, and also a user-defined channel mode.

The order in which events occur, combined with assigned channel mode, establish which following event detections are inhibited and/or enabled, as well as the actions taken: Time Base capture, flag setting (MRLA/B, TDLA/B), match disabling (MRLEA/B), output signal transition, and Service Request. Those channel mode characteristics are fixed in the predefined modes, but can be individually programmed in the user-defined channel mode.

A generic description of channel modes from the usage point of view can be found in Channel Modes Overview . Each mode is named with a mnemonic acronym for terse reference. The individual programmed attributes of the user-programmable channel mode are also described.

The modes are used differently for input and output signals, as explained in Predefined Channel Modes on Input Signal Processing and Channel Modes on Output Signal Generation. Modes also allow combining input processing and output generation in a single channel, as exemplified in Combining Input and Output Signals.

Channel Mode Logic and Event Flags shows a structural definition of channel logic and its relation to channel modes. A dynamic, event-oriented view of each channel mode can be found in Channel Mode Summary.

25. TCCEA provides compatibility with TPU when service request is inhibited.

43.14.5.4.1 Channel Mode Logic and Event Flags

Figure 43-306 shows a more detailed diagram of channel mode logic. The logic shown here is not necessarily identical to the actual channel logic implementation, but is equivalent with respect to conditions for event blocking, enabling, capture, and service requests.

Signals MSR, TSR, MCAP, TCAP, M1ET, M1EM2, M1BM2, M2BM1, M2BT, T1BM1, T2BM1, TBM2 and T1ET2 are decoded from programmed channel mode PDCM in predefined modes, and come directly from the UDCM register when user-defined mode is selected:

- TSR (1 bit) defines Service Requests issued by Transitions, as shown in Table 43-346.
- MSR (2 bits) defines Service Requests issued by Matches, as shown in Table 43-345.
- TCAP (1 bit) defines time base captures caused by Transitions, as shown in Table 43-346
- MCAP (1bit) defines time base captures caused by Matches, as shown in Table 43-347.
- M1ET, M1EM2, M1BM2, M2BM1, M2BT, T1BM1, T2BM1, TBM2, T1ET2 (1 bit each) define Match and Transition reciprocal blocking and enabling, as well as Transition ordering, as shown in Table 43-348 and Table 43-349.

Table 43-350 shows the decoded values of those control signals for each predefined channel mode. The first column shows the mnemonic reference for the predefined channel modes described in the following sections.

Changing PDCM or the UDCM when user mode is selected may set or reset any of the channel flags, or issue captures and service requests, so it is advisable to switch channel modes only in a quiescent channel state, with channel flags MRLEA/B, TDLA/B, MRLA/B cleared. Furthermore, an event flag asserted in one mode may keep asserted after the mode programming change, even if the flag is impossible to be set in the new mode.

Table 43-345. MSR signals - Match Service Requests

value	MSR
00	issue no Service Requests on Matches
01	issue Service Request on Match B only
10	issue Service Request on 2nd[1] Match
11	issue Service Request on both Matches

1. 2nd Match means the Match that happens after the 1st Match in time, either Match A or Match B.

Table 43-346. TCAP and TSR signals - Transition Captures and Service Requests

value	TCAP	TSR
0	1st[1, 1] Transition captures Time Bases corresponding to Transition A and Transition B[2] Transition A captures corresponding Time Base if it is the second transition; Transition B captures corresponding Time Base if it is the second transition.	issue Service Request on the 1st[1] Transition
1	Transition A captures corresponding Time Base. Transition B captures corresponding Time Base.	issue Service Request on the 2nd[3] Transition

1. 1st Transition means the Transition that happens first in time, either Transition A or Transition B.
2. Match capture(s) never overwrites a Transition capture. Transition captures can always overwrite a Match capture.
3. 2nd Transition means the Transition that happens second in time, either Transition A or Transition B

Table 43-347. MCAP signal - Match Capture

value	MCAP
0	Match A captures corresponding Time Base; Match B captures corresponding Time Base
1	either Match captures Time Bases corresponding to Match A and Match B[1]

1. Match capture(s) never overwrites a Transition capture. Transition captures can always overwrite a Match capture.

Table 43-348. TBM2 signal - Transition Blocks Match B

value	TBM2
0	Transition A Blocks Match B
1	Transition B Blocks Match B

Table 43-349. M1ET, M1EM2, M1BM2, M2BM1, M2BT signals

signal	active value meaning
M1ET (Match A Enable Transitions)	Transitions are initially blocked, and Match A enables Transitions
M1EM2 (Match A Enables Match B)	Match B is initially blocked[1, 1], and Match A enables Match B
M1BM2[2, 2] (Match A Blocks Match B)	Match B is initially enabled[1], and Match A blocks Match B[3, 3]
M2BM1[2] (Match B Blocks Match A)	Match A is initially enabled,and Match B blocks Match A[3]
M2BT (Match B Blocks Transitions)	Match B blocks Transitions

Table continues on the next page...

Table 43-349. M1ET, M1EM2, M1BM2, M2BM1, M2BT signals (continued)

signal	active value meaning
T1BM1 (Transition A Blocks Match A)	Transition A blocks Match A
T2BM1 (Transition B Blocks Match A)	Transition B blocks Match A
T1ET2 (Transition A Enables Transition B)	Transition B is initially blocked, and Transition A enables Transition B

1. The initial condition of M1EM2 prevails over M1BM2, while M1BM2 blocking prevails over M1EM2 enabling, so that Match B stays always blocked when both M1BM2 and M1EM2 are active. This combination is used in single-match modes (sm_*).
2. Blocking of one Match by the other is done through MRLEs.
3. Matches always block themselves by resetting their own MRLEs (Match A always blocks Match A, Match B always blocks Match B)

Table 43-350. Predefined Channel Mode control signals decoding

Predefined Mode	MSR	MCAP	M1ET	M1EM2	M1BM2	M2BM1	M2BT	T1BM1	T2BM1	TBM2[1]	T1ET2	TSR[1, 1]	TCAP[1]

sm_st_e[3]	11	0	off	On	On	On	off	On	off	0	On	0	0

1. signals TSR, TCAP and TBM2 replace the signal DTM used in previous eTPU versions.
2. bm_dt and sm_dt are exceptions in the match blocking logic by transitions. See Both Match Request Modes (bm_st, bm_dt) and Single Match Modes (sm_st, sm_dt).
3. sm_st_e is an exception in the capture scheme. See Single Match Enhanced Mode (sm_st_e).

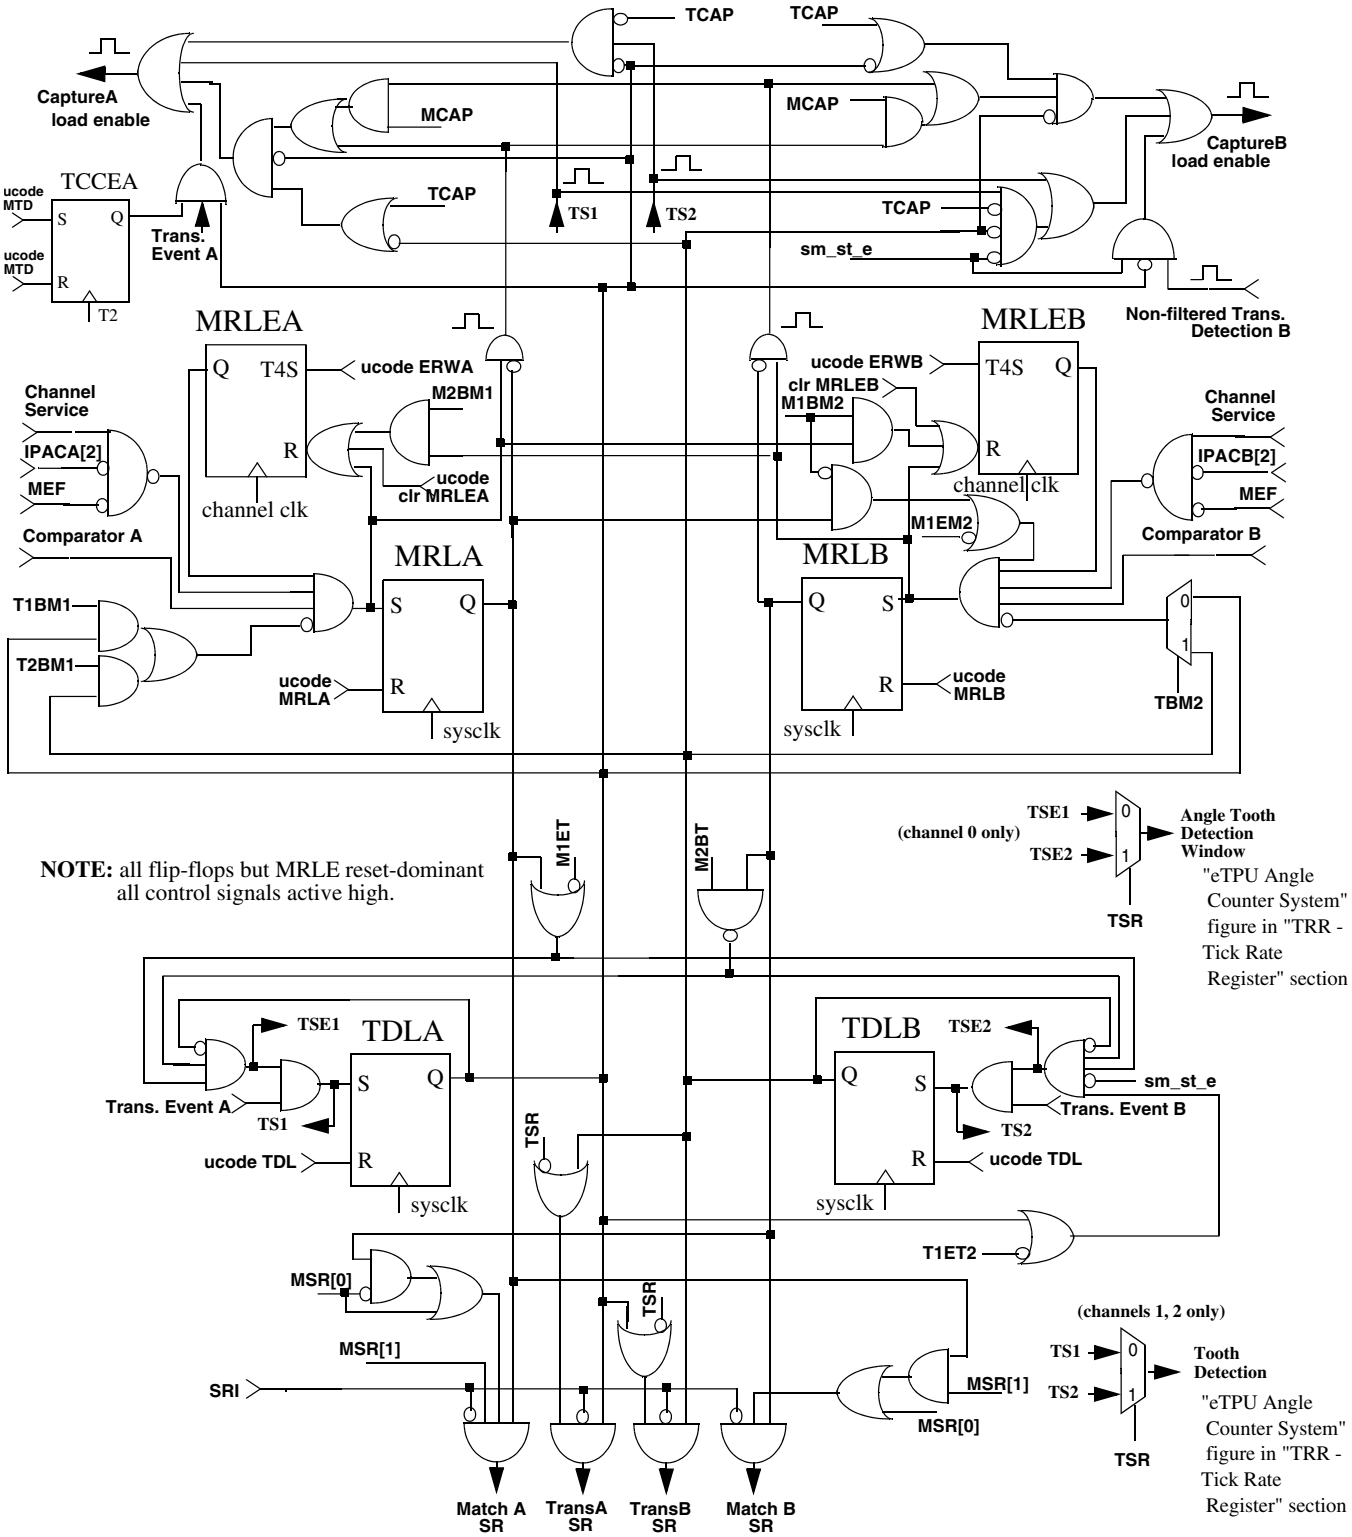

Figure 43-306. Channel Mode Logic and Event Flags

43.14.5.4.2 Channel Modes Overview

The predefined channel modes are divided, according to the way they treat transitions, in two basic modes:

- **Single Transition Modes** (mnemonic suffix **_st**): in these modes the first transition (flagged in TDLA) issues a service request, and captures both time bases (selected by TBSA[1] and TBSB[1]) except on sm_st_e. The second transition (flagged in TDLB) does not issue a service request, but it captures time base selected by TBSB[1], except on sm_st_e.
- **Double Transition Modes** (mnemonic suffix **_dt**): in these modes the second transition (flagged in TDLB) issues a service request, and each transition captures its own selected time base (Transition A and Transition B capture time bases selected by TBSA[1] and TBSB[1], respectively).

In predefined modes, Transition B is always (but not only) enabled by Transition A, so that transitions are always ordered: TDLA is set on the first transition and TDLB on the second. Unordered transitions are possible with user-defined mode, when UDCM bit T1ET2=0. Matches are generally not ordered, except on specific ordered match modes m2_o_st and m2_o_dt. Match capture(s) never overwrites a Transition capture, while Transition captures can always overwrite a Match capture, either in predefined or user-defined modes.

The following general rules apply to both predefined and user-defined modes:

- Blocking of one Match by the other, when it occurs, is done through MRLEs.
- Matches always block themselves by resetting their own MRLEs (Match A always blocks Match A, Match B always blocks Match B).

Predefined modes differ mostly by the way matches affects and are affected by other matches and transitions, as explained in next sections. However, some general rules on Match blocking apply:

- Match B is blocked by first transition (TDLA) in single transition modes, and by second transition (TDLB) in double transition modes.
- Both Matches are blocked by first transition in single transition modes.

Note

The rules above and in following sections may be overruled by the state of the channel latches if they are set/reset by microcode or if channel mode is changed. Care must be taken

to change channel modes, and is advisable to reset channel flags MRLA/B, TDLA/B and MRLEA/B before writing PDCM, or to UDCM when user-defined mode is selected.

43.14.5.4.2.1 Either Match, Blocking Modes (em_b_st, em_b_dt)

In these modes the first match recognition that occurs blocks the other match recognition and generates a service request. They end up with one service request for two programmed match recognitions where only the first match recognition has an actual effect. If both match recognitions occur at the same time, both MRLA and MRLB are set, before the mutual blocking takes effect. The associated logic is shown in the following figure.

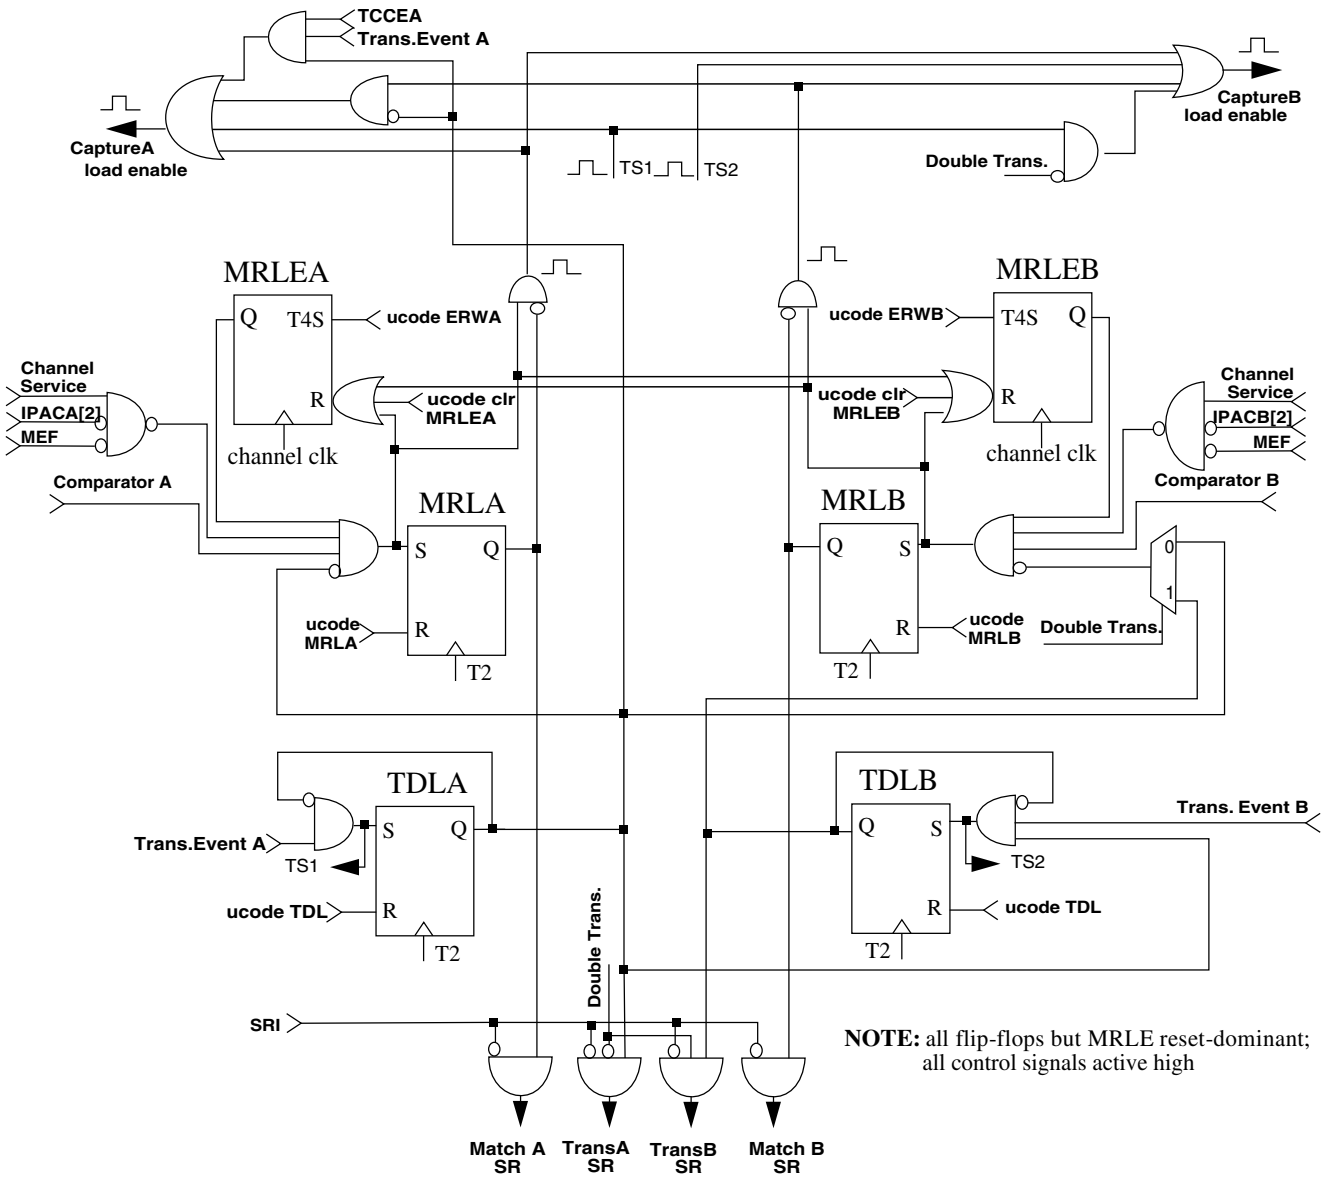

Figure 43-307. Either Match, Blocking Modes (em_b_st, em_b_dt)

43.14.5.4.2.2 Either Match, Non Blocking Modes (em_nb_st, em_nb_dt)

In these modes both match recognitions are independent and each of them generates service request. Each match recognition captures its related time base and does not block the other. The associated logic is shown in the following figure.

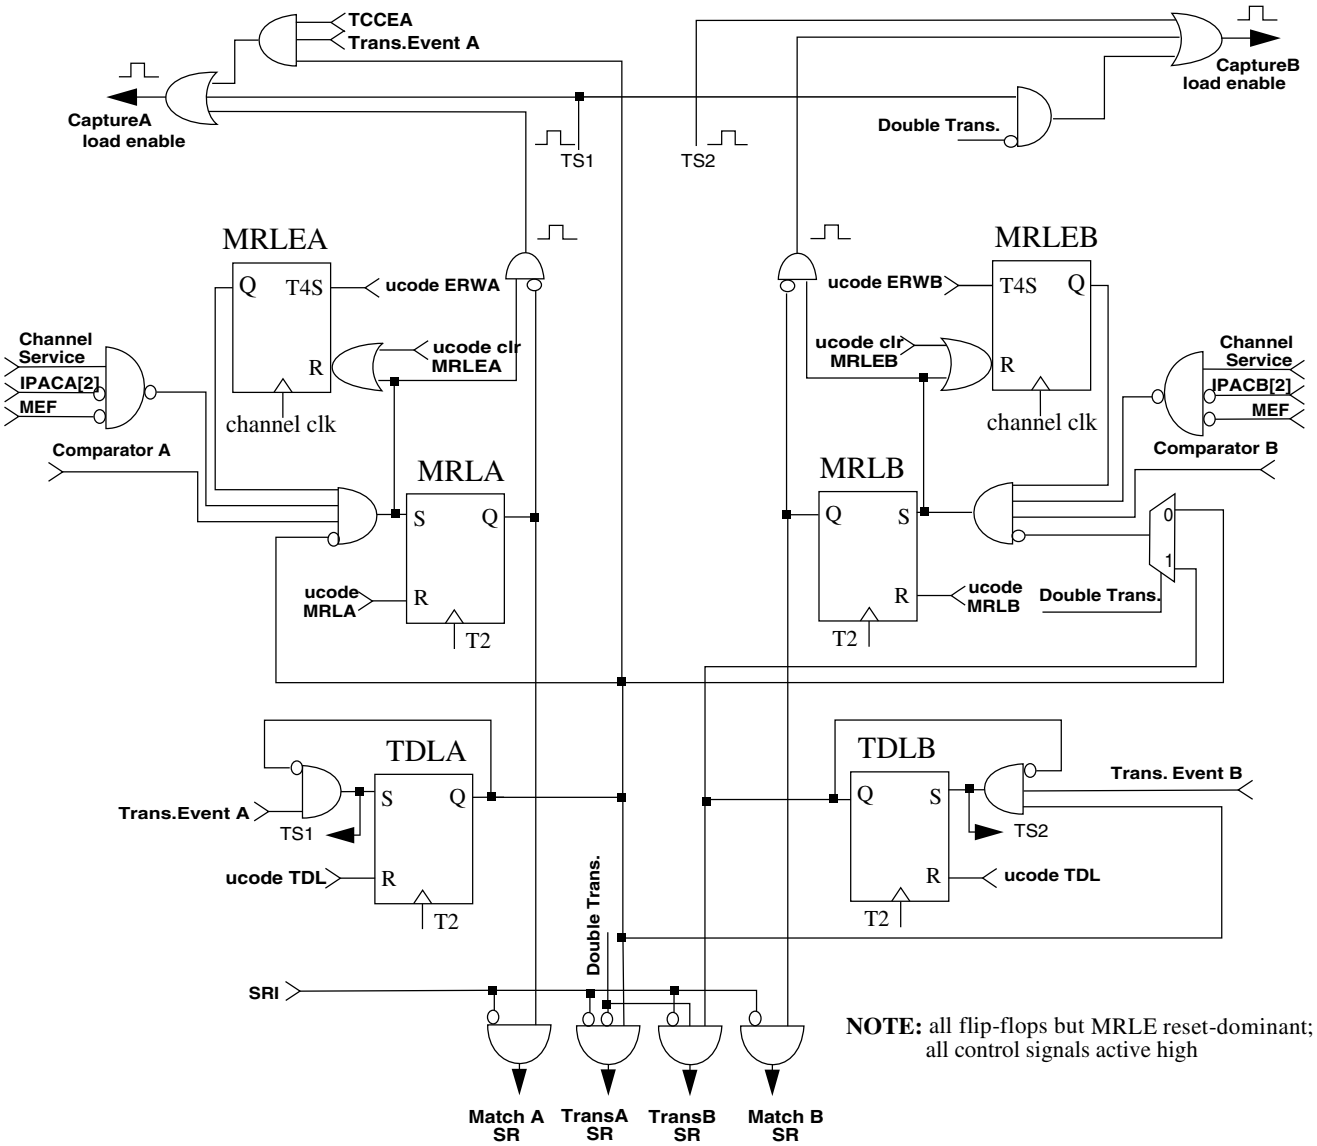

Figure 43-308. Either Match, Non Blocking Modes (em_nb_st, em_nb_dt)

43.14.5.4.2.3 Match B Request Modes (m2_st, m2_dt)

In these modes transitions are initially blocked, and are enabled by Match A. Match B recognition generates the match service request and disables Match A recognition. Each match recognition captures its own programmed timebase. In case of simultaneous match

recognition, both MRLA and MRLB are set, and OPACB register has priority over OPACA for selecting the pin action. The associated logic is shown in the following figure.

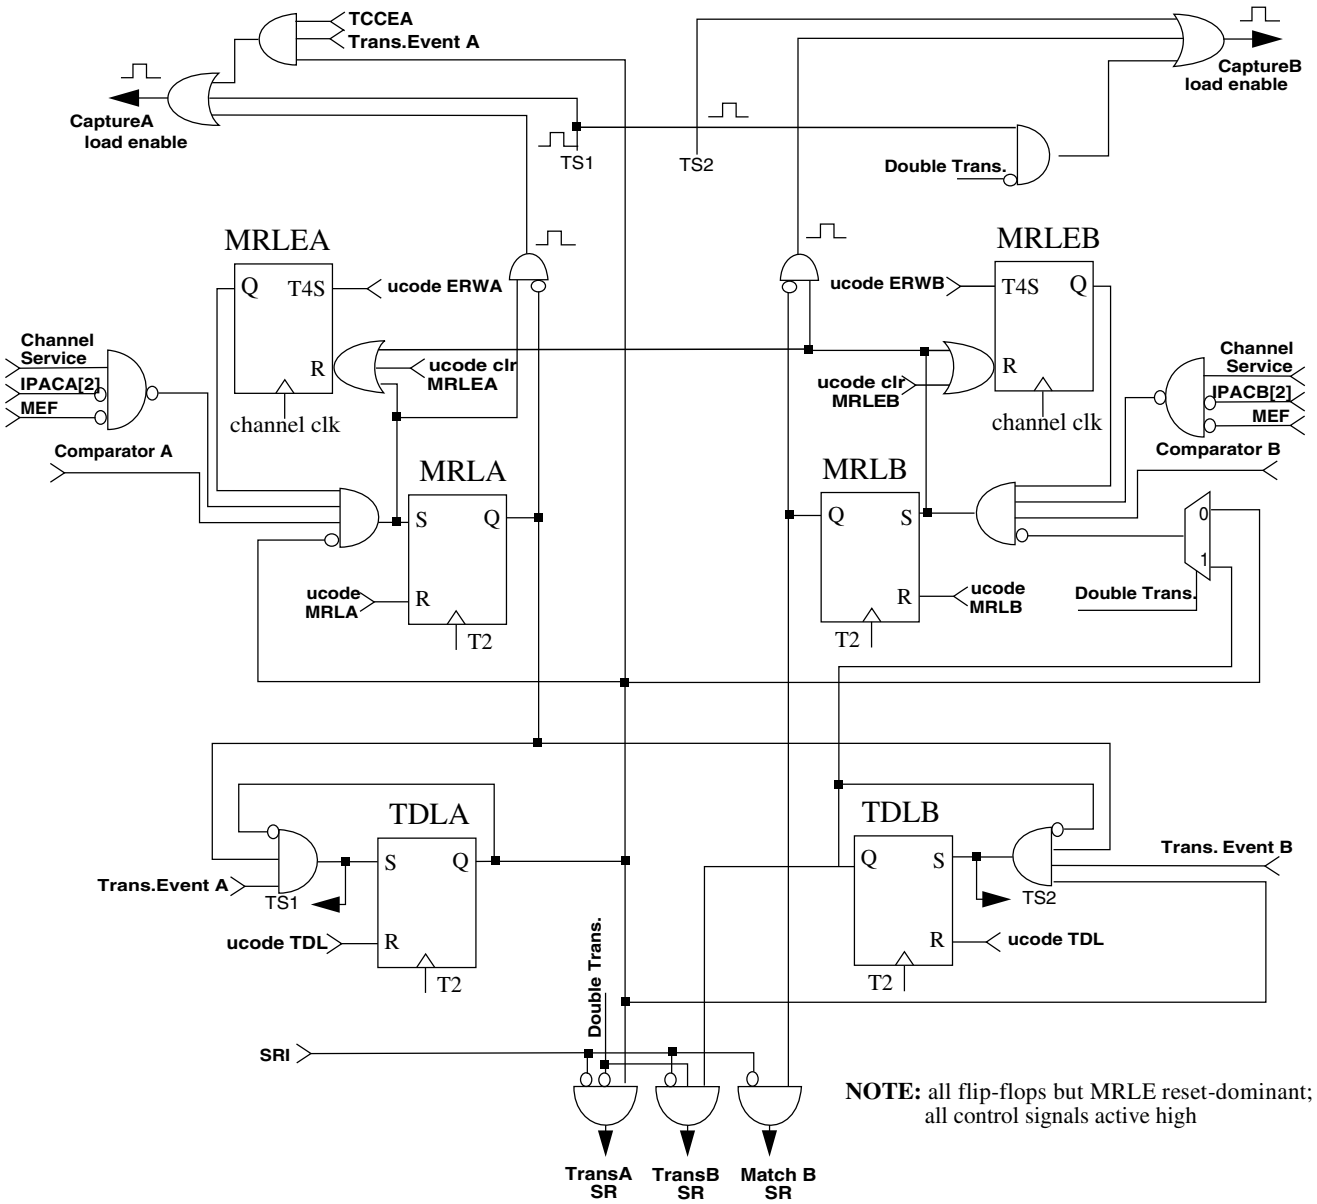

Figure 43-309. Match B Request Modes (m2_st, m2_dt)

43.14.5.4.2.4 Both Match Request Modes (bm_st, bm_dt)

In these modes, match service request is generated only after both match recognitions occurred. By definition this is a non-blocking match mode: match recognitions do not block each other, implementing a last-served scheme. Unlike other double transition

modes, bm_dt blocks Match A with Transition B (not with Transition A), so that the second transition blocks both matches. The associated logic is shown in the following figure.

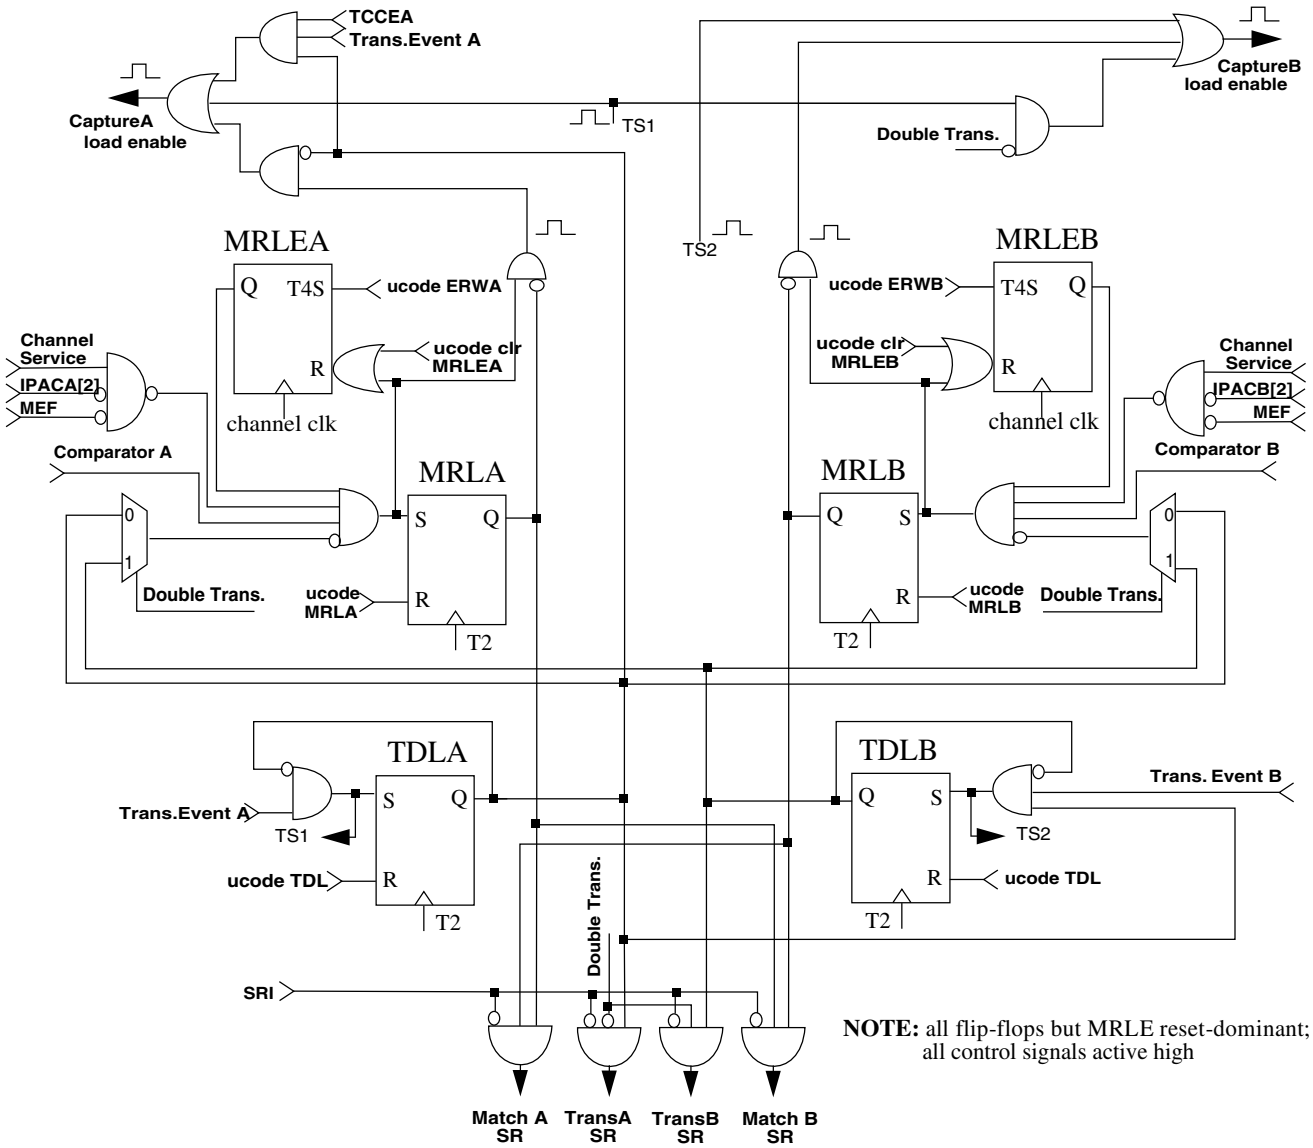

Figure 43-310. Both Match Request Modes (bm_st, bm_dt)

43.14.5.4.2.5 Ordered Modes with Match B Request (m2_o_st, m2_o_dt)

These are ordered match modes on which Match A recognition must precede Match B recognition (ordered 1->2). Match A asserts MRLA and enables Match B and transitions. Match B asserts MRLB, generates a match service request, and blocks both transitions. The associated logic is shown in the following figure.

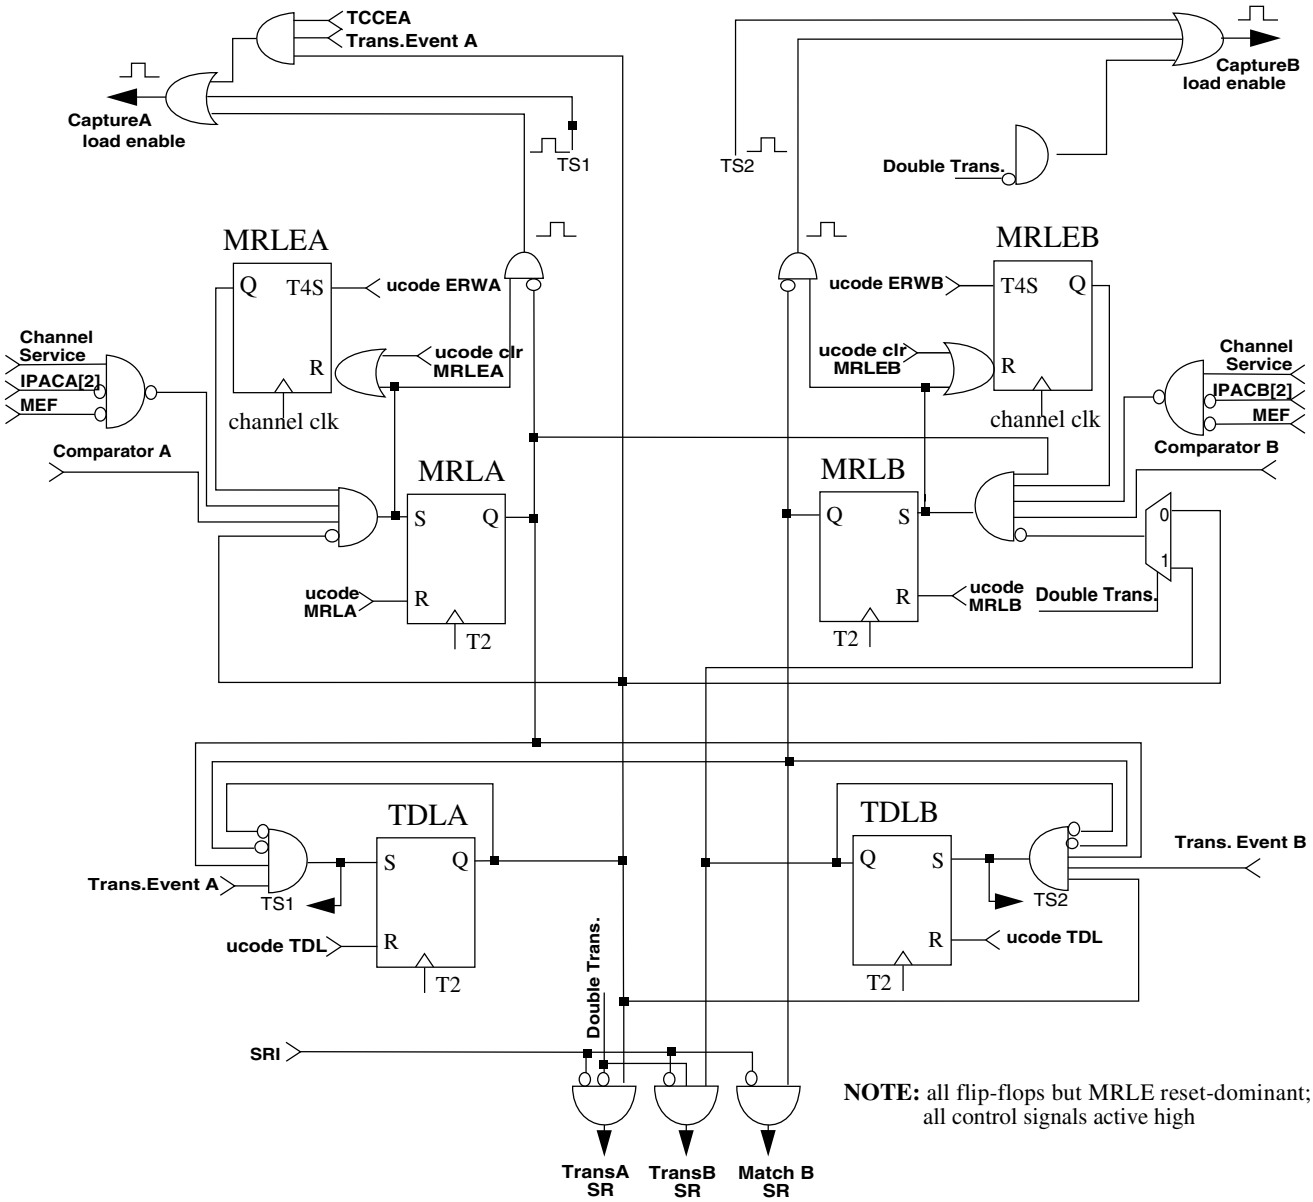

Figure 43-311. Ordered Modes with Match B Request (m2_o_st, m2_o_dt)

43.14.5.4.2.6 Single Match Modes (sm_st, sm_dt)

Single match modes support single or double transition with single match recognition. MRLB is never set, and MRLEB has no effect. The associated logic is shown in the following figure.

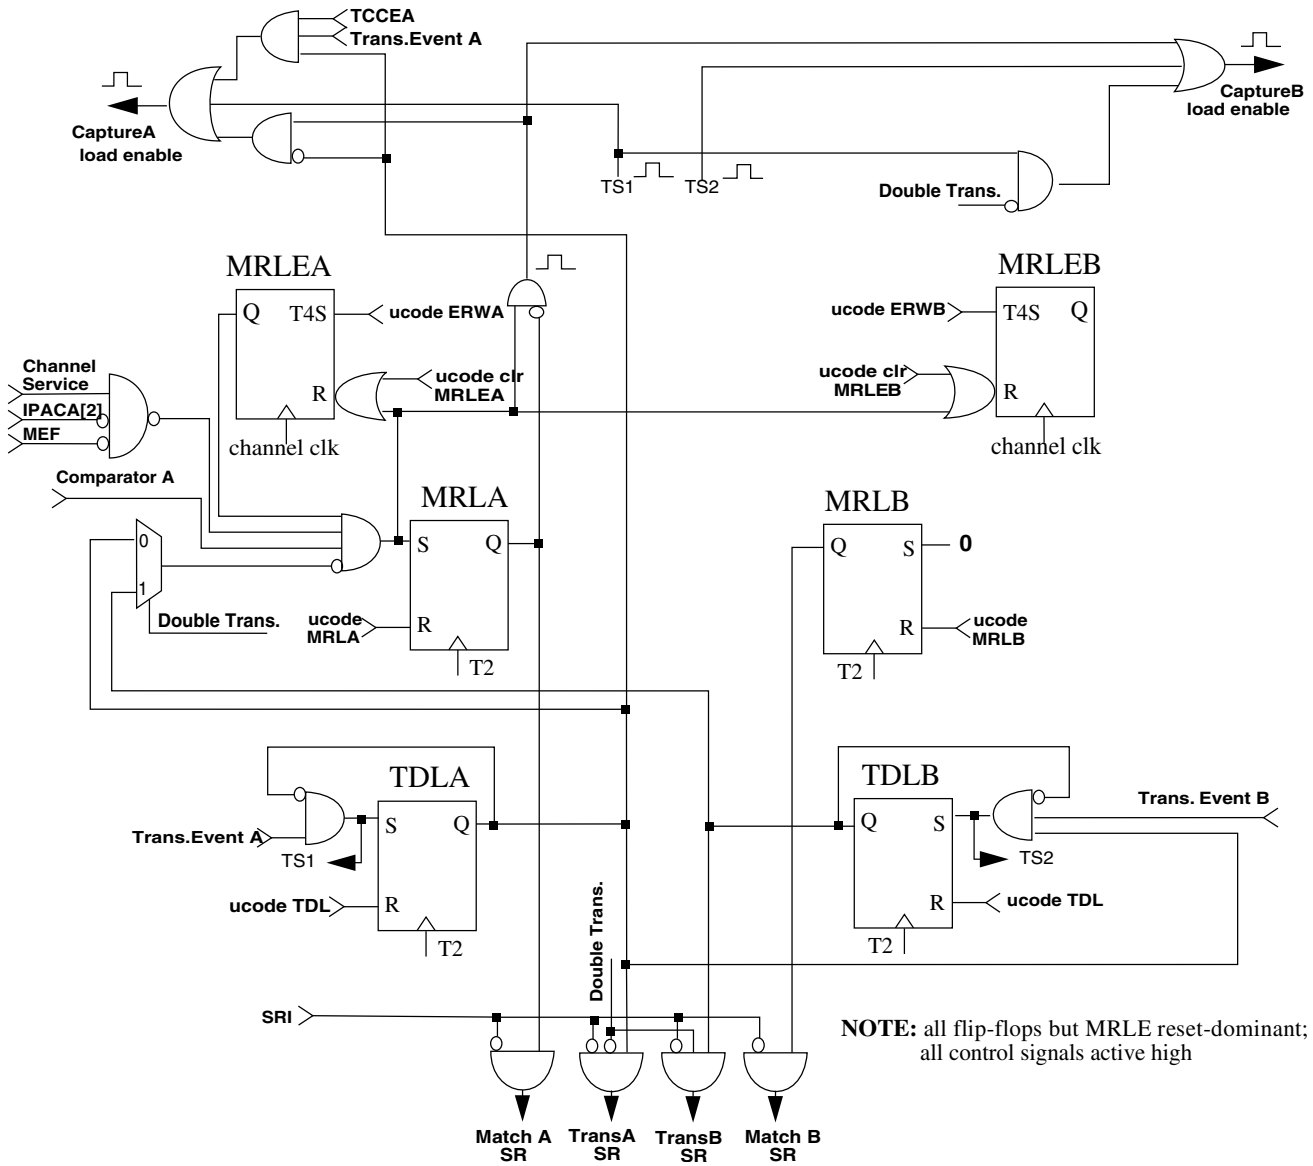

Figure 43-312. Single Match Modes (sm_st, sm_dt)

43.14.5.4.2.7 Single Match Enhanced Mode (sm_st_e)

This is an enhanced single transition and single capture mode, which provides non-filtered input captures in addition to the single capture, allowing one to measure the delay of the digital filter. In an output channel, it has the same functionality of sm_st (captures both time bases at once due to a match recognition). The associated logic is shown in the following figure.

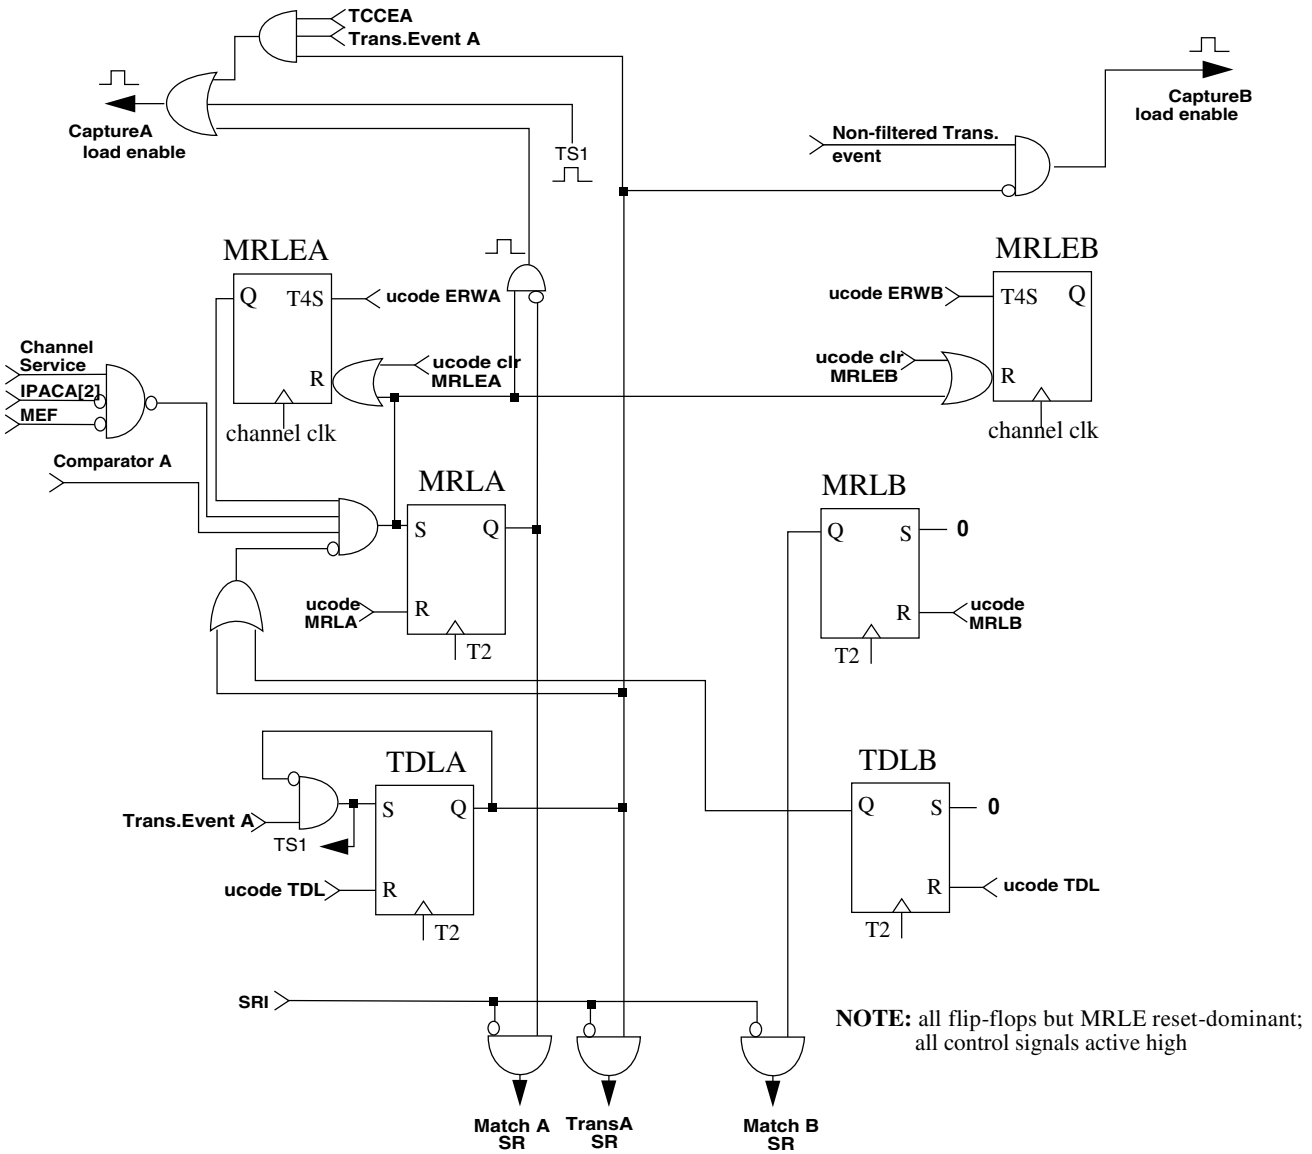

Figure 43-313. Single Match Enhanced Mode (sm_st_e)

43.14.5.4.3 Predefined Channel Modes on Input Signal Processing

When processing an input signal, the predefined channel modes can be classified in the following primary mode groups:

- Single Transition, Single Match: em_b_st, sm_st, sm_st_e
- Single Transition, Double Match: em_nb_st, bm_st, m2_st, m2_o_st
- Double Transition, Single Match: em_b_dt, sm_dt
- Double Transition, Double Match: em_nb_dt, bm_dt, m2_dt, m2_o_dt

In single transition modes, TDLA assertion may capture both time bases at once, while in double transition modes each transition captures its related time base in its related capture register.

Double transition is always ordered, i.e TDLB is enabled by TDLA and generates the service request.

The channel logic supports various input modes with combinations of single/double transition and single/double match, explained in the following subsections.

43.14.5.4.3.1 Either Match, Blocking, Single Transition (em_b_st)

On an input signal, this mode provides double timeout mechanism on a programmed transition edge with two timebases. The signal transition blocks both pending matches, indicating that no timeout condition occurred. The two match recognitions block each other, giving good separation in the entry table as to which match recognition caused the first timeout condition, and generating only one service request. Either match performs timebase captures which do not overwrite captures by transitions.

43.14.5.4.3.2 Either Match, Blocking, Double Transition (em_b_dt)

In double transition mode each transition is related to one match recognition. TDLA assertion captures its related timebase, blocks Match A and enables TDLB. TDLB assertion blocks Match B, captures its related timebase and generates a service request. Match recognitions block each other, so if there is a match timeout condition on TDLA, only one match service request is generated. This mode is good for qualifying two signal transitions by match timeout mechanisms, with one service request. Note that although TDLA assertion does not block Match B recognition, the value captured in CaptureA by TDLA assertion is not overwritten by this recognition. The second transition blocks Match B. Either match performs timebase captures which do not overwrite captures by transitions.

43.14.5.4.3.3 Either Match, Non Blocking, Single Transition (em_nb_st)

On an input signal, this is a double timeout mechanism of independent match recognitions of two different timebases. The match recognitions do not block each other, such that the microcode can check if one or two match recognitions occurred before their related signal transition. The signal transition detection (by IPACA) asserts TDLA, blocks both matches, captures both time bases and generates a transition service request, indicating that none of the two timeout conditions occurred. Any combination can be easily resolved by microcode (for example, signal transition after Match A and before Match B, or signal transition after both Match A and Match B).

Another possible use of this mode is allocating one match recognition for transition timeout and the other for another non-critical timed task, adding functionality to a single channel. Since the transition detection blocks both match recognitions, the match recognition of the other timed task is based on the fact that the comparator checks greater-equal conditions. It may be delayed if it occurs in the period between the signal transition detection (which blocks it) and the time TDLA is negated by microcode. If matches are enabled during the service, the same code can check if the match recognition of the timed task occurred in this period, by negating TDLA and writing to the CHAN register its own value (in order to update the MRLA flag in the branch logic).

43.14.5.4.3.4 Either Match, Non Blocking, Double Transition (em_nb_dt)

In this mode each transition is related to one match recognition, and the match recognitions are independent of each other. This mode can be used to give independent timeout conditions for the first and the second signal transition recognitions, and call service in any case of any timeout condition.

The first transition detection programmed in IPACA sets TDLA, captures its related timebase, blocks Match A recognition and enables TDLB assertion. The second transition detection programmed in IPACB sets TDLB, blocks Match B recognition, captures its related timebase and generates a service request. Any match recognition that occurs captures its related time base and generates a match service request, independent on the other match recognition.

43.14.5.4.3.5 Match B Request, Single Transition (m2_st)

On an input signal, this mode provides an open window filter for a single signal transition. MRLA assertion opens the window, and enables transition detection on TDLA from this time on. MRLB assertion blocks Match A (by negating MRLEA), providing conditional window opening, because transitions are indirectly blocked. It also generates service request, but if it happens after Match A it does not block transitions, providing a non-blocking timeout mechanism for the estimated signal transition time (typically it indicates a missing transition, or mis-prediction of the transition time).

Transitions can be detected from the microcycle following MRLA assertion. The Transition A detection asserts TDLA, blocks both matches, captures both timebases and generates service request.

Using this mode, the channel can replace software open window filtering of qualified transitions with the channel hardware window. The window opening and timeout can be scheduled for any of the two time bases or combination of them. Typically, Match A will be used to open a prediction window, and Match B will be used as a timeout condition

which does not close the prediction window. This configuration improves noise immunity from early signal transitions, and reduces the probability for blocking late signal transitions due to timeout mis-prediction.

Using these conditions, the microcode can easily resolve the state:

- If TDLA and MRLA are asserted and MRLB negated, signal transition is in the expected range.
- If MRLA and MRLB are both asserted, and TDLA is asserted, the signal transition had a timeout condition due to Match B mis-prediction.
- If MRLB is asserted and TDLA negated, a timeout condition occurred, and the expected signal transition had not occurred yet.
- If MRLA is negated and MRLB is asserted, the conditional window did not open at all (for example: a time window is open only after a specific angle, otherwise it is not opened).

43.14.5.4.3.6 Match B Request, Double Transition (m2_dt)

This mode is used as an open window filter for two signal transitions. In this case the Match A recognition opens the window (unless Match B recognition occurred first), and Match B recognition blocks Match A and generates a match service request. It is similar to m2_st, but in this case, it is the second transition that blocks Match B. MRLB assertion is a global timeout condition for the two pulses. Like m2_st, MRLB can conditionally eliminate the window from opening.

Using the TDLA, TDLB, MRLA and MRLB conditions, the microcode can easily resolve the state, in a similar manner as m2_st, with additional information on the second transition (TDLB).

43.14.5.4.3.7 Both Match Request, Single Transition (bm_st)

On an input signal, this is a double timeout mechanism on two different time bases. Both match recognitions must occur before the signal transition to generate a match timeout service request. Assertion of TDLA blocks both Match A and Match B recognitions, and captures both time bases, indicating there was no double timeout condition from both time bases.

Using the same timebase implements two timeout conditions, the first only sets its related MRL and the second generates a service request. Using these flags allows the microcode to check if one or both match recognitions precede the signal transition.

43.14.5.4.3.8 Both Match Request, Double Transition (bm_dt)

In this mode the first transition detection does not block matches, since both match recognitions are required to generate a match service request. The second transition detection asserts TDLB, blocks Match A and Match B, captures its related timebase and generates transition service request. In this mode, a Match A recognition which occurs after the assertion of TDLA does not capture a new value in CaptureA, to preserve the actual signal transition time. Assertion of TDLA, however, always captures its related timebase.

This mode allows putting a double match timeout condition on the second transition. Typically, a pulse trailing edge timing can be checked against two time bases, to indicate if the pulse has not ended when both MRLA and MRLB are asserted. When a transition service request is generated by TDLB assertion, the state of MRLA and MRLB indicates which timeout condition occurred, if any.

43.14.5.4.3.9 Ordered Mode with Match B Request, Single Transition (m2_o_st)

On an input channel, this mode provides a closing window filter for a single signal transition. Match A assertion captures its programmed time base in CaptureA, opens the filter window (enables assertion of TDLA), and enables assertion of MRLB. Match B recognition captures its related timebase, closes the window (disables assertion of TDLA) and generates a service request. Due to Match A and Match B ordering, the window is opened for at least one microcycle. Match B recognition indicates a window timeout condition which blocks late signal transitions, outside the prediction window. Transition detection blocks both matches, indicating the transition occurred inside the estimated window. Transitions can be detected from the microcycle following MRLA assertion until the microcycle on which MRLB is asserted. When TDLA is asserted inside the window range it disables both matches, captures both time bases and generates a transition service request.

Using this mode, the channel can replace software window filtering of qualified transitions with the channel hardware window. The window opening and closing time can be scheduled for any of the two time bases or a combination of them.

43.14.5.4.3.10 Ordered Mode with Match B Request, Double Transition (m2_o_dt)

In this mode the channel logic implements a window filter for two detected signal transitions. MRLA assertion captures its related timebase and enables the assertion of both TDLA and TDLB. MRLB assertion captures its related timebase and disables the assertion of both TDLA and TDLB. Transitions can be detected from the microcycle following MRLA assertion until the microcycle on which MRLB is asserted. The first

signal transition (following MRLA assertion) asserts TDLA, captures its related timebase and enables assertion of TDLB. The second signal transition detection asserts TDLB, blocks Match B, captures its related timebase and generates the service request.

If both signal transitions occur inside the scheduled window, Match B recognition is blocked. If one or both signal transitions do not occur inside the scheduled window, Match B recognition generates a match service request and blocks further transition detections. The microcode can resolve the state using MRLA, MRLB, TDLA and TDLB, which affect the entry point selection.

43.14.5.4.3.11 Single Match Enhanced Mode (sm_st_e)

This is an enhanced single transition and single match channel mode which provides timing information of the digital filter delay.

The CaptureA register captures the timebase selected by TBSA due to transition detection specified by IPACA or match recognition, as in sm_st mode. Initially, the CaptureB register continuously captures the unfiltered IPACB-selected signal transitions from the digital filter input, directly from the signal synchronizer. When an IPACA-qualified, filtered transition detection occurs, TDLA is set, MRLA assertion is blocked, and, in addition, captures into CaptureB are also blocked. On service, CaptureA and CaptureB (copied into ERTA and ERTB) holds the time of the qualified transition detection (ERTA), and the time of the last signal transition at the input of the digital filter (ERTB). Subtracting the time in ERTB from the time in ERTA provides the delay of the digital filter.

In a quiet environment, the two captures provide the accurate delay of the digital filter in granularity of two eTPU clocks. In a noisy environment, false transitions may be detected at the input of the digital filter due to the noise, and the delay measurement may be reduced, especially if IPACB selects both edge detection. The microcode can do sanity checks on this value to recognize noise effects (for example: calculated delay is less than the minimum delay of the digital filter).

Note

In Channel 0, if ETPUTBCR field AM=01 (Angle Mode), the unfiltered input comes from TCRCLK input and the filtered input comes from the TCRCLK filter output. The edge is selected by IPACA/B, and is independent of the edge selection by ETPUTBCR field TCR2CTL.

43.14.5.4.3.12 Single Match, Single Transition (sm_st)

In this mode the channel logic is functionally back-compatible to a TPU3 single action channel, but a match or transition detection captures at once both timebases. The mode recognizes a single transition with single match timeout. Either TDLA or MRLA generates service request and captures both timebases. Assertion of TDLA blocks future assertions of MRLA.

43.14.5.4.3.13 Single Match, Double Transition (sm_dt)

In this mode, the first transition detection asserts TDLA, captures a timebase in CaptureA and enables TDLB. The second signal transition asserts TDLB, blocks Match A, captures a timebase in CaptureB and generates a service request.

Match A (before TDLB) captures into CaptureB the timebase selected by TBSA, in order not to overwrite the captured value of TDLA.

This mode is used for scheduling one timeout condition on two input signal transitions (pulse timeout).

43.14.5.4.4 Channel Modes on Output Signal Generation

Since channel logic can generate output signal transitions based on Matches, the channel can be viewed as working in the following primary mode groups for signal generation:

- Single Match: em_b_st, sm_st, sm_st_e, em_b_dt, sm_dt
- Double Match: em_nb_st, bm_st, m2_st, m2_o_st, em_nb_dt, bm_dt, m2_dt, m2_o_dt

The channel logic supports various match channel modes with single/double match, as explained in the following subsections.

43.14.5.4.4.1 Either Match, Blocking Modes (em_b_st, em_b_dt)

On an output signal these modes are useful when using two different time bases to set a required signal transition. The first match condition which is met sets a required pin action, captures both time bases, blocks any effects of the other recognition, and generates a service request. Because the first match recognition blocks the other, the microcode can get good separation in the function entry table as to which match caused the timeout first, and both time bases are captured, enabling the microcode to compare one timebase to the other at the moment of the match recognition. These modes can be used for:

- Scheduling a required pin action to the first match recognition of two different time bases.
- Canceling a programmed pin action scheduled on one time base by match on another timebase (as a consequence of Table 43-351). Microcode has to set the OPAC register of the canceling match to no-action and the OPAC register of the other match to the required pin action which may be blocked. If Match A is the canceling match, it blocks the pin action also in case of two matches at the same time, since it has priority in this case. If Match B is the canceling match, it does not block the pin action in case of two matches at the same time.

43.14.5.4.4.2 Either Match, Non Blocking Modes (em_nb_st, em_nb_dt)

On an output signal these modes are useful in combination with the ME bit set on the entry point, to define an interlaced operation. For example, each match recognition can set a pin action, and the second pin action is not sensitive to microcode latency (ME bit asserted). Example for usage is PWM interlaced function on which the latency is determined by the period and not the duty cycle.

Another possibility is using one match for pin actions and the other match for an unrelated timed task without pin action (double the functionality of a single channel).

43.14.5.4.4.3 Match B Request Modes (m2_st, m2_dt)

On an output signal, these modes can generate narrow pulses or do conditional pin actions. A conditional pin action means that the pin state is changed only if the match recognitions occurred in the correct order, since the Match B recognition which generates the service request also has priority over the pin action and blocks future Match A recognitions.

Setting OPACA to a desired pin action and OPACB to no-action, and using different time bases for Match A and Match B defines a conditional OPACA pin action which can be blocked by Match B recognition. For example, setting Match A on time and Match B on angle can limit the pin action to a maximum angle value.

When pulses are generated, the service is requested at the trailing edge of the pulse, after MRLB is asserted.

43.14.5.4.4.4 Both Match Request Modes (bm_st, bm_dt)

On an output signal, each match recognition can affect the pin state, and capture its programmed time base. This way the pin action can be programmed separately for both match recognitions. For example, both match recognitions can negate the signal, and

service request is generated after both conditions are met. This mechanism can set two conditions to do a required pin action, and the first recognition changes the signal, but service is called only after both conditions occur.

When using the same time base, these modes can generate narrow pulses in any required order. For example, in a PWM function, when duty cycle is below 50% the function can get service on the low time and program the pulse to the required duty cycle of the high time. When duty cycle is equal or above 50%, the function can get service on the high time and program a negative pulse with the width of the required low time. To switch between the two states the function can program once the same transition time to MatchA and Match B with a required pin action, and on the next service program double match for the new state.

Another usage is generating a required pin action on one programmed time and service request later on another time, after the second match recognition occurs, or capturing some timebase on one time and generating a required signal transition and service request later.

43.14.5.4.4.5 Ordered Modes with Match B Request (m2_o_st, m2_o_dt)

The order of the match recognitions imply that OPACA register programmed pin action always precede the OPACB register pin action. Setting OPACA to no-action, based on the greater-equal comparator, enables using Match A on one time base to delay the signal effect of Match B on the other time base. This method implements a conditional pulse extension or conditional delay on signal transition.

These modes can also be used for deferred pulse generation with microcode service request after its trailing edge (if Match A condition comes after Match B condition). Another option is having Match A recognition associated with output pin actions and Match B recognition for a timed microcode task which has to be scheduled at a programmed time which may be delayed by the Match A pin action.

43.14.5.4.4.6 Single Match Modes (sm_st, sm_dt, sm_st_e)

There is no difference between plain and enhanced Single Match modes on an output signal.

In this mode the channel logic is functionally back-compatible to a TPU3 single match output channel. Match A recognition generates service request and sets the pin state according to OPACA register. It captures at once the timebase selected by TBSA in CaptureA and the timebase selected by TBSB in CaptureB.

43.14.5.4.4.7 Match/Transition Pin Action Conflict Resolution

In output signals, matches and/or transitions automatically cause pin actions defined by the OPACA/B and/or IPACA/B channel control registers (see Pin Control Registers). Simultaneous matches/transitions may be associated with different, possibly contradictory, pin actions. These conflicts are resolved according to the table below.

If an OPACA/B=000 (no action) prevails over non-zero OPAC according to the table below, then if Match A/Transition A and Match B/Transition B occur simultaneously, no output pin action occurs, that is: a match on the action logic with OPAC=000 inhibits simultaneous actions of the other OPAC, if prevailing according to the following table. That also applies when output actions are caused by inputs (OPAC=1xx).

Table 43-351. Simultaneous Match Pin Action Priority

Channel Mode	Priority
em_nb_st / em_nb_dt	OPACA
em_b_st / em_b_dt	OPACA
bm_st / bm_dt	OPACA
m2_st / m2_dt	OPACB
m2_o_st / m2_o_dt	in these modes there is no possibility of simultaneous matches
user-defined	OPACB if M2BM1 = 1 and M1BM2 = 0, OPACA otherwise

43.14.5.4.5 Combining Input and Output Signals

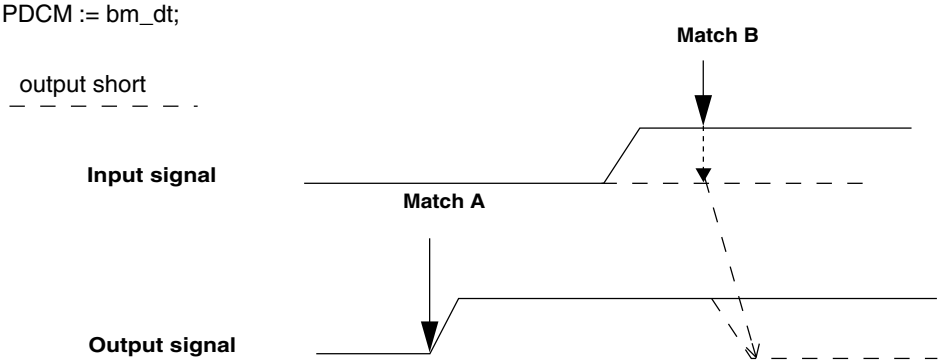
The processing of input signal can be combined with output signal generation. A detected input transition can trigger an output signal edge, even without microcode intervention, by using OPAC options 1xx.

The channel set-up examples below show these two capabilities combined (see the figure below).

The **first example** implements a fast (no microcode intervention) short-circuit protection feedback mechanism for driving high-current output devices. The signal after the high-current driver feeds back to the channel input. The input signal is normally delayed from the output signal by the device turn-on delay. After the channel output turns on, the channel logic must check if the driver output (connected to the channel input) follows the driven value after the maximum device turn-on delay. If it does not, the driver output is probably shorted, and the channel output must be turned off immediately to avoid damaging the device.

Match A causes the output to be driven high (for simplicity the output and input signals are shown as positive logic). It also causes a transition A, because IPACA=100 and the input is still low. Match B occurs after the expected driver delay, and causes a service request. If the output is shorted, a Transition B occurs on Match B because IPACB=100. This will cause the output to go low immediately, because OPACB=100.

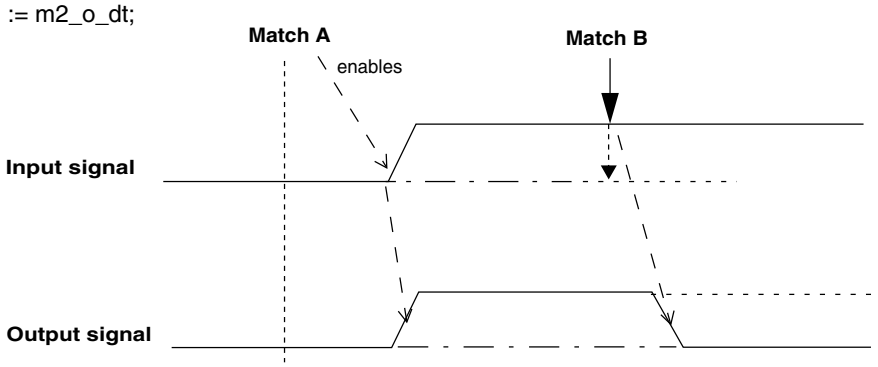
In the **second example**, an output pulse is generated from an input transition without microcode intervention. Match A opens a window for transitions and also enables Match B. A rising edge on input sets output high. On Match B the window closes, and input signal is checked: if sampled high, the output resets; otherwise it stays high.



In the **third example**, a pulse is generated depending on the value sampled on the input signal at a predetermined time. Match A samples the input signal, causing a Transition. Low level on input sets output low, otherwise it stays high. Match B sets output high. In both cases a service request is issued (microcode intervention), at the beginning and at the end of the pulse (Match B), if required (SRI := 0).

Note

When IPAC = 1xx, a match event can cause simultaneously a Match recognition and a Transition detection. Depending on the Channel Mode, these Match and Transition may have conflicting effects on other Transition/Match blocking or enabling. In these cases, blocking always prevails over enabling, effective on the next microcycle.



Example 1: Short-circuit protection feedback

IPACA := 100; OPACA := 001; MatchA := output activate time;
IPACB := 100; OPACB := 100; MatchB := MatchA + max. high-current driver turn-on delay;
PDCM := bm_dt;

Example 2: Pulse generation on windowed input transition

IPACA := 001; OPACA := 101; MatchA := window open time;
IPACB := 101; OPACB := 100; MatchB := window close time, input sampling;
PDCM := m2_o_dt;

Example 3: Pulse generation on input sampling

IPACA := 100; OPACA := 100; MatchA := window open time,input sampling;
IPACB := 000; OPACB := 001; MatchB := window close time = MatchA + pulse width;
PDCM := em_nb_dt;

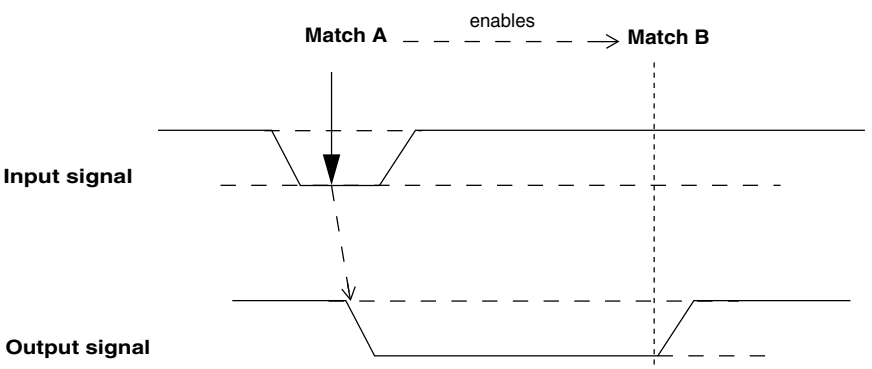


Figure 43-314. Input/Output combination

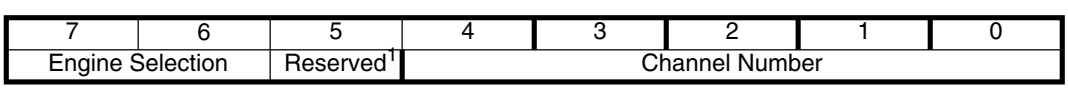
43.14.5.5 Channel Link



A channel can issue service requests to other channels through microcode, by assigning to the write-only microengine register LINK (refer to LINK Register) a value which specifies the target channel of the Link Service Request, as shown in the figure below.

Writing to the LINK register issues a link request to the target channel, setting its LSR flag. Each channel has its own LSR flag, which can be tested as a microcode branch condition (see Conditional/Unconditional Branch) and reset through the microcode field LSR (see Clear Link Service Request). The link branch condition samples, at the TST start, the value used to calculate the Entry Point.

Writing LINK with another channel target value in the same thread issues a Link Service Request to the new target, without negating the service request to the former one. This allows a channel to issue service requests to any number of channels, including itself. Neither LINK nor LSR microengine accesses are qualified by the CHAN register, i.e., they always access the serviced channel LINK and LSR, regardless of the value written in CHAN.

Channels can also receive link service requests from the Shared Subsystem Units (see Shared Subsystems Support). These links are set by the interrupt signals from the shared subsystem and are level-sensitive, that is, they keep on requesting link service as long as the interrupt is active. Therefore, it is not enough to clear the link service request through the LSR instruction field: one must clear beforehand the respective shared subsystem unit interrupt source.

If microcode executes an instruction with field LSR=0 (clear Link Service Request), the link branch condition is cleared. However, the link service request itself is cleared only if no link from other channel was received by the serviced channel during the same thread[26] . Note that this applies only to links that come from the other engine or the same channel: if only Shared Subsystem link was received during the thread, the link service is also cleared with field LSR=0. If microengine clears LSR of its channel and, simultaneously, Link Service Request is issued to the current serviced channel, the branch condition is cleared but the link service request remains pending.

NOTES:
1 reserved bit must be written 0.

Figure 43-315. Microengine LINK Register

26. That can only happen if the link service request came from the other Engine, or from the serviced channel itself.

A channel can issue Link Service Requests to channels in any of two Engines, determined by the LINK register field Engine Selection (2 bits), as shown in the following table. In a Single Engine eTPU, Link is ignored when sent to the other engine, or engine 2.

Table 43-352. LINK Engine Selection

Engine Selection	Description
00	this Engine
01	Engine 1
10[1, 1]	Engine 2
11[1]	the other Engine

1. ignored in Single Engine eTPU.

There is no explicit hardware mechanism to allow the thread to identify the link service request source, but it can be done by a software protocol using SDM parameters. All links are negated on reset.

43.14.5.6 Enhanced Digital Filter - EDF

The EDF eliminates passing of signal transitions which are caused by noise. Its purpose is to eliminate false transition service requests caused by noise pulses which are shorter than a programmed width.

See the chip-specific eTPU information for connections between eTPU and input glitch filters.

The EDF has three modes of operations, selected by the CDFC field in the ETPUECR register (see the ETPUECR register). These modes offer selections of trade-off between noise immunity and signal latency. CDFC also allows the filter to be bypassed. Table 43-353 gives an example of minimum detected signal pulse and maximum filtered noise pulse in the three EDF operation modes. In Angle Mode, if AM=01, the EDF in channel 0 is replaced with the digital filter and synchronizer of the TCRCLK signal. In this mode, channel 0 works in combination with the Angle Counter logic, and their operation is fully synchronized.

Following subsections provide the functional description of the eTPU channel digital filter.

43.14.5.6.1 Two-Sample Mode

In this mode the EDF works like the TPU2/3 digital filter. It uses the filter clock which is the eTPU clock divided by (2, 4, 8,.., 256) as a sampling clock. The filter clock is selected by the FPSCK field in the ETPUECR - Engine Configuration Register (see the ETPUECR register). The EDF compares two consecutive samples. If both samples have the same value, the input signal state is updated. Note that when the FPSCK field selects the eTPU clock divided by two, the EDF works like the TPU1 four-clock digital filter.

43.14.5.6.2 Three-Sample Mode

In this mode, like in the TPU2/3 mode, the EDF uses the filter clock as a sampling clock. The EDF compares three consecutive samples. If all three samples have the same value, the input signal state is updated.

The Three-Sample mode gives more signal latency than the Two-Sample mode, but also better noise immunity and better ratio between minimum detected signal pulse to maximum filtered noise pulse. When a certain filter clock frequency is selected for Two-sample mode, double filter clock frequency can be selected to get better latency in Three-sample mode.

43.14.5.6.3 Continuous Mode

In this mode the EDF compares all the values sampled at the rate of eTPU clock divided by two, between two consecutive filter clock pulses. If the signal is continuously stable for the entire digital filter clock period (i.e all the samples have the same signal value), the input signal state is updated.

This method gives the same latency and the same ratio between minimum detected signal pulse to maximum filtered noise pulse, as the Two-Sample mode, as long as there is no noise. Each sampled noise delays the signal transition detection by at least a whole digital filter clock period.

The Continuous mode gives the best noise immunity by comparing multiple samples of the noise. On the other hand, when a short noise pulse appears in the middle of the filter clock period at the same time of a real signal transition, the Continuous mode may reject a real signal transition and delay the response to the first filter clock period in which the signal is continuously stable. This may add to the latency and also to the minimum detected signal pulse in a noisy environment.

43.14.5.6.4 Bypass Mode

In bypass mode the signal that feeds the edge detection comes directly from the output of the synchronizer, not filtered. Bypass mode automatically makes the channel logic work in T2/T4 timing mode (see Channel Timing Modes).

43.14.5.6.5 Filter Clock Prescaler

Each channel configured as an input has an associated synchronizer followed by a digital filter connected to the signal that samples signal transitions. After reset, the digital filter filters out high and low pulse widths smaller than the period of two eTPU clocks with ETPUECR bit FCSS=0, or 1 eTPU clock with FCSS=1, preventing these transitions from being input to the transition detect logic. For FPSCK=0 and FCSS=0, the synchronizer and digital filter are guaranteed to pass pulses that are as wide as or wider than four eTPU clocks, meaning a minimum period of 8 eTPU clocks. These figures are halved by setting FCSS=1. By changing the FPSCK field in register ETPUECR the user can select a lower clock rate for the filter signal to define wider valid pulses and filter out wider noise pulses. The filter prescaler clock control is a division of the eTPU clock. To guarantee pulse detection by the digital filter, the pulse must cover at least the stated number of samples at the filter clock rate. For example, a two sample digital filter must sample two points in the pulse to detect it. The table below shows the minimum guaranteed detected pulse width and the maximum filtered noise pulse width. The table refers only to the digital filter operation. The external pulses may have to be wider (to ensure detection) or narrower (to ensure filtering) depending on the rise/fall delay differences in the MCU receivers and internal logic. Delays introduced by synchronizer, filter and edge detection logic are explained in Input/Output Signal Delays.

The TCRCLK signal also has a synchronizer and a filter. The FCSS bit has no influence on the clock prescaler of the TCRCLK filter, which works like the channel filter with FCSS=0.

Table 43-353. Pulse Widths and Delays

Filter Control (FPSCK)		Filter Clock Period[1]	Min. Width Guaranteed Detected / Max. Width filtered (Min. Filter Delay / Max. Filter Delay)[1, 1]	
FCSS = 0	FCSS = 1		Two-Sample or Continuous Mode	Three-Sample or Integrator[2] Mode
not avail.	000	1	2 / 1 (2 / 3)	3 / 2 (3 / 4)
0003	001	2	4 / 2 (3 / 3)	6 / 4 (5 / 5)
001	010	4	8 / 4 (5 / 7)	12 / 8 (9 / 11)
010	011	8	16 / 8 (9 / 15)	24 / 16 (17 / 23)
011	100	16	32 / 16 (17 / 31)	48 / 32 (33 / 47)
100	101	32	64 / 32 (33 / 63)	96 / 64 (65 / 95)

Table continues on the next page...

Table 43-353. Pulse Widths and Delays (continued)

Filter Control (FPSCK)		Filter Clock Period[1]	Min. Width Guaranteed Detected / Max. Width filtered (Min. Filter Delay / Max. Filter Delay)[1, 1]	
FCSS = 0	FCSS = 1		Two-Sample or Continuous Mode	Three-Sample or Integrator[2] Mode
101	110	64	128 / 64 (65 / 127)	192 / 128 (129 / 191)
110	111	128	256 / 128 (129 / 255)	384 / 256 (257 / 383)
111	not avail.	256	512 / 256 (257 / 511)	768 / 512 (513 / 767)

1. This table shows pulse widths and delays in number of periods of the eTPU clock.
2. Integrator mode is available for TCRCLK filtering only, see TCRCLK Digital Filter."
3. These delays also apply to the TCRCLK filter when TCRCF selects eTPU clock/2 as filter clock.

Note

The TCRCLK filter is clocked as if FCSS=0, always dividing eTPU clock /2 using FPSCK, regardless of the FCSS field.

43.14.5.7 Channel Timing Modes

Channels can work on two different timing schemes, defining the period of channel clocking, tied to T2 and T4 microengine phases, as explained in subsections below. Microengine T2 and T4 phases are shown in Microcycle and I/O Timing.

43.14.5.7.1 T2 Channel Timing

In T2 timing mode the channel event state can only be updated every two eTPU clocks (see Figure 43-343). Pin state, TDLs, MRLs and Capture registers are updated on the microengine's T2 clock phase. MRLE clears also happen on T2, but MRLE setting occurs on T4, together with the Match register write by microcode (see Write Channel Match and UDCM Registers).

Channels work in T2 timing mode when either ETPUCxCR bit T4DIS=1 or all the following conditions are true:

- ETPUTBCR bit TCR1CS is 0 (see the ETPUTBCR register.
- the Enhanced Digital Filter is not configured as bypass (see Enhanced Digital Filter - EDF).
- ETPUECR bit FCSS is 0 (see Filter Clock Prescaler).

43.14.5.7.2 T2/T4 Channel Timing

In T2/T4 timing mode the channel event state can be updated on any eTPU clock (see Figure 43-344). Pin state, TDLs, MRLs, MRLEs, and Capture registers are updated either on microengine's T2 or T4 clock phases. MRLE clears can happen on T2 or T4, but MRLE setting occurs on T4 only, together with the Match register write by microcode (see Write Channel Match and UDCM Registers).

Channels work in T2/T4 timing mode when ETPUCxCR bit T4DIS=0 and either one the following conditions are true:

- ETPUTBCR bit TCR1CS is 1 (see the ETPUTBCR register.
- the Enhanced Digital Filter is configured as bypass (see Enhanced Digital Filter - EDF).
- ETPUECR bit FCSS is 1 (see Filter Clock Prescaler).

T2/T4 timing mode demands special care on channel microcode that reprograms a match in a thread with matches enabled (entry point ME=1, see the “Entry Points” section). When the match register is written and the MRLA/B flag(s) is(are) cleared in the same instruction, a match can occur after MRLA/B is cleared, together with the set of respective MRLE. In this case, both MRL and MRLE will be set, and a match service request will occur if enabled. However, the match happened on the old match value, not on the new (reprogrammed) one. In order to prevent this ambiguity to the code that services the match, it is advisable to clear the MRLE (besides MRL) together with the match reprogramming, avoiding the match on the old value to occur while the new match value is being written. The set of the MRLE due to match reprogramming prevails over the MRLE clear, thus allowing the new programmed match to occur in the future.

A similar case occurs when a match is blocked by a transition, the blocking TDL is cleared and the blocked match is reprogrammed at the same instruction: in T2/T4 timing mode: a match can occur on the old match value. The solution is the same as the case above, that is, clear the respective MRLE in the same instruction.

43.14.6 Time Bases

Each eTPU engine has two Time Counter Registers, TCR1 and TCR2. They provide 24-bit time bases, shared by all 32 channels. Any channel can use both time bases to:

- Match channel's internal registers MatchA or MatchB;
- Capture time base value to channel's internal registers, CaptureA and/or CaptureB, when a match recognition or an Input transition detection occurs. For more information on channel events refer to Enhanced Channels.

The TCR1 and TCR2 counters are accessible by the microcode for read and write operations. Its current value is used for getting the current time, and the captured values are used for channel relative time calculations of future events. When they are written at the same time they are incremented from any clock source, the written value prevails.

TCR1 with ETPUTBCR[TCR1CS]=0 and TCR2 values are updated in T2 and read in T4 (see Microcycle and I/O Timing). TCR1 can also work at full-speed eTPU clock, and so be updated on both T2 and T4, when ETPUTBCR[TCR1CS]=1. Both TCR1 and TCR2 values can be imported from or exported to the STAC bus. When their values are imported (STAC Clients), these registers are written from the STAC bus and can only be read by microcode.

The TCR2 counters between the two Engines are out of phase by 1 eTPU clock, even when Time Bases are shared between them through STAC . It also applies to TCR1 counters if ETPUTBCR[TCR1CS]=0, but they can be in phase otherwise.

43.14.6.1 Timer Count Register 1 - TCR1

TCR1 can be used in the following modes:

- Internally Clocked Mode
- Externally Clocked Mode
- STAC Bus Client Mode

The host program can read TCR1 time base through the ETPUTB1R (see the ETPUTB1R register).

The TCR1 bus runs through all the local engine channels. In channels which select TCR1 as MatchA and/or MatchB source, when its value is greater or equal to the programmed match value, a Match A and/or Match B event occurs on that channel. A recognized match event sets its related Match Recognition Latch 1 or 2, and according to the Predefined Channel Modes (PDCM) it may generate a channel service request. For details on eTPU channels refer to Enhanced Channels.

43.14.6.1.1 Externally Clocked Mode

TCR1 can be driven externally by the TCRCLK input, after the digital filter. The TCR1 clock source is configured by the TCR1CTL bit, as shown in the following figure. For more information on clock source selection, please refer to the ETPUTBCR register.

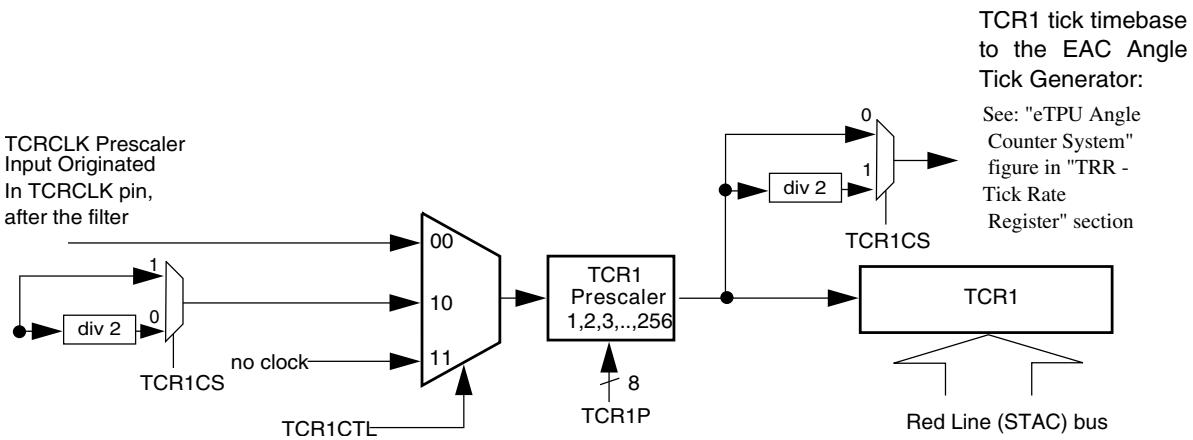


Figure 43-316. TCR1 Clock Selection

43.14.6.1.2 Internally Clocked Mode

TCR1 can be driven by the eTPU clock or eTPU clock divided by 2, before the prescaler. TCR1CTL can also be used to freeze TCR1 clock independently of TCR2 (unlike GTBE).

43.14.6.1.3 TCR1 Clock Prescaling

Any clock source selected by TCR1CTL is prescaled by a factor of 1 to 256, selected by ETPUTBCR field TCR1P. For more information on prescaler configuration refer to the ETPUTBCR register. The TCR1 Prescaler resets when the eTPU GTBE input is negated. After reset, it starts counting up to TCR1P when the eTPU GTBE input is asserted. When TCR1 increments (the eTPU GTBE input = 1), the prescaler starts a new count and the new TCR1P becomes effective. When TCR1 is written by microcode, the prescaler is reloaded with TCR1P and it becomes effective, if the eTPU GTBE input is asserted.

43.14.6.1.4 STAC Bus Client Mode

In this mode the TCR1 register is continuously updated from the STAC bus, and the clock selection and prescaling logic becomes ineffective. It is not writable by the microcode, and when read, it reflects the STAC bus imported value. The use of EAC is not allowed in client mode. This mode is configured through the ETPUREDCR register (see the ETPUREDCR register).

43.14.6.1.5 STAC Bus Server Mode

TCR1 bus can be exported to the STAC bus as a server, providing time information to other peripherals. This mode is configured through the register ETPUREDCR (see the ETPUREDCR register).

43.14.6.2 Timer Count Register 2 - TCR2

The TCR2 is a 24-bit counter which can be used in the following modes:

- Pin Transition Mode: Count the rise, fall or both transitions of TCRCLK signal.
- Angle Clock Mode: Count internal tooth angle in combination with the eTPU Angle Counter (EAC) hardware which implements an Angle PLL, and generates angle information to the channels. This mode is targeted for angle based applications.
- STAC (STAC) Bus Client Mode: TCR2 is driven by an external source (see STAC Bus Client Mode).
- Gated Mode: Count with rate derived from the eTPU clock divided by eight. The TCRCLK signal is used to gate this count, enabling pulse accumulator operations.
- Internally Clocked Modes: TCR2 is driven by internal clock, with count rate of eTPU clock divided by eight.

All clock sources pass through a prescaler. In addition, the TCR2 count can be originated from the EAC which is a hardware angle clock and angle counter. Figure 43-317 shows the diagram for TCR2 clock control. When TCR2 is not driven by the EAC or STAC, the ETPUTBCR field TCR2CTL selects the clock source, also allowing TCR2 to be frozen independently of TCR1 (see the ETPUTBCR register). When in Angle Mode, TCR2CTL selects the TCRCLK edge sensitivity.

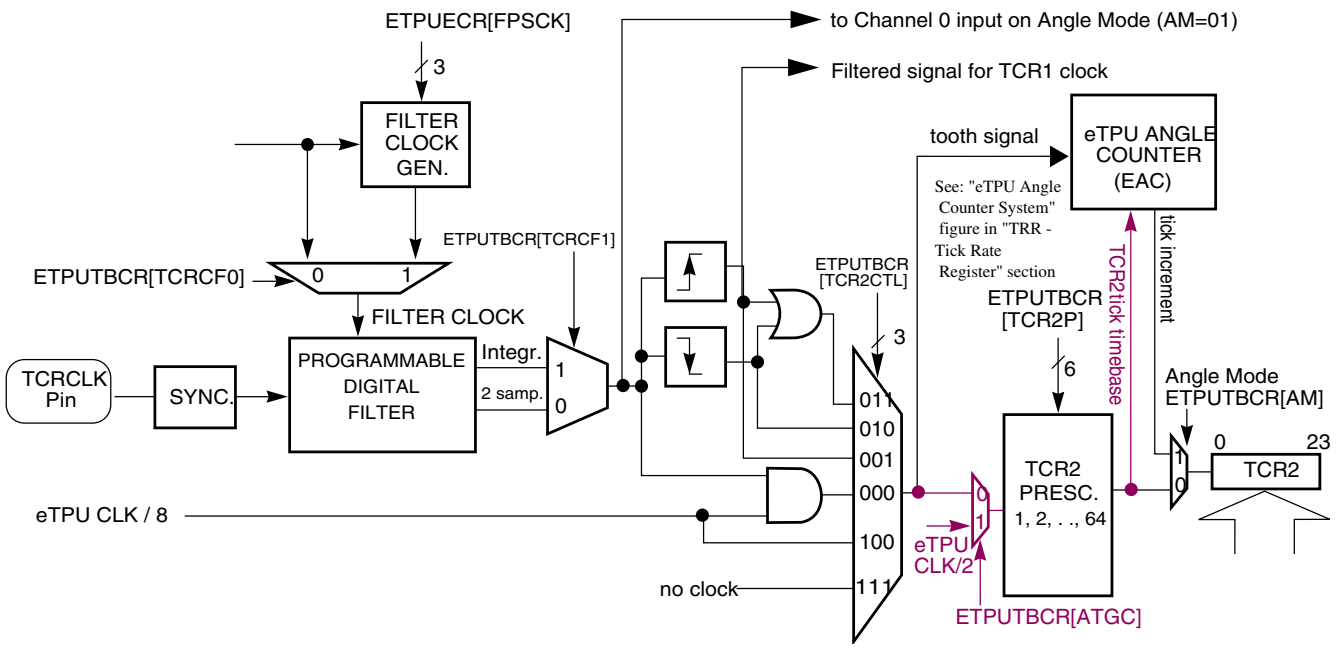

Figure 43-317. TCR2 Clock Control

The TCRCLK signal input is passed through a synchronizer and a programmable digital filter. In Angle Mode with AM=01, synchronizer and filter are also used in Channel 0, replacing its input synchronizer and filter, to get the same timing in the EAC and Channel 0. The TCRCLK synchronizer is an improved filter that provides best latency while maintaining proper noise filtering (see the field TCRCF in eTPU Engine 1 Time Base Configuration Register (eTPU_TBR_TBCR_ENG1)

The TCR2 bus runs through all the local engine channels. It transitions on clock T2 (see Microcycle and I/O Timing). In channels which select TCR2 as MatchA and/or MatchB source, TCR2 value is compared against MatchA and/or MatchB registers. A recognized match event sets its related Match Recognition Latch 1 or 2, and according to the Predefined Channel Modes (PDCM) it may generate a channel service request. For details on eTPU channels refer to Enhanced Channels.

The TCR2 counter is accessible by the microcode for read and write operations. Its current value is used for getting the current counter value (representing signal transitions, time or angle), and the captured values are used for channel relative count calculations of future events. The TCR2 value is readable to the host through the ETPUTB2R register (refer to the ETPUTB2R register). When the TCR2 bus value is imported from the STAC bus (STAC client mode), TCR2 is not writable by the microcode, and read access from the microcode or from the host reflect the imported TCR2 value.

43.14.6.2.1 TCR2 Clock Prescaling

Except in Angle Mode, any clock source selected by TCR2CTL is prescaled by a factor of 1 to 64, selected by ETPUTBCR field TCR2P. For more information on prescaler configuration refer to the ETPUTBCR register. The TCR2 Prescaler resets when the eTPU GTBE input is negated. After reset, it starts counting up to TCR2P when the eTPU GTBE input is asserted. When TCR2 increments (the eTPU GTBE input = 1), the prescaler starts a new count and the new TCR2P becomes effective. When TCR2 is written by microcode, the prescaler is reloaded with TCR2P and it becomes effective, if the eTPU GTBE input is asserted.

The counter that divides the eTPU clock by 8 before the prescaler also resets when the eTPU GTBE input is negated, or when TCR2 is written by microcode.

In Angle Mode the TCR2 prescaler is not used to directly increment TCR2, but can be used, selected by ETPUTBCR bit ATGC=1, as a clock source for the EAC generation of the angle ticks which increments TCR2. In this case, the TCR2 prescaler input is eTPU clock/2, independently of TCR2CTL. See Generating the Angle Ticks for details.

43.14.6.2.2 TCR2 Gated Mode

TCR2 Gated mode is selected in field TCR2CTL of register ETPUTBCR. In this mode the TCRCLK signal enables or disables transfer of the eTPU clock divided by 8 to the TCR2 prescaler. By programming the prescaler, TCR2 can run at rates from eTPU clock divided by eight down to eTPU clock divided by 512, in steps of eight eTPU clock divisions. For more information refer to the ETPUTBCR register.

43.14.6.2.3 TCR2 Signal Transition Modes

These modes are selected when the TCR2CTL field in ETPUTBCR is set to rise, fall or "rise-and-fall" . In these modes the TCRCLK signal is the TCR2 clock source, and its maximum transition rate depends on the TCRCLK digital filter mode of operation. The TCRCLK digital filter can be programmed to use the eTPU clock divided by two, or use the same filter clock of the channels, controlled by the TCRCF field in ETPUTBCR. It contains an up-down counter which operates as a digital integrator, optimizing signal latency in the selected mode and clock rate.

When eTPU clock divided by two is selected, the synchronizer and the digital filter are guaranteed to pass pulses that are wider than four eTPU clocks (two filter clocks). Otherwise the TCRCLK is filtered with the same filter clock as the channel input signals. For details on TCRCLK and channels digital filter control refer to the ETPUTBCR register and Enhanced Digital Filter - EDF .

43.14.6.2.4 STAC Bus Client Mode

In this mode the TCR2 register is continuously updated from the STAC bus, and the clock selection and prescaling logic becomes ineffective. It is not write accessible for the microcode, and when read, it reflects the STAC bus imported value. The use of EAC is not allowed in client mode. This mode is configured through the ETPUREDCR register (see the ETPUREDCR register).

43.14.6.2.5 STAC Bus Server Mode

When TCR2 bus is exported to the STAC bus as a server, it can provide either time or angle bus to other peripherals, according to its operation mode. This mode is configured through the ETPUREDCR register (see the ETPUREDCR register). To provide sequential update of the STAC clients, the Angle tick rate must not be faster than the STAC programmed update rate. This requirement puts a limitation on the angle clock count rate on high rate mode. In this case the Angle and Angle Fraction accumulator (see Angle Tick Generator" and Figure 43-323) are advanced at rate of eTPU clock divided by eight. Therefore, the STAC update rate for the Angle Bus must not be slower than eight eTPU clocks.

43.14.6.2.6 TCR2 Bus in Angle Clock Mode

In this mode the TCR2 counter operates as part of the eTPU Angle Counter (EAC). The TCR2 bus value reflects this angle representation in which it counts Angle Ticks. Angle Mode is selected when the AM bit is set in ETPUTBCR.

Note that when TCR2 works in Angle Mode, it does not count directly from the TCR2 clock input which indicates tooth signal transition. Its Angle counter is controlled by the Count Control and High Rate logic (see Count Control and High Rate Logic), which provides the interpolated pin position, and handle cases of missing tooth, acceleration, de-acceleration and mechanical corrections.

The EAC uses the TCRCLK signal to get the tooth transition indications. The TCR2CTL field in ETPUTBCR has to be set for the appropriate tooth edge detection rise, fall, "rise-and-fall" or none. TCR2 count clock comes from the EAC control and not directly from the physical tooth. This way the EAC control processes the signal transitions and handles missing teeth and flywheel mechanical corrections. Note that when TCR2CTL selects "none" for tooth edge selection, the TCR2 is not necessarily frozen, but can still be incremented by the EAC logic.

In Angle Mode, eTPU channel 0, 1 or 2 operation is combined with the EAC operation. When channel 0 is selected for EAC operation, the TCRCLK digital filter is used both by the EAC and by channel 0 to get full synchronization between the two logics.

The eTPU Angle Counter (EAC) logic runs continuously and updates the TCR2 Angle counter, eliminating the microcode latency in updating the TCR2 value.

43.14.6.3 STAC Interface

Both time bases TCR1 and TCR2 can be shared between the Engines and with other blocks in the same MCU. Each one of both eTPU engines can drive their time bases to the STAC (Shared Time and Count) bus, acting as a server, while any other block can capture the value into its resources and behave like a client. For further reference about the STAC bus operation refer to to the ETPUREDCR register.

The eTPU can export to the STAC bus or import from the STAC bus the following internal resources:

- TCR1: Can be exported to or imported from the STAC bus. TCR1 can only be imported from STAC bus when the engine is not in Angle Mode. When TCR1 is imported from the STAC bus, it becomes read-only for the microcode and reflects the imported values. For details refer to Timer Count Register 1 - TCR1.
- TCR2: Can be exported to or imported from the STAC bus. TCR2 can only be imported from the STAC bus when engine is not in Angle Mode. When TCR2 is imported from the STAC bus, it becomes read-only for the microcode, and reflects the imported values. When exported to the STAC bus, TCR2 can work in either Angle Mode or as a free running counter associated with the TCRCLK signal. For details refer to EAC - eTPU Angle Counter.

Proper configuration of the following bits is necessary to determine what can drive the STAC bus: ETPUTBCR[AM] and ETPUREDCR[REN2, RSC2], according to the following table.

Table 43-354. STAC Bus and Host Read Sources

AM (ETPUTBCR)	REN2, RSC2 (ETPUREDCR)	TCR2 Bus Source (Host read of ETPUTB2R)	STAC Bus Driver
00	0× (disabled)	TCR2/Time	×
01, 10 or 11	0× (disabled)	TCR2/Angle	×
00	11 (Server)	TCR2/Time	TCR2/Time
01, 10 or 11	11 (Server)	TCR2/Angle	TCR2/Angle
01, 10 or 11	10 (Client)	not allowed[1]	

1. STAC client configuration in Angle Mode is also not allowed for TCR1.

Note that Angle Mode is not available for STAC bus clients: configuring both at the same time brings unspecified results and must be avoided. When TCR2 is a stand-alone counter or a STAC Bus server, the same value that is driven to the internal TCR2 bus is also exported to the STAC bus (either Time Count or Angle).

STAC bus configuration is provided by the ETPUREDCR bits REN1/2 and RSC1/2. REN1/2 enable the STAC interface to interact with the resource (either TCR1 or TCR2 bus). RSC1/2 configure the resource (either TCR1 or TCR2 bus) as Server or Client.

Each time base / angle count resource from each engine receives a unique 4-bit hard-wired address that identifies it as a potential server. This address is used by the STAC Controller to coordinate which resource will drive the bus at a given STAC time-slot. For any time-slot there is a server driving the bus upon selection of the STAC Controller, and there may be a client linked to that server by the ETPUREDCR bits SRV1/2 on each Engine. When the server address on the Red Line STAC bus matches the value in SRV1/2, the client will load the STAC information into the appropriate resource. For information on eTPU STAC Bus configuration refer to the ETPUREDCR register.

The eTPU does not include a STAC Controller module, which is instantiated once in the system integration.

Note

Setting a timebase as client of itself is not allowed.

43.14.6.4 GTBE - Global Time Base Enable

GTBE bit in ETPUMCR register enables time bases in both engines, allowing them to be started synchronously. GTBE is divided in two block interface signals: the eTPU GTBE output and the eTPU GTBE input. GTBE bit sets the eTPU GTBE output , and the eTPU GTBE input enables time bases to start. The eTPU GTBE output signal can be used by MCU integration for synchronization between eTPU time bases and time bases from other modules. If the GTBE bit in ETPUMCR must enable only the eTPU time bases, the eTPU GTBE output is simply connected to the eTPU GTBE input. These two cases are shown in the figure below. Synchronization logic can be as simple as an OR logic gate.

Once the eTPU GTBE input transitions to 1, the Engine 1 Time Bases start 1 eTPU clock earlier than Time Bases in Engine 2, except when TCRCLK is selected as clock source or TCR1 when ETPUTBCR[TCR1CS]=1 . This happens independently of prescaler values as long as they are the same for both engines, because the prescalers also freeze when the eTPU GTBE input = 0. Microcode can always write to TCR1/2 registers, with either value of the eTPU GTBE input.

NOTE

The timebase prescalers are reset when the GTBE input is negated.

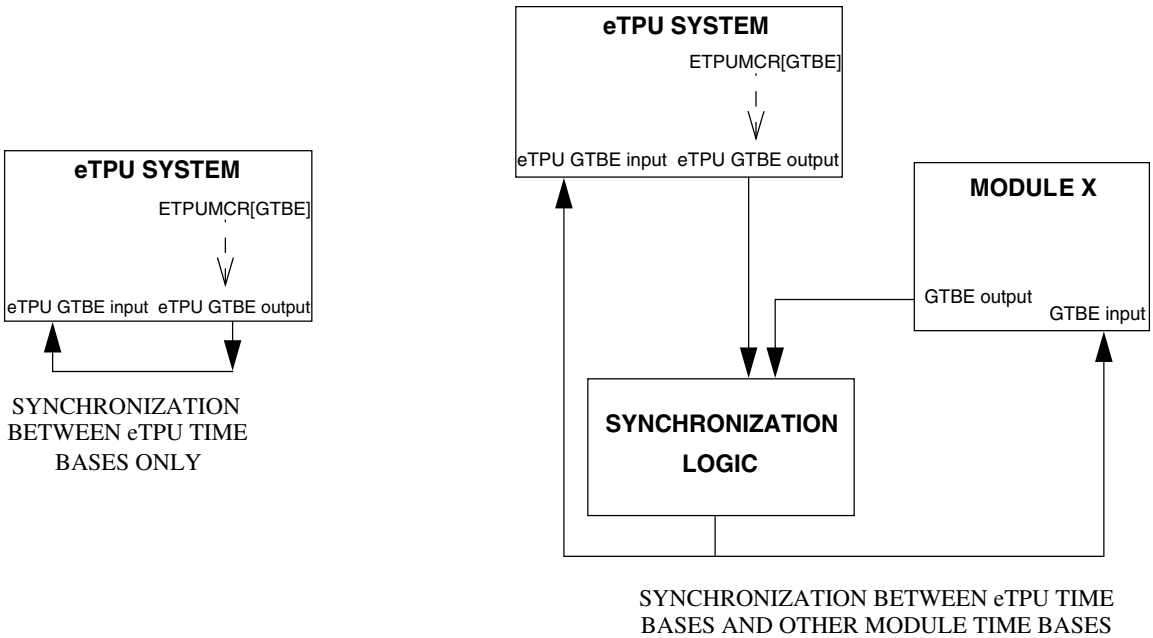

Figure 43-318. Time Base Synchronization

43.14.6.5 TCRCLK Digital Filter

The TCRCLK signal has an improved integrating digital filter with a 2-bit up-down counter. The counter counts up to 3 when a high signal level is detected, or down to 0 when a low level is detected. The signal state is updated to one when the counter stops at 3, or zero when the counter stops at 0. The field TCRCF in ETPUTBCR register (see the ETPUTBCR register) determines whether the TCRCLK signal input (after a synchronizer) is filtered with the same filter clock as the channel input signals (see Enhanced Digital Filter - EDF) or uses the eTPU clock divided by 2, and also whether the TCRCLK digital filter works in integrator mode or the same two sample mode as the channel filters (see Table 43-338).

The TCRCLK filter delay and prescaling determines the minimum detectable TCRCLK pulse widths and, therefore, its maximum frequency, as shown in Filter Clock Prescaler and Table 43-353 . The TCRCLK signal delay from the module input to TCR1/TCR2 incrementing or detection in the EAC logic is explained in Input/Output Signal Delays.

43.14.7 EAC - eTPU Angle Counter

43.14.7.1 General

The EAC logic contains a mechanism which follows the flywheel angle, based on the tooth rate. This hardware works in combination with the TCRCLK signal, the TCR2 counter and Channel 0, 1 or 2 (depending on the ETPUTBCR field AM) to generate angle information on the TCR2 bus which is passed to all the local engine channels. The EAC helps to implement a digital angle PLL (see Figure 43-322), which combines hardware with microcode processing at channel 0, 1 or 2 . The angle measurement is based on history knowledge of the tooth period, for predicting the period of the next tooth. The tooth period is partitioned into a programmable number of **Angle Ticks**. The eTPU application will use the divider in the MAC/Divide unit to calculate an integer and a fraction part of the angle tick such that the full tooth period gets the correct programmed number of angle ticks with no accumulated error.

Each single tooth can be divided in angle ticks, up to 1024. In a 60 teeth flywheel, 128 Angle Ticks per tooth provide resolution of ~0.05 degrees per tick, which meets the accuracy requirement of 0.1 degrees in current automotive applications.

The measurement of one tooth in angle ticks is independent on engine RPM; it is the tooth period itself (and the corresponding tick period) that is re-calculated for each new tooth, based on the difference between the estimated tooth and the actual detection.

For these applications, one of the eTPU channels 0, 1 or 2 is dedicated to service the physical tooth detection. Channel 0 shares the same filtered input as the TCRCLK signal to get the same timing as the EAC. The TCRCLK edge detection is selected by ETPUTBCR field TCR2CTL for the EAC, and by IPACA/B on channel 0, which must be set to detect the same edge(s). When channels 1 or 2 are selected to work with the EAC, IPACA/B is used to select the tooth signal edge detection for both the channel and the EAC, and the tooth signal that feeds the EAC is the same filtered input which feeds the channel.

Channel 0, 1 or 2 generates the signal transition service request, and can also be used for generation of a window filter on this transition, to qualify TCR2 clocks. For this purpose, the selected channel should be configured with double match window filtering mode (refer to Channel Modes). Depending on the channel mode set for the channel, Match A recognition opens the window, and Match B recognition may close it or leave it open. See Angle Logic and Channel Modes for details. Match B also generates a time-out service request. Its input signal transition comes from the tooth. The window can be defined by microcode to open at a predefined point inside the tooth period, and stay open for a desired percentage to the tooth period. The window can be measured in angle or

time This method improves the noise immunity by allowing transition detection only on an expected period, a feature which was software responsibility in previous TPU versions.

The EAC supports deceleration, acceleration, last tooth and missing tooth scenarios. The large range of angle ticks per tooth can be used to cover longer tick counts caused by one or more missing teeth, or to provide extra resolution for future application requirements. In case of a missing tooth, the EAC can be configured to insert a dummy tooth or to simply measure a longer tooth.

Figure 43-323 shows the block diagram of the Angle Counter system. TCR1 or TCR2 prescaler is used as a time base which measures the tooth period and is used for partitioning the period to angle ticks.

43.14.7.2 Angle Mode Registers

In Angle Mode, the registers described below control eTPU angle operations. They are accessible only by microengine as source and destination registers in microinstructions. When eTPU is not in angle mode (AM bit is negated in ETPUTBCR register), all angle mode registers can be used as general purpose registers.

43.14.7.2.1 TPR - Tooth Program Register

TPR provides configuration for the Angle Counter circuit. In this register, the microcode can properly adjust the tooth count (controlling last tooth, missing teeth, dummy tooth insertion, halt until tooth detection) and the number of angle ticks per tooth (field TICKS). Note that this register is sampled into a temporary register in the EAC logic when the High Rate Mode is detected (see High Rate Mode (Acceleration) and TPR Buffering), which means that changes to this register may take effect only for the next tooth.

Refer to Count Control and High Rate Logic and to Special Cases of Missing Teeth and Last Tooth until Handling False Tooth Detection for a detailed explanation about the use of this register. The figure below provides a detailed description of TPR register.

Several conflict issues on TPR writes are explained in Special TPR Write Cases.

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	LAST	MISSCNT [1:0]		IPH	HOLD	MISS CNT [2]	TICKS									
RESET:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 43-319. TPR Register

LAST —Last Tooth Indication

Asserted by microcode and negated when a tooth is detected or inserted via IPH.

1 = Last Tooth - reset TCR2 Counter at the end of the tooth tick count (after physical tooth or IPH=1) when MISSCNT=0.

0 = Not Last Tooth.

If the tooth is detected or inserted before the tooth tick count completes (going High Rate mode, see High Rate Mode (Acceleration)), LAST resets immediately, but TCR2 resets only when the tooth count completes and MISSCNT=0.

MISSCNT — Missing Tooth Counter

Decremented on each estimated tooth, stops at zero. Used for generation of up to 7 "Dummy Teeth" whenever it holds a non-zero value.

If the tooth is detected or inserted before the missing tooth tick count completes (going High Rate mode, see High Rate Mode (Acceleration)), MISSCNT resets immediately, but missing teeth count continues in High Rate mode (see TPR Buffering).

IPH — Insert Physical Tooth

This bit generates a dummy physical tooth which has the same effect as a real physical tooth, and resets itself subsequently. If EAC is in Halt mode, it switches back to Normal mode[1]. If EAC is in Normal Mode, it switches to High Rate Mode. If Angle Logic is frozen by HOLD=1 (see below), it returns to the state it was at the freezing moment.

1 = Insert dummy physical tooth.

0 = No Operation.

Note: IPH reads as 1 in the next microinstruction after it is asserted, negating subsequently. However, it can be set twice in two consecutive microinstructions to generate two teeth and make the EAC go from Halt to Normal to High Rate Mode.

HOLD — Force EAC Hold

This bit forces the EAC to halt its operation in a special EAC freeze mode until a new physical tooth (a real one or emulated with IPH=1) is detected. Assertion of this bit immediately freezes the EAC in the middle of the tooth period. When a new physical tooth is detected, the bit is automatically negated by the EAC. The HOLD bit can be used for synchronizing the EAC tooth count, in case that a false physical tooth is detected due to noise.

1 = Force EAC to halt until detection of a physical tooth.

0 = Normal Operation.

TICKS — Angle Ticks Number in the Current Tooth

This field defines the number of angle ticks in the current physical tooth. It partitions the tooth period to the required number of angle ticks. The actual number of angle ticks in a tooth is (TICKS+1).

Note: In High Rate mode (see High Rate Mode (Acceleration)), TPR writes are immediately effective only for bits IPH and HOLD. All other fields changes are "buffered" and become effective when EAC leaves High Rate mode. See also Special TPR Write Cases.

Note: Bits LAST, IPH and HOLD must not be asserted all at once

1. missing a physical tooth naturally causes EAC to get into Halt mode.

43.14.7.2.2 TCR2 - Timer Counter 2

In Angle Mode, TCR2 (see the following figure) counts angle ticks instead of time.

Figure 43-320. TCR2 in Angle Mode

This 24-bit free-running counter is used to generate an accumulated Angle Fraction value. It is updated by the Angle Tick Generator - refer to Angle Tick Generator for more details. Refer to Count Control and High Rate Logic for a detailed explanation about the use of this register in Angle Mode.

TCR2 provides continuous count of the angle in units of angle ticks. The Angle Tick Counter in TCR2 can be reset due to "Last Tooth" microcode indication. TCR2 Prescaling is disregarded in Angle Mode: physical tooth detection is done by EAC regardless of the value set in TCR2P.

43.14.7.2.3 TRR - Tick Rate Register

The exact period of the Angle Tick is programmed in the Tick Rate Register (see the figure below) by microcode. The TRR time unit depends on the ETPUTBCR bit ATGC (see Figure 43-323):

- if ATGC=0, the TRR time unit is the period of TCR1 clocks taken as eTPU clocks divided by 2*(TCR1P + 1), even if TCR1CS=1 (see the ETPUTBCR register) .
- if ATGC=1, the TRR time unit is given by the eTPU clock divided by 2*(TCR2P+1), using the TCR2 prescaler fed by eTPU clock/2 (independently of TCR1CS).

Refer to Calculating the Angle Tick Period Integer and Fraction for a complete description about the mechanism to calculate the value to be written into this register.

Figure 43-321. TRR Register

INTEGER — The integer part of TCR1/TCR2 clocks in one Angle Tick.

This number, decremented by one, works as a down-counter preload value. A value of INTEGER=0 represents an integer of 32768. A new value written is reloaded into the counter (becoming effective) when a new tick starts or a tooth is detected or inserted via IPH.

FRACTION — Nine-bit fractional part of TCR1/TCR2 clocks in one angle tick.

The FRACTION value is accumulated in the EAC Fraction Accumulator, and whenever the result overflows (i.e., the accumulated fraction added up to an integer), the Tick Prescaler is halted for one TRR time unit.

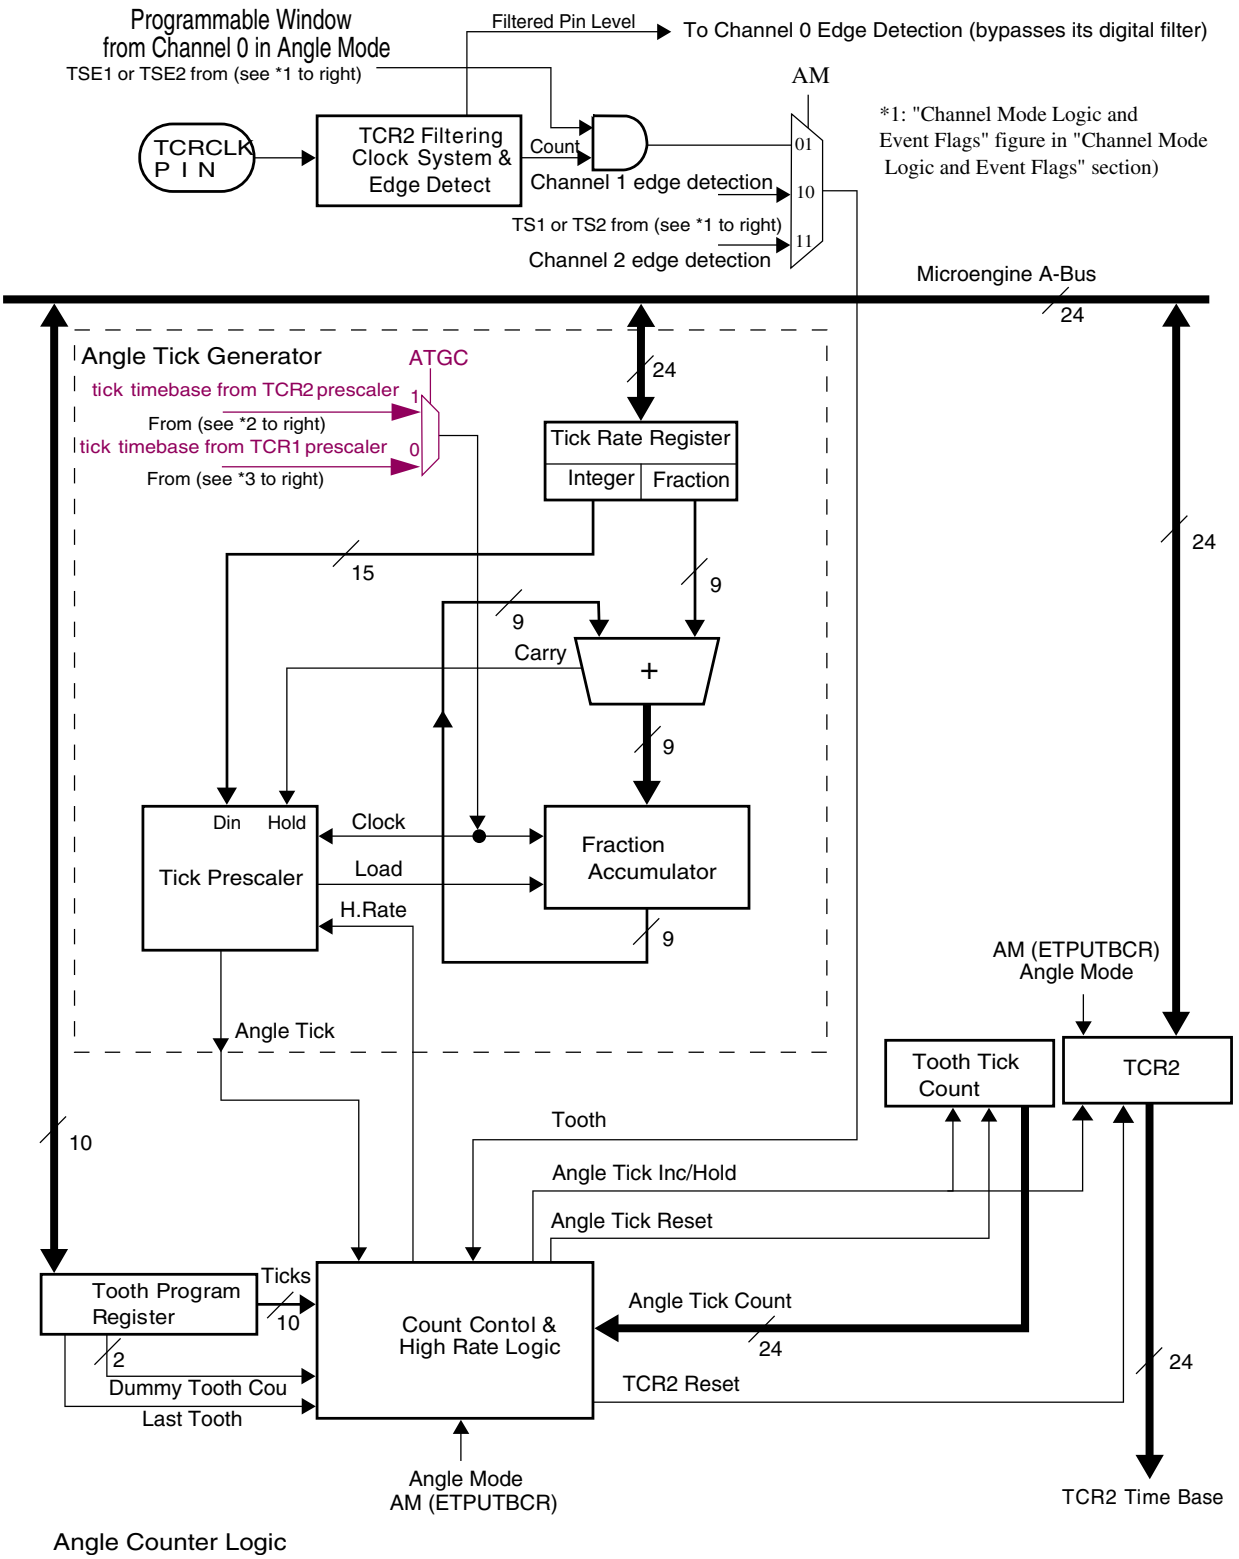

Figure 43-323. eTPU Angle Counter System

43.14.7.3 Acceleration and Deceleration

Acceleration and deceleration affect the new tooth period relative to the known period of the last tooth. Changes in tooth period may be extreme at very low engine RPM (such as cold start and warm start). The worst case of tooth period changes is caused during missing teeth, since there is more time for changes in angular velocity to be unnoticed by the EAC hardware. For example, on cold start (~20 RPM) there may be extreme acceleration: the ratio between a known tooth period before two missing teeth and the new tooth period after the missing teeth can be very high (up to a factor of 75). Acceleration and deceleration effects from tooth to tooth are less extreme as the engine climbs to high RPM.

In case of deceleration, the estimated tooth period ends before the actual tooth detection arrives. In this case, the EAC hardware waits at the end of the current tooth period, when it is said to be in **Halt mode**, until the real tooth indication is received, then continues with normal operation (**Normal mode**). See Figure 43-322.

In case of acceleration, the actual tooth period is shorter than the estimated tooth period. As a result, a new physical tooth indication arrives before the end of the estimated tooth period. In this case the EAC closes the gap on **High Rate mode** by counting on eTPU clock divided by eight to the end of the tooth, advances to the next tooth, and switches back to normal operation mode. See Figure 43-322.

The reason that the EAC does not jump directly to the next tooth is the need to provide sequential angle count throughout the whole tooth period, for channels or external STAC clients (if TCR2 is a STAC server) which compare angle in "equal" mode. These peripherals must get all the valid angle values in a sequential manner, to avoid missing angle matches.

TCR2 advancing from one tooth to another is a continuous count, and can be optionally reset at the end of the tooth. An estimated tooth is generated after the Tooth Tick Counter reaches the TICKS programmed value.

The EAC works continuously and switches automatically between Normal, Halt and High Rate modes. It relies on the microcode to calculate the estimated tooth period on every tooth, and to update the correct angle tick and tooth parameters in the EAC control registers. On high RPM, tooth period changes are reduced from tooth to tooth, and the EAC may follow the angle with good accuracy for several teeth without microcode intervention.

The EAC handles missing teeth by insertion of "dummy" teeth, or by enlarging the expected tooth period. It is a good practice to locate the flywheel missing teeth in non-critical angles, since a missing tooth may increase the angle measurement error (acceleration and deceleration is detected late).

43.14.7.4 Angle Tick Generator

The Angle Tick Generator is responsible for generating a programmed number of angle ticks in the tooth period. It generates the ticks in an average rate which ensures completion of the correct number of angle counts in the estimated period of the tooth, since the count of one tooth in angle ticks is independent on engine RPM. The main output of the Angle Tick Generator is the tick clock that feeds TCR2 in Angle Mode, as well as the internal Tooth Tick Counter (see Figure 43-323). The Tooth Tick Counter counts ticks within a tooth, from 0 up to TICKS, is controlled by the Angle Tick Generator logic and cannot be accessed by microcode. Refer to Figure 43-324 for a generic presentation of the angle tick count and the measurement of a single tooth period.

43.14.7.4.1 Calculating the Angle Tick Period Integer and Fraction

On each tooth the microcode has to update the exact period of a single angle tick used for counting the internal angle in the tooth. The period of an angle tick is determined by the EAC configuration, see Generating the Angle Ticks for details.

The microcode can use the eTPU MAC Divider unit (see MAC and Divide Unit (MDU)) to divide the tooth period by the number of angle ticks per tooth, which is stored in the TICKS field of TPR (refer to Angle Mode Registers). This division yields the integer part of the angle tick period and the remainder. Dividing again the remainder shifted left nine positions, by the number of angle ticks per tooth translates the remainder to a 9-bit fraction. The microcode concatenates the 15-bit integer and the 9-bit fraction to a 24-bit value and writes it to TRR. The new rate is effective immediately after the next Angle Tick is generated by the Angle Tick Generator[27] .

For high RPM, note that shifting the tooth period value nine positions to the left prior to the first divide operation would calculate, in one operation, the integer and the fraction. For example: On 60 teeth flywheel running at 1000 RPM, tooth period is 1 msec. If TCR1/TCR2 counts @25 MHz, it counts 25,000 times in a tooth, which can be represented by 15 bits. Therefore the tooth period can be shifted nine positions to the left prior to divide operation, and be represented with 24 bits.

Using shift left nine positions and one divide operation would get the result in MACL register (in MDU) which holds the integer and nine bits of the fraction:

```
Angle_Tick_Rate {Integer[14:0], Fraction[8:0]} = (ToothPeriod[28] <<9) / Ticks
TRR = Angle_Tick_Rate {Integer[14:0], Fraction[8:0]}
```

27. In High-rate mode, the tick keeps being updated at the rate of eTPU clock/8 until it goes back to Normal mode, when the new TRR value is used.

On low RPM the initial tooth period, measured in TCR1/TCR2 counts, may be too big to be shifted nine positions to the left. For lower RPM (for example 500 RPM) the tooth period cannot be represented by 15 bits, and shifting it nine positions to the left would lose the MSB. In this case, two divide operations are required as follows: first divide the Tooth Period by the number of TICKS - the integer is stored in MACL and remainder in MACH. MACL is saved in another register. MACH is shifted 9 positions to the left and divided again by TICKS. In parallel with the second divide, the register which saved the original MACL is shifted left 9 positions. After the divide MACL contains the 9 bits fraction and the other register contains the 15-bit integer, shifted left nine times. The logical OR of the two registers is written to the TRR:

```
Angle_Tick_Rate {Integer[14:0]} = (ToothPeriod) / Ticks
Remainder[9:0]                  = ToothPeriod) mod Ticks
Angle_Tick_Rate {Fraction[8:0]} = (Remainder[9:0] << 9) / Ticks
TRR = Angle_Tick_Rate {Integer[14:0], Fraction[8:0]} = (Integer[14:0] << 9) | Fraction[8:0]
```

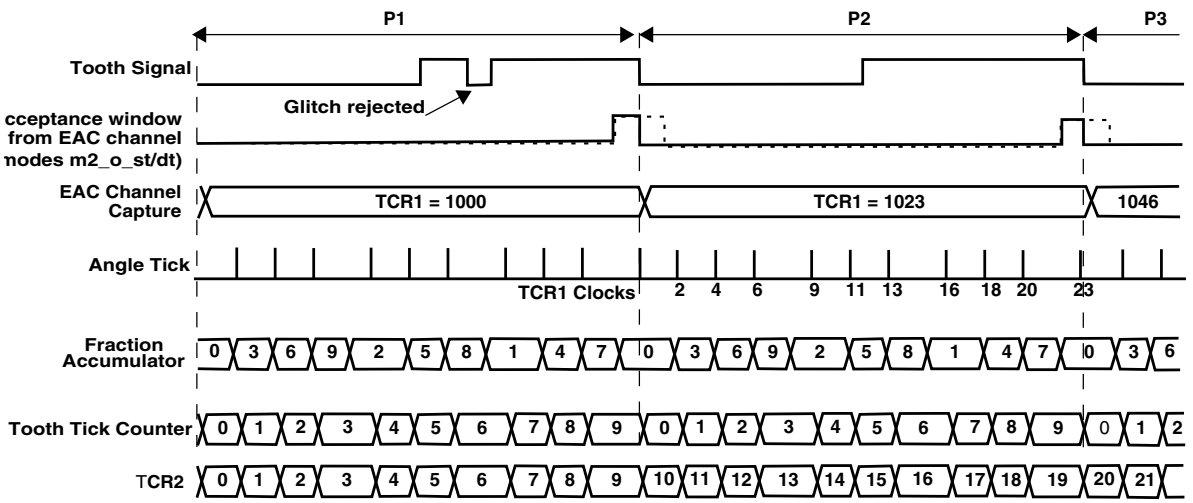

Figure 43-324. Angle Ticks Generation

43.14.7.4.2 Generating the Angle Ticks

The integer part of TRR is preloaded to a prescaler, which counts in time intervals as follows (see Figure 43-323):

28.

The tooth period (ToothPeriod) is not, in general, the value of estimated tooth time. It is obtained by microcode by subtracting TCR1 values between two teeth detections, converted to TCR2 periods if ATGC=1. Its comparison with the estimated tooth time indicates acceleration (if minor) or deceleration (if greater) to the microcode.

- if ETPUTBCR bit ATGC=0, one unit of TCR1 clock period (if TCR1CS=0) or twice the TCR1 clock period (if TCR1CS=1)[29], that is, eTPU clock period*2*(TCR1P+1) (independently of TCR1CS).
- if ATGC=1, two units of the eTPU clock period multiplied by the TCR2 prescaler factor, that is, eTPU clock period*2*(TCR2P+1).

When the down counter reaches zero, it generates an angle tick pulse to the Angle Counter Logic and a Load pulse to the Fraction Accumulator. It is then preloaded with most updated TRR integer part. Due to the Load pulse, the 9-bit fraction is accumulated in a 9-bit Fraction Accumulator. If a fraction overflow condition occurs (the 9-bit adder asserts carry out), the accumulator saves the lower 9 bits of the addition result, which is the remaining fractional part. The carry out bit indicates an accumulated integer "one" which means that the angle tick is early by one input clock. It halts the prescaler operation for one input clock to compensate the accumulated error generated by the integer prescaler. As a result, the average angle tick period takes into account both the integer and the fraction parts. The accuracy depends on the bit count of the fraction. Using 9-bit fraction part while the width of the field TICKS in register TPR is 10 bits provides accuracy of two LSB on a full scale (TICKS=1023) or one LSB on lower scale (TICKS<=511).

When the Tick Prescaler gets High Rate mode indication from the Angle Counter Logic, it generates angle ticks at a rate of eTPU clock divided by eight. In this case it does not generate Load pulses to the Fraction Accumulator, ignores its "hold" input and preloads internally to a fixed period of eight eTPU clocks. When High Rate mode is entered, the prescaler is preloaded to a period of eight eTPU clocks before its first angle tick generation, ensuring separation of at least eight eTPU clocks between the last Normal mode angle tick and the first High Rate mode angle tick. The fraction accumulator resets when the tick count advances to the next tooth, or when TRR is written by the microcode.

43.14.7.5 Count Control and High Rate Logic

The Count Control and High Rate Logic controls TCR2 operation in Angle Mode, using the angle ticks generated by the Angle Tick Generator. Count Control logic is responsible for advancing, holding and resetting the TCR2 and Tooth Tick Counter in the proper timing, such that the TCR2 time base will reflect the correct estimated angle. This logic also includes the Tooth Program Register (TPR, see Angle Mode Registers for more information).

29. The EAC logic overall runs at a rate of eTPU clock divided by 2, therefore the tick generator takes the halved TCR1 clock when TCR1CS=1 and ATGC=0.

The Count Control and High Rate Logic handles deceleration, acceleration, missing teeth and last tooth. On High Rate (acceleration) it ensures that the angle bus scans all valid angle values in a rate which can be traced by the STAC bus. This operation enables external STAC clients (if TCR2 is a STAC server) or channels working in "equal-only" comparator mode to match the TCR2 exported angle information in "equal" mode, in an exact match.

Because the eTPU channels are capable of capturing either TCR1 or TCR2 due to signal transition, the microcode can get either the angle or time of the physical pin transition. Since the EAC channel (0, 1 or 2) is connected to the physical tooth, the microcode can get the EAC error in angle domain (tooth appears at the wrong angle) or time domain (physical tooth captured time into the EAC channel, relative to the estimated tooth time). Note that in angle mode, the transition detect logic of the channel 0, if selected as the EAC channel, is fed from the digital filter of the TCRCLK signal, and not from the channel 0 internal digital filter. This ensures synchronous operation of channel 0 and the EAC hardware.

Another feature of the eTPU channel, when working in Single Match And Single Transition Enhanced Mode (refer to Single Match Enhanced Mode (sm_st_e)), is capturing a single time base due to signal transition before and after the digital filter. This option allows subtracting the digital filter delay to get accurate signal transition timing on the channel. This way, the TCRCLK signal may be programmed with a slow and reliable digital filter, and get accurate time measurement of the digital filter delay.

To assert the end of the estimated tooth period the Count Control and High Rate logic compares the TICKS field in TPR (refer to Angle Mode Registers) with the current value of the tooth tick counter. When the Tooth Tick value is greater or equal to TICKS, it determines the end of the estimated tooth period. On acceleration this event occurs during High Rate mode operation, after the arrival of a physical tooth. In deceleration, this event occurs during Normal Mode, before the arrival of a physical tooth. On constant angular velocity, this event appears together with the arrival of a physical tooth.

The following sections describe the operation of the Counter Control and High Rate logic.

43.14.7.5.1 Normal Mode

In Normal mode the Counter Control logic advances TCR2 and the Tooth Tick counter as if the engine has a constant speed during the tooth period. It receives the angle ticks from the Angle Tick Generator in an average rate which is determined by the Tooth Rate Register (TRR). This is the reset mode.

When the Tooth Tick Counter is about to reach the last value effectively stored in TPR field TICKS plus one, the hardware detects the end of the estimated tooth period. If the physical tooth and the estimated tooth arrive at the same time the EAC stays in Normal mode, the Tooth Tick Counter is reset, and TCR2 is incremented (depending on TPR bits LAST and MISSCNT). If the physical tooth and the estimated tooth do not arrive at the same time, either acceleration or deceleration is detected, and the EAC switches to the proper mode. See the figure below for a detailed diagram of Normal Mode behavior.

The microcode which services the EAC channel physical tooth transition may update TRR according to various conditions to give the best estimation of the current tooth period, according to the previous tooth period and other engine parameters.

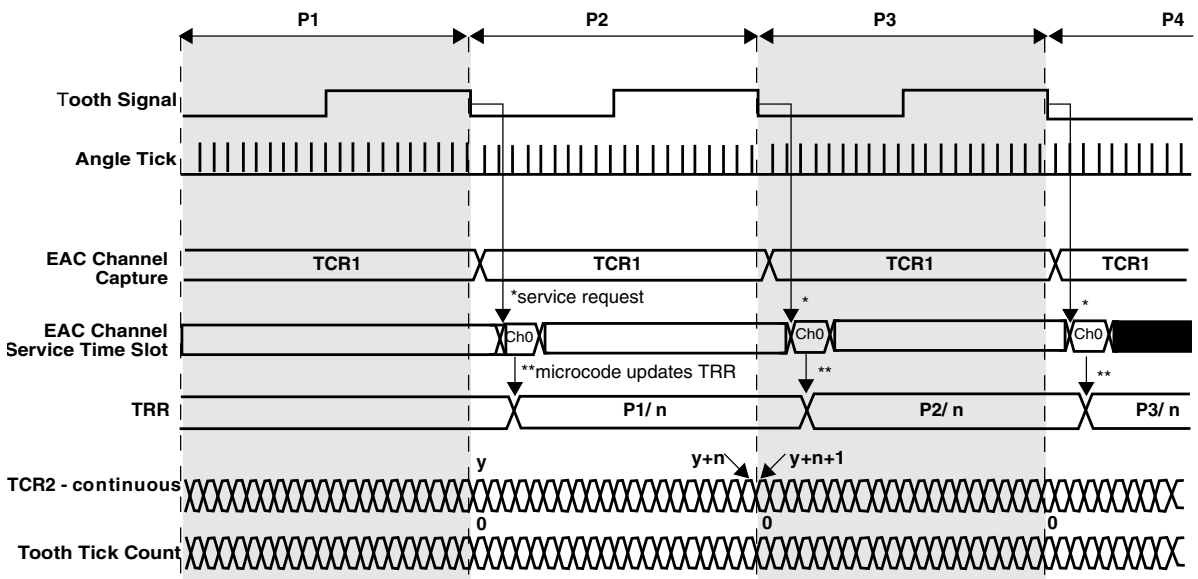

Figure 43-325. Normal Mode

43.14.7.5.2 Halt Mode (Deceleration)

In case of deceleration, the Tooth Tick Counter reaches the TICKS value before the arrival of the next tooth. The Count Control logic does not reset neither advances TCR2 and Tooth Tick Counters. The Count Control logic halts TCR2 and Tooth Tick Counters at the end of the tooth, waiting for the physical tooth to arrive.

When the physical tooth is detected the EAC switches back to Normal Mode and releases TCR2 to count the angle ticks of the new tooth, also resetting the Tooth Tick Counter. Only then TCR2 may wrap to 0, if TPR bit LAST is asserted. See the figure below for a detailed diagram of Halt Mode behavior.

The microcode service caused by the physical tooth determines the deceleration, calculates the new tooth period and Angle Tick period and updates TRR. This operation slows the angle tick rate generated by the Angle Tick Generator on-the-fly, to the rate required for the new tooth period.

Since the microcode service is initiated by the physical tooth edge, microcode latency may introduce a small angle error caused by using the TRR value of the previous tooth at the beginning of the current tooth. On high RPM, deceleration is relatively small but the microcode latency may take a significant percentage of the tooth period. On low RPM microcode service latency takes little percentage of the tooth period, but there may be cases of extreme acceleration and deceleration. The microcode latency can be calculated knowing TCR1 value during the service time, and TCR1 value captured in the EAC channel due to the physical tooth pin transition. The duration of the Halt mode is obtained using the estimated tooth time.

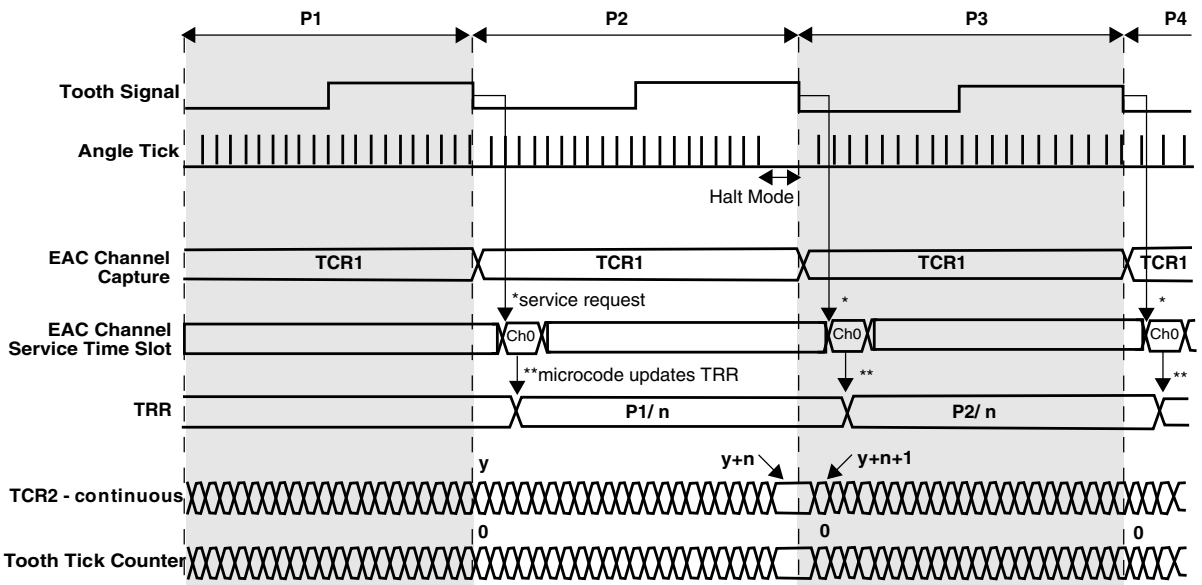

Figure 43-326. Halt Mode - Deceleration

43.14.7.5.3 High Rate Mode (Acceleration)

In case of acceleration, the next tooth arrives before the Tooth Tick Counter reaches the TICKS value. In this case the High Rate logic is responsible for closing the gap and advancing the tooth on the correct timing. The High Rate mode operates as follows:

- When the acceleration is detected (physical tooth arrives before the Tooth Tick Counter reaches the TICKS value), the Count Control and High Rate logic switches to High Rate mode in which both the Tooth Tick Counter and TCR2 count at rate of

eTPU clock divided by eight, until the Tooth Tick Counter reaches the current TICKS value. To ensure correct operation, the TICKS value is sampled in the logic at the beginning of the mode.

- At this point, which represents the estimated tooth edge, the logic resets the Tooth Tick Counter and advances TCR2 (or resets it if LAST is asserted and MISSCNT = 0).
- The control logic switches back to Normal Mode, using the most updated TRR value as input to the Angle Tick Generator. The logic samples the updated TICKS value for the tooth estimation, last tooth indication and number of missing teeth from TPR.

In High Rate mode the angle ticks are provided at high speed until the end of the current tooth. This operation is required to scan all the valid angle values of the current tooth, in a rate which is not too high for the STAC bus continuous update, but much higher than the rate dictated by TRR.

EAC channel microcode, which services the physical tooth transition detection, can start its service either before High Rate mode operation is complete (the Tooth Tick Counter has not reached the TICKS value) or after the EAC switched back to Normal mode. Any physical teeth received while the EAC is in High Rate Mode does not alter the immediate EAC state, but it is still detected by the EAC channel logic and can, therefore, alter future EAC behavior (for instance, closing the tooth detection window - see Angle Logic and Channel Modes).

At the beginning of High Rate mode operation, the TPR value is preloaded into a temporary register in the Counter Control Logic, used for scanning all the valid values to the end of the current tooth, with its appropriate LAST and MISSCNT attributes. While the EAC is in High Rate mode operation, the effect of microcode update of TPR fields LAST, MISSCNT and TICKS is delayed to the next estimated tooth, after the High Rate mode operation is complete (see Special TPR Write Cases). This is because the current physical tooth represents the next estimated tooth. If the microcode updates this field after High Rate mode operation is complete, the current physical tooth and estimated tooth are the same, and the effect is immediate. Either in High-Rate mode or not, the value read by microengine is the same written, even if not yet effective, until the EAC resets LAST and/or IPH, or decrements MISSCNT. Typically the microcode service may occur during the High Rate mode on extreme acceleration situation at low RPM. Therefore, the microcode operations are always related to the real physical tooth. From the above it can be seen that the microcode updates of the TICKS field in TPR affect the end time of the current physical tooth. For correct operation, this field should be updated before the Tooth Tick Counter has reached either the old or the new TICKS value.

During High Rate mode operation, TRR is ignored and the Angle Tick Generator uses eTPU clock divided by eight. Therefore, the TRR update by microcode will take effect only after the EAC switches back to Normal mode. If microcode service occurs after the Tooth Tick Counter has been reset, the EAC is already back in Normal mode, and some angle ticks may have been counted at the rate of the previous tooth. In this case the new TRR value will have immediate effect on the angle tick period, and the microcode should take into consideration the delay from the physical tooth to the estimated tooth in calculation of the next tooth period. See the figure below for a detailed diagram of High Rate Mode behavior.

An angle error may be introduced by the duration of the High Rate mode. Also, the scheduler latency may introduce a small accumulated error by using TRR value of the previous estimated tooth at the beginning of the current tooth. After the estimated tooth has advanced, the duration of the High Rate mode operation is the actual delay from the physical tooth edge to the estimated tooth edge. This delay can be obtained by comparing the estimated tooth time with the EAC channel capture register which captured TCR1 on the physical pin transition.

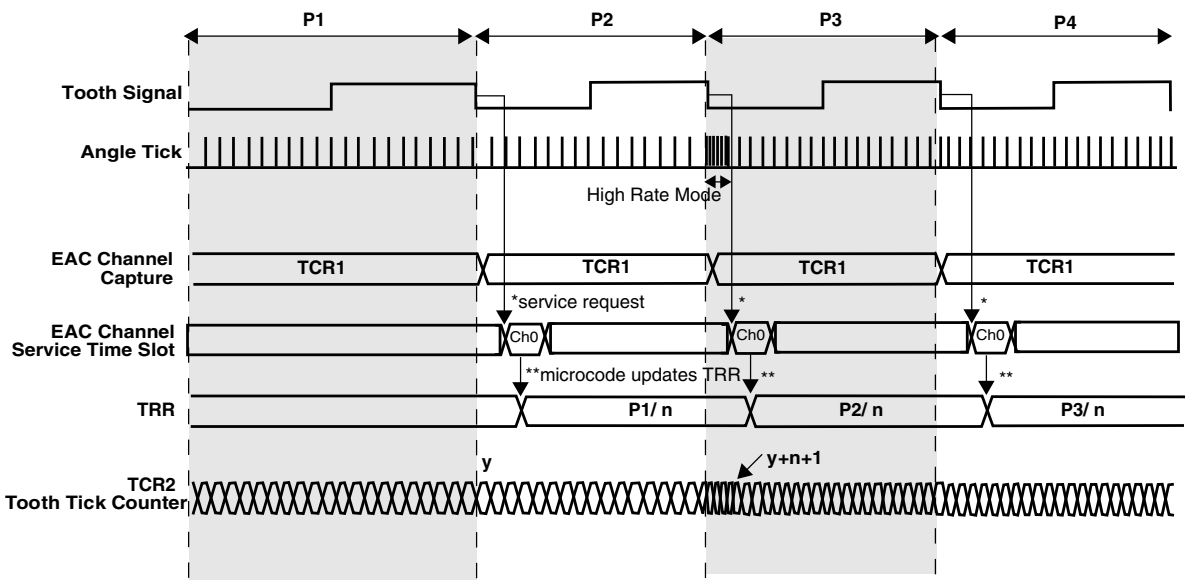

Figure 43-327. High Rate Mode - Acceleration

43.14.7.6 Special Cases of Missing Teeth and Last Tooth

The EAC handles cases of up to three missing teeth and the last tooth in the engine cycle. The following paragraphs describe these functions.

43.14.7.6.1 Handling the Last Tooth

The microcode can set the TCR2 counter to work in engine periods (wrap-around count) or continuous angle measurement.

For periodic operation, during the last engine cycle tooth the EAC microcode has to set the LAST flag in TPR. As a result, when the tooth period is ended, the Counter Control Logic generates a reset command to both the Tooth Tick Counter and TCR2 instead of an advance command. The operation resets the TCR2 based angle count, indicating a new period of the engine cycle. This implementation provides an engine cycle based periodic angle measurement.

43.14.7.6.2 Handling Missing Teeth

The EAC can handle up to three missing teeth in two ways:

- Count the angle ticks relative to the last physical tooth. The microcode should update the TPR TICKS field to the number of angle ticks included in two, three or four teeth, according to the flywheel type (one, two or three missing teeth). EAC hardware works in its regular manner.
- Insert a "dummy" tooth instead of the missing tooth, at the estimated point in time. After the "dummy" tooth, the Angle Tick Counter is incremented as if there was a physical tooth. A "dummy" tooth can be inserted only during Normal or High Rate operation modes. The microcode inserts "dummy" teeth by writing to the MISSCNT field in TPR.

In the first option the missing tooth is not counted on the angle measurement. For example, a flywheel with 59 physical teeth and one missing tooth can be considered as 58 identical teeth numbered (0-57) and tooth number 58 has a double number of angle TICKS. In this case a 720 degrees engine cycle has 118 teeth. TCR2 reflects the real angle, since it counts angle ticks continuously.

In the second option, the missing teeth are counted as "regular" teeth by automatic insertion of "dummy" teeth. The microcode has to write a non-zero value to the MISSCNT field in TPR. This field is a 3-bit down counter which affects the operation of the Counter Control logic.

For example, a flywheel with 59 physical teeth (0-58) and one missing tooth (59) can be considered as 60 teeth numbered (0-59), all having the same number of angle ticks. The microcode has to write "001" to the MISSCNT bits during the period of tooth number 58 to indicate that next tooth (59) is missing.

When the Tooth Tick Counter reaches the TICKS value, TCR2 is incremented as if a physical tooth has been detected. In addition, the MISSCNT value initializes a "dummy tooth counter" which is decremented to indicate the number of left "dummy teeth" which still need to be generated. Because a dummy tooth was counted, EAC does not enter Halt Mode and Tooth Tick Counter continues incrementing in the absence of a physical tooth detection.

In case of extreme acceleration on very low RPM (cold start) there can be a situation that the first physical tooth after one or two missing teeth appears even before the "dummy" tooth is generated. Due to the acceleration the EAC switches to High Rate mode in order to run through all the valid angle values, including the dummy teeth. When the Tooth Tick Counter reaches the TICKS value on High Rate mode, and the "dummy tooth" down counter is not zero, the generated "dummy tooth" advances to the next tooth and decrements the "dummy tooth" counter, but does not switch the EAC back to Normal mode. The last "dummy tooth" decrements the counter to zero, indicating that no more dummy teeth are to be inserted, and the next tooth is an estimated physical tooth. The EAC continues at High Rate mode until the Tooth Tick Counter reaches the TICKS value again, then advances to the next tooth while switching back to Normal mode. When in High Rate mode, the TPR register does not reflect the MISSCNT downcounting, see TPR Buffering for details.

MISSCNT can be rewritten before it reaches 0, allowing it to count more than 7 missing teeth, as long as no physical tooth arrives between the first MISSCNT write and the rewrite.

43.14.7.6.3 Combining Missing Teeth and Last Tooth

The Last Tooth indication takes effect when there are no more missing teeth to be generated, i.e the "dummy tooth" counter value is zero. If, for example, the microcode sets the missing teeth counter to "10" (two missing teeth) and sets the LAST flag, the first and the second dummy teeth will increment TCR2, and the third estimated tooth, which correlates with the physical tooth (the first of the next cycle), will reset TCR2, because LAST was set. This scheme enables the microcode to define one or more missing teeth to be replaced by "dummy tooth" insertion, and the end of the engine cycle in one service request. It is assumed that the two missing teeth must come together in the same engine cycle, and not split between two engine cycles (either the missing teeth are both last in an engine cycle or both not last, but not last in one engine cycle and first in the next).

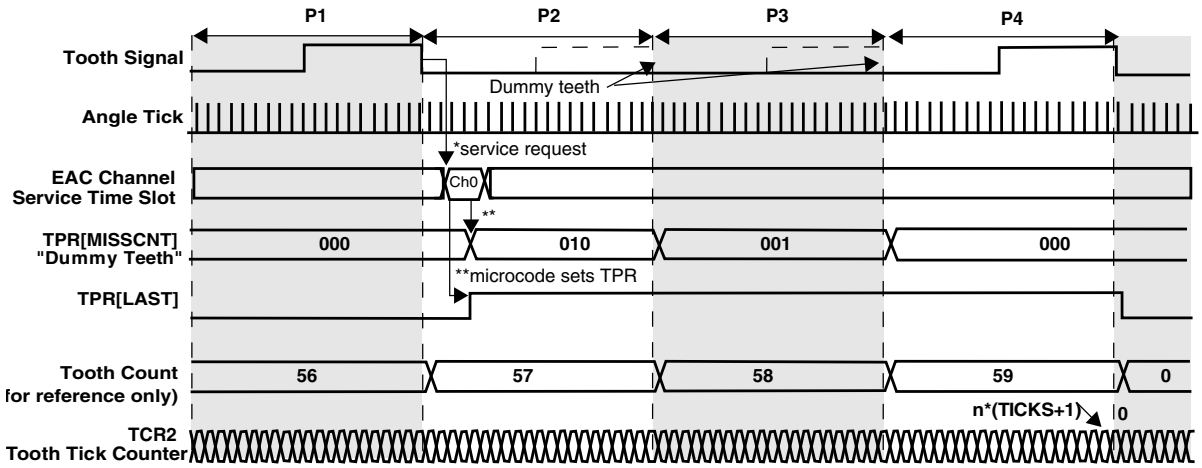

Figure 43-328. Missing Teeth and Last Tooth Combination

43.14.7.7 Handling Mechanical Tooth Correction

The EAC can handle tooth edge detection errors caused by flywheel mechanical errors. The eTPU application can hold a vector of tooth mechanical errors with one entry per tooth. This error can be measured in angle ticks which are independent of engine RPM. The TRR can be updated to the fixed period of any tooth, including its mechanical error.

Because TCR2 counts continuously, without being reset, the mechanical correction is transparent. Though the tooth has its own programmed TICKS value, TCR2 simply counts angle ticks, disregarding the boundary between two adjacent teeth.

43.14.7.8 Handling Mis-detected Tooth

When a physical tooth signal is missed by the engine sensor, the EAC may get into Halt mode at the end of the estimated tooth period, expecting the physical arrival. In this case, a Match timeout event of EAC channel will call service which detects extreme deceleration. The microcode can assert the IPH bit in TPR, to force the detection of the missed physical tooth. It can also calculate the accumulated angle bus error, and fix the next estimated tooth period, to close the gap.

43.14.7.9 Handling False Tooth Detection

Most of the false tooth detection, caused by noises on the engine tooth sensor, can be eliminated by the window blanking filtering, timed by EAC channel match recognitions. The EAC also provides means of fixing false detection of an additional tooth which passed the window filter. When such an event occurs, the EAC switched to High Rate

mode (advancing to the next tooth) and when the next physical tooth arrives, an extreme acceleration is detected: the EAC sees the remaining portion of the current tooth period as another tooth period. The microcode can detect the situation when the acceleration in not realistic, or when immediately after the detection of this extreme acceleration, the following tooth indicates extreme deceleration back to the original RPM.

When the microcode detects such a case, the Tooth Counter has been advanced by mistake to the next tooth. The microcode can set the HOLD bit in the TPR, forcing the EAC to freeze and wait for the next physical tooth to close the gap. When the next physical tooth arrives, HOLD is automatically negated and the EAC proceeds from that point to the remaining portion of the tooth period, in the same mode it was when HOLD bit was asserted.

43.14.7.10 Angle Logic and Channel Modes

The TCRCLK transition detection is qualified by a signal that comes from channel 0 (see Figure 43-323) and depends on the particular mode (PDCM) programmed for that channel. This configures a window for TCRCLK detection for the angle logic which is the same (except on High Rate mode, see High Rate Mode (Acceleration)) used to set the TDLA flag on single transition modes, and TDLB on double transition modes (see signals TSE1,TSE2 in Figure 43-306). The same applies when channels 1 or 2 are used to control EAC (see signals TS1, TS2 in Figure 43-306) . As a consequence, the window depends on the channel mode as follows:

- on all modes, the window closes upon a tooth edge detection: TDLA asserted on single transition modes, TDLB asserted on double transition modes.
- on mode m2_st: the window opens on Match A (which enables Transition A) and does not close with Match B. If Match B comes before Match A, it blocks Match A and, hence, Transition A.
- on mode m2_o_st: the window opens on Match A (which enables Transition A) and closes on Match B. Match B is enabled by Match A, so it cannot come before.
- on all other Single Transition modes, the window is "always open", independently of matches.
- on mode m2_dt: the window opens on Transition A, which is enabled by Match A. The window does not close with Match B, but if it comes before Match A the later gets blocked and, hence, blocks Transitions. Match A is also a condition for the window, so the microcode closes it by clearing MRLA.

- on mode m2_o_dt: the window opens on Transition A, which is enabled by Match A. The window closes on Match B, which is enabled by Match A. Match A is also a condition for the window, so the microcode closes it by clearing MRLA.
- on all other Double Transition modes, the window opens on Transition A.

43.14.7.11 Restarting Angle Logic

It is not recommended to change the ETPUTBCR field AM while GTBE=1. However, if the Angle Logic must be restarted without interfering with the timebase count running on TCR1, the procedure below must be followed:

1. write ETPUTBCR setting AM=00 and TCR2CTL=111 at once. That prevents TCR2 from incrementing while the Angle logic is disabled. The Angle Logic state-machine resets to Normal mode and the tick prescaler to the initial count with AM=00, but not the microengine registers TPR and TRR.
2. start a thread to reconfigure the EAC. The thread must set the EAC controlling channel (0, 1 or 2) flags in a state, depending on the channel mode, that lets the channel tooth detection window open (see Angle Logic and Channel Modes). It can optionally write TCR2 with an angle preset value equivalent to the first tooth expected after restart. The thread must also set TPR bit HOLD=1. The TPR bit IPH must be 0.
3. after the thread is finished, write ETPUTBCR setting AM=01, 10 or 11, and TCR2CTL according to the desired tooth edge selection if AM=01 .

The first tooth detected after this procedure restarts the TCR2 counting, unfreezing the Angle Mode logic into normal mode.

43.14.7.12 Special TPR Write Cases

This section describes how simultaneous modification of TPR fields are resolved, and how the effect of TPR writes depend on the EAC mode.

43.14.7.12.1 TPR Buffering

In High Rate mode (see High Rate Mode (Acceleration)), TPR writes are immediately effective only for bits IPH and HOLD. Writes to all other fields are "buffered" and become effective when EAC leaves High Rate mode. However, if TPR is written a

second time right after IPH is asserted in Normal mode, this second write behaves as if EAC is still in Normal mode. Only in the next microcycle (after execution of a nop, for instance) the TPR writes are buffered, acknowledging High Rate mode.

MISSCNT and LAST can be written any value during High Rate mode, and the value that prevails for the next tooth is the one sampled when EAC goes back to Normal mode (or the value written in Normal or Halt mode thereafter). If MISSCNT and/or LAST are not zero when High Rate mode begins, they are sampled into the internal EAC logic and are effective while High Rate lasts (missing teeth count continues, and TCR2 is reset at the end of High Rate if LAST=1). However, their values in TPR are reset when High Rate mode starts. After that and until the end of High Rate mode, the value read by microcode is the same written. This behavior prevents read-modify-writes to TPR from unwillingly rewriting LAST or MISSCNT.

43.14.7.12.2 IPH and LAST

If both IPH and LAST are asserted in the same microinstruction with HOLD=0, the EAC acts as if LAST was set first and then IPH right after, so that:

- in Normal mode, it goes to High Rate with LAST=1;
- in Halt mode, it goes to Normal Mode resetting LAST (and TCR2);
- in High Rate mode, IPH is ignored and LAST becomes effective in the next tooth (physical or inserted) after it goes back to Normal mode.

43.14.7.12.3 IPH and TICKS

Because of different results depending on the EAC mode at the time of TPR write, it is not advisable to write 1 to IPH and change TICKS at the same microinstruction. A consistent behavior is obtained if IPH is written first and TICKS on the second microinstruction after (for instance with a nop between them), making the new TICKS value valid for the next tooth regardless of the mode.

The mode-dependent behavior is (assuming HOLD=0):

- in Normal mode, the new TICKS value becomes valid before EAC goes High Rate due to the IPH;
- in Halt mode, the EAC goes to Normal mode, and new TICKS is valid for the next tooth;
- in High Rate mode, the new TICKS value is effective when EAC leaves High Rate mode, and IPH is ignored;

43.14.7.12.4 IPH and MISSCNT

If both IPH and MISSCNT are written non-zero values with HOLD=0:

- in Normal mode, at the next microcycle the EAC goes to High Rate mode, the MISSCNT field in TPR goes to 0, and the missing teeth are counted in High Rate mode.
- in Halt mode, the EAC goes to Normal mode for one microcycle and then, yet another microcycle later, goes to High Rate mode, counting the missing teeth. The TPR fields IPH and MISSCNT are zeroed on the transition from Normal to High Rate mode.
- in High Rate mode, IPH is ignored (resetting at the next microcycle) and MISSCNT is buffered (see TPR Buffering).

43.14.7.12.5 IPH and HOLD

If IPH and HOLD are asserted at once, IPH cancels the HOLD and both reset. The EAC is not frozen, regardless of the EAC mode (High Rate, Normal or Halt).

43.14.7.12.6 LAST and HOLD

If LAST and HOLD are written 1 at once, LAST asserts and EAC is frozen. Afterwards, when a physical tooth is detected or IPH is asserted, the EAC is unfrozen in the same state it was before, and LAST is kept asserted.

43.14.8 Microengine

Each eTPU engine has a microengine that fetches, decodes and executes microinstructions. The Microengine only works when there are service requests to be attended, otherwise it turns to idle state, controlled by Hardware Scheduler (see Scheduler).

Microcode is stored in Shared Code Memory (SCM) that is 32-bit wide. Microengine can access SDM using a different bus from the one used to accesses code memory, so that code and data can be accessed at the same time (Harvard Architecture).

Some of eTPU functionality can only be made through the microengine, like configuring channels and interrupting host. Microengine gives eTPU a high degree of flexibility, since any desired treatment for channel's events can be implemented; however, that

flexibility comes at the cost of channel service's latency. Latency is worsened when channels from a same eTPU engine contend for microengine service. In the figure below, a block diagram of microengine architecture is shown.

Follows a summary of Microengine features:

- P, DIOB, A, B, C, D, SR, RAR, LINK, CHAN, MACL, MACH, ERTA, ERTB, TCR1, TCR2, TPR, TRR registers are accessible by microcode.
- 24-bit ALU and Post-ALU shifter performs basic arithmetic and logical operations described in ALU and Post-ALU Shifter.
- MDU (MAC/Divide Unit) performs integer MAC, multiply and divide operations.
- Fixed Microinstruction Size of 32bits.
- Fixed-length instruction execution (2 eTPU clocks)
- Static superscalar operation

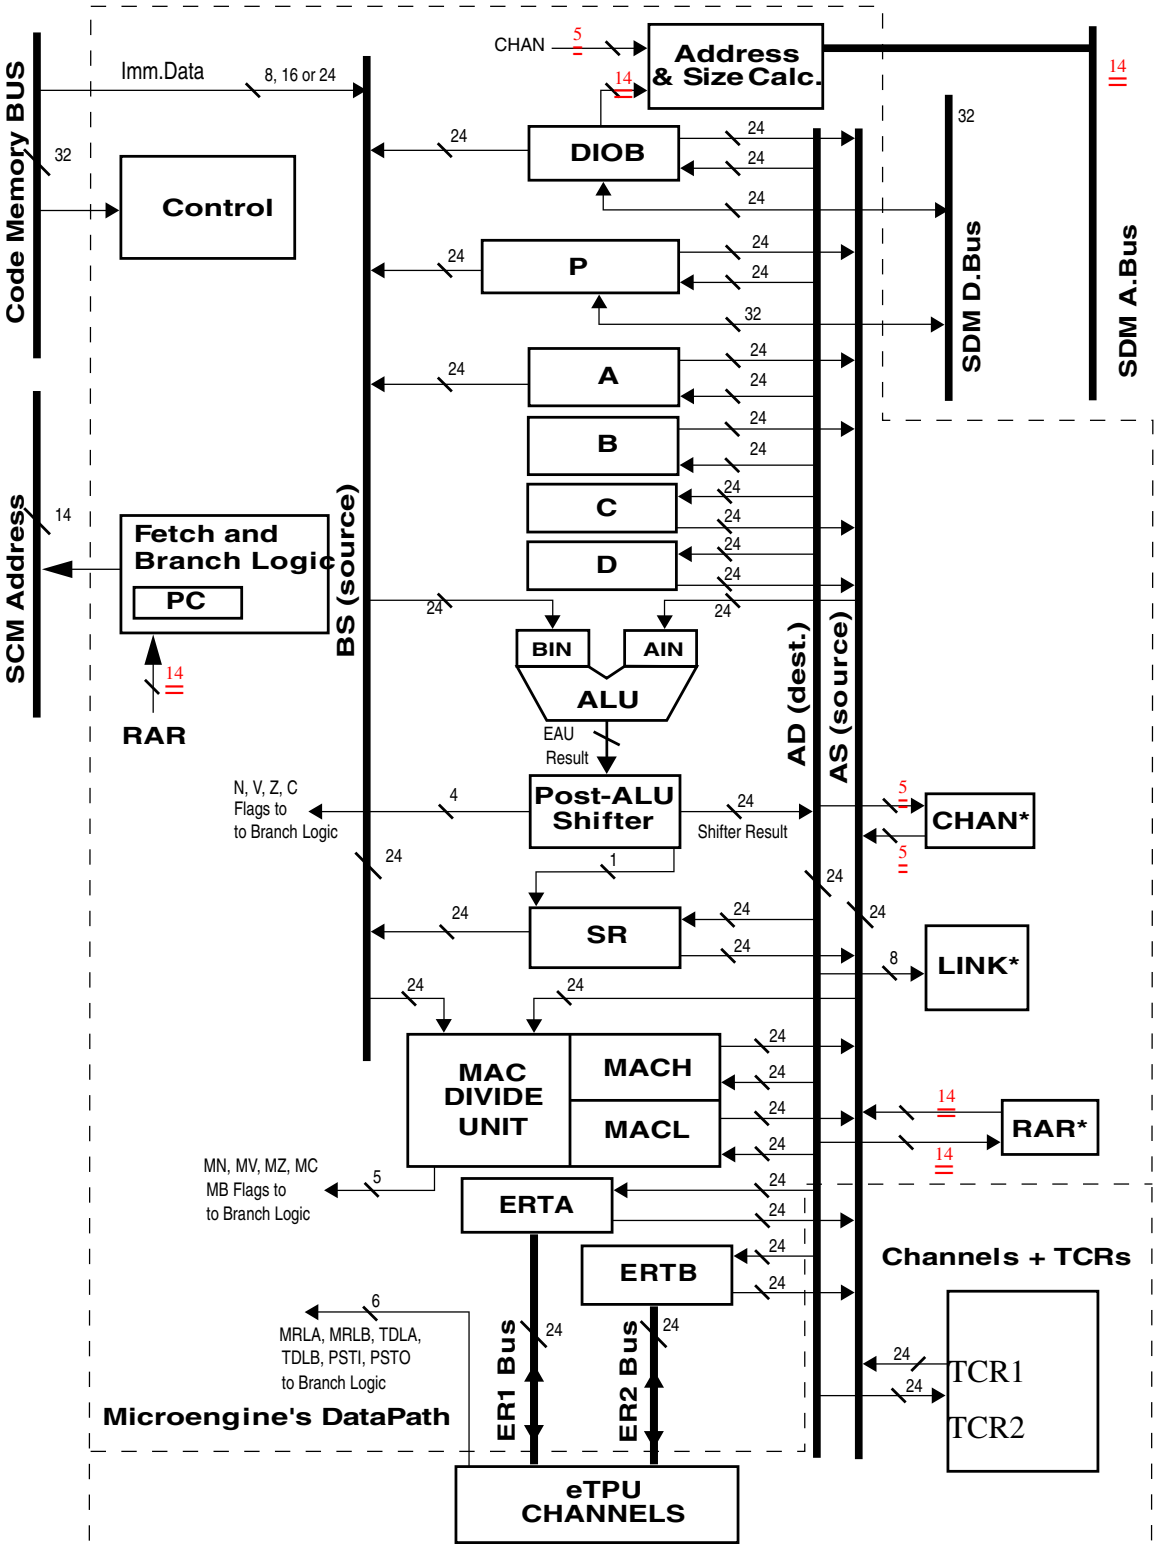

Figure 43-329. Microengine Block Diagram

43.14.8.1 Registers

eTPU microengine accesses a total of 18 registers. Fourteen of them are special purpose (registers A, B, C and D are for general use). Special purpose registers except CHAN and LINK can also be used as general use if the operation that use their contents are not performed. Register description is intended to just introduce their functionalities and not to provide detailed explanation of it since it will be described in Microinstruction Set . Registers less than 24 bits in size are right-justified.

None of the registers have guaranteed reset values. However, some are initialized just before the thread starts (see Time Slot Transition).

43.14.8.1.1 P Register

P register is the only one that is 32-bit wide. It can be used as source and destination for arithmetic/logical operation, and as source and destination for SDM read/write operations.

For P source/destination possibilities in ALU/MDU microoperations, see Selecting Sources and Destination.

When P is used as SDM read/write operations source or destination there are only 3 possibilities of access: all 32 bits, lower 24 bits and upper 8 bits. SDM operations are explained in detail in SDM Microoperations.

P is automatically loaded with one parameter before the thread starts (parameter preload). For more information see Entry Point Format and Time Slot Transition.

Upper 8 bits of P register can be used as application state, since these bits can be tested as branch conditions. P[31:24] is also used in dispatch microoperation (see Dispatch Microoperation), and bit pairs P[29:28], P[27:26], P[25:24] can be directly copied into Channel flags 1 and 0 using field FLC. Together with Entry Table Condition Encoding, it provides fast state resolution without code execution.

43.14.8.1.2 DIOB Register

DIOB is an abbreviation for Data Input/Output Buffer. DIOB is 24-bit wide and can be used as source and destination for arithmetic/logical operations as well as SDM data source and destination. DIOB only can be accessed as 24 bits, both in arithmetic/logical and SDM read/write operations. When using DIOB to perform an SDM access, only lower 24 bits of SDM will be accessible (SDM upper 8 bits always remains unchanged).

DIOB can also be used as SDM addressing register, when DIOB contents is used as absolute SDM address (14-bit wide). In this case DIOB can also be pre-decremented or post-incremented (see Indirect Addressing Mode).

DIOB is automatically loaded with one parameter before the thread starts (parameter preload). For more information see Entry Point Format and Time Slot Transition.

43.14.8.1.3 ERTA and ERTB Registers

ERTA/B registers are 24-bit wide and can be used as source or destination in arithmetic/logical operations. ERTA/B are the only source for channel's match registers write (see Write Channel Match and UDCM Registers). ERTA can also be the source for UDCM write.

When a thread starts to be executed, ERTA and ERTB are loaded with a copy of CaptureA and CaptureB registers respectively. ERTA/B can be used to receive a copy of MatchA and MatchB registers. ERTA/B are the only destination of MatchA/B read operation (see Special T4ABS Source Operation: Read Match Registers).

ERTA and ERTB also receive a copy of CaptureA and CaptureB registers when CHAN register is written (see CHAN Register). For more information about Capture and Match registers see MatchA and MatchB Registers and CaptureA and CaptureB Registers.

43.14.8.1.4 SR register - Shift Register

SR is a 24-bit wide register that can be used as source and destination register for arithmetic/logical operations. SR can shift right its contents by 1 bit at time and, at the same time, receive in its bit 23 the lost bit of a shift-right operation in post-ALU shifter (ALU and Post-ALU Shifter), allowing SR to be used to perform 48-bit shift right (see Shift Operations).

43.14.8.1.5 MACH and MACL Registers

Both MACH and MACL are 24-bit registers, part of MAC/Divide unit (see MAC and Divide Unit (MDU)). They can be used as source and destination in most arithmetic/logic operations. When multiply or divide operations are used (multiply-accumulate included), MACH and MACL have special purpose and some restrictions apply, see MAC and Divide Unit (MDU) for more information.

43.14.8.1.6 LINK Register

Link Register is an 8-bit wide register and can be used only as destination in arithmetic operations. LINK is a write-only command register, which precludes its use as a source register for ALU operations. When LINK register is written, it issues a service request for the channel number and eTPU engine equal to the number written in LINK register (see Functions and Threads and Channel Link for information about Link Service Request).

43.14.8.1.7 RAR Register

RAR is a 14-bit register and can be used as source and destination in arithmetic operations. RAR also receives the contents of PC register when a subroutine call is executed. The contents of RAR register is loaded into PC when a return from subroutine is executed. RAR is loaded with value 0x3FFF during TST. For more information about subroutine call and return see Branch Operations and Return From Subroutine respectively.

43.14.8.1.8 CHAN Register

CHAN is a 5-bit register that can be used as source and destination in arithmetic operations. The contents of CHAN register affects the execution of many channel-related microinstructions, because its number indicates the **selected channel** . CHAN register must not be used to store temporary values in arithmetic operations. For more details, refer to Channel Selection Register - CHAN.

43.14.8.1.9 Counter Registers: TCR1, TCR2, TPR and TRR

All these registers are 24-bit wide except TPR, which is a 16-bit register. They can be read or written in arithmetic/logical operations, and have special-purpose uses for time base and angle mode operations. For more information about those registers see Time Bases and EAC - eTPU Angle Counter.

43.14.8.1.10 General Purpose Registers: A, B, C and D

A, B, C and D are 24-bit general purpose registers, which can be used to store intermediate values and do not have other specific uses with any eTPU feature.

43.14.8.2 ALU and Post-ALU Shifter

The ALU executes 24-bit arithmetic and logical operations. ALU's output goes directly to a 1-bit shifter, called post-ALU shifter, so it is possible, for example, to add and shift using only one microinstruction.

In some microinstruction formats, it is not possible to specify the operation executed by ALU. In these cases ALU will always perform addition.

In formats which have the field ALUOP for ALU operation selection, all of them can be performed, including add/subtract using C (carry) flag as ALU's carry-in, bitwise AND/OR/NOT/XOR, and shift/rotate of 2, 4, 8 and 16 bits. See ALU/MDU Operation Selection.

Subtraction, inversion, increment and decrement can be performed by combinations of source inversion and setting ALU's carry-in to 1.

ALU always performs 24-bit operations on its inputs, called **A-source** and **B-source**, and outputs a 24-bit result. 8-, and 16-bit inputs are zero padded to 24 bits. Likewise, ALU 24-bit output is always truncated to the destination register size.

43.14.8.2.1 ALU Flags

Four flags - Carry, Negative, Overflow, Zero - described below, are related to ALU and post-ALU shift operations. Operation size and shifting affect flags generation logic. Operation size determines the result boundary to be used for flags generation. Operation size is determined by size of sources and destination (see Flags Sampling Control). For more information about flag generation, see Flags Sampling Control . ALU flags can be used as branch condition (see Conditional/Unconditional Branch) or conditional ALU/MDU operation (see Conditional ALU/MDU Operation Execution).

Field CCS/CCSV in microinstructions can force **no update** of all flags. Not all flags are updated in all ALU operations: Overflow is updated only on addition and absolute value operations, Carry flag is updated in most ALU operations, and only Zero and Negative are updated in all ALU operations.

ALU flags are never updated when microinstruction starts an MDU operation, regardless of CCS/CCSV, but are updated normally afterwards, on ALU operations that are executed in parallel with an ongoing MDU operation (MDU has its own flags).

Note

Operation size can be smaller than destination register. For example: 0xFFFF + 0x0001 (both 16-bit sources) stores 0x10000 in a 24-bit register and sets Zero and Carry flags because operation size is 16 bits.

43.14.8.2.1.1 Carry Flag (C)

In an unsigned addition without shifting, Carry Flag is the ALU carry from bit 7 to 8, 15 to 16, or 23 to 24 on 8-, 16- and 24-bit operation sizes respectively. In an unsigned subtraction without shifting, Carry Flag represent the sign of ALU's result considering operation size (Carry Flag equal to 1 means a negative result).

Carry Flag definition is operation-dependent. The Carry flag in add/subtraction with Post-ALU shift is defined in Table 43-360 . Find the definitions for other operations in the following sections.

43.14.8.2.1.2 Negative flag (N)

Negative flag indicates the sign of result based on the operation size, regardless of the operation performed, as shown in the following table.

Table 43-356. Negative (N) flag behavior

Operation Size	Value
8 bits	N = result[7]
16 bits	N = result[15]
24 bits	N = result[23]

Note

The N flag may not reflect the sign of the value actually written into the destination register, if it does not have the same size of the operation (see Flags Sampling Control). This is always the case for registers RAR (14 bits) and CHAN (5 bits).

43.14.8.2.1.3 Overflow (V)

Overflow is updated only on addition (with or without carry) and absolute value operations. In signed operations, overflow flag indicates that the result of arithmetic operation (add or subtraction) can not be represented by a word of the size of the operation. Overflow flag behavior for addition is defined in the following table. Overflow flag for Absolute operation is explained in Absolute Value Operation . V Flag is calculated using ALU adder output (i.e., it is not affected by 1-bit shift/rotate operations).

Table 43-357. Overflow Flag on Addition - V

Op. Size	Value[1]
8 bits	(AS[7] & BS[7] & !alu_adder_output[7]) | (!AS[7] & !BS[7] & alu_adder_output[7])
16 bits	(AS[15] & BS[15] & !alu_adder_output[15]) | (!AS[15] & !BS[15] & alu_adder_output[15])
24 bits	(AS[23] & BS[23] & !alu_adder_output[23]) | (!AS[23] & !BS[23] & alu_adder_output[23])

1. BS is taken after any inversion by the BINV field, but not added to the carry bit (CIN field)

NOTE

For V-flag definition on the absolute operation, see “Absolute Value Operation".

43.14.8.2.1.4 Zero Flag (Z)

Zero flag equal to 1 indicates that the result from the ALU, limited to the operation size, is zero, regardless of the operation performed, whether the result is written, or where it is written. It depends on the operation size, as shown in the following table.

Table 43-358. Zero Flag - Z

Operation Size	Value
8 bits	Z = (result[7:0] == 0x00)
16 bits	Z = (result[15:0] == 0x0000)
24 bits	Z = (result[23:0] == 0x000000)

43.14.8.2.2 ALU ADD Operation with and without shifting

ADD operation is selected by ALUOP or ALUOPI fields and when none of them is available in a microinstruction format[30] . Optionally, result can be shifted or rotated right by 1 bit, which is selected by SHF, ALUOP or ALUOPI fields. See Microinstruction Set for more details. The following table describes how CIN and BINV fields change ADD operation behavior.

Table 43-359. Types of ADD operations

BINV	CIN	Operation (adder output)
1	1	AS + BS
1	0	AS + BS + 1
0	0	AS - BS
0	1	AS - BS - 1

ALU adder output can be 1-bit shifted or 1-bit rotated right as follows:

Shift right:

```
if BINV==1
  result [23:0] = adder_output[24:1]
else
  result [23:0] = adder_output [24:1] xor 0x800000
endif
```

Shift left:

30. ALU operations only occur on formats where a destination field is found (T2ABD/T2D).

```
result[23:1] = adder_output[22:0]
result[0]    = 0
```

Rotate right:

```
case(opsize/CCSV)
8-bit:
  result[6:0]   = adder_output[7:1]
  result[7]     = adder_output[0]
  result[23:8]  = adder_output[23:8]
16-bit:
  result[14:0]  = adder_output[15:1]
  result[15]    = adder_output[0]
  result[23:16] = adder_output[23:16]
24-bit:
  result[22:0]  = adder_output[23:1]
  result[23]    = adder_output[0]
```

Note

Only for the Post-ALU rotate right, the operation size is determined by the field CCSV (see Flags Sampling Control). For example: if CCSV=00, T4ABS=P (24-bits), T4BBS=A (24 bits), T2ABD=B (24 bits), and ALUOP="Add ROR", then B gets A+P with bits 7:0 rotated, even though the operation size is 24 bits.

The following table describes Carry flag behavior.

Table 43-360. Carry flag update on ADD operation

BINV[1]	Op. Size	shift/rotate	Value
1	8 bits	none	adder carry from bit 7 to bit 8
1	16 bits	none	adder carry from bit 15 to bit 16
1	24 bits	none	alu_adder_output[24]
0	8 bits	none	!adder carry from bit 7 to bit 8
0	16 bits	none	!adder carry from bit 15 to bit 16
0	24 bits	none	!alu_adder_output[24]
0 or 1	8 bits	shift left	alu_adder_output[7]
0 or 1	16 bits	shift left	alu_adder_output[15]
0 or 1	24 bits	shift left	alu_adder_output[23]
0 or 1	x	shift right	alu_adder_output[0]
1	8 bits	rotate right	adder carry from bit 7 to bit 8
1	16 bits	rotate right	adder carry from bit 15 to bit 16
1	24 bits	rotate right	alu_adder_output[24]
0	8 bits	rotate right	!adder carry from bit 7 to bit 8
0	16 bits	rotate right	!adder carry from bit 15 to bit 16
0	24 bits	rotate right	!alu_adder_output[24]
		except on max-constant generation (see Max Const Generation With T4BBS=111)	

1. BINV has no effect on carry-out when used to code max constant (see Max Const Generation With T4BBS=111).

Flags N and Z on shift are updated according to the result after shift. Flag V with shift is updated according to the ADD operation only, the same way as without shift.

43.14.8.2.3 ADC Operation

ADC operation is selected by the ALUOP field. CIN field is ignored when this operation is selected. The following table describes how BINV change ADC operation behavior.

Table 43-361. Types of ADC operations

BINV	CIN	Operation
1	x	AS + BS + C flag
0	x	AS - BS - C flag

Flags behave exactly the same way as for ADD operation without shift/rotate.

43.14.8.2.4 Bitwise Operations

Bitwise AND, OR and XOR are selected by ALUOP field. On these operations CIN field is ignored and BINV field inverts (bitwise NOT) BS. C and V Flags are never updated on these operations. The following table describes AND, OR and XOR bitwise operations.

Table 43-362. Types of Bitwise Operations

ALUOP	BINV	Operation
10000	1	AS | BS
10000	0	AS | (~BS)
10001	1	AS ^ BS
10001	0	AS ^ (~BS)
10010	1	AS & BS
10010	0	AS & (~BS)

43.14.8.2.5 Set Bit / Clear Bit Operations

These operations set or clear the AS bit determined by BS[4:0]. If the bit number resolves to a value greater than 23, no bit is set or cleared (i.e., result is equal to AS). On these operations CIN field is ignored and BINV field inverts (bitwise NOT) BS. C and V flags are never updated for set/clear bit operations. These operations **override** B-Source size to 8 bits.

set bit (BINV = 1):

```
result = AS | (1 << BS)
```

clear bit (BINV = 1):

```
result = AS & ~(1 << BS)
```

set bit (BINV = 0):

```
result = AS | (1 << (31 - BS))
```

clear bit (BINV = 0):

```
result = AS & ~(1 << (31 - BS))
```

43.14.8.2.6 Exchange Bit

Exchange the AS bit determined by BS with C flag. If the bit number resolves to a value greater than 23, no exchange is performed (i.e., result is equal to AS and C flag is not updated). This operation **overrides** BS size to 8 bits. On this operation, CIN field is ignored and BINV field inverts (bitwise NOT) BS. V flag is never updated on exchange bit operation. C flag is always updated, regardless of CCSV, unless BS > 23.

Exchange Bit (BINV=1):

```
if BS <= 23
begin
  temp_C_flag = AS[BS]
  if C_flag == 1
    result = AS | (1 << BS)
  else
    result = AS & ~(1 << BS)
  C_flag = temp_C_flag
end
```

Exchange Bit (BINV = 0):

```
if (31 - BS) <= 23
begin
  temp_C_flag = AS[31 - BS]
  if C_flag == 1
    result = AS | (1 << (31 - BS))
  else
    result = AS & ~(1 << (31 - BS))
  C_flag = temp_C_flag
end
```

43.14.8.2.7 Multibit shift/rotate Operations

These operations shift or rotate AS by 2, 4, 8 or 16 bits. Size of shift/rotate is determined by BS[1:0]. The following table describes the number of shifted/rotated bits depending on BS[1:0] value.

Table 43-363. Number of shifted/rotated bits for each BS[1:0] value

BS[1:0]	Bits Shifted/Rotated
0	2
1	4
2	8
3	16

Shift right is a logical operation (i.e., zeros are inserted on left). Multibit shift and rotate operations **overrides** BS size to 8 bits. The shifts and rotate operate on 24 bits, independently of the operation size.

V flag is never updated for multibit shift or rotate operations. Carry flag behavior is described in the following table. CIN is ignored in these operations, but BINV is effective.

Table 43-364. Carry flag value on multibit shift/rotate operations

ALUOP	BS[1:0]	C flag value[1]
11001 (shift left)	0	AS[22]
11001 (shift left)	1	AS[20]
11001 (shift left)	2	AS[16]
11001 (shift left)	3	AS[8]
11010 (shift right)	0	AS[1]
11010 (shift right)	1	AS[3]
11010 (shift right)	2	AS[7]
11010 (shift right)	3	AS[15]
11011 (rotate right)	0	AS[2]
11011 (rotate right)	1	AS[4]
11011 (rotate right)	2	AS[8]
11011 (rotate right)	3	AS[16]

1. CCS/CCSV can disable flag update on multibit shift/rotate, but the specified flag size in CCSV is ignored for the C flag.

43.14.8.2.8 Absolute Value Operation

Absolute Value operation is selected by ALUOP field. On this operation, AS is interpreted as a signed number and its absolute value is the result. V and N flags are updated with the result signal determined by the operation size. AS bit 23 after size override and sign extension (if any, see A-Source Size Override), regardless of A-source register size, is used to check the operand signal and is copied to C-flag. Note that if AS is 8-bit or 16-bit, its sign is taken into account and copied to C only if sign-extension is performed. The following table summarizes flag updating for Absolute Value operation.

This operation is independent of B-source. Instruction fields T4BBS, BINV and CINV are ignored in this operation. The Absolute Value operation size is the minor between A-source size and Destination size.

Table 43-365. ALU Flags in Absolute Value operation

operation size	V, N[1]	C	Z
8	alu_output[[7]	AS[23]	alu_output[7:0] == 0
16	alu_output[15]		alu_output[15:0] == 0
23	alu_output[23]		alu_output[23:0] == 0

1. V, N can be 1 on 8- and 16-bit Absolute Value, because the operand sign is always taken from bit 23. V, N can also be 1 in 23-bit Absolute Value (or 8-bit and 16-bit with sign extension), if the operand is 0×800000 (0×80, 0×8000).

43.14.8.3 MAC and Divide Unit (MDU)

MDU is an autonomous resource in the microengine which can carry out sequential multiply, multiply-accumulate, fractional multiplication and divide operations, selected through the microinstruction fields ALUOP or ALUOPI. The unit supports signed and unsigned multiply and fractional multiplication of any combination of 8, 16 or 24 bit operands [31], and also signed and unsigned 24-bit multiply-accumulate. Divide operation is unsigned, and both operands are always 24-bit wide.

Depending on the size of operands and the type of operation, MDU can take more than one microcycle to execute the operation, but microengine continues to execute microinstructions in parallel. When the microcode issues an END command, any MDU executing operation terminate immediately and is left incomplete. When selecting an operation that uses MDU, the result is always placed in MACH and MACL registers, and the register selected as destination does not have its value changed (Selecting Sources and Destination). During calculations, MACH and MACL holds temporary values and should not be written, otherwise the result is unspecified. One must not start an MDU operation while MDU is already busy: the result is unspecified for both the ongoing operation and the started one.

MDU Operations update its own set of 5 flags, described in MDU Flags. MDU operations never update C, N, V and Z flags. CIN and BINV microinstruction fields affect MDU operations according to the follwoing table.

31. There is no distinct selection of 24-bit fractional multiplication, for it works exactly as a 24-bit ordinary multiplication.

Table 43-366. CIN and BINV with MDU Operations

B-source operand	BINV	CIN	Op. Performed
signed	1	1	AS mdu_op BS
	0	0	AS mdu_op (-BS)
	1	0	reserved
	0	1	reserved
unsigned[1]	1	1	AS mdu_op BS
	1	0	AS mdu_op (BS+1)
	0	x	reserved

1. includes the B-source (unsigned) in fmults (signed) operations.

43.14.8.3.1 Multiply and Multiply-Accumulate Operation Length

MDU needs 2 sources, A source and B source, to perform an operation. The time needed to perform a multiply or multiply-accumulate is:

- on 24-bit x 8 bit multiplies: 2 microcycles (one start-MDU plus one execution microcycle)
- on 24-bit x 16 bit multiplies: 3 microcycles (one start-MDU plus two execution microcycles)
- on 24 bit x 24 bit multiplies/macs: 4 microcycles (one start-MDU plus three execution microcycles)

An internal pipeline in MDU allows multiply-accumulate (or even non-fractional multiply) operations to start one microinstruction before a multiplication or multiply-accumulate (signed or unsigned) has been completed (e.g., one can start one multiply or multiply-accumulate once every three microinstructions). However, by doing that it is not possible to read the result in MACH and MACL (although the MDU flags can be tested), so this is intended to be used in a multiply-accumulate sequence. It is also allowed to mix different sizes in multiply/mac sequences.

Multiply-accumulate operations are similar to multiply operations, except that the contents of MACH and MACL registers are added to the multiplication result.

When multiply or multiply accumulate operations finish, MACL and MACH hold the least and the most significant 24-bit words, respectively.

43.14.8.3.2 Divide Operation Length

The divide operation is always unsigned. The division completes in 13 microcycles, meaning that after the start divide microinstruction, one has to wait for 12 microcycles and then read the result and the remainder in MACH and MACL registers. During the 12 execution microcycles, microengine can execute microinstructions unrelated to the MDU.

43.14.8.3.3 Signed Multiplication (mults)

MDU signed multiplication is defined as follows:

```
(signed) MACH,MACL = (signed) AS * (signed) BS
```

MC and MV flags are reset. MZ is set if result is 0, resets otherwise. MN is set if result is negative.

43.14.8.3.4 Unsigned Multiplication (multu)

MDU unsigned multiplication is defined as follows:

```
(unsigned) MACH|MACL = (unsigned) AS * (unsigned) BS
```

MC and MV flags are reset. MZ is set if result is 0, resets otherwise. MN is a copy of the most significant bit of result.

43.14.8.3.5 Signed Multiply-Accumulate (macs)

MDU signed multiply-accumulate is defined as follows:

```
(signed/unsigned) {MACH,MACL} += (signed) AS * (signed) BS
```

MC is not altered.

MV is set if result can not be represented by a 48-bit signed number. MACS never resets MV flag: it is left as is if no overflow occurs, or set it otherwise. This allows checking the overflow flag only once at the end of a series of multiply-accumulate operations in a scalar product calculation.

```
if (({MACH,MACL} += AS * BS < -2^47) || ({MACH,MACL} += AS * BS > 2^47 - 1))
  MV = 1
```

MZ is set if result is 0, resets otherwise. MN is a copy of the most significant bit of result.

Note that only 24-bit multiply-accumulate is available.

43.14.8.3.6 Unsigned Multiply-Accumulate (macu)

MDU Unsigned Multiply-Accumulate is defined as follows:

```
(signed/unsigned) {MACH,MACL} += (unsigned) AS * (unsigned) BS
```

MC is set if result can not be represented by a 48-bit unsigned non-negative number. MACU never resets MC flag: MC flag is left as is if no carry occurs, or set otherwise. This allows checking the carry flag only once at the end of a series of multiply-accumulate operations in a scalar product calculation.

```
if (({MACH,MACL} += AS * BS < 0) || ({MACH,MACL} += AS * BS > 2^48 - 1))
  MC = 1
```

MV is not altered.

MZ is set if result is 0, resets otherwise. MN is a copy of the most significant bit of result.

Note that only 24-bit multiply-accumulate is available.

43.14.8.3.7 Signed Fractional Multiplication (fmults)

MDU Signed Fractional Multiplication takes the B-Source as an **unsigned** 8- or 16-bit[32, 32] fraction between 0 and $(2^8 - 1)/2^8$ (inclusive) for the 8-bit operation, or between 0 and $(2^{16}-1)/2^{16}$ (inclusive) for the 16-bit operation. Only A-Source is taken as a signed number. The value of B-Source is considered the unsigned numerator of a fraction with denominator 2^8 or 2^{16} for the 8- and 16-bit operations, respectively.

The integer part of the result is stored in MACH, and the fractional part in MACL. The result is signed, so that the concatenation of MACH and MACL form a 48-bit fixed point number with a 24-bit integer part, both for 8- and 16-bit operations. To calculate the unsigned numerator of the fractional part (with denominator 2^{24}) of the result, one must take the absolute value of MACL considering the signal of the result (not MACL alone), i.e.: if flag MN=1, invert MACL and add 1.

MDU flags are updated in the same way as in the Signed Multiplication.

43.14.8.3.8 Unsigned Fractional Multiplication (fmultu)

MDU Unsigned Fractional Multiplication takes both A-Source and B-Source as unsigned operands. B-Source is taken as an 8- or 16-bit[1] fraction between 0 and $(2^8 - 1)/2^8$ (inclusive) for the 8-bit operation, or between 0 and $(2^{16}-1)/2^{16}$ (inclusive) for the 16-bit operation. The value of B-Source is considered the numerator of a fraction with denominator 2^8 or 2^{16} for the 8- and 16-bit operations, respectively.

32. 24-bit fractional signed/unsigned multiplication is equivalent to mults/multu.

The integer part of the result is stored in MACH, and the fractional part in MACL. The fractional part in MACL is the numerator of a fraction with denominator 2^{24} . The concatenation of MACH and MACL form a 48-bit fixed point number with a 24-bit integer part, both for 8- and 16-bit operations.

MDU flags are updated in the same way as in the Unsigned Multiplication.

43.14.8.3.9 Unsigned Divide (div)

At the end of a divide operation MACL holds the result of the division, taking A-source as numerator and B-source as denominator, while MACH holds the remainder. If a divide by 0 is executed, MACL holds the maximum unsigned number (0xFFFFFF) as result and flag MV is set to indicate division by 0 (otherwise reset). The contents of MACH become indetermined.

MC flag is always reset.

MZ flag is set if MACL equals 0, and reset otherwise.

MN receives a copy of MACH bit 23 (msb from the remainder).

Note that signed division is not available.

43.14.8.3.10 MDU Flags

MDU has its own flags to indicate the result and status of an MDU operation. They are: MC, MZ, MV, MN and MB. All MDU flags are updated with the final result at the end of the operation, and do not change until the next operation finishes. Therefore it is possible to start a new MDU operation and test the flags of the previous one in parallel, except for mult/mac with 8-bit operand (takes only 1 microcycle).

43.14.8.3.10.1 MDU Negative Flag - MN

MN flag is always a copy of MACH bit 23 at the end of the operation, either in signed or unsigned ones. Note that MACH holds the rest of a division operation, which is always unsigned.

43.14.8.3.10.2 MDU Carry Flag - MC

MDU carry flag indicates if the result cannot be represented by a 48-bit number, in Signed and Unsigned Multiply Accumulates. It is reset in the other operations.

43.14.8.3.10.3 MDU Zero Flag - MZ

In multiply and multiply-accumulate operations, MDU zero flag is asserted if MACH and MACL are equal to zero at the end of an operation. In divide operations, zero flag is asserted if MACL (result) is equal to 0.

43.14.8.3.10.4 MDU Overflow Flag - MV

In multiply operations, MV flag is negated and keeps negated in the end, because the result of a multiplication can always fit in a 48-bit result (MACH and MACL concatenated). In a multiply-accumulate operation, MV is asserted if the result size is wider than 48 bits. MV flag work in both signed and unsigned operations.

In divide operations it is only asserted if a divide-by-zero operation was executed.

43.14.8.3.10.5 MDU Busy Flag (MB)

MB tests as true at the next microinstruction after the MDU start operation, and as false at the last microcycle of any MDU operation execution.

43.14.8.4 Branch Conditions

Microengine allows conditional branch. There are five sets of flags that can be tested in a conditional branch: ALU flags, MDU flags, P flags, Channel flags, and Semaphore flag (flag SMLCK).

When a thread starts to be executed, the values in MDU and ALU flags are not initialized. ALU flags are described in ALU Flags, MDU flags are described in MDU Flags. MDU and ALU flags are updated during execution of microinstructions.

P flags are actually the upper byte of P register, which optionally can work as user defined flags (see P Register).

Channel flags Flags0, Flag1, MRLA, MRLB, TDLA, TDLB, PSS, PRSS and PSTO are obtained from the selected channel (value in CHAN register), while channel flags, LSR, FM[0] and FM[1] are selected by the serviced channel, regardless of the CHAN value[33] .

Flags TDLA/B, MRLA/B, LSR, FM and PSS, are sampled at the beginning of a thread. Flag PSS does not change during its execution while CHAN register is not written. When a write in CHAN register is performed, all flags except LSR and FM are updated according to the channel specified by CHAN value. Flags MRLA/B and TDLA/B are reset when their respective latches in channel are cleared by microcode.

33. Serviced channel does not change during execution of a thread, and it is the channel that requested a service (initial value of CHAN register when a thread starts).

Table 43-367. Channel Flags as Branch Condition

Flag	Description	Service or Selected Channel
Flag0	State Resolution flag	reflects the selected channel (CHAN)
Flag1	State Resolution flag	reflects the selected channel (CHAN)
MRLA	Match A Recognition Latch	these flags reflect the selected channel (CHAN)see MRLA/B - Match Recognition Latches and TDLA/B - Transition Detect Latches for more information.
MRLB	Match B Recognition Latch	
TDLA	Transition A Detection Latch	
TDLB	Transition B Detection Latch	
LSR	Link Service Request	reflects the serviced channel.
PRSS	Input Pin state sampled at service request	reflects the selected channel (CHAN). Does not change if CHAN is not changed.
PSS	Sampled Input Pin State	reflects the selected channel (CHAN). Does not change if CHAN is not changed (see Pin Control Registers).
PSTI	Current Input Pin State.	reflects the selected channel (CHAN). Changes any time.
PSTO	Current Output Pin State	reflects the selected channel (CHAN). Changes any time.
FM	Function Mode Bits	reflects the Function Mode for serviced channel (see the ETPUCnSCR register)

Semaphore condition SMLCK always indicates if a semaphore is locked for the Engine, resolving as false before any lock attempt. For each trial, the SMLCK flag is updated. The SMLCK value set in one thread is not meaningful to the other. After a free, the SMLCK condition tests as false until a new lock attempt on the same thread.

Branch conditions are selected through instruction fields BCC and BCF (see Conditional/ Unconditional Branch).

43.14.9 Microinstruction Set

Each microinstruction can execute up to 3 microoperations in parallel. Microinstructions are grouped into formats, and there are four types of microoperations:

- ALU/MDU Operations
- SDM Operations
- Channel Configuration/Control Operations
- Flow Control Operations

Each microinstruction format is defined by a set of microinstruction fields, which determine the operations, each belonging to one of the groups above (there may be several in one group). Complete microinstruction formats are shown in Microinstruction formats.

Parallelism conflicts may arise when two operations are executed in the same microinstruction. These situations are explained in Microinstruction Parallelism Issues.

43.14.9.1 SDM Microoperations

The access to SDM is made by providing an address and a register to perform a data transfer, except semaphore operations, which are also classified in the SDM group. Only P and DIOB registers can exchange data with SDM. Microengine always addresses SDM in 32-bit boundaries, for 8, 24, or 32 bit wide data.

Direction is determined by the field RW in all addressing modes: RW=0 selects read and RW=1 selects write.

43.14.9.1.1 SDM Addressing Modes

There are 4 addressing modes in eTPU:

- Absolute
- Selected Channel Relative
- Indirect
- Engine Relative

The addressing modes Absolute and Selected Channel Relative use immediate bits to form the physical address of SDM, which is identified in microinstruction as a field called AID. AID field can be 3-, 7-, or 8-bit wide depending on the addressing mode.

43.14.9.1.1.1 Absolute Addressing Mode

In Absolute addressing mode, the address range is 256 parameters, addressed by field AID, which in this mode is 8-bit wide. These parameters are located in SDM addresses from 0 to 255.

```
physical_address = AID[7:0]
```

43.14.9.1.1.2 Selected Channel Relative Addressing Mode

In Selected Channel Relative addressing mode, only the first 8 (with 3-bit AID) or 128 (with 7-bit AID) parameters of the selected channel are accessible, depending on the microinstruction format. Physical address is calculated using the channel parameter base

address that is specified in field CPBA of ETPUCnCR register (see the ETPUCnCR register). AID field is added to channel parameter base address to compose the physical address. The address equation is:

```
physical_address = selected_channel_parameter_base_address + AID[6:0], or
physical_address = selected_channel_parameter_base_address + AID[2:0]
```

43.14.9.1.1.3 Indirect Addressing Mode

In Indirect Addressing mode the physical address is taken from DIOB register. Only DIOB bits 14 to 2 are relevant. Since the SDM word address is shifted two bits up in DIOB, its contents hold the same parameter address value used by Host. The address equation for SDM access is:

```
physical_address = DIOB[13:2], or
physical_address = (truncated to 12 bits) (DIOB / 4)
```

Indirect addressing mode is used to access the Shared Subsystem Area when ETPUCxCR bit SSMAE=1 and DIOB addresses the 16 Kbytes just above the SDM range (DIOB bit 14 = 1). See Shared Subsystems Support for more details. If SSMAE=0, accesses with DIOB bit 14 = 1 hit the same SDM addresses as with bit 14 = 0, providing full backwards compatibility with respect to DIOB contents.

Indirect addressing mode can have post-increment or pre-decrement on DIOB, allowing stack operations. See DIOB Stack Operation for more information.

43.14.9.1.1.4 Engine Relative Addressing Mode

In Engine Relative Addressing mode the physical address is the concatenation of the ETPUECR field ERBA (see the ETPUECR register) with the 7-bit AID instruction field. This allows the same function microcode, when running on distinct engines, to access different address spaces, global to the engine only.

The SDM physical word address in Engine Relative Addressing mode is calculated as follows:

```
physical address = (ETPUECR[ERBA]<< 7) + AID[6:0]
```

43.14.9.1.2 SDM Source/Destination Registers

When performing an SDM operation, only DIOB or P can be used as data source or destination. P is 32-bit wide, and DIOB is 24-bit wide. Microinstruction field P/D (1 bit) is used to choose between P and DIOB as data the source or destination. When the P/D field is not available in microinstructions that support SDM access, the source/destination is P.

Table 43-368. SDM source/destination Register Selection

P/D	meaning
0	P access
1	DIOB access

43.14.9.1.3 SDM Operation Size

When using DIOB register to perform SDM data transfers, the operation size is always 24-bit wide (lower 24 bits of SDM). When using P register, the operation size can be 8-, 24- or 32-bit wide, which is controlled by microcode RSIZ field (2 bits). RSIZ meaning is shown in the following table.

Table 43-369. SDM P access Size

RSIZ	P access	DIOB access
00	full 32-bit access (i.e. P[31:0]=SDM[addr] [31:0])	RESERVED
01	only upper 8 bits are transferred (i.e. P[31:24] = SDM[addr] [31:24])	RESERVED
10	only lower 24 bits are transferred (i.e. P[23:0] = SDM[addr] [23:0])	DIOB = SDM[addr] [23:0
11	RESERVED	RESERVED

RSIZ is not available in all microinstructions that support SDM access. In microinstructions where RSIZ field is not available, SDM access will be 24 bits by default.

When performing a Zero SDM write operation (see Zero SDM Operation), RSIZ defines the size of operation regardless of the P/D field (SDM Source/Destination Registers).

43.14.9.1.4 SDM access direction

RW field defines the direction of the access in the SDM. The access direction is summarized in the following table.

Table 43-370. SDM access direction

R/W	Meaning
0	read SDM parameter into P or DIOB registers
1	write SDM parameter from P or DIOB registers

43.14.9.1.5 Zero SDM Operation

Zero SDM operation is controlled by microcode field ZRO (1bit). When ZRO field is 0, the data portion written in SDM or in P/DIOB (SDM read) registers will always be 0x0. When performing a Zero SDM write operation, the RSIZ is relevant regardless of the P/D field (usually RSIZ is meaningful only for P/D = 0), which means that zero SDM write operation can be performed with 32, 24 or 8 bits according to SDM operation size. These conditions are summarized in the following table.

Table 43-371. Zero SDM Operation

ZRO	RW	P/D	Meaning
0	0	0	Clear P register. Size is determined by RSIZ field. See SDM Operation Size
0	0	1	Clear DIOB (all 24 bits), independently of RSIZ
0	1	x	Clear SDM parameter. Size is determined by RSIZ field. See SDM Operation Size
1	RW	P/D	Regular SDM operation

Note

When field STC is present, STC=11 also disables Zero SDM operation (see Table 43-372). The conflicts with DIOB operations (see DIOB Stack Operation) and ALU operations are resolved like a normal SDM operation (see Table 43-413).

Zero SDM read operations do check memory errors on the read data, however discarded. Zero SDM write operations normally update the ECC of the written data.

43.14.9.1.6 DIOB Stack Operation

SDM Indirect Addressing Mode (see Indirect Addressing Mode) is used if STC field (2 bits) exists in the microinstruction, controlling automatic increment/decrement of DIOB register, as shown in the following table, thus allowing stack operations. DIOB is incremented and decremented in word addresses, only from bits 15 downto 2, i.e.: the bits 23 to 16 and 1 to 0 are left untouched by STC pre-decrement and post-increment.

Table 43-372. DIOB Post-Increment / Pre-Decrement - STC

STC	Meaning
00	Post-Increment of DIOB
01	Pre-Decrement of DIOB
10	No Increment/Decrement (normal access)
11	No SDM Access[1]

1. also disables Zero SDM operation.

43.14.9.1.7 Semaphore Operations

Semaphore lock and free operations are available through eTPU microcode. For more information about semaphores see Hardware Semaphores. There are 2 microinstruction fields that control semaphore operations: FL (1 bit) and SMPR (2 bits). Serviced channel sees 4 semaphores, selected by field SMPR.

Table 43-373. Semaphore Operations Fields

Field	Meaning
FL	0 = free semaphore, 1 = lock semaphore
SMPR	semaphore number selector

When freeing a semaphore, the field SMPR has no meaning. This is because only one semaphore can be locked at a time by each engine, so when freeing a semaphore it is not necessary to specify its number.

Note

If microcode tries to lock a semaphore already locked for the same Engine, the semaphore continues locked for the Engine and the SMLCK branch condition resolves as true.

43.14.9.2 ALU/MDU Operations

ALU/MDU microoperations mostly comprises two sources, one destination and one operation. The operation is generally selected through fields ALUOP, ALUOPI or SHF. In formats where there is no operation selection field (ALUOP, ALUOPI or SHF), the operation performed is always addition; however, it is possible to perform subtraction, increment or decrement using fields BINV (see B-Source Inversion) and CIN (see Carry-in Control).

43.14.9.2.1 Source and Destination Register Set Selection

Microcode field T4ABS allows selection of a source from either one of two register sets, shown in Table 43-377. The same applies to T2ABD, used for ALU destination selection with other two register sets, as shown in Table 43-378. Microinstruction fields ABSE and ABDE control the register set selection for source and destination, respectively, when available at the format. In formats without ABSE/ABDE, the field T4BBS determines the register sets used by T2ABD and T4ABS, as shown in Microinstructions Without Fields ABSE and ABDE.

43.14.9.2.1.1 Microinstructions With Fields ABSE and ABDE

In microinstructions where ABSE and ABDE fields are available (1 bit each), ABSE controls register set selection for T4ABS and ABDE controls register set selection for T2ABD. The following table shows the meaning of values for ABSE and ABDE fields.

Table 43-374. Register Set Selection by ABSE or ABDE

ABSE or ABDE	Register Set Selected
0	second
1	first

43.14.9.2.1.2 Microinstructions Without Fields ABSE and ABDE

When ABSE and ABDE are not available in a microinstruction format, register set is selected by T4BBS field. The following table explains how to select a register set either for T4ABS and T2ABD.

Table 43-375. Register Set Selection by T4BBS w/o ABSE,ABDE

T4BBS	Register Set For T2ABD	Register Set For T4ABS
0xx	first	first
100	second	second
101	second	first
110	first	second
111	first	first
none[1]	first	first

1. refers to operations with immediate data as B-source, without ABSE,ABDE.

43.14.9.2.2 Selecting Sources and Destination

All ALU/MDU operations need 2 sources (called AS and BS) and 1 destination (called AD), except for some of those that use immediate data (see Operations With Immediate Data). Fields T4ABS (4 bits), ABSE (1 bit), T4BBS (3 bits) select sources, while T2ABD (4 bits) and ABDE (1 bit) select the destination. When MDU is used (multiply/divide), T2ABD destination selection is ignored and results are stored in MACH and MACL (see MAC and Divide Unit (MDU)). ABSE and ABDE are not available in some microinstruction formats that support ALU/MDU operations. However, in all formats where ABSE is available, ABDE is also available and vice-versa. The existence of

ABSE/ABDE fields changes the meaning of T4BBS field, as shown in the table below. On instructions with immediate data, it is used as B-source (see Operations With Immediate Data).

All sources and destinations have a size associated to it, and these sizes are used to select flag sample position (see Flags Sampling Control). Sizes can be 8, 16 or 24 bits. Registers that are not exactly of one of these sizes are treated as the immediately upper size (e.g., CHAN[4:0] is an 8-bit source). See Flags Sampling Control for more information.

Some parallelism issues arise when selecting P, DIOB, ERTA or ERTB as destination registers, since they can be modified by other microoperations in the same microinstruction (see Microinstruction Parallelism Issues for details).

Table 43-376. B Source Selection - T4BBS

T4BBS	Meaning in microinstruction formats with ABSE/ABDE	Meaning in microinstruction formats without ABSE/ABDE[1]
000	BS[23:0] = P[23:0]	
001	BS[23:0] = A[23:0]	
010	BS[23:0] = SR[23:0]	
011	BS[23:0] = DIOB[23:0]	
100	reserved	BS = 0
101	reserved	BS = 0
110	reserved	BS = 0
111	BS=0, or Max const., if CIN=0 and BINV=0 (see Generating "max" constant).	

1. T4BBS also selects A-source and destination register set in this case, according to Table 43-375.

T4ABS selects one source from 2 register sets, shown in the following table. ABSE and T4BBS control which set T4ABS field uses to select the source. For more information about how to select a register set for T4ABS and T2ABD see Source and Destination Register Set Selection . All sources are zero-filled to 24 bits, unless sign-extension is specified (see A-Source Size Override).

Table 43-377. A Source Selection - T4ABS

T4ABS	First Register Set		Second Register Set	
	Selected Register	Size	Selected Register	Size
0000	AS[7:0]=P[7:0]	8	AS[7:0]=0	8
0001	AS[7:0]=P[15:8]	8	AS[23:0]=C[23:0]	24
0010	AS[7:0]=P[31:24]	8	AS[15:0] = TPR[15:0]	16
0011	AS[23:0] = ERTB[23:0]	24	AS[23:0] = B[23:0]	24
0100	AS[23:0] = D[23:0]	24	AS[23:0] = TRR[23:0]	24

Table continues on the next page...

Table 43-377. A Source Selection - T4ABS (continued)

T4ABS	First Register Set		Second Register Set	
	Selected Register	Size	Selected Register	Size
0101	AS[15:0] = P[15:0]	16	AS[7:0] = 0, read_match[1]	8
0110	AS[15:0] = P[31:16]	16	AS[13:0] = RAR[13:0]	16
0111	AS[7:0] = P[23:16]	8	AS[23:0] = MACH[23:0]	24
1000	AS[23:0] = P[23:0]	24	AS[23:0] = MACL[23:0]	24
1001	AS[23:0] = A[23:0]	24	AS[4:0]=CHAN[4:0]	8
1010	AS[23:0] = SR[23:0]	24	AS[14 :2] = CHAN_BASE[2]	16
1011	AS[23:0] = DIOB[23:0]	24	AS[13:0] = ENGINE_BASE[3]	16
1100	AS[23:0] = TCR1[23:0]	24	Reserved	-
1101	AS[23:0] = TCR2[23:0]	24	Reserved	-
1110	AS[23:0] = ERTA[23:0]	24	Reserved	-
1111	AS[23:0] = 0	24	Reserved	-

1. T4ABS=0101 with second register set also reads MatchA/B registers into ERTA/B (see Special T4ABS Source Operation: Read Match Registers).
2. CHAN_BASE is the selected channel's base SDM address in channel relative address mode (see CHAN_BASE as a Source).
3. ENGINE_BASE is the ETPUECR field ERBA shifted left 9 positions.

T2ABD selects the destination from 1 of 2 register sets, shown in the following table. ABDE and T4BBS control which set T2ABD field uses to select the destination.

Table 43-378. Destination Selection - T2ABD

T2ABD	First Register Set		Second Register Set	
	Selected Register	Size	Selected Register	Size
0000	A[23:0] = AD[23:0]	24	C[23:0] = AD[23:0]	24
0001	SR[23:0] = AD[23:0]	24	LINK[7:0] = AD[7:0]	8
0010	ERTA[23:0] = AD[23:0][1]	24	TPR[15:0] = AD[15:0]	16
0011	ERTB[23:0] = AD[23:0][2]	24	B[23:0] = AD[23:0]	24
0100	DIOB[23:0] = AD[23:0]	24	CHAN[4:0] = AD[4:0]	8
0101	P[15:0] = AD[15:0]	16	D[23:0] = AD[23:0]	24
0110	P[31:16] = AD[15:0]	16	RAR[12:0] = AD[12:0]	16
0111	P[23:0] = AD[23:0]	24	MACH[23:0] = AD[23:0]	24
1000	TCR1[23:0] = AD[23:0]	24	MACL[23:0] = AD[23:0]	24
1001	TCR2[23:0] = AD[23:0]	24	Reserved	-
1010	P[31:24] = AD[7:0]	8	Reserved	-
1011	P[23:16] = AD[7:0]	8	Reserved	-
1100	P[15:8] = AD[7:0]	8	Reserved	-
1101	P[7:0] = AD[7:0]	8	Reserved	-
1110	TRR[23:0] = AD[23:0]	24	Reserved	-
1111	no destination selected[3]	24	Reserved	-

1. T2ABD=0010 with first register set also writes to MatchA or UDCM registers of the selected channel if field ERWA=0 (see Write Channel Match and UDCM Registers).
2. T2ABD=0011 with first register set also writes to MatchB register of the selected channel if field ERWB=0.
3. if no destination is selected, ALU flags are updated, although the result is lost.

43.14.9.2.2.1 Max Const Generation With T4BBS=111

When T4BBS = 111, BINV = 0, and CIN = 0, the value assigned to BS will be 0x800000, and not 0x0 as expected. See Generating "max" constant for detailed explanation about this.

43.14.9.2.2.2 Special T4ABS Source Operation: Read Match Registers

When T4ABS = 0101 and the source for T4ABS is selected from the second register set, the constant 0x00 is used as AS (8-bit size) and the following register transfer is performed in parallel as well: match registers of the selected channel (value in CHAN register) are copied to ERTA/ERTB registers, where ERTA receives the value of MatchA register and ERTB receives the value of MatchB register (see ER - Event Registers). Note that ALU destination can still be chosen by T2ABD in parallel. When ERTA or ERTB is selected by T2ABD, a parallelism issue arises (see ALU Operations and Read Match Registers).

43.14.9.2.2.3 CHAN_BASE as a Source

Each channel has a parameter base address in SDM, which is configured in ETPUCxCR registers, CPBA field (see the ETPUCnCR register). CHAN_BASE, which represents a parameter address (CPBA*2), can be used as A-source using T4ABS=1010 when T4ABS selects a source from the second register set. In this case, CHAN_BASE is loaded into AS[13:2] to form the byte address (AS[23:14]=0, AS[1:0]=0). For example, in Indirect addressing mode, where the destination register is DIOB, CHAN_BASE is loaded into DIOB[13:2], which is the parameter address, and DIOB[13:0] represents the byte address. CHAN_BASE is the base address of the selected channel (given by CHAN register).

43.14.9.2.3 Flags Sampling Control

This section explains how the flags Z (zero), C (carry), N (negative) and V (overflow) are updated in an ALU operation. When there are post-ALU shift operations, the ALU Carry Out is not directly sampled in Carry flag, but passed to the post-ALU shifter (see Shift Operations). Since the size of source operands in ALU operations is variable, flags can be sampled as an operation of 8, 16 or 24 bits wide. The operation size selection is automatic, based on defined sizes of sources and destination, using the equation:

```
operation_size = minor(size_of(destination), greater(size_of(A-Source),
size_of(B-Source)))
```

Operation size can also be shown with the following table:

Table 43-379. Operation Size Determination

A Source	B Source	Destination	Operation Size
x	x	8 bits	8 bits
8 bits	8 bits	x	8 bits
16 or 24 bits	x	16 bits	16 bits
16 bits	8 or 16 bits	24 bits	16 bits
8 or 16 bits	16 bits	24 bits	16 bits
24 bits	x	24 bits	24 bits
x	24 bits	24 bits	24 bits

Note

Whenever BS = (constant) 0, its size is considered 8 bits, and all 24 bits in B-bus are set to 0. Therefore, all operations with BS = (constant) 0 have their size determined by AS and Destination only.

CCS field (1 bit) controls whether flags will be updated or not (Table 43-381). When CCS bit exists in a microinstruction, the operation size will be used to sample flags. In some microinstructions CCS field is replaced by CCSV (2 bits, Table 43-380). Flag sampling according to CCSV can be set as defined by the operation size, or fixed as 8 or 16 bit operations.

Note

For the post-ALU rotate right operation, CCSV also determines the rotate size: whether 8-bit, 16-bit, or determined by the operation size.

Table 43-380. Flag Sampling Using CCSV field

CCSV	Meaning
00	sample flags as an 8 bit operation
01	sample flags as a 16 bit operation
10	sample flags as defined by operation size
11	do not sample flags

Table 43-381. Flag Sampling Using CCS field

CCS	Meaning
0	sample flags as defined by operation size
1	do not sample flags

When neither CCS nor CCSV are present in the microinstruction, flags are not sampled. CCS and CCSV do not affect the Carry update on Exchange Bit operation (see Exchange Bit), but does control the N and Z flags.

43.14.9.2.4 B-Source Inversion

The data selected as second source (T4BBS) can be inverted (bitwise boolean NOT) before operation. This is controlled by microinstruction field BINV (1 bit, in the following table). A zero value for BINV activates B-source inversion.

Table 43-382. B-Source Inversion - BINV

BINV	Meaning
0	invert B-source[1]
1	keep B-source bus unchanged

1. Except on max-constant selection, see Generating "max" constant .

BINV also selects between *adc* or *sbc* enhanced ALU operation, using inverted C flag as carry-in besides BS inversion for *sbc* . Note that BINV does not invert carry in fixed-carry operations (see Table 43-383).

When BINV = 0, T4BBS = 111 and CIN = 0, the value assigned to BS is 0x800000, instead of 0x0. See Generating "max" constant for more details.

43.14.9.2.5 Carry-in Control

CIN field (1 bit, Table 43-383) controls the carry-in for addition/subtraction operations. Functionality of CIN field depends on the arithmetic operation selected by ALUOP. When ALUOP is not available in microinstruction, the operation selected is *add* . For carry-in control in MDU operations, see the following table.

Table 43-383. ALU Carry-In Control

operation	CIN=0	CIN=1
add (addition)	carry-in used is 1[1]	carry-in used is 0
adc (addition with carry)[2]	carry-in used is C flag	
sbc (subtraction with borrow)[3]	carry-in used is inverted C flag	

1. Except on max-constant selection, see Generating "max" constant .

2. Selected by ALUOP=11000 and BINV=1
3. Selected by ALUOP=11000 and BINV=0

43.14.9.2.5.1 Generating "max" constant

When T4BBS = 111, CIN = 0 and BINV = 0, BS is assigned to 0x800000 (called "max constant") instead of 0x000000. This is an exception for CIN and BINV fields: when "max constant" is selected, the carry in is 0 and B-source ("max constant" itself) is not inverted, neither the carry out.

"Max constant" is the value which, added to a time base value minus 1, gives the farthest wrapped time base value that satisfies a channel greater-equal comparison. See Enhanced Channels for more info.

43.14.9.2.6 Shift Operations

There are three types of shift operations: ALU, post-ALU and Shift Register. ALU shift operations are covered in ALU/MDU Operation Selection . Post-ALU and Shift Register are covered in the following sections.

43.14.9.2.6.1 Shift Register Operations

SR can be used as a general purpose register and it can easily shift-right its contents, combined or not to post-ALU shift operations. If field SRC (1 bit) in microcode is 0, SR will shift its contents 1 bit to the right according to the algorithmic description below. SR shifting operation depends also on SHF or ALUOP fields. ALUOP and SHF never exist both on the same microinstruction format.

Table 43-384. Shift Register Control - SRC

SRC	Meaning
0	shift right SR 1 bit
1	no shift

SR Operation:

```
SR[22:0] = SR[23:1];
if SHF == "01" or ALUOP == "10110" then
 SR[23] = ALU_OUT[0];
else
  SR[23] = 0;
endif;
```

43.14.9.2.6.2 Post-ALU Shift Operations

Post-ALU shift can be selected by SHF field (2 bits) or by some specific ALUOP field values. SHF and ALUOP fields are never both available in the same microinstruction format. When selecting post-ALU shift operation using ALUOP field, ALU will always add the sources before shifting the result.

Table 43-385. Post-ALU Shift Operation

Post ALU Operation	SHF[1]	ALUOP
shift left (1 bit)	00	10101
shift right (1 bit)	01	10110
rotate right (1 bit)	10	10111
no shift/rotate	11	any other[2]

1. ALU performs AS+BS before shift/rotate for all SHF values.
2. some ALUOP combinations perform shift/rotate, but not using the Post-ALU Shifter (see Table 43-390)

Carry flag is only updated when CCS or CCSV fields allow it (see Flags Sampling Control). Algorithmic descriptions of post-ALU shift operations are presented in ALU ADD Operation with and without shifting .

43.14.9.2.7 Conditional ALU/MDU Operation Execution

The 3-bit field AS/CE allows conditional execution of arithmetic operation, as shown in the following table . The same field can also be used for overriding the size of A-Source (see A-Source Size Override).

Table 43-386. ALU/MDU Conditional Execution

AS/CE	Meaning
000	used for A-Source size override (see A-Source Size Override)
001	
010	execute if C = 1
011	execute if C = 0
100	execute if Z = 1
101	execute if Z = 0
110	execute if N = 1
111	execute unconditionally/no size override

Other operations not related to ALU/MDU in the same microinstruction are not affected by the AS/CE field.

If a conditional operation is selected, there is no A-Source size override; similarly, when size override for A-Source is selected, the ALU/MDU operation executes unconditionally.

When a conditional ALU/MDU operation is not executed:

- the destination register is not updated. If the destination is CHAN, no actions associated with CHAN assignment occur (see Channel Selection Register - CHAN).
- the ALU and MDU flags are not updated.
- MDU does not start any operation, i.e., MACH and MACL are not updated.
- SR does not shift.
- T4ABS-selected read-match does not occur.

43.14.9.2.8 A-Source Size Override

Some values if the AS/CE field are used for A-Source Size Override, as shown in the following table.

Table 43-387. A-Source Size Override

AS/CE	Meaning
000	A-source size override to 8 bits
001	A-source size override to 16 bits
010	used for conditional execution (see Conditional ALU/MDU Operation Execution)
011	
100	
101	
110	
111	execute unconditionally/no size override

Register size override zero-pads an overridden source to 24-bits (if no sign extension is performed, see A-source Sign Extension) and affects operation size calculation. When register source is wider than size override, most significant bits of selected register are not used as A source (zeros are used instead). When size override is wider than selected register, register value is padded to zeros.

When size override is used with MDU operations, it affects only the operand values, but not the operation size: MDU operation size is fully determined by the operation definition (fields ALUOP, ALUOPI).

Table 43-388. AS/CE field A source size override funcionality

Size Override	Size of Selected Register	AS Value[1]
8 bits	8 bits	reg[7:0]

Table continues on the next page...

Table 43-388. AS/CE field A source size override funcionality (continued)

Size Override	Size of Selected Register	AS Value[1]
8-bits	16 bits	reg[7:0]
8bits	24 bits	reg[7:0]
16 bits	8 bits	reg[15:0]
16 bits	16 bits	reg[15:0]
16 bits	24 bits	reg[15:0]

1. All values are zero-padded to 24 bits

43.14.9.2.9 A-source Sign Extension

The SEXT microinstruction field forces sign extension of A source according to the size of A operand, either overridden or not by AS/CE field, according to the following table. The sign is taken from the size-overridden value, not the original one.

Table 43-389. A source Sign Extension

SEXT	Meaning
0	extends sign of A source from its size to 24-bits
1	does not extend sign of A source

A-source sign is not extended in microinstructions without SEXT field, even if AS/CE field is present.

43.14.9.2.10 ALU/MDU Operation Selection

When field ALUOP is available in microinstruction, enhanced ALU operations shown in the following table can be performed, otherwise addition is performed. The ALU operations are defined in ALU and Post-ALU Shifter. The MDU operations are defined in MAC and Divide Unit (MDU).

Table 43-390. ALU Operation Selection - ALUOP

ALUOP	Operation	Comment
00000	AS mults BS[7:0]	signed multiplication
00001	AS multu BS[7:0]	unsigned multiplication
00010	AS fmults BS[7:0]	signed fractional multiplication
00011	AS fmultu BS[7:0]	unsigned fractional multiplication
00100	AS mults BS[15:0]	signed multiplication
00101	AS multu BS[15:0]	unsigned multiplication
00110	AS fmults BS[15:0]	signed fractional multiplication

Table continues on the next page...

Table 43-390. ALU Operation Selection - ALUOP (continued)

ALUOP	Operation	Comment
00111	AS fmultu BS[15:0]	unsigned fractional multiplication
01000	AS mults BS[23:0]	signed multiplication
01001	AS multu BS[23:0]	unsigned multiplication
01010	AS macs BS[23:0]	signed multiply-accumulate
01011	AS macu BS[23:0]	unsigned multiply-accumulate
01100	AS div BS[7:0]	unsigned division by 8-bit value
01101	AS div BS[15:0]	unsigned division by 16-bit value
01110	AS div BS [23:0]	unsigned division by 24-bit value
01111	n.a.	RESERVED
10000	AS[23:0] | BS[23:0]	24 bit bitwise OR
10001	AS[23:0] ^ BS[23:0]	24 bit bitwise XOR
10010	AS[23:0] & BS[23:0]	24 bit bitwise AND
10011	abs(AS)	absolute value of AS
10100	AS + BS	arithmetic addition
10101	(AS + BS) shl 1	arithmetic addition with 1-bit post-ALU shift left. (Post-ALU Shift Operations)
10110	(AS + BS) shr 1	arithmetic addition with 1-bit post-ALU shift right (Post-ALU Shift Operations)
10111	(AS + BS) ror 1	arithmetic addition with 1-bit post-ALU rotate right (Post-ALU Shift Operations)
11000	AS adc/sbc BS[1]	addition/subtraction with C flag (Carry-in Control)
11001	AS shl (2^(BS[1:0]+1))	AS is shifted left: 2 bits for BS=0; 4 for BS=1; 8 for BS=2; 16 for BS=3
11010	AS shr (2^(BS[1:0]+1))	AS is shifted right: 2 bits for BS=0; 4 for BS=1; 8 for BS=2; 16 for BS=3
11011	AS ror (2^(BS[1:0]+1))	AS is rotated right: 2 bits for BS=0; 4 for BS=1; 8 for BS=2; 16 for BS=3
11100	AS exch BS[4:0]	exchange C flag and AS bit determined by BS (Exchange Bit)
11101	AS setb BS[4:0]	set bit in AS determined by BS [2, 2]
11110	AS clrb BS[4:0]	clear bit in AS determined by BS[3]
11111	n.a.	RESERVED

1. Addition/Subtraction is selected by field BINV (see B-Source Inversion)
2. In setb and clrb operations, the register that drives A source is not changed, unless selected as destination of the operation.
3. In setb and clrb operations, the register that drives A source is not changed, unless selected as destination of the operation.

43.14.9.2.11 Operations With Immediate Data

Immediate data can be used with some specific microinstruction formats. eTPU microcode allows 8-, 16- or 24-bit immediate data. Immediate data is loaded as B-source, so T4BBS field is not available. When using 24-bit immediate, an add is performed with A-source = 0 and flags are not updated. ALU operations are available with 8-bit immediate, although the field that selects ALU operation in this case is ALUOPI.

43.14.9.2.11.1 24-bit Immediate Destination

When using 24-bit immediate data, the destination register is selected by T2D field (2 bits), according to the following table.

Table 43-391. 24-bit Immediate Destination - T2D

T2D	Target Register
00	P[23:0]
01	A
10	SR
11	DIOB

43.14.9.2.11.2 Enhanced ALU Operations With Immediate Data

Enhanced operations with immediate data, selected by ALUOPI (5 bits) are allowed only with an 8 bit immediate operand (see the following table).

Table 43-392. ALU Operation Selection With Immediate Data - ALUOPI

ALUOPI	Operation	Comment
00000	AS mults #imm8	signed multiplication
00001	AS multu #imm8	unsigned multiplication
00010	AS fmults #imm8	signed fractional multiplication
00011	AS fmultu #imm8	unsigned fractional multiplication
00100	AS div #imm8	unsigned division
00101	n.a.	reserved
00110	n.a.	reserved
00111	n.a.	reserved
01000	AD[7:0] = AS[7:0] | #imm8, AD[23:8] = AS[23:8]	bitwise OR
01001	AD[7:0] = AS[7:0] ^ #imm8, AD[23:8] = AS[23:8]	bitwise XOR
01010	AD[7:0] = AS[7:0] & #imm8, AD[23:8] = AS[23:8]	bitwise AND
01011	AD[7:0] = AS[7:0] & #imm8, AD[23:8] = 0×0	bitwise AND with clear
01100	AD[15:8] = AS[15:8] | #imm8, AD[23:16] = AS[23:16], AD[7:0] = AS[7:0]	bitwise OR
01101	AD[15:8] = AS[15:8] ^ #imm8, AD[23:16] = AS[23:16], AD[7:0] = AS[7:0]	bitwise XOR

Table continues on the next page...

Table 43-392. ALU Operation Selection With Immediate Data - ALUOPI (continued)

ALUOPI	Operation	Comment
01110	AD[15:8] = AS[15:8] & #imm8, AD[23:16] = AS[23:16], AD[7:0] = AS[7:0]	bitwise AND
01111	AD[15:8] = AS[15:8] & #imm8, AD[23:16] = 0×0, AD[7:0] = 0×0	bitwise AND with clear
10000	AD[23:16] = AS[23:16] | #imm8, AD[15:0] = AS[15:0]	bitwise OR
10001	AD[23:16] = AS[23:16] ^ #imm8, AD[15:0] = AS[15:0]	bitwise XOR
10010	AD[23:16] = AS[23:16] & #imm8, AD[15:0] = AS[15:0]	bitwise AND
10011	AD[23:16] = AS[23:16] & #imm8, AD[15:0] = 0x0	bitwise AND with clear
10100	AS + #imm8	arithmetic addition
10101	(AS + #imm8) shl 1	arithmetic addition with 1-bit shift left.
10110	(AS + #imm8) shr 1	arithmetic addition with 1-bit shift right
10111	(AS + #imm8) ror 1	arithmetic addition with 1-bit rotate right
11000	n.a.	reserved
11001	AS shl (2^(#imm8[1:0]+1))	AS is shifted left: 2 bits for #imm8=0; 4 for #imm8=1; 8 for #imm8=2; 16 for #imm8=3
11010	AS shr (2^(#imm8[1:0]+1))	AS is shifted right: 2 bits for #imm8=0; 4 for #imm8=1; 8 for #imm8=2; 16 for #imm8=3
11011	AS ror (2^(#imm8[1:0]+1))	AS is rotated right: 2 bits for #imm8=0; 4 for #imm8=1; 8 for #imm8=2; 16 for #imm8=3
11100	AS exch #imm8[4:0]	exchange C flag and AS bit determined by #imm8[4:0] (see Exchange Bit)
11101	n.a.	reserved
11110	n.a.	reserved
11111	n.a.	reserved

43.14.9.3 Channel Control and Configuration Microoperations

Channel Control and Configuration fields set configuration values in the channel logic of the channel selected by the CHAN register, except fields LSR and CIRC.

43.14.9.3.1 Channel Flags Operations

Each channel has two associated hardware flags, called Channel Flag 0 and Channel Flag 1. Microcode field FLC (3 bits) allows them to be set or cleared, as shown in the following table . These flags can be tested by microcode as a branch condition, and may also influence in the Entry Point taken, allowing fast state decoding. For more details, see Entry Points.

Table 43-393. P Flags Operation - FLC

FLC	Meaning
000	clear flag0
001	set flag0
010	clear flag1
011	set flag1
100	copy flag1:flag0 from P[25:24]
101	copy flag1:flag0 from P[27:26]
110	copy flag1:flag0 from P[29:28]
111	no operation

43.14.9.3.2 Comparator and Time Base Selection

TBSA and TBSB fields (4-bit wide each) are used to configure the type of the comparator and the time bases used for match or capture (see the following tables). TBSA can also be used to control the Output Buffer Enable signal (See Pin Control Registers).

Table 43-394. Time Base Selection A - TBSA

TBSA[3] = 0	**TBSA bit**	**2**	**1**	**0**
	bitfield	**Comparator selection**	**Capture selection**	**Match TB selection**
	0	greater or equal	TCR1	TCR1
	1	equal-only	TCR2	TCR2
TBSA[3] = 1	**action**	**2**	**1**	**0**
	set OBE=1	0	0	0
	set OBE=0	0	0	1
	do nothing	1	1	1
	reserved	all other values		

Table 43-395. Time Base Selection B - TBSB

TBSB[3] = 0	**TBSB bit**	**2**	**1**	**0**
	bitfield	**Comparator selection**	**Capture selection**	**Match TB selection**
	0	greater or equal	TCR1	TCR1
	1	equal-only	TCR2	TCR2
TBSB[3] = 1	action	**2**	**1**	**0**
	do nothing	1	1	1
	reserved	all other values		

43.14.9.3.3 Transition Detection and Pin Action Control

IPACA/B and OPACA/B fields are used to configure transition detection sensitivity (for the channel input signal) or output pin action control (for the channel output signal), as defined in the table below. IPACA and IPACB have the same format, where IPACA is related to Match A and first transition detection, and IPACB to Match B and second transition detection. The same applies in analogue way to OPACA and OPACB.

For the output signal, configuring OPAC registers does not change the current signal state, but defines the action to be done when a match or transition detection occurs. See Match Recognition and Channel Modes on Output Signal Generation for more information.

IPACA/B=1xx also enables assertion of MRLA/B during Time Slot Transition. See Match Recognition.

Table 43-396. Input and Output Pin Action Control - IPACA/B and OPACA/B

value	IPAC meaning	OPAC meaning
000	Do not detect transitions	Do not change output signal
001	Detect rising edge only	Match[1] sets output signal high
010	Detect falling edge only	Match[1] sets output signal low
011	Detect both edges	Match[1] toggles output signal
100	Detect input signal = 0 on Match[1, 1]	Transition detection sets output signal low
101	Detect input signal = 1 on Match[1]	Transition detection sets output signal high
110	reserved	Transition detection toggles output signal
111	do not change IPAC	do not change OPAC

1. Match A is used for IPACA/OPACA, and Match B for IPACB/OPACB.

43.14.9.3.4 Immediate Pin State Control

It is possible to change output signal state immediately by using PSC (2 bits) and PSCS (1 bit) fields.

Table 43-397. Immediate Pin State Control - PSC and PSCS

PSC	PSCS	Meaning
00	0	set signal as specified by OPACA (see Transition Detection and Pin Action Control)
00	1	set signal as specified by OPACB (see Transition Detection and Pin Action Control)
01	x	set signal high
10	x	set signal low
11	x	don't change signal state

43.14.9.3.5 Write Channel Match and UDCM Registers

Match registers can have their values changed using ERWA and ERWB fields (1 bit each). They also set their respective MRLE register (see Match Recognition).

ERWA can also be used to program the UDCM register (see UDCM - User Defined Channel Mode). The field CMW selects where the contents of ERTA is copied when ERWA is active (see the following table).

Table 43-398. Write MatchA/B - ERWA/B

Field	CMW	Value	Action
ERWA	1	0	write ERTA value in MatchA. Enable matches for MatchA register (MRLEA=1)
	0	0	write ERTA value into UDCM
	1	1	don't change UDCM, MatchA and MRLEA
	0	1	reserved
ERWB	1	0	write ERTB value in MatchB. Enable matches for MatchB register (set MRLEB=1)
	1	1	don't change MatchB and MRLEB
	0		
	0	0	reserved

If ERTA or ERTB is a destination of an ALU operation and, at the same time, the respective ERWA/B field is active, the new ERTA value is the one written into the MatchA/B register or the UDCM register.

43.14.9.3.6 Clear Transition/Match Event Registers

Flags MRLA, MRLB, TDLA and TDLB (see ER - Event Registers) indicate the state of matches and transitions detected in the selected channel, and it is possible to clear those flags using the microcode fields MRLA, MRLB (1 bit each) and TDL (1 or 2 bits, depending on the format). The flags cleared by these microcode fields are the actual channel flags, and also the ones sampled into the branch logic.

TDL can be one or two bits wide, depending on the microinstruction format (see Microinstruction formats). Two-bit TDL allows independent clearing of TDLA and/or TDLB . Table 43-400 defines the two-bit TDL field.

Table 43-399. Clear Transition/Match Event Registers - MRLA/B, TDL

Field	Meaning
MRLA	0 = clear MRLA event register, 1 = don't change
MRLB	0 = clear MRLB event register, 1 = don't change
TDL (1 bit)	0 = clear TDLA and TDLB flags, 1 = don't change

Table 43-400. Independent TDLA/B clear - two-bit TDL

value	Meaning
0 0	clear TDLA
0 1	clear TDLB
1 0	clear both TDLA and TDLB
1 1	do not clear TDLA or TDLB

43.14.9.3.7 Disable Matches

Microcode field MRLE (1 bit) allows disabling matches on channel selected by CHAN register, for both MatchA and MatchB registers, by clearing their respective MRLE bits. Matches can be enabled for each Match register using ERWA and ERWB fields (see Write Channel Match and UDCM Registers).

Table 43-401. Disable Matches - MRLE

MRLE	Meaning
0	Disable matches for Match A and Match B
1	don't change match enabling

Some instruction formats have a two-bit MRLE field (see Microinstruction formats) which allows independent disabling of Matches 1 and 2, as shown in the following table.

Table 43-402. Two-bit MRLE

MRLE	Meaning
0 0	Disable Match A (clear MRLEA)
0 1	Disable both Matches (clear MRLEA and MRLEB)
1 0	Disable Match B (clear MRLEB)
1 1	nop

43.14.9.3.8 Disable Match and Transition Service Requests

Microcode field MTD (2 bits) disables match and transition service requests for the selected channel. MTD does not disable Link Service Request and Host Service Request. MTD sets or resets register SRI (for more details see SRI - Match/Transition Service Request Inhibit Latch) and TCCEA (see TCCEA - Transition Continuous Capture Enable) .

Table 43-403. Disable Match and Transition Service Request - MTD

MTD	Action on SRI	Action on TCCEA
00	SRI = 0: enable service requests for match and transition	TCCEA = 0: disable transition captures[1] when TDLA = 1
01	SRI = 1: disable service requests for match and transition	
10	SRI = 1: disable service requests for match and transition	TCCEA = 1: enable transition captures[2] when TDLA = 1
11	don't change	

1. Disables only captures on transition events specified by IPACA.
2. Enables only captures into CaptureA register, on transition events specified by IPACA.

43.14.9.3.9 Predefined Channel Modes

Microcode PDCM field (4 bits) defines the channel mode (see Channel Modes).

PDCM coding is shown in the table below. Note that PDCM bit 0 selects between Single Transition (PDCM[0]=0) and Double Transition (PDCM[0]=1) predefined modes.

PDCM is also used to select the user-defined channel mode, defined by the channel register UDCM (see UDCM - User Defined Channel Mode).

Table 43-404. Predefined Channel Modes

PDCM	Channel mode
0000	em_b_st
0001	em_b_dt
0010	em_nb_st
0011	em_nb_dt

Table continues on the next page...

Table 43-404. Predefined Channel Modes (continued)

PDCM	Channel mode
0100	m2_st
0101	m2_dt
0110	bm_st
0111	bm_dt
1000	m2_o_st
1001	m2_o_dt
1010	**user-defined channel mode**
1011	reserved
1100	sm_st
1101	sm_dt
1110	sm_st_e
1111	keep current channel mode

43.14.9.3.10 Channel Interrupt and Data Transfer Requests

Microcode can issue Interrupt Requests, Data Transfer Requests and Global Exception through CIRC field. For more information see Interrupts and Data Transfer Requests.

Table 43-405. Channel and Data Transfer Requests - CIRC

CIRC	Meaning
000	Channel Interrupt Request from selected channel
001	Data Transfer Request from selected channel
010	Channel Interrupt and Data Transfer requests from selected channel
011	Channel Interrupt and Data Transfer requests from serviced channel
100	Channel Interrupt Request from service channel
101	Data Transfer Request from service channel
110	Global Exception
111	don't request interrupt

43.14.9.3.11 Clear Link Service Request

Microcode LSR field (1 bit) is used to clear the Link Service Request flag of the serviced channel (may not be the one selected by CHAN). The LSR branch condition is always cleared, but not the Link Service Request, if another channel link was received by the serviced channel during the executing thread. See Channel Link for more information.

Table 43-406. Link Service Request Negation Control - LSR

LSR	Meaning
0	clear Link Service Request (flag LSR)
1	don't change

43.14.9.4 Flow Control Microoperations

eTPU has *jump* and *call* microoperations to change microcode flow. Besides, eTPU has *dispatch jump* and *dispatch call* that can be used to implement a jump table. In *call* (or *dispatch call*) microoperation, the return address is saved in RAR register. If nested sub-routine calls are necessary, return address values have to be saved in a stack, usually implemented with DIOB register.

Flow Control microoperations are also provided to repeat a given microinstruction, to finish the current thread execution, and to halt the microengine.

43.14.9.4.1 Ending Current Thread - END

Microcode END field (1 bit) finishes current thread and allows other channels to be serviced. If END field is 0, the current instruction is completed and the thread is finished. END = 1 has no effect, and the next microinstruction is executed Any MDU operation (see MAC and Divide Unit (MDU)) that could be still pending when the thread is finished is left incomplete. END also releases any semaphore locked by the Engine.

43.14.9.4.2 Branch Operations

Branch operations can be **jump** or **call** . The target address of *jump* or *call* microoperations is always immediate and absolute. Branch microoperation is affected by FLS field (refer to Flush Pipeline).

43.14.9.4.2.1 Selecting Jump or Call Microoperations

The only difference between *jump* and *call* microoperations is that when a *call* is executed the value of PC or PC+1 (depending on flush, see Flush Pipeline) is saved in RAR register. The microcode field J/C (1 bit) selects whether *jump* or a *call* is executed, according to the following table.

Table 43-407. Jump / Call Selection - J/C

J/C	Meaning
0	jump
1	call

43.14.9.4.2.2 Branch Target Address

Microcode BAF field (14 bits) indicates the absolute address of a *jump/call target*.

43.14.9.4.2.3 Conditional/Unconditional Branch

Jump and *call* can be conditional or unconditional, depending on the BCC (6 bits) and BCF (1 bit) fields, as shown in Table 43-408 and Table 43-409 . BCF determines whether branch is taken when condition specified by BCC is true or false. When a branch condition uses the channel flags, the channel context is related to the channel number written in CHAN register.

Table 43-408. Branch Condition Inversion - BCF

BCF	Meaning
0	branch if condition determined by BCC is false
1	branch if condition determined by BCC is true

Table 43-409. Branch Condition Selection - BCC

BCC	Meaning	BCC	Meaning
001110	Flag 0	001111	Flag 1
100000	V ALU flag	110000	PSS channel flag
100001	N ALU flag	110001	PRSS channel flag
100010	C ALU flag	110010	"Less Than" ALU flag combination (signed) [1]
100011	Z ALU flag	110011	"Lower or Equal" ALU flag combination (unsigned)[2]
100100	MV MDU flag	110100	P[24]
100101	MN MDU flag	110101	P[25]
100110	MC MDU flag	110110	P[26]
100111	MZ MDU flag	110111	P[27]
101000	TDLA channel flag	111000	P[28]
101001	TDLB channel flag	111001	P[29]
101010	MRLA channel flag	111010	P[30]
101011	MRLB channel flag	111011	P[31]
101100	LSR channel flag	111100	PSTO channel flag
101101	MB flag MDU flag	111101	PSTI channel flag

Table continues on the next page...

Table 43-409. Branch Condition Selection - BCC (continued)

BCC	Meaning	BCC	Meaning
101110	FM[1] channel flag	111110	SMLCK semaphore flag
101111	FM[0] channel flag	111111	false
all other values reserved			

1. "less than" is a signed comparison, equal to the xor between ALU flags V and N; e.g., 0 < 0xFFFFFF tests as false (0 < -1).
2. "lower equal" is an unsigned comparison, equal to Z or C; e.g., 0 < 0xFFFFFF tests as true.

43.14.9.4.3 Dispatch Microoperation

Dispatch microoperation is an unconditional branch where the target address is always PC+P[31:24] (unsigned). Dispatch is affected by FLS field (refer to Flush Pipeline). Dispatch microoperation is defined by R/D field (2 bits, see the following table). Field R/D can also be used to define return from sub-routine (see Return From Subroutine).

Table 43-410. Return and Dispatch - R/D

R/D	Meaning
00	return from subroutine (see Return From Subroutine)
01	dispatch jump
10	dispatch call
11	don't change microinstruction flow

43.14.9.4.4 Return From Subroutine

When a subroutine *call* or a *dispatch call* microoperation is executed, the return address is saved in RAR register. To return from a subroutine a microoperation is available to load the contents of RAR register back to the PC. Fields R/D (2 bits) or RTN (1 bit, see the table below) can be used to return from subroutine. For R/D field, see Table 43-410 .

Return from subroutine microoperation is affected by FLS (see Flush Pipeline) when field R/D is used. Return execution through RTN always flushes the pipeline.

Table 43-411. Return from Sub-routine - RTN

RTN	Meaning
0	return with pipeline flush
1	do not return

43.14.9.4.5 Flush Pipeline

When a branch, dispatch or subroutine return microoperation is executed, the next microinstruction can be executed unconditionally before the flow change takes effect, since microengine has a three-stage pipeline. Executing the next microinstruction after a branch maximizes execution performance. This feature is controlled by field FLS (1 bit, see the table below). When FLS=0 the pipeline is flushed, so the next microinstruction placed after a branch is decoded as NOP if the branch is taken. If FLS=1, the microinstruction placed after the branch is executed, either if the branch is taken or not, as shown in the figure below.

Flush also controls which value is stored in RAR in a call: in case of no flush, it is the address of the branch/dispatch instruction + 2, even if RAR is the ALU destination of the instruction after the call; in case of a flush, it is the address of the instruction following branch/dispatch.

If a branch with no flush is followed by another branch with no flush, the instructions are executed in the following order:

1. first branch
2. second branch
3. first branch's destination instruction
4. second branch's destination instruction, and the flow proceeds normally from then on

The destination of the first branch must not be another flow changing instruction (branch, return or dispatch). Similar flows apply when returns or dispatches are used instead of branches. This scheme can be used to implement quick table look-ups with a dispatch replacing the first branch, for instance.

Table 43-412. Flush Pipeline - FLS

FLS	Meaning
0	flush pipeline when jump / call / dispatch jump / dispatch call / return is executed
1	do not flush pipeline when jump / call / dispatch jump / dispatch call / return is executed

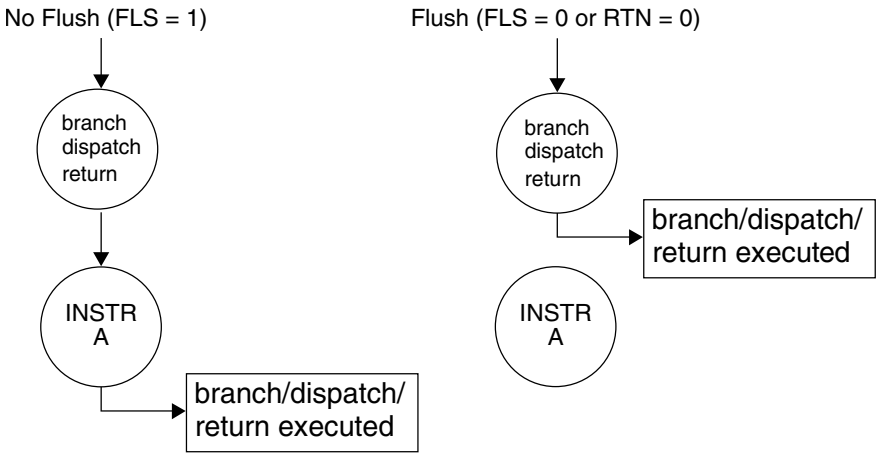

Figure 43-330. Flush Pipeline

43.14.9.4.6 HALT microinstruction

HALT is a microinstruction provided to implement software breakpoints (see Software Breakpoints). Note that HALT is coded as a microinstruction format, not a field (see Microinstruction formats). The execution of this instruction puts the microengine in halt state. For more information about the implications of microengine halt state, see Microengine Halt State . HALT is valid only if software breakpoints are enabled at the Debug interface . If software breakpoints are not enabled, HALT executes as a NOP and is treated as an Illegal Instruction (see Illegal Instructions).

43.14.9.4.7 NOP microinstruction

There is not a unique microinstruction with an assigned opcode to do No Operation. NOP microinstruction is achieved through any of the formats shown on Microinstruction formats where the user can assign to each individual field the corresponding value for "No Operation". However, to prevent future impacts of instruction changes on object code compatibility, the instruction value 0x4FFFFFFF should always be used for NOP.

43.14.9.5 Illegal Instructions

An instruction is considered illegal if any reserved field value is used, including when the fields marked rsv in the instruction formats (see Microinstruction formats are assigned value 0. A HALT instruction is exceptionally considered illegal when executed with software breakpoints disabled (see HALT microinstruction). Global Exception may be issued up to two microcycles after instruction fetch. The execution results of an illegal instruction on the microengine, channel logic or host interface are unspecified, except for the HALT case.

If the microengine decodes an illegal instruction, the following actions are taken:

- a Global Exception is issued.
- flag ILF1/2 on register ETPUMCR is set to indicate this occurrence to the Host.
- a breakpoint occurs, if NDEDI is present and configured to do so (for more details, see the NDEDI details).

43.14.9.6 Microinstruction Parallelism Issues

This section clarifies parallelism issues that arise when two non-commutative microoperations appear in the same microinstruction.

43.14.9.6.1 ALU Operations and Read Match Registers

ALU operations have only one destination register, but there is one case where source selection determines destination: read Match register in ERTA and ERTB registers. In this case if ALU destination is ERTA or ERTB a conflict arises. The ALU destination value overwrites the value read from the match registers.

43.14.9.6.2 ALU and SDM Operations

P and DIOB registers can be selected as destination by both ALU and SDM (read) microoperations in the same microinstruction. Since P and DIOB update from SDM data happens after P and DIOB update for ALU/MDU microoperations, the data read from SDM remains in P or DIOB after an operation when one of them is specified as destination for both ALU and SDM microoperations. In this case, the value loaded into P or DIOB is the one read from SDM. However, the ALU operation is executed and its flags are updated accordingly.

When P or DIOB is destination of an SDM read and also an ALU source at the same microinstruction, the value before the read is used for the ALU operation.

If DIOB is the ALU destination and P is loaded from SDM or vice-versa, no conflict occurs, and the result is the same as if operations occurred separately.

All the above also applies to Zero SDM operations.

When using P or DIOB as destination for ALU operations and also as source for a SDM write operation, the data written in SDM is the one calculated by ALU, which means it is possible to calculate a value and write it in an SDM address using only one microinstruction.

The old value of DIOB or the old value minus 4 (pre-decrement) is always used when DIOB is selected as address (indirect address mode), no matter if DIOB is selected as destination of either the SDM or ALU. For the value loaded into DIOB, refer to the following table.

Table 43-413. DIOB load from SDM and ALU

DIOB selected as SDM read destination?	DIOB selected as ALU destination?	DIOB load value
no	no	DIOB, --DIOB (pre-decrement), or DIOB++ (post-increment)
yes	no	SDM read data (post-inc and pre-dec ignored)
yes	yes	SDM read data (post-inc, pre-dec and ALU result ignored)
no	yes	ALU result (post-inc an pre-dec ignored)

When CHAN is the destination of an ALU operation in parallel with a channel-relative SDM access, the CHAN value used to calculate the address is the one before the ALU operation.

43.14.9.6.3 ERTA/B as ALU destination and ERWA/B

The value in ERTA and ERTB registers can be written in match registers of the selected channel by using fields ERWA and ERWB (Write Channel Match and UDCM Registers). If, at the same microinstruction, ERTA or ERTB is destination of an ALU/MDU microoperation, the value written in Match registers is the ALU/MDU result.

The same applies to UDCM when ERTA is the destination of an ALU operation and instruction fields ERWA and CMW are active .

If an ALU operation occurs in parallel with ERWA/B but ERTA/B are not the destination of an ALU/MDU operation, then UDCM and MatchA/B receives the ERTA/B value.

43.14.9.6.4 ERWA/B and MRLE

ERWA/B automatically sets the MRLEA/B channel latch, respectively (see Write Channel Match and UDCM Registers). Microinstruction fields ERWA/B independently sets MRLEA/B channel flags, regardless of MRLE.

43.14.9.6.5 CHAN assignment, Read Match and ERWA/B

When CHAN is a destination of an ALU operation it causes a read of the CaptureA/B register values into ERTA/B. The Capture registers loaded into ERTA/B are selected by the new CHAN value. The value of the CaptureA/B registers overwrites any read-match commanded simultaneously.

If CHAN assignment happens with an ERWA/B operation in the same instruction, the updated Match register(s) belong to the new selected channel.

43.14.9.6.6 Read Match and ERWA/B

If a read match operation is executed with ERWA/B in the same microinstruction, the MatchA/B registers receive the old values of ERTA/B, and the ERTA/B registers receive the old MatchA/B values simultaneously, i.e.: ERTA/B and MatchA/B swap their values.

If ERTA/B is the destination of an ALU operation at the same instruction, MatchA/B gets the ALU result (see ERTA/B as ALU destination and ERWA/B), but the ERTA/B not being written still receives the old MatchA/B values.

Note

Read match, ERWA/B and CHAN assignment can be active at the same instruction. Combining rules CHAN assignment, Read Match and ERWA/B and Read Match and ERWA/B, the result is: ERTA/B receives the CaptureA/B values of the new CHAN value, and MatchA/B of the new channel receives the old ERTA/B value(s).

43.14.9.6.7 Stack accesses and ALU operations

Post-increment is ignored in a stack operation (field STC) if DIOB is loaded from SDM: DIOB keeps the value read from SDM. Pre-decrement is ignored in a stack operation (field STC) if DIOB is destination of an ALU operation, for DIOB load value, but not for DIOB as address. Post-increment/pre-decrement remains valid in all other situations. These rules can be summarized in the following equivalent C code, and in Table 43-413 .

```
DIOB = *DIOB[15:2];       // read without posinc/predec
*DIOB[15:2] = DIOB;       // write without posinc/predec
DIOB = *(--DIOB[15:2]);   // read with predec
DIOB = *DIOB[15:2];       // read with posinc (ignored)
*(--DIOB[15:2]) = DIOB;   // write with predec
*DIOB[15:2]++ = DIOB;     // write with posinc (value written is before
increment)
```

43.14.9.6.8 SRC and ALU/MDU operations

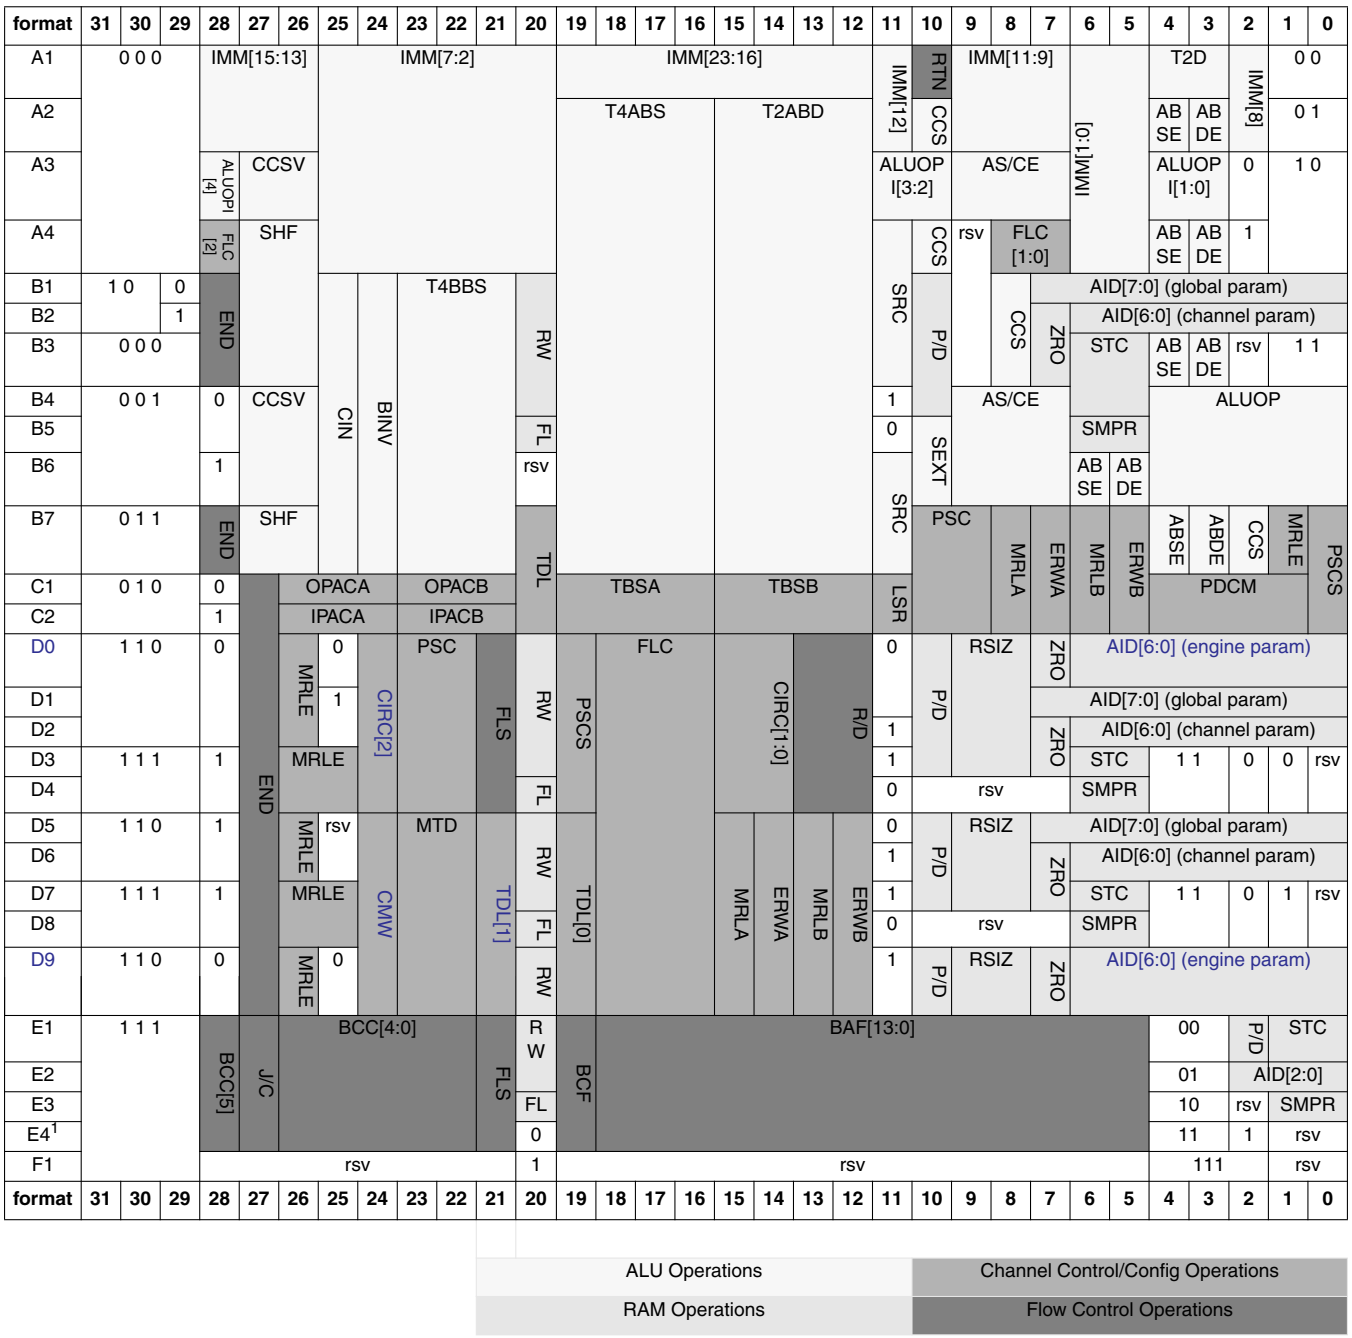
If operation SRC is active (field SRC = 0) and register SR is selected as destination of an ALU operation, the value of the ALU operation prevails over the shifted value.

The value of SR used as source in the ALU/MDU operation is the one before the shift.

43.14.9.6.9 Semaphore lock/free and SMLCK branch condition

When the SMLCK branch condition is tested at the same microinstruction of a semaphore lock or free, the condition is evaluated after the semaphore action (either free or lock) is taken.

43.14.9.6.10 Dispatch and SDM Read



When the most significant byte of P is read from SDM (read 8 msb bits or 32 bits) and a dispatch instruction is executed simultaneously, the dispatch target address is calculated upon the P value before the read.

43.14.9.6.11 CHAN Assignment, PSC/PSCS, and clear MRLEA/B, MRLA/B, TDLA/B

When clear MRLEs, MRLA/B or TDLs is done and a CHAN assignment is done at the same time, the flag selected by the old CHAN value is cleared in the channel, but the branch conditions receive the state of the flags selected by the new CHAN.

When a pin action is commanded through PCS/PSCS and a CHAN assignment is done simultaneously, the output signal affected is selected with the old CHAN value.

43.14.9.7 Microinstruction formats

NOTES:
1 format E4 is deprecated; the same result can be obtained with format E1 with field STC=11

Figure 43-331. Microinstruction formats

All bits marked "rsvd" are reserved, and must be coded as 1.

43.14.10 Shared Subsystems Support

Shared Subsystems support allows eTPU to control other modules, either independently or sharing control with the host. A notable example of shared subsystem is the Reaction Module (see the **Reaction Module chapter** for details), which is connected to the eTPU as shown in the figure below. The host CPU accesses the Reaction Module through the eTPU, which can also access the same registers.

When bit SSMAE=1 in the CCR_ENG1 or CCR_ENG2 register, the eTPU channel's threads can control shared subsystems by accessing their registers, which are mapped onto the higher 16 Kbytes of the microcode data address space (byte addresses/DIOB values 0x4000 to 0x7FFF, equivalent to parameters 0x1000 to 0x1FFF), as shown in Figure 43-333. The shared subsystem registers are accessible by microcode only with the indirect address mode (see SDM Addressing Modes).

When ETPUCxCR bit SSMAE=0, the channel's threads can access only the SDM, mirrored throughout the whole DIOB address range .

The same Shared Subsystem register address space is accessible by the host through the Shared Subsystem Area within the eTPU memory map (see Figure 43-333 and Memory Map), allowing shared control and/or supervision between the host and the eTPU. The arbitration mechanism between host and eTPU accesses is the same used for SDM accesses (see SDM Arbitration). The CDC (see Coherent Dual-parameter Controller - CDC) cannot be used for coherent transfers between SDM and the Shared Subsystem Area, or within the Shared Subsystem Area itself.

Note

The detailed register map within the Shared Subsystem Area depends on the subsystem module.

A Shared Subsystem may be divided into submodules or channels, hereafter called **Shared Subsystem Units** (or **Shared Units** for short), which can be individually controlled by an eTPU function (see Functions and Threads)

A Shared Unit is logically linked with an eTPU channel through the ETPUSSSnIR configuration[34]. There is one ETPUSSSnIR register for each Shared Unit to configure its interface with the eTPU (see eTPU Shared Subsystem n Integration Register, SSSnIR). The Shared Unit uses the Link Service Request (LSR) mechanism to request service to the eTPU. The Link Service Request is targeted to the channel/engine configured in the ETPUSSSnIR fields LENG and LCHAN. The function assigned to this channel must be written to service the Shared Unit. The Shared Unit link service request may have the same source as an interrupt to the host.

34. However, in the case of Reaction Module, the ETPUSSSnIR configuration does not determine which eTPU channel output enables the Reaction Channel modulation; this is defined in the Reaction Module configuration.

Note

Shared Unit link service requests are level-sensitive to the eTPU. If it comes from an interrupt source, the link service request stays asserted as long as the interrupt is asserted and enabled, so the interrupt request must be cleared before the clear of the LSR flag in the link service request thread.

The ETPUSSSnIR field LENG can also be used by the host to disable Link Service Requests to the eTPU. The eTPU microcode can only disable LSRs from the Shared Unit through configuration specific to the Shared Unit itself.

Note that more than one Shared Unit can generate LSRs to the same eTPU channel, in which case the LSR source can be determined by microcode through the Shared Unit status register(s). An eTPU channel configured as a Shared Unit LSR target can also receive Link Service Requests from other eTPU channels or Shared Units. The same LSR service and flag behavior found in links between eTPU channels applies to Shared Unit links (see Channel Link).

The table below summarizes the mapping of Reaction Module resources into Shared Subsystem Support.

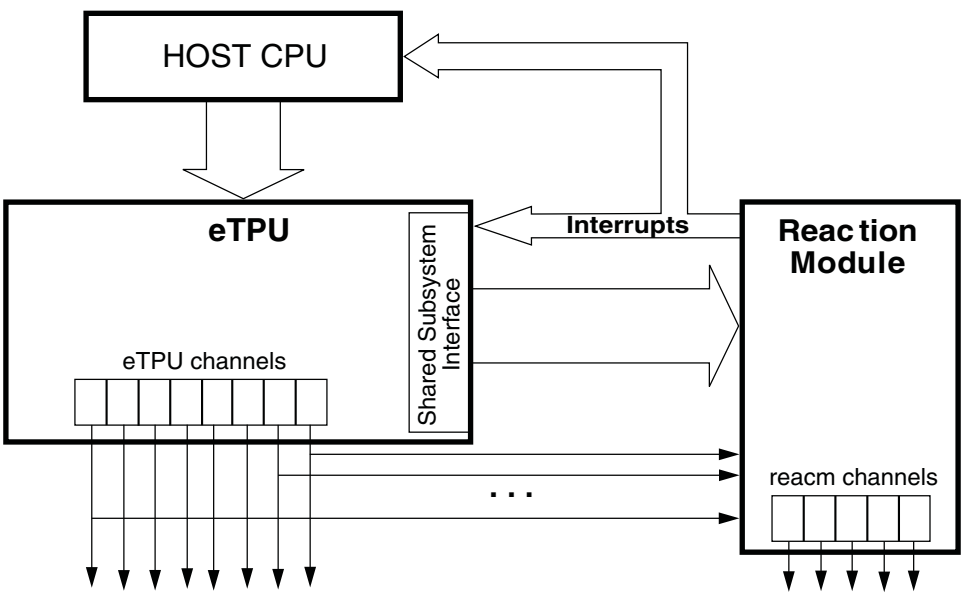


Figure 43-332. Shared Subsystem Block Diagram example: Reaction Module

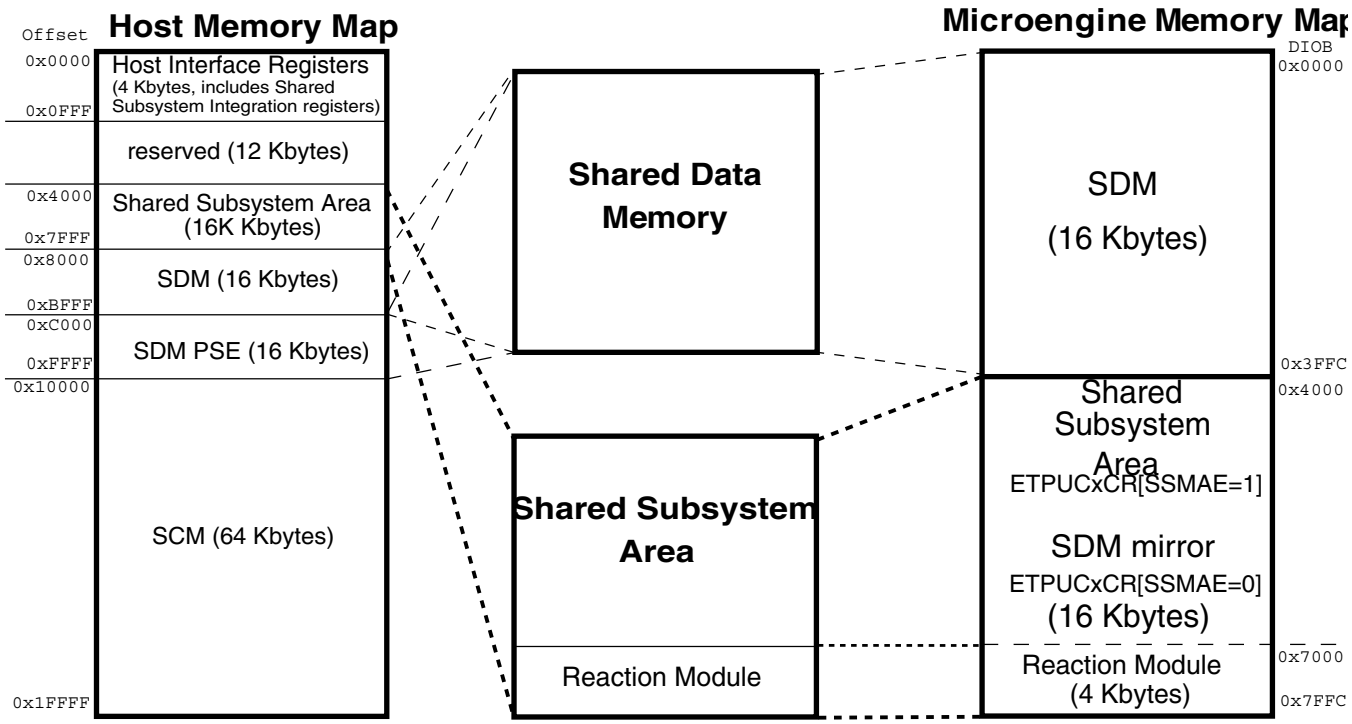

Figure 43-333. Shared Subsystem Memory Mapping

Table 43-414. Reaction Module Shared Subsystem Support

Reaction Module Resource	Host Mapping	eTPU/Microengine Mapping
Register access	eTPU Base + 0×7000	DIOB address 0×7000 (indirect address mode)
Interrupts	See Interrupts chapter	Link Service Requests mapped through Subsystem Integration registers ETPUSSSnIR
DMA Requests	See eDMA chapter	Not applicable

43.14.11 Development Support Features

Following sections describe several features available to support development. Most debug features are accessible through a separate debug bus, and are not available through registers in the standard eTPU memory map. The details of the access to this interface are MCU-dependent (see Debug Interface chapter). The microengines can also be put in halt state by a device-level debug request..

NOTE

The behavior of the debug support logic is not specified in the event of a non-correctable memory error on either SCM or SDM (see Memory Error Support).

43.14.11.1 Nexus Class 3 Support

NDEDI is an IP block designed to support Nexus functionality for the eTPU. It provides a Nexus class 3 or class 1 debug interface, depending on the MCU (see Configuration section). Nexus is a development support external interface defined by the **IEEE standard ISTO 5001-1999**. More details about it can be found in the NDEDI details.

Some of the next subsections describe debug features provided by the eTPU microengine debug support combined with the NDEDI block.

43.14.11.2 Microengine Halt State

Halt is a microengine state where it suspends execution during a thread, or does not start executing a scheduled thread from idle state. While Idle State is entered from END execution without any other scheduled thread, microengine enters Halt State by any of the following events:

- execution of the HALT microinstruction (software breakpoint).
- external halt request through the Debug Interface (includes Nexus breakpoint request via EVTI input pin - see Nexus Class 3 Support).
- the other Engine enters halt state and they are configured to halt simultaneously (bit HTWIN is asserted via Nexus Interface).
- System level device debug request assertion and NDEDI register NDEDIETPUx_DC field CBI=1. If same register's field CBT=1, microengine halts at the next time-slot boundary, if CBT=0 it halts immediately. As a particular case, microengines come halted out of reset if device debug request is asserted, since CBI reset value is 1. Microengine does not execute out of reset, either in halt (device debug request asserted) or idle state (device debug request negated), but halt enables several other features (see below).

- occurrence of any of the hardware breakpoint conditions. See Hardware Breakpoints for details.
- execution of a single-step microinstruction: microengine returns to halt state after executing a single microinstruction while in halt state. See Single-step Execution and Forced Microinstruction Execution for details.

When microengine enters halt state, it automatically triggers the following actions:

- suspends input signal sampling and filters (respective Engine channels only), if NDEDI_ENGINEx_DC[PINS] = 1 at the Debug Interface.
- releases the SDM arbitration for Host or CDC accesses, no matter if microengine was halted in the middle of a dual parameter (back-to-back) access.
- stops TCR1/2 clocks of the respective Engine, if signal ndedi_stop_tcr is asserted at the Debug Interface.
- if the other Engine is also in halt state or stopped, allows turning the eTPU Module Configuration Register (eTPU_SCR_MCR) VIS bit to 1.

If all halt conditions are cleared when VIS=1, microengine(s) keep on halt state until VIS=0, when it automatically exits halt state, except on single-step (see Single-step Execution), so that single-step execution is ignored while VIS=1.

MDU continues executing until it finishes any ongoing operation even if microengine is in halt state, except when the halted instruction is an END.

There are two kinds of halt state, depending on the previous microengine state when halted:

1. **halt_idle**, if the engine was not executing a thread when halted; the engine cannot leave halt_idle to fetch instructions, so one cannot single-step or follow a program flow; it can, however, execute forced instructions (see Forced Microinstruction Execution).
2. **halt_exec**, if the engine was executing a thread when halted. The engine can single-step and continue a program flow from halt_exec.

When microengine exits halt state, any dependable action is suspended and, if exiting halt_exec, the instruction pointed by the PC is fetched, while the instruction already fetched before halt is executed. Note that both the PC and the prefetched instructions can be modified during halt state, with a forced execution of a branch instruction (see Forced Microinstruction Execution).

43.14.11.3 Hardware Breakpoints

Microengine can enter halt state through a command from the Debug Interface, configuring a hardware breakpoint. Hardware breakpoints can halt the microengine on specific conditions, listed below. These conditions depend on NDEDI configuration (for more details see the NDEDI details).

- CHAN register assignment (only by microcode, not by time slot transition).
- SDM read and/or write to a given address and/or write data. The breakpoint is always qualified by the SDM address, but the following variations are allowed:
  - break on write only, read only, or read-and-write.
  - break on higher-byte write data value, lower 24-bit write value, full word (32-bit) write value, or regardless of data. Break on read data is not supported.
- PC (program counter) value.
- Beginning of a thread with a Host Service Request pending.
- Beginning of a thread with a Link Service Request pending.
- Beginning of a thread with a Match Service Request pending.
- Beginning of a thread with a Transition Service Request pending.
- End of a thread.
- Illegal instruction execution.

All these conditions can also be qualified by the value of the CHAN register.

NOTE

Data breakpoints are not supported on Shared Subsystem Area accesses (see Shared Subsystems Support).

Hardware breakpoints halt the microengine before the halted instruction is executed, except on data breakpoints. Data breakpoints allow the instruction that performs the data access to be executed before the microengine is halted.

Note

Data breakpoints in eTPU versions before eTPU2 halt the breakpoint instruction before its execution in all cases, including data breakpoints.

On any of these conditions, halt of one microengine does not depend on the halt of the other, unless the other engine is configured to do so, via Nexus Interface. Occurrence of any of these conditions halts the microengine, i.e., the conditions are logically "ored" together, and they can be individually enabled.

While in halt state, the microengine can also execute any forced microinstruction not in the normal program flow (see Forced Microinstruction Execution) or, if in halt_exec, in single-step (see Single-step Execution).

There are situations when requests for stopping an engine, breakpoint and service can occur simultaneously. Breakpoint requests always prevails over a stop request (eTPU Engine 1 Configuration Register (eTPU_SCR_ECR_ENG1) or eTPU Engine 2 Configuration Register (eTPU_SCR_ECR_ENG2) bit MDIS=1 or device debug request=1). When the eTPU is idle: stop request prevails over Service Request if there is not a hardware breakpoint request; a hardware breakpoint request leads to debug mode immediately if there is no Service Request, and after TST if there is Service Request (regardless of stop requests). The rules above are summarized in the the following table, showing the destination state of the microengine in each situation.

Table 43-415. Breakpoint, Stop and Service Requests resolution from Idle

Breakpoint Request	MDIS	Service Request	Final State
no	0	0	Idle
no	1	0	Stop
no	0	1	TST
no	1	1	Stop
Yes	0	0	Halt_idle
Yes	1	0	Halt_idle
Yes	0	1	TST[1, 1]
Yes	1	1	TST[1]

1. breaks after TST, if signal ndedi_sync_break is still asserted.

When a thread is ending, it goes to Idle or TST only if there is neither a hardware breakpoint request nor a request to stop (eTPU Engine 1 Configuration Register (eTPU_SCR_ECR_ENG1) or eTPU Engine 2 Configuration Register (eTPU_SCR_ECR_ENG2) bit MDIS=1 or device debug request=1). When thread is ending and there are simultaneous hardware breakpoint and stop (MDIS=1 or device debug request=1) requests, hardware breakpoint prevails and the engine enters Debug mode (Halt_idle state).

If the engine entered Debug mode after a thread finished (Halt_idle state) and a "go" command comes from the debug interface, the engine state machine goes to Idle and the rules above apply. It means that if a "go" is issued in Halt_idle state with MDIS=1, the engine goes to Idle for one microcycle and then stops (if MDIS or device debug request keeps asserted and there is no other breakpoint request).

Note

Hardware breakpoint requests are ignored for the first microinstruction executed when microengine leaves halt.

43.14.11.4 Hardware Watchpoints

Debug Interface allows watchpoints on the same conditions available for hardware breakpoints (see Hardware Breakpoints).

Note

Data breakpoints are not supported on Shared Subsystem Area accesses (see Shared Subsystems Support).

43.14.11.5 Software Breakpoints

A software breakpoint occurs when microengine executes a HALT microinstruction. Any number of software breakpoints can be set in code, usually replacing an active microinstruction.

Like any other microinstruction, HALT increments the PC and pre-fetches the next instruction. So, before the halt state is suspended, if the original program flow must be followed, the original instruction at the HALT address must be executed, regardless if the software breakpoint is removed (replacing HALT by the original microinstruction) or not. Follows the procedure to resume execution from a software breakpoint:

1. restore the original instruction in SCM (replace HALT).
2. force a jump with flush to the original instruction (see Forced Microinstruction Execution).
3. if the software breakpoint must be kept: single-step and replace the original instruction with a HALT.
4. let the flow continue, issuing a GO command (leaving halt state).

Special care must be taken if HALT is followed by another HALT, and the second HALT is removed when microengine was halted by the first one. In this case, replacing the second HALT with the original microinstruction is not enough to remove the second breakpoint, because the second HALT was already prefetched and would be executed anyway when halt was suspended. The debugger must also do a forced execution of unconditional branch with flush to the original microinstruction address. That will clear the pipeline, replacing the prefetched instruction with a NOP, and load PC with the address of the removed breakpoint. So, when halt state is suspended, the original microinstruction will be fetched while NOP is executed, and program flow continues normally from then on.

Note

A HALT instruction placed after a no-flushing branch, dispatch or return may be a problem from the debugger application standpoint: after the HALT is executed, the eTPU debug interface informs the address of the branch/dispatch/return destination, and the debugger application has no direct way to identify which HALT instruction was executed, if multiple HALTs lead to the same address. This can be solved if the debug support block (NDEDI) has a register holding the address of the last instruction executed, otherwise one should forbid non-flushed HALT instructions. See the NDEDI details.

Software breakpoint setting and removal is possible only with SCM RAM implementations or ROM implementations with SCM RAM emulation (see). There is only one way of inserting software breakpoints into SCM RAM: writing bit VIS=1 in register ETPUMCR eTPU Engine 1 Configuration Register (eTPU_SCR_ECR_ENG1), and then accessing SCM as an ordinary RAM from the slave bus. This can be done only if both Engines are halted or stopped.

43.14.11.6 Single-step Execution

When microengine is already in halt_exec state, it can run the next microinstruction in the normal program flow and get back to halt state. PC is incremented, or assigned the BAF value in a branch with satisfied condition. Note that the executed instruction was already prefetched in the instruction pipeline, and a new microinstruction is fetched during its execution. The prefetched instruction may be cleared during halt state by the forced execution of a branch with flush (see Forced Microinstruction Execution), making single-step execute a NOP instead of the next instruction in the program flow.

Single-step execution is controlled by the debug interface, and is a feature available from Nexus if eTPU is connected to the NDEDI block (see NDEDI details).

The single-step execution of a NOP instruction can be useful to control input signal sampling and filtering, if NDEDI_ENGINEx_DC[PINS] = 1 at the Debug Interface (see NDEDI details). Single-step does not happen if VIS=1.

43.14.11.7 Forced Microinstruction Execution

When microengine is already in halt state (either halt_idle or halt_exec), it can run forced microinstructions through the debug interface. This feature is available from Nexus if eTPU is connected to the NDEDI block (see NDEDI details). The microinstruction, specified by the user, is not fetched from SCM and comes directly from the debug interface. MDU start commands issued by forced instructions are executed, and the MDU runs the operation until the end, independently of the halt state. The microinstruction field END is ignored.

During forced execution of any instruction except Branches, Returns and Dispatches, the PC does not change, and the prefetched instruction in the pipeline is bypassed, but not discarded. When halt state is suspended, the prefetched instruction is executed and the instruction pointed by the PC is prefetched in parallel (two-stage pipeline).

Forced execution of a Branch, Dispatch or Return loads the PC with the BAF field (if branch condition is satisfied), PC+P or RAR, respectively. If branch condition is not satisfied, PC value stays unaltered. The flush control (field FLS) also works, so that a successful forced branch with flush replaces the prefetched instruction with a NOP. So, to clear the instruction pipeline during halt, all one has to do is an unconditional branch to the desired address with flush. HALT instructions must not be executed as forced.

Forced operations that depend on the serviced channel are unspecified when executed in halt_idle and must be avoided.

Note

Forced instructions must not be commanded when eTPU Module Configuration Register (eTPU_SCR_MCR) bit VIS=1.

43.14.11.8 Microengine Register Access

eTPU provides no direct access to microengine and channel registers from the slave bus or any other interface. However, these registers can be read and written in halt state by executing forced microinstructions (see Forced Microinstruction Execution). Immediate data microinstructions may be used to set register values. Some registers are not

selectable for immediate data destination, so intermediary register(s) - notably P - may have to be used to carry the desired new value to the target register in two or more microinstructions. Usually the previous values of intermediary register(s) must be previously saved and restored after the whole operation.

Similar procedures apply for register reads: their contents must be dumped to SDM, where they can be read from the slave bus.

43.14.11.9 Microengine Flag Access

Microengine halt state allows reading the branch conditions flags through forced microinstructions or, more easily, through the NDEDI register NDEDI_ENGINEx_CFSR (see the NDEDI details). Flag conditions set by the user are seen by microengine for the next microinstruction execution. The flag set options are limited by the possibilities of forced microinstruction execution.

If the eTPU runs (not single-stepping) after exiting the halted state, the conditions modified during halt may remain only for the first microcycle after the halted state. After the first microcycle, branch conditions are altered only according to their regular update scheme.

43.14.11.10 Microengine Stall

Microengine can get into a stall state, attending a request from a debug interface signal assertion. The reason for a Stall request from NDEDI (or from any other debug support block) should be a temporary lack of resources, for instance queue full. During stall the microengine suspends execution, but all the other Engine logic continues operating: time bases, angle logic, channel logic, input sampling and filters. Stall differs from Halt, not enabling any of the debug features that Halt enables (see Microengine Halt State). It also does not break an atomic microengine access, unlike halt.

The Microengine can be stalled when idle and from the moment TST ends, before executing the first thread microinstruction, until just before the last thread microinstruction is executed. Stall requests are ignored in any other occasions. Microengines in a dual engine system can be independently stalled. If a forced end is issued when microengine is in stall coming from execution, the END is executed only when the microengine resumes execution from stall.

43.14.12 Safety Features

This section describes embedded safety features: MISC and memory error support.

The Multiple Input Signature Calculator - MISC - is an SCM test feature accessible through registers ETPUMCR and ETPUMISCCMPR (see eTPU Module Configuration Register (eTPU_SCR_MCR) and eTPU MISC Compare Register (eTPU_SCR_MISCCMPR)). MISC allows SCM test "on the fly", i.e., while eTPU is running, with no impact on eTPU functionality or performance.

Memory Error support features comprises SCM and SDM error detection, correction, report, and soft error.

43.14.12.1 SCM Test - Multiple Input Signature Calculator

The Multiple Input Signature Calculator (MISC) comprises special hardware that sequentially reads all SCM positions and calculates, in parallel, a 32-bit signature from a 32-input CRC signature calculator with the following polynomial:

$$1 + x^{1} + x^{2} + x^{22} + x^{31}$$

A complete description of the signature calculation procedure can be found in MISC Algorithm.

Once started by the Host the MISC runs continuously, restarting after the completion of each cycle, when it sets the ETPUMCR register flag SCMMISC (see eTPU Module Configuration Register (eTPU_SCR_MCR)). The average time for a MISC calculation can be measured by checking SCMMISC state at regular intervals, incrementing a counter and clearing SCMMISC if it is set.

MISC accesses to the SCM array are executed if none of the engines is accessing the SCM, to avoid degradation of the microengine performance: it happens while no channel is being serviced. An ongoing MISC operation can be aborted by writing 0 to SCMMISEN.

The Host must load the register ETPUMISCCMPR (see eTPU MISC Compare Register (eTPU_SCR_MISCCMPR)) with the expected value to be found at the end of the MISC cycle, and then start the signature calculation writing bit SCMMISEN=1 in register ETPUMCR (see eTPU Module Configuration Register (eTPU_SCR_MCR)). MISC zeroes the signature accumulator and starts reading SCM data and calculating the signature. After last SCM position is read, MISC compares the value in signature accumulator against the value in ETPUMISCCMPR: if there is a mismatch MISC stops, a Global Exception is issued and the bit SCMMISF in register ETPUMCR assumes value

1. If no mismatch is found, MISC repeats the procedure automatically. When signature is being calculated, SCM address starts at the last SCM address and counts down to 0. The conditions for executing a MISC operation are (see also Table 43-334):

- Both microengines in idle state (no channel is being serviced) or stopped, in any combination (e.g., engine 1 idle with engine 2 stopped).
- ETPUMCR bit VIS = 0.
- ETPUMCR bit SCMMISEN=1.

Note that MISC can run regardless of SCM implementation type (RAM or ROM).

If SCMMISEN=0 or VIS=1, the MISC logic stays at its initial state, with address counter pointing to the last SCM position and accumulator reset.

MISC can also be used to perform single-bit error fixes in the SCM. For more details, see Error Fixing).

43.14.12.2 Memory Error Support

Error Correction Code (ECC) support for SDM and SCM provides guaranteed single bit error correction and double bit error detection. Error detection and correction is performed on read accesses and on write accesses less than 32-bit wide to the SCM.

SDM ECC is calculated per byte, 5 bits wide each, totalling 20 ECC bits for each 32-bit word. That allows the ECC to be updated without a read-modify-write operation on writes of any size.

Error is not checked on bytes not selected on SDM read accesses, either by the Host, CDC or microengine. For instance, the most significant byte is not checked for errors on a microengine 24-bit read access.

Error detection also works for host accesses to the PSE area (see Parameter Sign Extension Area). In this case, error is not detected in the most significant byte (bits 31:24). Also, because of sign extension, error is always detected on the bits 23:16, regardless if they are selected, whenever the most significant byte is read.

SCM ECC is 7 bits wide, comprising the whole 32-bit word. Read-modify-write is automatically made when 16-bit or 8-bit wide writes are made into the SCM in a host access. SCM errors are also detected on Entry Table accesses during TST (see Time Slot Transition) and on MISC accesses, which are considered microengine accesses with regards to interrupt generation and error reporting.

43.14.12.2.1 Error Detection Disabling

The error detection logic in SDM and SCM can be disabled by setting the eTPU Memory Error Control Register (eTPU_MESR_MECR) bits DEDD and CEDD, respectively. The disabled state turns ineffective any action due to error detection, including error correction. Note that error detection is always enabled out of reset.

43.14.12.2.2 Memory Error Flags

SDM single (correctable) and non-correctable bit errors are flagged in eTPU Memory Error Status Register (eTPU_MESR_MESR) bits DCERR and DNCERR, respectively..

SCM correctable and non-correctable errors are flagged in the ETPUMESR register bits CCERR and CNCERR, respectively.

Double bit errors are guaranteed to be flagged, while three or more simultaneous bit errors in an SDM byte or SCM word are not. An error flagged as non-correctable can be in two or more bits.

Overrun flags DCOVR and CCOVR indicate, for SDM and SCM respectively, when a correctable error occurs when DCERR, CCERR are already asserted. Similarly, overrun flags DNCOVR/CNCOVR assert when a non-correctable error occurs when DNCERR/ CNCERR are asserted already.

43.14.12.2.3 Memory Error Reports

The address, syndrome and data of a non-correctable SDM access can be sampled into the registers eTPU Data Error Report Address Register (eTPU_MESR_DERAR), eTPU Data Error Report Syndrome Register (eTPU_MESR_DERSR), and eTPU Data Error Report Data Register (eTPU_MESR_DERDR), respectively.. The register ETPUDERAR also captures the SDM read access originator, whether the host, CDC, or specific eTPU channel service (see ETPUDERAR register, ETPUDERSR register, and ETPUDERDR register).

Similarly, non-correctable SCM accesses address, syndrome and data are stored in the registers eTPU Code Error Report Address Register (eTPU_MESR_CERAR), eTPU Code Error Report Syndrome Register (eTPU_MESR_CERSR), and eTPU Code Error Report Data Register (eTPU_MESR_CERDR), respectively. The register ETPUCERAR also captures the SCM read access originator, whether the host, MISC, or specific eTPU channel service (see ETPUCERAR register, ETPUCERSR register, and ETPUCERDR register). The occurrence of a non-correctable error overwrites the report register values from a correctable error, either on SDM (DCERR=1) or SCM (CCERR=1).

The last address, syndrome and data of a correctable SDM access can also be sampled into registers ETPUDERAR, ETPUDERSR and ETPUDERDR, but only if the ETPUMESR bit DNCERR is 0. That prevents access address, syndrome and data from a correctable error to overwrite the same information from a non-correctable access.

Similarly, the last address, syndrome and data from a correctable SCM access are stored in registers ETPUCERAR, ETPUCERSR and ETPUCERDR only if ETPUMESR bit CNCERR is 0.

For either SDM or SCM, a new correctable error overwrites the report registers' values from an earlier correctable error, but report values from a non-correctable error are not overwritten, as long as bit DNCERR/CNCERR is asserted, neither by a new correctable error nor by a non-correctable one.

The sampling of SDM and SCM error report registers can be disabled through the ETPUMECR bits DRDIS and CRDIS, respectively. When DRDIS (CRDIS) is asserted, the update of the SDM (SCM) error report registers is disabled, but not of ETPUMESR bits DCERR, DNCERR (CCERR, CNCERR). DRDIS, CRDIS must be set before reading the respective report registers to assure their coherent reading, preventing them to be updated between reads.

43.14.12.2.4 Error Detection and Wait-states

Microengine SDM accesses do not take any wait-state due to ECC support. Host SDM read accesses take two wait-states minimum[35, 35] in MCUs with SDM ECC support, regardless if an error was detected or not, if the SDM error detection is enabled (eTPU Memory Error Control Register (eTPU_MESR_MECR) bit DEDD=0). Host SDM read accesses take a minimum of one wait-state if the SDM error detection is disabled (ETPUMECR bit DEDD=1). Host SDM write accesses take one wait-state minimum, regardless of ECC support presence or enabling.

Host SCM read accesses have two wait-states[35], regardless if an error was detected or not. Writes from the host to the SCM take one wait-state on 32-bit accesses, and one additional wait-state (two wait-states total[35] on 16-bit and 8-bit wide accesses. Those figures are not affected by the SCM error detection disabling (ETPUMECR bit CEDD).

43.14.12.2.5 Memory Error Interrupts

For **microengine accesses**, the Global Exception interrupt asserts whenever a non-correctable error is detected, either on SCM or SDM (see Interrupts and Data Transfer Requests). These errors are flagged by eTPU Module Configuration Register

35. one wait-state more, compared with eTPU versions before eTPU2 and previous eTPU2 without ECC support

(eTPU_SCR_MCR) bits SCMERR and SDMERR, respectively.. Single bit errors are corrected and activate the Memory Error Correction Interrupt if it is enabled (see Interrupt Types and Sources), but do not generate Global Exceptions.

For **host accesses** a bus error is issued whenever a non-correctable error is detected, either on SCM or SDM (but not through the CDC) and it also generates a Global Exception. Single bit errors are corrected (if the error correction feature is available) and do not cause bus transfer errors, but assert the Memory Error Correction Interrupt if it is enabled (see Interrupt Types and Sources).

43.14.12.2.6 Effect of Errors on Microcode Execution

Correctable errors, either on SCM or SDM, do not affect microcode execution if detection/correction is enabled.

The executing thread is affected by a non-correctable SDM error as follows:

- If ETPUMECR bit DTEND = 1: on SDM errors due to a read operation, if the instruction is not also an END, the following instruction automatically executes an END, and its operations may be executed, totally or partially. On SDM errors during the TST preload, the thread automatically ends on the first instruction, if the error occurs on a preload parameter selected by the entry point bit PP (see Entry Point Format section.) The first instruction may be executed totally or partially. Data read into P or DIOB may be corrupted in either case.
- If ETPUMECR bit DTEND = 0: the TST or thread continues the execution flow normally. Data read into P or DIOB may be corrupted in either case.

The executing thread is affected by a non-correctable SCM error as follows:

- If ETPUMECR bit CTEND=1: on SCM errors, the corrupted instruction is not executed, instead replaced by a simple END. Due to instruction prefetching, an error may be detected and yet not affect the thread execution. However, an error detected in a prefetched instruction may cause error report and global or memory error interrupts, even if not executed. If a non-correctable error occurs on the entry table read during TST (see Time Slot Transition section), the first instruction in the thread is replaced with a simple END, a global exception is issued and the reports and flags are normally updated.
- If ETPUMECR bit CTEND=0: the execution flow continues normally, and the results depend on the particular instruction corruption.

Table 43-416. Error Support Summary if CEDD = DEDD = 0

Action	SCM		SDM	
	single bit error	double bit error	single bit error	double bit error
Memory Error Correction Interrupt	Asserts	Not asserted	Asserts	Not asserted

Table continues on the next page...

Table 43-416. Error Support Summary if CEDD = DEDD = 0 (continued)

Action		SCM		SDM	
		single bit error	double bit error	single bit error	double bit error
Global Exception		Not asserted	Asserts	Not asserted	Asserts
Bus Error (host reads)		Not issued	Issued	Not issued	Issued
Thread	CTEND = 0	Normal execution	Potential erroneous execution[1]	Normal execution	see DTEND
	CTEND = 1		Terminates before erroneous execution[2]		
	DTEND = 0		see CTEND		Potential erroneous execution
	DTEND = 1				Terminates after erroneous read[3]
Code Error Report Registers	CNCERR = 0	Updates ETPUCERAR, ETPUCERSR, ETPUCERDR		Not related	
	CNCERR = 1	ETPUCERAR, ETPUCERSR, ETPUCERDR not updated			
Data Error Report Registers	DNCERR = 0	Not related		Updates ETPUDERAR, ETPUDERSR, ETPUDERDR	
	DNCERR = 1			ETPUDERAR, ETPUDERSR, ETPUDERDR not updated	

1. The thread executes correctly if the error is detected on an instruction fetched but not executed.
2. The erroneous instruction is not executed at all, and replaced by a simple END.
3. The instruction following the erroneous read may be executed totally or partially.

43.14.12.2.7 Error Correction Code (ECC) and Syndrome Definition

SDM ECC is composed of 5 Hsiao code[36] bits for each data byte. **SCM ECC** is composed of 7 Hsiao code bits for each 32-bit word.

Table 43-417 shows the encoding of the SDM syndrome and global parity fields as they read on the eTPU Data Error Report Syndrome Register (eTPU_MESR_DERSR) register. There is one syndrome and one global parity for each byte in an SDM word, numbered SYND0 to SYND3 from the least to the most significant.

Table 43-417. SDM Syndrome Definition

SYNDn (hex)	Result	SYNDn (hex)	Result
0E	error on data bit 8n+7	10	error on **code** bit 8n+4
15	error on data bit 8n+6	08	error on **code** bit 8n+3
07	error on data bit 8n+5	04	error on **code** bit 8n+2

Table continues on the next page...

36. Hsiao, M.Y;.A Class of Optimal Minimum Odd-weight-column SEC-DED Codes; IBM Journal of Research and Development http://ieeexplore.ieee.org/xpl/freeabs_all.jsp?arnumber=5391627

Table 43-417. SDM Syndrome Definition (continued)

SYNDn (hex)	Result	SYNDn (hex)	Result
1A	error on data bit 8n+4	02	error on **code** bit 8n+1
19	error on data bit 8n+3	01	error on **code** bit 8n
13	error on data bit 8n+2		
16	error on data bit 8n+1	00	no error
1C	error on data bit 8n	any other	non-correctable error

The following table shows the definition of the SCM syndrome field as it reads on the eTPU Code Error Report Syndrome Register (eTPU_MESR_CERSR) register.

Table 43-418. SCM Syndrome Definition

SYND (hex)	Result	SYND (hex)	Result	SYND (hex)	Result
40	error on **code** bit 6	58	error on data bit 25	46	error on data bit 11
20	error on **code** bit 5	0B	error on data bit 24	4A	error on data bit 10
10	error on **code** bit 4	54	error on data bit 23	52	error on data bit 9
08	error on **code** bit 3	15	error on data bit 22	62	error on data bit 8
04	error on **code** bit 2	16	error on data bit 21	13	error on data bit 7
02	error on **code** bit 1	34	error on data bit 20	29	error on data bit 6
01	error on **code** bit 0	25	error on data bit 19	31	error on data bit 5
		26	error on data bit 18	43	error on data bit 4
49	error on data bit 31	64	error on data bit 17	45	error on data bit 3
0D	error on data bit 30	2C	error on data bit 16	19	error on data bit 2
0E	error on data bit 29	1A	error on data bit 15	51	error on data bit 1
38	error on data bit 28	23	error on data bit 14	61	error on data bit 0
4C	error on data bit 27	2A	error on data bit 13	00	no error
1C	error on data bit 26	32	error on data bit 12	any other	non-correctable error

43.14.12.2.8 Error Injection

Errors can be injected into the SDM read data path through the eTPU Data Error Injection Address Register (eTPU_MESR_DEIAR), eTPU Data Error Injection Data Pattern Register (eTPU_MESR_DEIDPR) and eTPU Data Error Injection Parity Pattern Register (eTPU_MESR_DEIPPR) registers. They define bit flips on accesses at the specific address specified in ETPUDEIAR.

SDM error injection is enabled independently for host and microengine accesses by the eTPU Module Configuration Register (eTPU_SCR_MCR) bits HDEIE and MDEIE, respectively. The user must program ETPUDEIAR, ETPUDEIDPR and ETPUDEIPPR with HDEIE=MDEIE=0, and only then enable error injection by setting HDEIE=1 and/or MDEIE=1 to avoid races (see ETPUMESR register).

Similarly, SCM errors can be injected into the SCM read data path through the eTPU Code Error Injection Address Register (eTPU_MESR_CEIAR), eTPU Code Error Injection Data Pattern Register (eTPU_MESR_CEIDPR) and eTPU Code Error Injection Parity Pattern Register (eTPU_MESR_CEIPPR) registers, enabled by the eTPU Module Configuration Register (eTPU_SCR_MCR) bit CEIE. Errors are injected on host accesses to the address specified in ETPUCEIAR when ETPUMCR bit VIS=1, or on microengine and MISC accesses when VIS=0.

43.14.12.2.9 Error Fixing

Single bit **soft errors** can be fixed by rewriting the right value, as corrected by the ECC logic, into the same address of the erroneous data. eTPU provides means to perform such fixes safely, coherently and concurrently with the normal operation.

SDM fixes can be done using the CDC (see Coherent Dual-parameter Controller - CDC), limited to the lower 8 Kbytes of SDM. The Host application simply has to program a transfer with both origin and destination positions pointing to the address of the data to be fixed. Because the PBBASE field has an address granularity of 8 bytes, a word adjacent to the one to be fixed must also be rewritten. The CDC transfer is atomic, therefore the fix is done coherently and does not interfere with the application code or data flows.

SCM fixes can be done by programming the eTPU Code Error Fix Register (eTPU_MESR_CEFR) (see the eTPU Code Error Report Syndrome Register (eTPU_MESR_CERSR) register). The fixes are performed by the MISC logic, which must be enabled (see SCM Test - Multiple Input Signature Calculator). The modes available, selected by the ETPUCEFR field CFIXM, are:

- **Automatic Fix Mode (CFIXM=11)**: the MISC logic automatically rewrites the contents of an address whenever it finds a correctable error; the CFIXM field keeps its value if a fix is made.

43.14.13 Performance Monitoring Features

43.14.13.1 Idle Counter

The Idle Counter Registers ETPUIDLER eTPU Idle Register for Engine 1 (eTPU_ER_IDLER_ENG1) and eTPU Idle Register for Engine 2 (eTPU_ER_IDLER_ENG2) continuously counts microcycles in which the microengine is not busy with channel service. It can be used to measure the microengine utilization by rating the count measured during a period of time to the number of microcycles contained in the period. The Idle counter does not count microcycles when the engine is stopped, or is in TST or halt states.

43.14.13.2 Latency Monitor

eTPU implements six Latency Monitors to measure the time taken to service a request. Each Latency Monitor provides:

- The measure of the greatest latency found during actual thread executions, accessed from the eTPU Latency Monitor Measure Register for Engine 1 (eTPU_LMR_LM*n*MR_ENG1) and eTPU Latency Monitor Measure Register for Engine 2 (eTPU_LMR_LM*n*MR_ENG2) registers.
- A comparison between the measured latency and a threshold, determined through the eTPU Latency Monitor Measure Register for Engine 2 (eTPU_LMR_LM*n*MR_ENG2) and eTPU Latency Monitor Configuration Register for Engine 2 (eTPU_LMR_LM*n*CR_ENG2) registers.

Each Latency Monitor works independently in one of the following modes, selected with the ETPULMnCR field LMM:

- **Disabled mode**: no latency measures or actions are taken.
- **Channel mode**: monitors the latency of an individual channel.
- **Priority mode**: monitors the combined latency of all channels in a given priority level - High, Medium or Low (see Scheduler).

Channel and Priority modes are detailed in the subsections below. The following applies to both modes :

- after each latency measurement, the value measured is compared with the MAXLAT value in the register ETPULMnMR; and if MAXLAT is not zero and the new measured value is greater.
- after each latency measurement, the value measured is compared with the MAXLAT value in the register ETPULMnCR, and if the new measured value is greater:
  - a Global Exception is issued.
  - the ETPUMCR flag LTO1 (engine 1) or LTO2 (engine 2) is set, independently of the LATENCY value in ETPULMnMR.

NOTE

The LATENCY value is updated even if MAXLAT=0.

NOTE

MAXLAT=0 just inhibits the assertion of the LTO1/2 flag and Global Exception due to the respective Latency Monitor. Other Latency Monitor instances with non-zero MAXLAT value may assert LTO1/2 and Global Exception.

43.14.13.2.1 Channel Mode

When the Latency Monitor operates in Channel mode:

- only the channel selected by the ETPULMnCR field MONCHAN is monitored,
- any combination of Host Service Requests (HSR), Channel Service Requests and Link Service Requests can be selected for monitoring, based on the ETPULMnCR field SRSEL,
- the latency is counted in microcycles, from the moment the logic OR of all the service requests selected by SRSEL asserts to the moment this logic OR negates.
- the latency count is interrupted when the channel is disabled, either by writing ETPUCnCR field CPR = 0, or by a watchdog timeout. Latency is counted until the channel is disabled and is not discarded; a new count can start from zero when the channel is re-enabled.

NOTE

If a selected service request type or a combination of them continues asserted during and after its service thread execution, its latency counter will keep on running; this can happen, for instance, if either matches can service requests (e.g. channel modes em_st/em_dt), one match happens before the other is serviced, and only one of them is cleared. The Latency Monitor can, in cases like this, yield pessimistic measurements.

NOTE

The Latency Monitor in channel mode must be disabled before the channel it monitors is disabled.

43.14.13.2.2 Priority Mode

When the Latency Monitor operates in Priority mode:

- only the combination of channels assigned with the priority selected by the ETPULMnCR fields SRSEL is monitored.
- the latency is measured in microcycles, starting from either of these two events, whichever happens first:
  - the logic OR of service requests of the selected priority transitions from 0 to 1 at a moment when all their grants are at state negated.
  - the grants of the selected priority are cleared by the scheduler at the end of the thread, and any of the service requests at the same priority is still active soon after the thread ends.
- the latency is measured until the grants of the selected priority are cleared by the scheduler, after the measurement started.

Note

A Latency Monitor in priority mode must be disabled before any of the channels in the selected priority is disabled, or any disabled channel is assigned with the selected priority.

43.14.13.3 Watchdog Monitor Operation

The watchdog mechanism can also be used to monitor, without interfering with the application execution, whether the execution time of any individual thread or a sequence of threads reaches a given limit. This can be achieved by asserting the eTPU Watchdog Timer Register for Engine 1 (eTPU_ER_WDTR_ENG1) and eTPU Watchdog Timer Register for Engine 2 (eTPU_ER_WDTR_ENG2) bits WMO.

43.15 Initialization/Application Information

43.15.1 Configuration Sequence

After initial power-on reset the eTPU remains in an idle state[37, 37], requiring initialization of several registers before any function can begin execution. Also, if the SCM is implemented in RAM, it should be initialized with the eTPU application code prior to configuring the eTPU. Configuration procedures are summarized as follows:

- If SCM is implemented as RAM, load the eTPU application code (see SCM access).
- Initialize SDM (optional if no ECC support available)
- Initialize the SCM MISC logic (optional, see SCM Test - Multiple Input Signature Calculator).
- Initialize Watchdog and Latency Monitors (optional)
- Initialize the eTPU time base configuration registers eTPU Engine 1 Time Base Configuration Register (eTPU_TBR_TBCR_ENG1) and eTPU Engine 2 Time Base Configuration Register (eTPU_TBR_TBCR_ENG2) to setup:
  - TCR1 and TCR2 prescalers and clock sources.
  - Select digital filtering mode.
  - TCRCLK signal filter control.
  - Angle mode operation (if necessary).
- Initialize the eTPU engine configuration registers eTPU Engine 1 Configuration Register (eTPU_SCR_ECR_ENG1) and eTPU Engine 2 Configuration Register (eTPU_SCR_ECR_ENG2) to setup:
  - Entry table base.
  - Filter prescaler clock control.
- Initialize eTPU STAC configuration registers eTPU Engine 1 STAC Configuration Register (eTPU_TBR_STAC_ENG1) and eTPU Engine 2 STAC Configuration Register (eTPU_TBR_STAC_ENG2) if one needs to setup TCR1/2 resource Client/Server operation.
- Write to the Channel Configuration registers eTPU Channel n Configuration Register for Engine 1 (eTPU_CCCR_C*n*CR_ENG1) and eTPU Channel n Configuration Register for Engine 2 (eTPU_CCCR_C*n*CR_ENG2) to choose the Function to be performed by each channel, and its parameter base address.

37. except when device debug request is asserted on power-on reset: in this case, the microengines wake-up in halt state.

- Write to channel status control registers eTPU Channel n Status Control Register for Engine 1 (eTPU_CCCR_C*n*SCR_ENG1) and eTPU Channel n Status Control Register for Engine 2 (eTPU_CCCR_C*n*SCR_ENG2) to choose among the possible variations within the function flow (FM bits).
- Write to SDM for parameter initialization of each configured channel.
- Write to registers eTPU Watchdog Timer Register for Engine 1 (eTPU_ER_WDTR_ENG1) and eTPU Watchdog Timer Register for Engine 2 (eTPU_ER_WDTR_ENG2) if one needs to enable and setup the Watchdog(s) mode and timeout.
- Write to channel n Host Service Request registers eTPU Channel n Host Service Request Register for Engine 1 (eTPU_CCCR_C*n*HSRR_ENG1) and eTPU Channel n Host Service Request Register for Engine 2 (eTPU_CCCR_C*n*HSRR_ENG2) to initialize the active channels.
- Write to the channel interrupt enable register eTPU Channel Interrupt Enable Register for Engine 1 (eTPU_GCR_CIER_ENG1) and eTPU Channel Interrupt Enable Register for Engine 2 (eTPU_GCR_CIER_ENG2) if interrupts are to be enabled from the appropriate channels. Likewise for Data Transfer Requests (ETPUCDTRER). This can also be done through ETPUCxCR.
- Write to channel n configuration registers eTPU Channel n Configuration Register for Engine 1 (eTPU_CCCR_C*n*CR_ENG1) and eTPU Channel n Configuration Register for Engine 2 (eTPU_CCCR_C*n*CR_ENG2) to enable each channel by assigning it a high, middle, or low priority (CPR field).[37]
- Monitor the Host service request registers (ETPUCxHSRR) eTPU Channel n Host Service Request Register for Engine 1 (eTPU_CCCR_C*n*HSRR_ENG1) and eTPU Channel n Host Service Request Register for Engine 2 (eTPU_CCCR_C*n*HSRR_ENG2) for completion of initialization.
- Write ETPUMCR eTPU Module Configuration Register (eTPU_SCR_MCR) bit GTBE=1 to start TCR1/TCR2 time base counting at same time in both Engines (may be done before or never, depending on the particular application and use of Red Line bus).

43.15.2 Reset Options

43.15.2.1 Hardware Reset

Hardware reset is achieved by assertion of device synchronous reset . Both Engines and common logic is reset, and even the System Configuration and Global Channel registers assume their reset values.

Note

All eTPU input clocks must pulse during reset so that both engines are reset, even if they are in Module Disable or Stop mode.

43.15.2.2 Software Reset

eTPU has no Software reset. To abort infinite microcode loops, the Force END mechanism must be used (see field FEND in eTPU Engine 1 Configuration Register (eTPU_SCR_ECR_ENG1) and eTPU Engine 2 Configuration Register (eTPU_SCR_ECR_ENG2)). .

43.15.3 Multiple Parameter Coherency Methods

Follows a description of two methods for coherent transfer of multiple parameters between Host and eTPU. Both methods involve the use of two parameter areas: the Transfer Parameter Area (hereafter called TPA), which is the SDM area directly accessed by the Host for reads and writes, and the Permanent Parameter Area (hereafter called PPA), which are the SDM positions where channel parameters are normally accessed by the Function microcode. Note that parameters in either TPA or PPA do not have to be in sequential addresses. TPAs and PPAs allocation are completely defined by the application, and there may be any number of them, independently of the channels.

The methods described here are not the only solutions for the coherent transfer problem, and both can coexist in eTPU and even used in combination. Also note that for transfers of a pair of parameters, the Coherent Dual-parameter Controller is faster and have less impact on both eTPU and Host performance. That said, the methods are:

- **Transfer Service**: a microengine thread transfers, upon Host Service Request, data from/to a TPA to/from a PPA.Coherency is guaranteed by the fact that a thread is atomic with respect to other threads in the same Engine, and so are its transfers. If parameters in PPA are shared by both Engines, hardware semaphores have to be used to access them.
- **Mailbox**: for Host to eTPU transfers, the microcode checks a flag, set by the host, indicating the existence of new parameter data in the TPA. It can, then, either access TPA data directly or copy it to the PPA. For eTPU to Host transfers, when microcode changes PPA, it copies them to the TPA and flags updated TPA data to Host, possibly using an Interrupt or a Data Transfer Request. The Mailbox flag is reset when data is copied: by the eTPU microcode, when it transfers TPA to PPA (possibly followed by an Interrupt); by the Host, when it reads data from the TPA. This indicates that TPA is free for another transfer.

Transfer Service has the advantage of separating the task of data transfer from the functional service thread that accesses the parameters, with less impact to the latter. Compared to the Mailbox method, however, it has bigger average latency, because the Transfer Service thread has to contend for a time slot to execute. This latency can be minimized if Transfer Service thread is assigned to a separate channel with higher priority, but even so it does not guarantee that PPA is updated before the next execution of the functional thread that uses it.

Mailbox method, on the other hand, makes the functional thread check for the existence of new data (Host to eTPU). It does not have to be responsible for the transfer, though: it may access the TPA directly, and a Transfer Service can then be used to copy data from TPA to PPA.

43.15.4 Programming Hints and Caveats

43.15.4.1 Atomic dual access after a call, return

A dual, back-to-back parameter access is not atomic after a call, a jump, or a return if they occurred in parallel with an odd SDM access. It is safer to make a pair of parameter accesses that must be coherent begin at the second instruction after a call/jump/return.

43.15.4.2 Resource polling

The use of polling while waiting for a condition or a resource (except semaphore lock) should be avoided in order not to hang the microengine in long loops. This general programming guideline is greatly enforced in eTPU, as a thread cannot be preempted for any reason. Safer polling, albeit with long and indeterministic latency, can be obtained if a thread issues a channel link to the serviced channel and terminates. The microengine is then free to other tasks, and the next poll happens at the next time the channel is serviced. This mechanism can be combined with finite (timed out) loops for better latency.

43.15.4.3 Changing Channel Function, Parameter Base, or Entry Table Scheme

Channel Function, Parameter Base Address and Entry Table Scheme are determined by the eTPU Channel n Configuration Register for Engine 1 (eTPU_CCCR_C*n*CR_ENG1) and eTPU Channel n Configuration Register for Engine 2 (eTPU_CCCR_C*n*CR_ENG2) fields CFS, CPBA and ETCS. They cannot be changed when the channel is enabled. If the channel is disabled first, one may still have service requests from the previous function, so before the channel is enabled again one must be sure that:

- the first thread executed in the new function is the initialization one.
- the initialization thread of the new function clears any previously pending service request.

Follows a safe procedure for function changing:

1. disable the channel (write ETPUCnCR field CPR=00).
2. change the function configuration (ETPUCnCR fields CFS and/or CPBA and/or ETCS).
3. request the initialization thread, writing eTPU Channel n Host Service Request Register for Engine 1 (eTPU_CCCR_C*n*HSRR_ENG1) and eTPU Channel n Host Service Request Register for Engine 2 (eTPU_CCCR_C*n*HSRR_ENG2) with the initialization HSR (channel still disabled).
4. enable the channel (write ETPUCnCR field CPR > 0); the initialization HSR is serviced before any other formerly pending service requests, clearing them.

43.15.4.4 Checking and Clearing Interrupts of a Stopped Engine

An Engine may be stopped with interrupts (or DMA requests) pending. This includes the case when the Engine's MDIS bit is set and a thread is still running: the thread will complete execution, possibly issuing an interrupt or DMA request before the engine stops, setting the STF bit.

As soon as the engine stops the channel registers become inaccessible, issuing bus errors when accessed. Interrupts and DMA requests can still be checked and cleared through the Global Channel Registers, though. DMA requests can also be cleared by the hardware handshaking with the DMA controller when the engine is stopped.

43.15.5 Estimating Worst Case Latency

Reliable systems are designed to work under worst-case conditions. This section explains how to estimate worst-case latency (WCL) for any eTPU function in any system. The appendix covers the following topics:

- Introduction to Worst-Case Latency
- Using Worst-Case Latency Estimates to Evaluate Performance
- Priority Scheme Details used in WCL Analyses
- First-Pass WCL Analysis
- Second-Pass WCL Analysis

The first-pass WCL analysis is based on a deterministic, generalized formula that is easy to apply. Because of the generalizations in the formula, the first analysis result is almost always much worse than the real worst case. If the desired system performance is within the limits of this first analysis, then no further analysis is required; the system is well within the performance limits of the eTPU. If the desired system performance exceeds that indicated by the first analysis, the second-pass WCL analysis should be applied. The second-pass analysis is not a generalized formula, but rather uses specific system details for a realistic worst-case estimation.

43.15.5.1 Using Worst-Case Latency Estimates to Evaluate Performance

Once WCL is found for a channel, the user must determine how to use this number to analyze performance. To analyze the performance of a channel running the PWM function, for example, some information about what happens in each thread is necessary.

The following example refers to old TPU PWM function, which is not optimized to the eTPU enhanced hardware. For PWM, thread 1 is the initialization thread, and threads 2 and 3 are used during normal function execution. (PWM threads 4, 5, and 6 are for special modes and will be assumed to be unused on channel 5). Thread 2 writes a time into the channel 5 match register and performs other operations that will cause the channel 5 signal to go from low to high at the time indicated in the match register (match time). At match time, the signal goes high and channel 5 requests service from the eTPU Microengine to execute thread 3. Thread 3 writes a time into the channel 5 match register and performs other operations that will cause the channel 5 signal to go from high to low at match time. At match time, the signal goes low and channel 5 requests service from the eTPU Microengine to execute thread 2. A PWM wave is kept running on the system by the eTPU executing thread 2, then thread 3, then thread 2, then thread 3, and so on.

Since the definition of worse-case latency assumes a fully loaded running system, initialization threads are not part of worst-case calculations. For the channel 5 example, the two PWM threads in are thus the two normal running threads, threads 2 and 3.

does not define which thread is thread 2 and which is thread 3. Since the worst-case latency derived from the first-pass analysis is the worst case between any2 threads (not counting initialization threads), it is safe to say that the worst-case latency shown in represents both the worst-case high time and the worst-case low time.

Notice in that worst-case latency is drawn from the end of the execution of the first PWM thread to the end of the execution of the next PWM thread. It is drawn from end to end because the microcode instructions that make up the threads control the channel hardware. To make sure that all the microcode instructions needed to change the pin thread have been executed, it is necessary to include the execution time of the second thread.

Thread information for each function is found in the programming notes for individual TPU functions. Refer to Freescale Programming Note TPUPN00/D, Using the TPU Function Library and TPU Emulation Mode, for a list of available programming notes. Similar documentation will we provided for the eTPU new functions.

43.15.5.2 Priority Scheme Details Used in WCL Analysis

The user assigns functions to channel numbers and gives each active channel a priority level of high, middle, or low. The Scheduler uses the channel number and channel priority level to determine the order in which to grant service.

The scheduler allocates time slots to specific priority levels of high, middle, or low. One function thread is executed in each time slot. The length of a time slot varies according to the length of the executing thread. When fully loaded, the scheduler always assigns time

slots in a seven-slot sequence (see the following table). After a seven-slot sequence is completed, another seven-slot sequence begins (see Figure 43-335). Note that in eTPU, when no service request exists, the scheduler goes to thread 1, but WCL calculation considers full load.

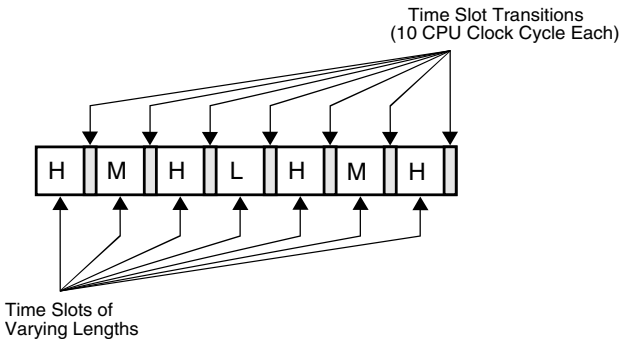

Figure 43-334. Time-Slot Sequence

This sequence scheme gives higher-priority channels more service time than lower-priority channels. High-priority channels are allocated four of seven time slots, middle-priority channels are allocated two of seven time slots, and low-priority channels are allocated one of seven time slots.

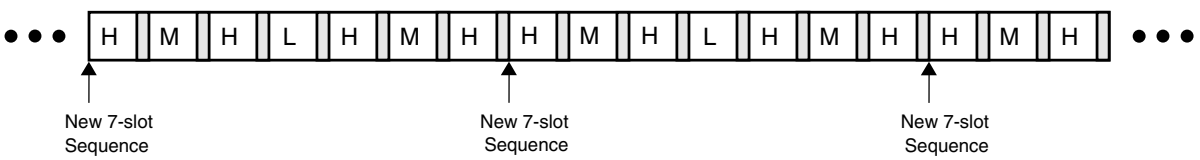

Figure 43-335. Multiple Time-Slot Sequences

43.15.5.2.1 Priority Passing

If no channel of the priority level assigned to the time slot is requesting service, the eTPU scheduler can pass priority to other levels. If no high-level channel is requesting service during a high level time slot, a middle-level channel is granted service; or, if no middle level-channel is requesting service, a low-level channel is granted service. If no middle-level channel is requesting service during a middle-level time slot, a high-level channel is granted service; or, if no high-level channel is requesting service, a low-level channel is granted service. If no low-level channel is requesting service during a low-level time slot, a high-level channel is granted service; or, if no high-level channel is requesting service, a middle-level channel is granted service. If no channel is requesting service, the time slot sequence is reset to state 1 and the scheduler idles until a request is received.

Priority passing is implemented in hardware and does not contribute to worst-case latency.

43.15.5.2.2 Time-Slot Transition

After each time slot, the eTPU must prepare for the next time slot. This preparation time between each time slot is called a time-slot transition. See Time Slot Transition . Time-slot transitions can take from six up to ten eTPU clocks.

43.15.5.2.3 Channel Number Priority

If more than one channel of a priority level is requesting service, the lowest numbered channel is granted service first. For example, if channels 0, 5, and 9 are all high-level channels requesting service during a high time slot, channel 0 is granted service first. Continuing this example, if channel 0 requests service again immediately after being serviced, it is not serviced again until channels 5 and 9 are serviced. This scheme is implemented so that continuously-requesting low numbered channels do not take all the time on the eTPU execution unit and leave no time for other channels.

The scheduler uses registers to keep track of which channels have been serviced and which require servicing. Each channel has two register bit: a service request register (SRR) and a service grant register (SGR). The SRR is set when a channel requests service. After the channel has been granted service, the SGR is set and the SRR is cleared.

SGRs are not cleared individually by channel, but rather as priority level groups. The clearing of a group of SGRs begins a new cycle for that priority level. An SGR group is cleared on the condition that a channel of that priority level has just been serviced, and no other channel of that priority level is requesting service (has a set SRR) and has not been granted service (has a clear SGR).

For example, if a middle-priority channel has just been serviced (either in a middle-priority time slot or a high or low-priority time slot gained by priority passing), the SRRs and SGRs of all middle-priority channels are compared. If there is no middle-priority channel with its SRR set and SGR cleared, the scheduler clears all middle-level SGRs. If there is a middle-level channel with its SRR set and SGR cleared, the scheduler does not clear the SGR group, and the requesting middle-level channel is serviced on the next middle-level time slot (or possibly sooner by priority passing).

43.15.5.2.4 SDM Collision Rate

Most function threads read or write to the eTPU SDM at least once. Because both the eTPU Microengine and Host can access the SDM but not at the same time, the Microengine may suspend execution during the SDM access while waiting for the Host to finish accessing the SDM. At other times the Host may wait for the Microengine. Wait states can take up to two eTPU clocks, when the Host accesses the SDM directly, without

using CDC. Microengine(s) wait-states must be added into the worst-case latency calculation. The system designer should estimate the percentage of SDM accesses in the system that will result in Microengine wait-states. This percentage is called the RAM collision rate (RCR). In each collision with direct Host accesses to the SDM the Microengine(s) wait for two eTPU clocks.

In eTPU the Coherent Dual-parameter Controller (CDC) may also access the SDM for atomic transfers of two parameters. eTPU Microengine may wait on this operation (if it is in service time) until the transfer is complete. CDC always transfers two parameters, making four consecutive accesses (read, write, read, write) of one eTPU clock each. The system designer should estimate the percentage of SDM accesses in the system that will result in a Microengine wait due to coherent transfer, and multiply it with the average number of eTPU clocks the Microengine waits for each transfer. This percentage is called Coherent Parameter Collision Rate (CPCR).

In addition, Microengine to Microengine multiple parameter coherent communication, using the hardware semaphores, may hold one Microengine which waits to lock the semaphore while the other Microengine is holding it. This waiting is due to a software loop, not hardware wait-states. Note that single parameter access of one Microengine does not affect the timing of the other Microengine due to SDM time interlace. This implies that single parameter Microengine to Microengine communication does not affect the performance. The Microengine which waits for the semaphore will loop until it is freed by the other Microengine. This time depends on the eTPU application. The system designer should estimate the percentage of Microengine to Microengine coherent parameter communication that will result in eTPU semaphore loops, and multiply it with the average number of eTPU clocks the Microengine loops for each such transfer. This percentage is called CCR (Communication Collision Rate).

A 100% collision rate for a system is the theoretical worst case. In many systems, however, the RCR, CPCR and CCR would be very low, sometimes even near 0%. This is because the eTPU is an independent processor capable of servicing most function needs, so that the Host rarely needs to access the eTPU SDM. Also coherent Microengine to Microengine communication of more than one parameter may be rare. To find a realistic RCR, CPCR the system designer should evaluate the Host code and find the percentage of time it accesses the eTPU SDM with or without using the CDC. This percentage gives a good RCR and CPCR. The eTPU application provides a good estimation of CCR.

Note

The programming practice of polling a flag in the eTPU SDM causes a very high RCR and should be avoided in high-performance systems.

After the collision rate for a system is found, it can be applied to the WCL calculations for each channel. The system designer can use the collision percentage and the number of SDM accesses (with and without semaphores) to estimate the eTPU loop time for a function. Note that in old TPU functions CPCR and CCR are both zero.

The estimation of eTPU wait time is as follows:

Variables:

N1 = Number of simple RAM accesses in the longest thread

RCRWait = Maximal eTPU clocks wait time for simple RAM collision = 2

CPCRWait = Average eTPU clocks for Coherent Parameter Transfer (using CDC).

N2 = Number of eTPU-eTPU semaphore RAM accesses in the longest thread

CCRWait = Average eTPU clocks for Microengine-Microengine communication transfer.

Estimated Wait Time:

Function eTPU maximal wait time =

N1 *(RCR * RCRWait + CPCR * CPCRWait) + N2* CCR * CCRWait

43.15.5.3 First-Pass Worst-Case Latency Analysis

Following is the first-pass calculation of worst-case latency for a channel. Remember that this analysis uses generalizations that usually produce a result much worse than the real worst case. If the worst-case result from the first analysis is too long for the desired performance, use the second analysis for a more realistic worst-case analysis.

43.15.5.3.1 Worst-Case Assumptions and Formula

To estimate worst-case latency for a channel, assume this worst-case condition: the channel has just been serviced in a time slot of its priority level, and all other channels in the system are continuously requesting service and have cleared SGRs. The worst-case latency is the time from the end of the channel's service until the end of the channel's next service. See the following figure.

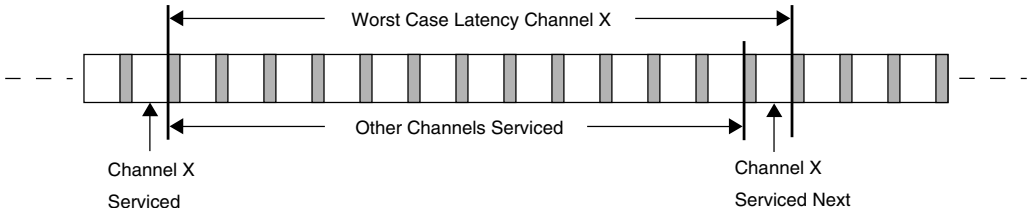

Figure 43-336. First-Pass Worst-Case Latency

To estimate worst-case latency:

- Find the worst-case service time for each active channel.
- Using the H-M-H-L-H-M-H time-slot sequence, map the channels that are granted for each time slot.
- Add time for six-clock time-slot transitions.

43.15.5.3.1.1 Mapping the Channels for Each Time Slot

To determine when a channel will be serviced again, it is necessary to determine which other channels will be serviced first. Do this by assuming all channels are continuously requesting service and mapping the channels into the time-slot sequence.

43.15.5.3.1.2 Adding Time for Time-Slot Transitions

Add six eTPU clocks for time-slot transitions which occur after each time slot.

43.15.5.3.2 First-Pass Analysis Worst-Case Latency Examples

The examples in this section assume the system configuration shown in the following table.

Table 43-419. System Configuration Example

Channel	Priority	Function[1, 2]
0	High	PWM (driving a DC motor)
1	Middle	PPWA (Mode 0, measuring the DC motor speed)
2	Low	DIO (Input)

1. 9% RAM Collision Rate (RCR)
2. CPU clock rate = 40 MHz, or 25 ns per clock period

43.15.5.3.2.1 Finding the WCL for PWM on Channel 0

The following shows how to find the WCL for PWM on channel 0.

1. Find the worst-case service time for each active channel.

   a. Longest thread of PWM is 24 CPU clocks with four RAM accesses.

      24 + ((4 RAM accesses+1) * 0.09 * 2 CPU clock waits) = 24.9 CPU clocks, rounded up to 25 CPU clocks (since there are no partial clock periods)

      Channel 0 worst-case service time = 25 CPU clocks.

   b. Longest thread of PPWA in mode 0 is 44 CPU clocks with nine RAM accesses.

      44 + ((9 RAM accesses+1) * 0.09 * 2 CPU clock waits) = 45.8 CPU clocks, rounded up to 46 CPU clocks

      Channel 1 worst-case service time = 46 CPU clocks.

   c. Longest thread of DIO is ten CPU clocks with four RAM accesses.

      10 + ((4 RAM accesses+1) * 0.09 * 2 CPU clock waits) = 10.9 CPU clocks, rounded up to 11 CPU clocks

      Channel 2 worst-case service time = 11 CPU clocks.

2. Assume channel 0 has just been serviced and that channels 1 and 2 are continuously requesting service. Using the H-M-H-L-H-M-H time-slot sequence, map the channels that are granted for each time slot. See the following figure.

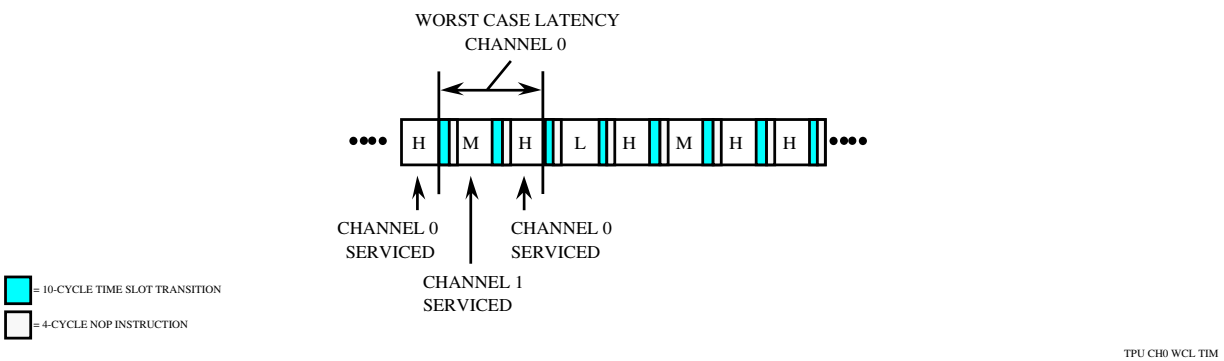

Figure 43-337. Next Servicing for Channel 0

   Channel 1 will be serviced in the middle-priority time slot before channel 0 is serviced again.

3. Add time for the six-clock CPU time-slot transitions. See the above figure and the following table.

   A four-clock NOP occurs after each channel is serviced since there is one channel in each priority level, i.e., a new cycle for a priority level is started after each channel is serviced. Time-slot transitions occur after each time slot.

Table 43-420. Worst-Case Latency for Channel 0

Channel 0 worst-case service time	25 clocks
Channel 1 worst-case service time	46 clocks
Two 6-clock time-slot transitions	12 clocks
Total clocks	83 clocks

83 clocks * 25 ns/clock = 2075 ns

Conclusion: in this system configuration PWM can run with a minimum high time or low time of 2075 ns.

Note that in double match eTPU system the PWM can be serviced once in each period, and there is no latency for minimum high time. The latency in eTPU PWM function will represent the minimum PWM period.

43.15.5.3.2.2 Finding the WCL for PPWA on Channel 1

The following shows how to find the WCL for PPWA on channel 1.

1. Find the worst-case service time for each active channel. See step 1 of previous example.
2. Assume channel 1 has just been serviced and that channels 0 and 2 are continuously requesting service. Using the H-M-H-L-H-M-H time-slot sequence, map the channels that are granted for each time slot. See the following figure.

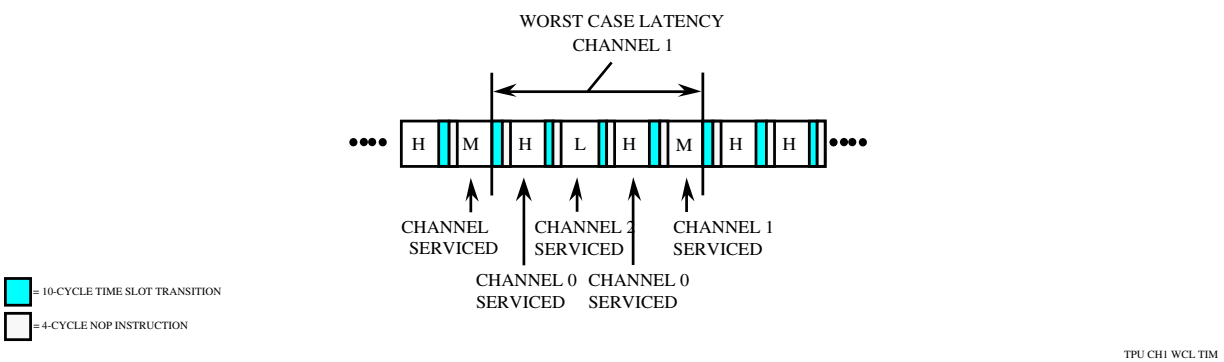

Figure 43-338. Next Servicing for Channel 1

Channel 0 will be serviced twice and channel 2 once before channel 1 is serviced again.

3. Add time for the six-clock CPU time-slot transitions. See the above figure and the following table.

Table 43-421. Worst Case Latency for Channel 1

Two Channel 0 worst-case service times	50 clocks
Channel 1 worst-case service time	46 clocks
Channel 2 worst-case service time	11 clocks
Four 6-clock time-slot transitions	24 clocks
Total clocks	131 clocks

131 clocks * 25 ns/clock = 3275 ns

Conclusion: in this system configuration PPWA can measure a period or pulse of minimum 3275 ns.

Note that PPWA function optimized for eTPU hardware can use double transition mode to measure very narrow pulses with one service after the second transition, and latency will affect only the minimum gap between two input pulses. Also the function threads would have more efficient coding.

43.15.5.3.2.3 Finding the WCL for DIO on Channel 2

The following shows how to find the WCL for DIO on channel 2.

1. Find the worst-case service time for each active channel. See step 1 of previous examples.
2. Assume channel 2 has just been serviced and that channels 0 and 1 are continuously requesting service. Using the H-M-H-L-H-M-H time-slot sequence, map the channels that are granted for each time slot. See the following figure.

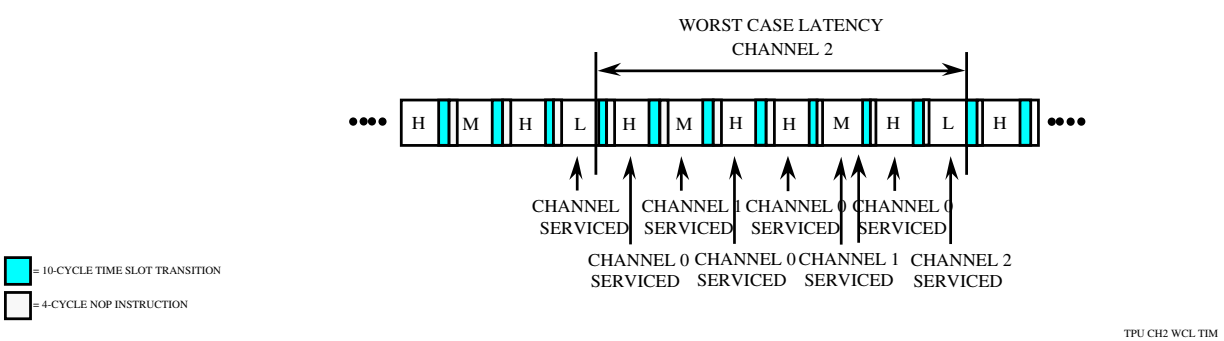

Figure 43-339. Next Servicing for Channel 2

Channel 0 will be serviced four times and channel 1 twice before channel 2 is serviced again.

3. Add time for the ten-clock CPU time-slot transitions and the four-clock NOPs. See the above figure and the following figure.

Table 43-422. Worst Case Latency for Channel 2

Four Channel 0 worst-case service times	100 clocks
Two Channel 1 worst-case service time	92 clocks
Channel 2 worst-case service time	11 clocks
Seven 6-clock time-slot transitions	42 clocks
Total clocks	245 clocks

245 clocks * 25 ns/clock = 6125 ns

Conclusion: in this system configuration DIO can keep track of the input level at a minimum of every 6125 ns.

Note that DIO function optimized for eTPU hardware can use double transition mode to measure two pin transitions at a time and reduce the service time, improving the overall system performance and latency.

43.15.5.4 Second-Pass Worst-Case Latency Analysis

Following is an example of a second-pass analysis for calculating worst-case latency for a channel. The second-pass analysis is useful for higher-performance systems, since it gives a more realistic worst-case latency result than first-pass analysis.

This example uses a relatively simple system in order to illustrate the basic principles of second-pass analysis. For a more complex example of second-pass analysis, refer to Multiphase Motor Commutation TPU Function (COMM)(TPUPN09/ D).

43.15.5.4.1 Second-Pass Analysis Guidelines

Rather than use a fixed formula, a second-pass analysis relies on the application of the following guidelines.

1. The first-pass analysis makes the assumption that all channels in the system are continually requesting service. For many systems this is an unrealistic assumption. For example, if TCR1 is counting at a rate of 2 MHz (500 ns per count) and a

channel is running the DIO function with a match rate of 20,000 TCR1 counts, the DIO will request service every 10 ms (20,000 * 500 ns = 10,000,000 ns or 10 ms). It is therefore unrealistic to assume that the channel running this DIO function is continuously requesting service. Figure out a realistic service request rate for each channel. Time slots can then be mapped to each channel at the real rate of request.

2. If a function is active during system initialization but not during the high-speed running mode of the system, then that system does not need to be included in the high-speed worst-case latency calculations.
3. Use a realistic SDM collision rate.
4. Be careful when assigning functions priority levels and channel numbers. Decide which function or functions will be most difficult to make perform at the desired level. Assign those channels high priority and low channel numbers. Try different priority and channel assignments to see how it affects the system.
5. The seven-slot sequence of || H | M | H | L | H | M | H || is asymmetrical when put back-to-back with other seven-slot sequences. Note that in the following sequence there are two high-priority slots next to each other:

   || H | M | H | L | H | M | H |||| H | M | H | L | H | M | H ||
6. Make sure that when mapping out channels to the sequence, you choose a worst-case slot to start the mapping. For example, when estimating WCL for a high-priority channel, do not start the mapping in the last high-priority slot in a seven-slot sequence, as that is a best case for a high-priority channel since another high-priority time slot is next.
7. Instead of always using the longest thread in the function as the worst-case thread, evaluate the threads in the function that will be used in the system and use the appropriate worst-case threads. For example, in the preceding example of first-pass analysis, the PWM was shown to be able to achieve a high time and low time of 2475 ns under worst-case conditions. This was derived using the longest PWM thread of 24 CPU clocks. This longest thread is actually thread 2, the thread that is entered after the pin has just gone high. Thread 3, the thread that is entered after the pin has just gone low, requires only 2 CPU clocks. Therefore, in the first-pass example, the high time was correctly derived, but the low time is actually shorter than was estimated.

43.15.5.4.2 Second-Pass Analysis Example

This example requires three 50% PWM waveforms: one 5 kHz (200 ms/period) and two 50 kHz (20 ms/period), each running DC motors. (Remember that the PWM function requests service from the eTPU after each high time and after each low time, so the eTPU must handle a request every 100 ms for the 5 kHz PWM and every 10 ms for the 50 MHz PWM.)

Note

This example uses square waves for simplicity. Notice that to use a PWM waveform in the typical way, in which the pulse is modulated, the pulse must not be modulated in a way that violates the worst-case latency requirements.

This example also uses one DIO channel monitoring a signal level every millisecond and one PPWA channel in mode 0 monitoring the speed of the 5-kHz DC motor. The PPWA must measure periods of 5 kHz (200 ms/period).

The CPU is interrupted by the channel running the PPWA function after measuring 200 periods (every 40 ms). The interrupt service routine performs an averaging of the period accumulation and checks it against a known parameter. The interrupt service time is so short and infrequent that it is a tiny fraction of total system time. The interrupt service routine contains no polling of the SDM. Therefore a realistic RCR = 0%.

43.15.5.4.2.1 First-Try System Configuration

Try a system configuration that seems likely to work. If it does not, change priority levels or channel numbers.

The 5 kHz and 50 kHz PWMs are the most time-critical functions. Those are assigned high priority. PPWA is assigned middle priority. The DIO is low performance and is assigned low priority. Refer to the following table.

Table 43-423. First-Try System Configuration

Channel	Priority	Function[1], [2]
0	High	PWM at 50 kHz (needs a 4-µs WCL)
1	High	PWM at 50 kHz (needs a 4-µs WCL)
2	High	PWM at 5 kHz (needs a 40-µs WCL)
8	Middle	PPWA at 5 kHz (needs a 80-µs WCL)
15	Low	DIO as input at rate of 1 ms

1. 0% RAM collision rate
2. CPU clock rate = 40 MHz, or 60 ns per clock period

With this system configuration, worst-case service time for each active channel is determined as follows:

1. Longest thread of PWM is 24 CPU clocks with four RAM accesses.

   24 + ((4 RAM accesses+1) * 0 * 2 CPU clock waits) = 24 CPU clocks

   Channels 0-2 worst-case service time = 24 CPU clocks.

2. Longest thread of PPWA in mode 0 is 44 CPU clocks with nine RAM accesses.

   44 + ((9 RAM accesses +1)* 0 * 2 CPU clock waits) = 44 CPU clocks

   Channel 8 worst-case service time = 44 CPU clocks.

3. Longest thread of DIO is ten CPU clocks with four RAM accesses.

   10 + ((4 RAM accesses+1) * 0 * 2 CPU clock waits) = 10 CPU clocks

   Channel 15 worst-case service time = 10 CPU clocks.

   To find the WCL for channel 0, assume channel 0 has just finished service.

   Map the channels in the H-M-H-L-H-M-H sequence. See the following figure.

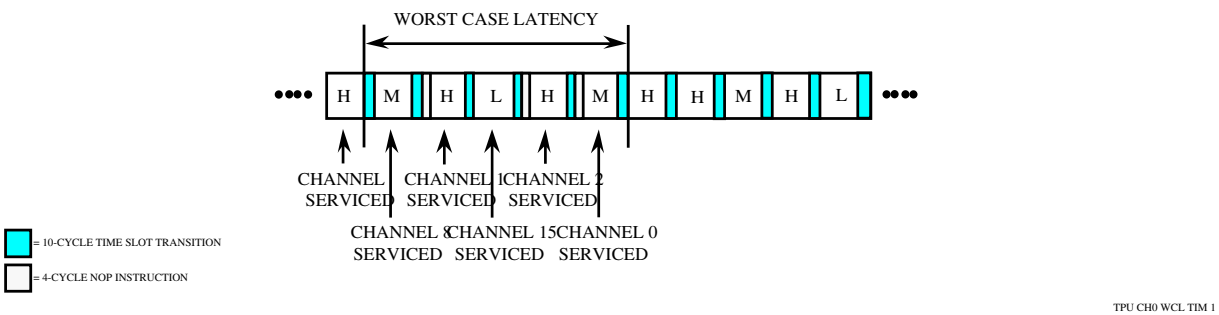

Figure 43-340. Worst-Case Latency for Channel 0 (First Try)

Conclusion: with this system configuration, worst-case latencies for channels 0 and 1 are too high (WCL for channel 1 is the same as WCL for channel 0). Try a different system configuration.

43.15.5.4.2.2 Second-Try System Configuration

The second-try system configuration is shown in the following table.

Table 43-424. Second-Try System Configuration

Channel	Priority	Function[1], [2]
0	High	PWM at 50 kHz (needs a 4-µs WCL)
1	High	PWM at 50 kHz (needs a 4-µs WCL)
2	Middle	PWM at 5 kHz (needs a 40-µs WCL)
8	Middle	PPWA at 5 kHz (needs a 80-µs WCL)
15	Low	DIO as input at rate of 1 ms

1. 0% RAM collision rate
2. CPU clock rate = 40 MHz, or 60 ns per clock period

To find the WCL for channel 0, assume channel 0 has just finished service. Map the channels in the H-M-H-L-H-M-H sequence. See the following figure.

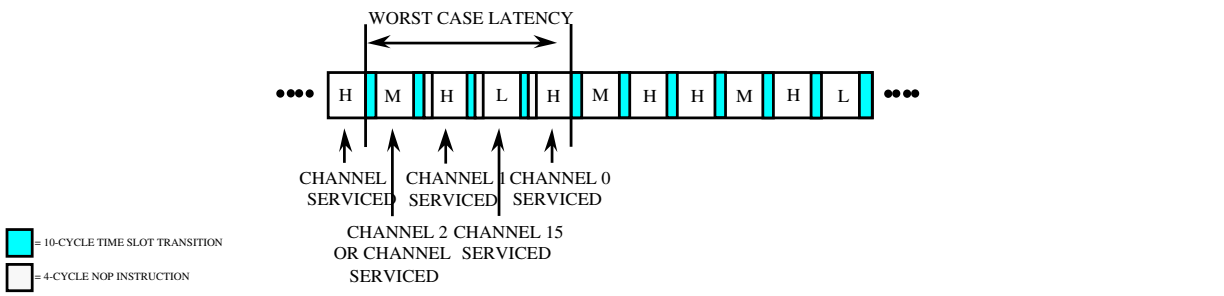

Figure 43-341. Worst-Case Latency for Channel 0 (Second Try)

Conclusion: with this system configuration, the WCL of both channel 0 and channel 1 is 3.85 ms, which is within the limit of 4 ms needed for a 50-kHz PWM.

Next, find the WCL for channel 2. Assume channel 2 has just finished service. Map the channels in the H-M-H-L-H-M-H sequence. See the following figure.

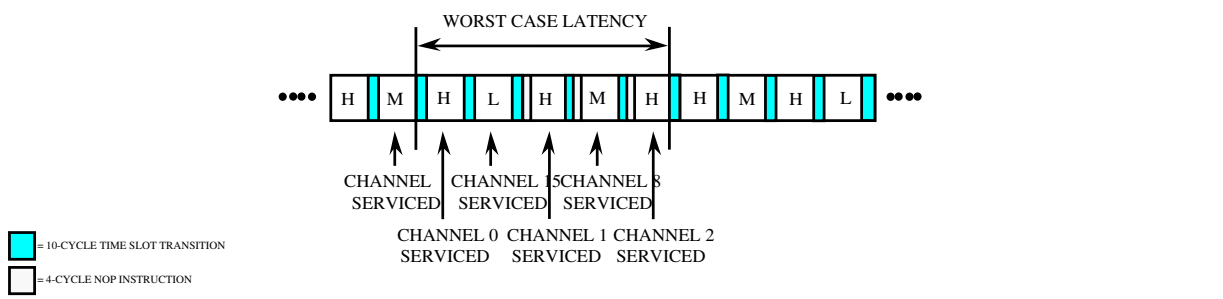

Figure 43-342. Worst-Case Latency for Channel 2

Conclusion: with this system configuration, the WCL for channels 2 and 8 is 4.7 ms, which is within the 40 and 80 ms WCL requirements.

Notice that channels 2 and 8 are well within their WCL requirements. The system could be reconfigured as shown in the following table to give channels 0 and 1 a larger margin while still keeping channels 2, 8 and 15 within their WCL requirements.

Table 43-425. Second-Try System with Channel 0 and 1 Reconfigured

Channel	Priority	Function[1], [2]
0	High	PWM at 50 kHz (needs a 10-µs WCL)
1	High	PWM at 50 kHz (needs a 10-µs WCL)
2	Middle	PWM at 5 kHz (needs a 40-µs WCL)
8	Low	PPWA at 5 kHz (needs a 80-µs WCL)
15	Low	DIO as input at rate of 1 ms

1. 0% RAM collision rate
2. CPU clock rate = 40 MHz, or 60 ns per clock period

43.15.6 Endianness

The following table shows the parameter addresses for big and little endian machines.

Table 43-426. Parameter Addresses and Endianness

Parameter	byte address offset (n = word address offset)	
	big endian	little endian
32-bit	4*n	
24-bit	4*n + 1	4*n
32-bit parameter's most significant byte	4*n	4*n + 3
24-bit parameter's most significant byte	4*n + 1	4*n + 2
least significant byte	4*n + 3	4*n

43.15.7 Memory Error Service Procedures

Follows separate procedures for correctable and non-correctable error interrupt service routines. It is assumed that the non-correctable error ISR has higher priority, and cannot be preempted by the correctable error ISR. For memory error support details, see Memory Error Support.

Note

The memory error support hardware does not (and is not intended to) guarantee that no error occurred will go unreported. However, combined with the procedures below, the information loss is minimized to statistical irrelevance on most scenarios.

43.15.7.1 Non-correctable Error Service Procedure

The basic procedure below can be followed in a Global Exception or a bus error machine check service routine. It handles the service for both SCM and SDM errors, as they are symmetrical at this level. However, a real implementation is likely to split the procedure in two, one for each memory.

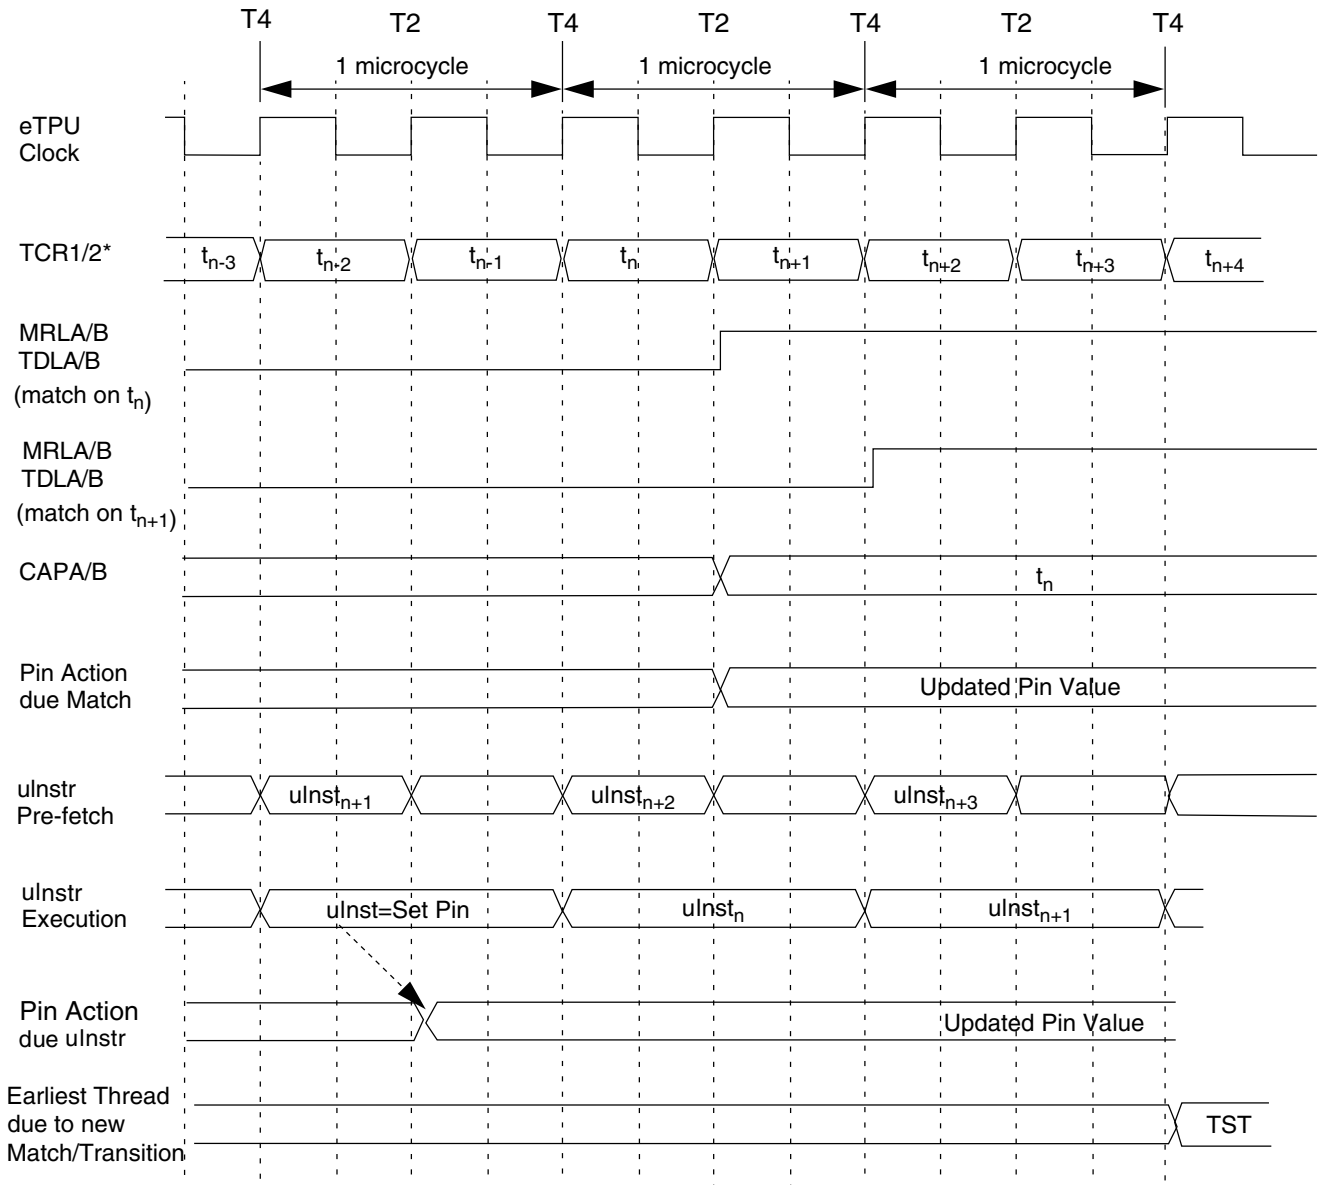
1. Confirm/identify the error source, checking assertion of the eTPU Module Configuration Register (eTPU_SCR_MCR) bits SCMERR and SDMERR.
2. Save the state(s) of eTPU Module Configuration Register (eTPU_SCR_MCR) bit(s) CRDIS/DRDIS.
3. Set the eTPU Module Configuration Register (eTPU_SCR_MCR) CRDIS/DRDIS=1 to disable further updates to the respective report registers, guaranteeing coherency.
4. Check whether the report registers were updated by a correctable or non-correctable error; to do this, check the eTPU Code Error Report Syndrome Register (eTPU_MESR_CERSR) syndrome (for SCM) and/or the eTPU Data Error Report Syndrome Register (eTPU_MESR_DERSR) syndromes (for SDM, only those with the respective BE flags asserted). If it is a correctable error report, skip the steps 5 and 6 for the respective memory.
5. Identify the error source (host, microengine or MISC/CDC) by checking the field ERR_ACC in the register(s) eTPU Code Error Report Address Register (eTPU_MESR_CERAR) and eTPU Data Error Report Address Register (eTPU_MESR_DERAR); take or schedule the appropriate application-dependent recover actions.
6. Update error statistics as needed; it may include recording the access source, address, data and syndrome from the registers ETPUCERAR and ETPUDERAR, eTPU Code Error Report Data Register (eTPU_MESR_CERDR) and eTPU Data Error Report Data Register (eTPU_MESR_DERDR), ETPUCERSR and ETPUDERSR.
7. Save the status of non-correctable error overflows flagged in the eTPU Memory Error Status Register (eTPU_MESR_MESR) bit(s) CNCOVR/DNCOVR.

8. Set the eTPU Memory Error Control Register (eTPU_MESR_MECR) bit(s) CRDIS/DRDIS to the state(s) saved in the step 2. That assures the access coherency of a preempted Correctable Error Service Procedure (which may have set CRDIS/DRDIS before this procedure) is not disturbed.
9. Clear ETPUMESR bits CNCOVR/DNCOVR and CNCERR/DNCERR at once, in a single write to ETPUMESR.
10. Use the overrun status saved on step 7 to update the error statistics, as needed.
11. Check the other Global Exception flags in ETPUMCR; take or schedule the appropriate (application dependent) recover actions.
12. Clear the Global Exception, writing ETPUMCR bit GEC=1.

43.15.7.2 Correctable Error Service Procedure

The basic procedure below can be followed in a Memory Error Interrupt service routine (see Interrupts and Data Transfer Requests). It handles the service for both SCM and SDM errors, as they are symmetrical at this level. However, a real implementation is likely to split the procedure in two, one for each memory.

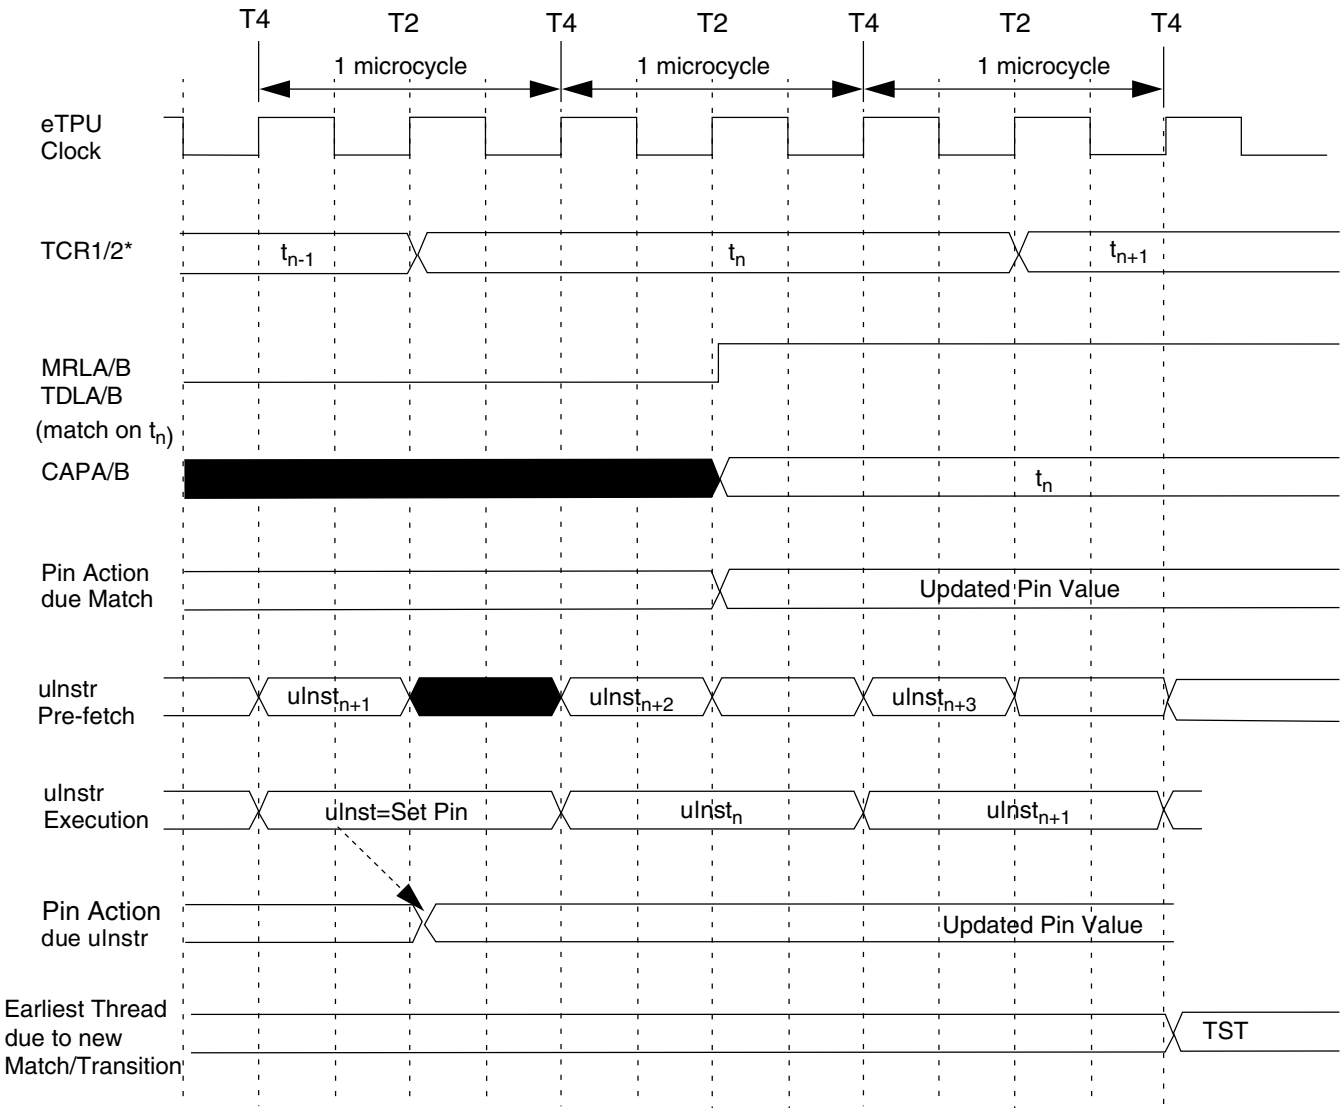
1. Confirm/identify the error source, checking assertion of the eTPU Memory Error Status Register (eTPU_MESR_MESR) bits CCERR/DCERR.
2. Set the eTPU Memory Error Control Register (eTPU_MESR_MECR) bits CRDIS=1 and/or DRDIS=1, to disable further updates to the respective report registers, guaranteeing coherency.
3. Check whether the report registers were updated by a correctable or non-correctable error; to do this, check the eTPU Code Error Report Syndrome Register (eTPU_MESR_CERSR) syndrome (for SCM) and/or the eTPU Data Error Report Syndrome Register (eTPU_MESR_DERSR) syndromes (for SDM, only those with the respective BE flags asserted). If it is a non-correctable error report, skip the steps 4 and 5 for the respective memory.
4. Identify the error source (host, microengine or MISC/CDC) by checking the field ERR_ACC in the register(s) eTPU Code Error Report Address Register (eTPU_MESR_CERAR) and eTPU Data Error Report Address Register (eTPU_MESR_DERAR); take or schedule the appropriate application-dependent recover actions, which may include soft-error fixing (see Error Fixing).



5. Update error statistics as needed; it may include recording the access source, address, data and syndrome from the registers ETPUCERAR and ETPUDERAR, eTPU Code Error Report Data Register (eTPU_MESR_CERDR) and eTPU Data Error Report Data Register (eTPU_MESR_DERDR), ETPUCERSR and ETPUDERSR.
6. Save the status of correctable error overflows flagged in the eTPU Memory Error Status Register (eTPU_MESR_MESR) bits CCOVR/DCOVR.
7. Set the ETPUMECR bit(s) CRDIS/DRDIS=0.
8. Clear ETPUMESR bit(s) CCOVR/DCOVR and CCERR/DCERR at once, in a single write to ETPUMESR.
9. Use the saved overrun status to update the error statistics, as needed.

43.16 Appendices

43.16.1 Microcycle and I/O Timing



43.16.1.1 Execution and Channel Timing

The following figure shows the main timings related to microinstruction execution when channels and timebases run on T2 timing. For timings of eTPU block internal interface signals, consult the eTPU Integration Guide. For timings internal to the eTPU, refer to the **eTPU Creation Guide**.

Note: *TCR clock/prescaler selection = 1 x eTPU clock

Figure 43-343. Execution, Timebase and Channel T2 Timing

Note: *TCR clock/prescaler selection = 4x eTPU clock

Figure 43-344. Execution, Timebase and Channel T2/T4 Timing

The sequential occurrence of the four T states (T1-T4) constitutes a microcycle. Only T2 and T4 are taken as reference for timings, either internal or external. T2 and T4 have the timing of the positive eTPU clock pulses, and are used in most of the eTPU logic in an edge-triggered design style.

Two additional T states are derived from the eTPU clocks: $\overline{T2}$ and $\overline{T4}$. $\overline{T2}$ occurs when the eTPU loses SDM arbitration to a bus master. $\overline{T4}$ occurs in halt state (due to a breakpoint or device debug request assertion, for instance), or in stall state (due to an NDEDI queue full); see Development Support Features for more details.

$\overline{T2}$ and $\overline{T4}$ states are defined as microcycle timing states (not to be confounded with logic states) of one eTPU clock in which the T clocks continue to run, but the control signals associated with the clocks are unaffected. That is, no operation occurs during these states.

Both $\overline{T2}$ and $\overline{T4}$ states occur in multiples of two eTPU clocks to keep the microengine synchronized with the free running channels, which are unaffected and keep on working as in T2 and T4.

Thus, the eTPU has two types of timing states:

- $\overline{T2}$: hold execution for SDM access, from clock pulse T2 until one of the next T2 clock pulses of another microcycle.
- $\overline{T4}$: hold execution in debug mode or stall, from clock pulse T4 until one of the next T4 clock pulses of another microcycle.

The two following figures show the timing of $\overline{T2}$ and $\overline{T4}$ timing states, respectively.

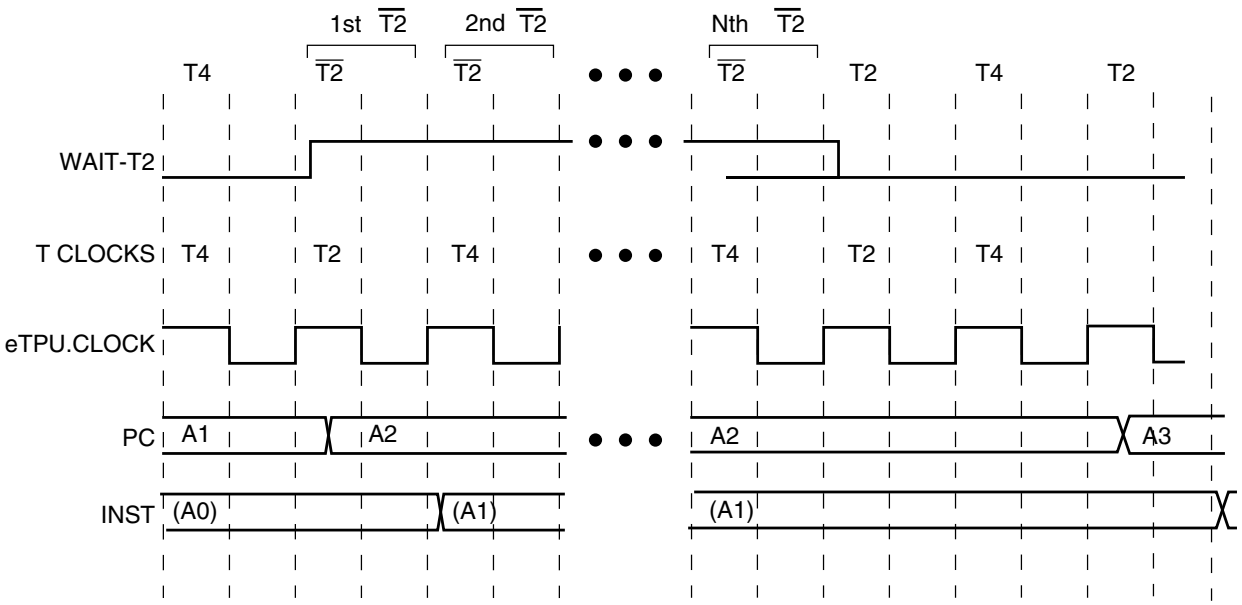


Figure 43-345. $\overline{T2}$ timing

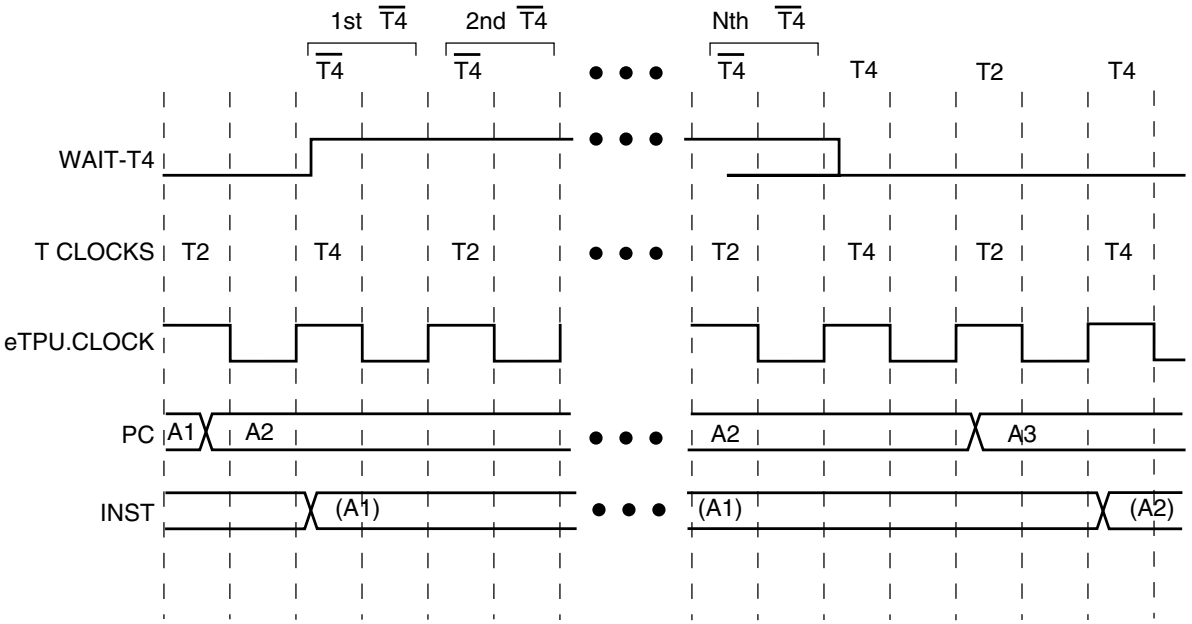

Figure 43-346. $\overline{T4}$ timing

43.16.1.2 Input/Output Signal Delays

The synchronizer, filter and edge detection logic delay the input signal transitions.

The Filter Delay varies with the filter clock (eTPU Engine 1 Configuration Register (eTPU_SCR_ECR_ENG1) and eTPU Engine 2 Configuration Register (eTPU_SCR_ECR_ENG2) field FPSCK) and the filter mode used, as shown in the Table 43-353 . For any given transition, it depends on the phase of the filter clock when the input transition happens. In integration mode (TCRCLK filtering only), it also depends on the state of the integrator counter. The Total Delay is defined as the number of eTPU clock rising edges between the input transition and the setting of TDLA/B, TCR1/2 incrementing, or EAC tooth sensing (TCRCLK) in angle mode. The synchronizer delay is 2 or 3 eTPU clocks, depending on the phase of the synchronizer when the input transition happens. The edge detection takes 1 more eTPU clock. The total delays are, thus:

```
Min. Total Delay = Min. Synchronizer Delay + Min. Filter Delay + Edge Detection Delay
Min. Total Delay = 3 + Min. Filter Delay
Max. Total Delay = Max. Synchronizer Delay + Max. Filter Delay + Edge Detection Delay
Max. Total Delay = 4 + Max. Filter Delay
```

The channel filters can be bypassed, so nullifying the filter delays in the equations above.

See the chip-specific eTPU information for connections between eTPU and input glitch filters.

The channel output flip-flops drive the eTPU output signals directly, without any synchronous delays.

43.16.2 Channel Mode Summary

The initial state considered for all submodes is channel flags MRLEA and MRLEB asserted, MRLA, MRLB, TDLA and TDLB negated. From initial state one can follow the table below and verify how each submode behaves in a determined sequence of events. Note that the actions performed by an event type depend on all previous events following the initial state, for a given channel submode.

There are three columns for each event: one for event type, one for enable/disable actions and one for capture. **Event type** column can be matchA, matchB, transA and transB (for double transition modes). **Enable/disable actions** column (identified as "**[blocks] (enables)**" in column head) specifies which other events are enabled or disabled. Initially disabled events (specified in **"initially blocked"** column) are usually enabled by other events.

In double transition submodes, the first transition detected is always considered transA and the second is considered transB. This means that transA event actually enables the detection of transB event. This is not explicit in the table, since it is a general behavior for all double transition submodes.

A sequence of four events (two matches and two transitions) are necessary to describe the behavior of some channel submodes. When a determined sequence of events has less than four events, the other event columns are left blank.

Cells in an **"event type"** column that have light-grayed background indicate that a service request is generated. More than one event in the same event sequence can issue service request.

Note

The two tables below do not exhaust all possibilities of channel logic event sequences, because it does not account for possible microcode interventions. For instance, if matches are blocked

by first transition and microcode resets TDLA, the matches become enabled again, and from this point on the channel behaves as if the first transition had never occurred.

Table 43-427. Channel Mode Summary 1 of 2

Mode	Initially Blocked	1st Event			2nd Event		
		Event Type	[Blocks] (Enables)[1]	Capture	Event Type	[Blocks] (Enables)	Capture

1. Transition 1 always enables Transition 2.
2. Shading indicates that a service request is generated.
3. sm_st is compatible with TPU3 channel logic.
4. It is not possible to include all functionality of this submode in table.

43.16.3 MISC Algorithm

The MISC generator is based on the following polynomial:

$G(x) = 1 + x^1 + x^2 + x^{22} + x^{31}$ (equivalent to feedback mask = 0x80400007)

The MISC signature generation starts by clearing the MISC Accumulator value to 0 and preloading the MISC Counter with the highest SCM address. It then steps through each address decrementing the counter, reading 32 bit values and following the algorithm below:

```
If the least significant bit in MISC is 1 then
    MISC = MISC right shifted by 1 bit
    MISC = MISC XOR 0x80400007
else
    MISC = MISC right shifted by 1 bit
end if
MISC = MISC XOR RAM data
```

The code example below shows an excerpt of C code that calculates the MISC signature for a given array of data, based on the previous algorithm:

```
#define SCM_size    (MAX_SCM_ADDRESS / 4)    /* last byte address - converted to 32-bit word */
#define POLY        0x80400007               /* G(x) = 1 + x^1 +x^2 + x^22 + x^31 */
/*****************************************************************************
 FUNCTION : void calc_misc()
 PURPOSE : This function calculates the MISC value.
 INPUTS NOTES : none
 RETURNS NOTES : MISC value
 GENERAL NOTES : the array 'unsigned int data[]' represents the actual memory
                 array, organized in 32-bit words.
*****************************************************************************/
unsigned int calc_misc (void)
{
  int j; /* loop counter */
  unsigned int misc = 0;
  for (j = (SCM_size-1); j >= 0 ; j--) {    /* SCM_size has the number of 32-bit words in SCM
*/
      if (misc & 0x1) {
          misc >>= 1;
          misc ^= POLY;
      }
      else {
          misc >>= 1;
      }
      misc ^= data[j];          /* data[j] is the actual 32-bit word taken from the SCM
array
*/
  }
  return (misc);          /* final signature calculated */

};
```

The value calculated by this algorithm must be loaded into register eTPU MISC Compare Register (eTPU_SCR_MISCCMPR) prior to activating the SCM MISC calculator in eTPU. Once the MISC calculator is activated (bit SCMMISEN in register eTPU Module Configuration Register (eTPU_SCR_MCR) is written to 1) eTPU itself will start this procedure[38] reading the SCM whenever allowed by microengine. At the end of the cycle, when all the array has been read and the SCM signature is calculated, the Host CPU can be notified via Global Exception if the MISC Accumulator does not match the value in ETPUMISCCMPR.

The average time taken by MISC to complete the signature of the whole SCM can be given by the formula:

```
Average MISC period = S / (4 * F * (1 - L))
```

where f is clock frequency, S is SCM size in bytes and L is eTPU load (as a percentage of execution clocks over a period of time, including TST clocks).

Further detail on MISC calculation can be found on SCM Test - Multiple Input Signature Calculator. The application note **AN2192 - Detecting Errors in the Dual Port RAM (DPTRAM) Module** is also a good source of information (although it refers to TPU) on MISC signature.

38. eTPU MISC hardware is optimized to read 32-bit words from memory and to calculate this CRC in parallel, rather than shifting one bit at a time. The actual implementation inside eTPU, although bringing to the same results, does not match exactly the algorithm shown here.

Chapter 44
Reaction Module 2 (REACM2)

44.1 Reaction Module 2 chip-specific module information

The Reaction Module 2 (REACM2) is a dedicated module designed to control 10 output channels. Each channel has three output pins.

The device uses the Reaction Module 2 to provide closed loop control functionality. It receives SAR ADC results from the BCTU and drives output signals. The device supports one instance of reaction module.

- Timer input channel 0-3 is directly connected with the eTPU (engine1).
- Timer inputs channel 4-15 of the Reaction Module 2 may come from eTPU or eMIOS. The mux is implemented for these timer inputs in IOMUX (see Generic pins/balls).
- The Reaction Module 2 receives the conversion results from SAR-ADC via BCTU. BCTU triggers the SAR-ADC and then sends the conversion results it received from the SAR-ADC to the Reaction Module.

Table 44-1. REACM2 Inputs

REACM2 channel	eTPU_A	eTPU_B	eMIOS0	eMIOS1
0	10	—	—	—

The following figure shows the interaction of the Reaction Module 2 with other modules in the device.

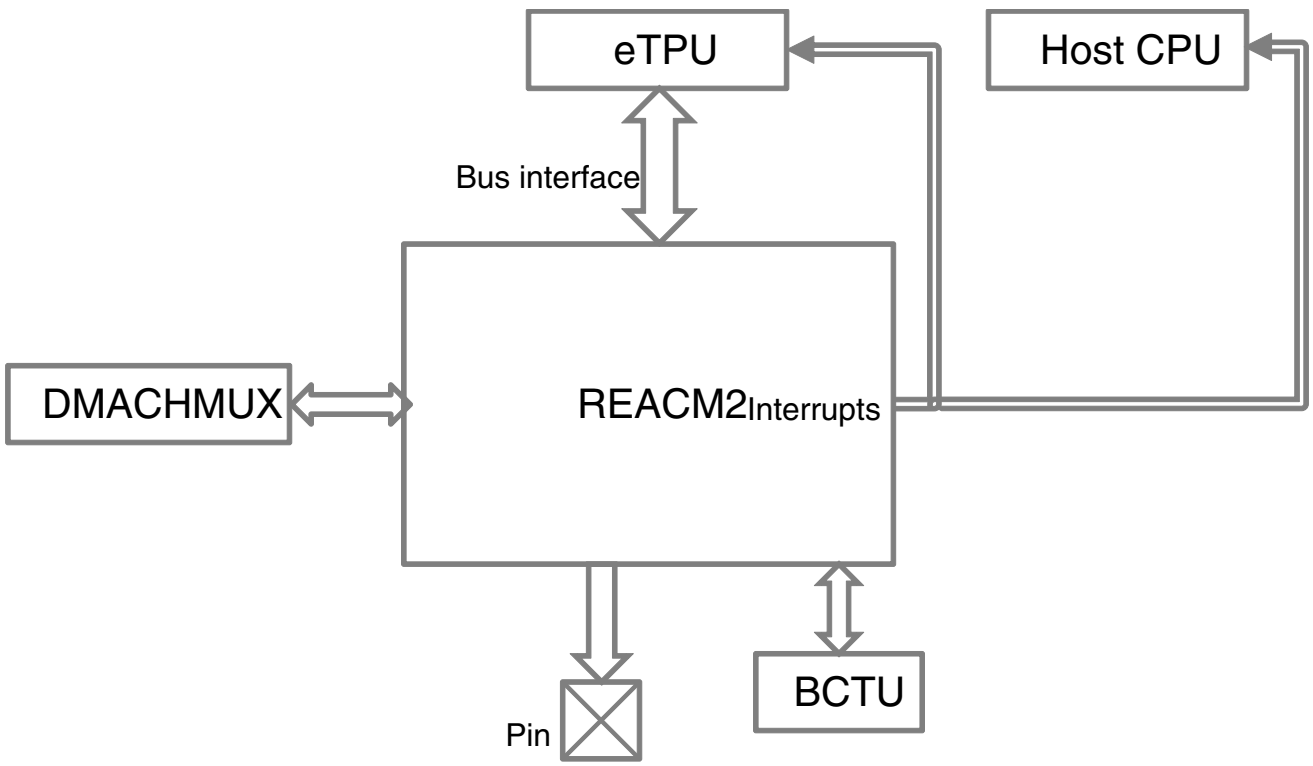

Figure 44-1. Reaction Module 2 SoC Interaction

44.2 Introduction

The REACM2 is composed of 10 reaction channels. Each channel contains three outputs. Its main application is in the area of solenoid control for direct injection systems, valve control in automatic transmissions, and other current control applications. It is connected to the on-chip ADC which monitors the current on the solenoid or valve. Based on that the reaction channel generates an output signal that modulates the current circulating in

the solenoid or valve. It is a cost-effective solution due to extensive sharing of several resources among channels and parameterized register banks for adequate dimensioning of resources and functionality.

44.2.1 Features

The REACM2 features include:

- Per channel architecture for independent output control
- Interface with on-chip ADC for fast response times
- Interfaced to timer modules
- Hardware connection with on-chip timer channels with channel routing capability
- Shared Modulation Control bank
- Dynamic timer allocation
- Three outputs per channel to support different driver architectures
- Flexibility to operate based on timing and threshold
- On-the-fly capture of ADC result reference for fast calibration
- Open and short circuit monitoring capability

44.2.2 Modes of Operation

Operation modes of this module are described below.

44.2.2.1 Programming Mode

After reset, the Reaction module is in the Programming mode. In this mode all channels are disabled and outputs are at logic zero. Note that this state does not necessarily mean that zero is the neutral state for the channel load, thus care must be taken in order to disconnect the channel from the load in this case.

In the programming mode the host CPU writes all module parameters including:

1. Modulation word data
2. Channel control data

3. Threshold data
4. Timer Bank data
5. Hold (on/off) Timer bank data
6. Timer router data
7. ADC router data
8. Period Shift Delay time
9. Period Generator timers

The last action to perform is to *enable* the channel. After that the channel is able to respond to timer signals and ADC data, thus able to perform modulation on the output pins. It is recommended to keep the timer signals inactive until all data to all reaction channels are programmed and all channels have been put in the *enabled* mode.

44.2.2.2 Low Power Mode

Coming out from reset all channels are in the disabled state. The channel may also be in low power mode depending on an instantiation parameter that configures the initial state of the MDIS in the Module Configuration Register. If MDIS=1 the module clock may be disabled, allowing for a low power state. The low power mode is controlled either by the MDIS bit or by a global stop signal. There is no explicit clock gating implemented in hardware within the Reaction Module. Reaction module clock gating is implemented in the SoC. Low power mode must be entered only when all channels are disabled by CHEN=00.

44.2.2.3 Channel Modes

After a channel is put in *enabled* mode that channel is also said to be in the *normal* mode of operation, which means it responds to timer signals from the timer inputs connected to the Reaction Module and also to ADC results received from the on-chip ADC module. Channel outputs are controlled in accordance with those inputs in order to perform an output modulation process. When performing a modulation the Reaction Channel is said to be in the *active state*. The Reaction Channel modes are described below in relation to the ability to execute a modulation:

- Disabled: the channel cannot execute modulation.
- Enabled: the channel is able to execute a modulation. It may be in the *Active* or *Inactive* states.
  - Inactive state: the channel is not executing a modulation.
  - Active state: the channel is executing a modulation.

44.2.2.4 Debug Mode

The Reaction Module Debug operation is defined by bits FRZ and FREN in the Module Configuration Register. In debug mode all Timers are freezed (halted), including the timers in the Shared Time Bank and Hold (on/off) timers. The module can enter debug mode in two different ways, either by software control or by the hardware debug input signal controlled by the chip logic. In both cases the Reaction Module enters debug mode only if enabled by the FREN bit:

- If both FREN and FRZ bits are set, the module enters debug mode.
- If FREN bit is set and a global debug signal is asserted, the module enters debug mode.

In debug mode, the channel outputs are held at HOD, LOD, or DOFF state, as determined by the channel current state. When resuming normal operation after exiting debug mode, the channel performs the read of the first Mod Word and the channel output is set to DOFF until the next timer control rising edge occurs.

MAXL flag is the only flag that operates in debug mode. All other flags retain the present state while the module is in debug mode. Note that the corresponding error flag in the Global Error Flag register is also set.

The ADC Input Sensor Input Register allows direct access for write to the TAG and ADC result values input to the Reaction Module. This software control may be used for module debug purposes.

44.2.3 Block Diagram

Figure 44-2 shows the on-chip connections of the reaction module. The ADC module is the source of data monitored from external sensors, usually voltage information, which is used by the reaction channel modulation to generate a PWM signal control signal in order

to maintain the load current within a certain predefined boundary. eTPU is commonly used as the source for controlling the activation of a reaction channel. Alternatively eMIOS or PIT can be used to provide that control signal.

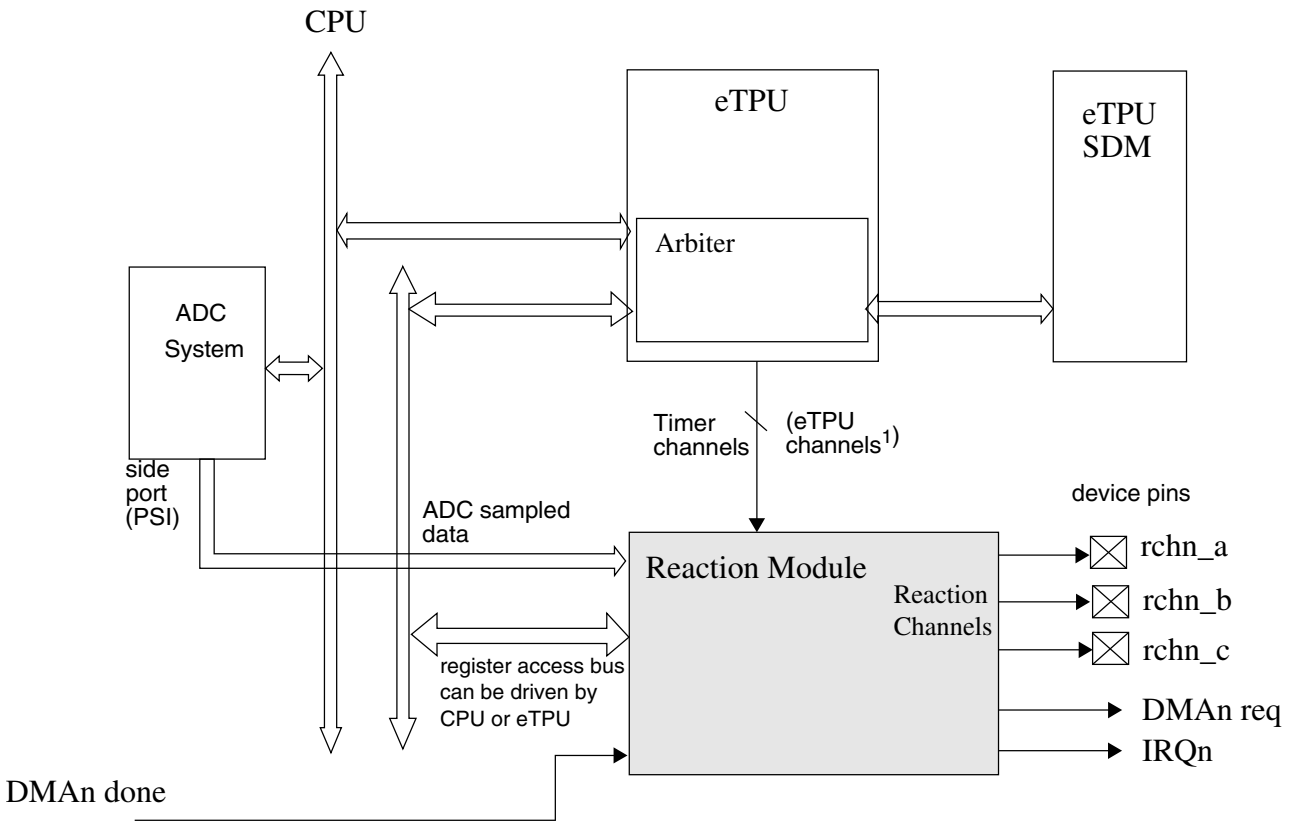

Figure 44-2. Reaction Module System Interconnection

The Reaction Module provides 10 channels with three outputs per channel. The channel outputs are programmed independently from each other. The outputs do not have a predefined ON or OFF state meaning as the definition of ON and OFF depends upon the application.

Figure 44-3 describes the interconnection between the reaction channel and the blocks in the Reaction Module. The indexes next to the blocks indicate the order in which each submodule executes an action during the modulation process. A simplified sequence of these steps is described as follows:

1. A new ADC result from the BCTU module is received, triggering one reaction channel
2. The triggered reaction channel generates the Modulation Word address based on the data programmed in the internal configuration register
3. A Modulation word is selected by the reaction channel

4. The selected Modulation word generates the address for the Threshold Bank
5. The Threshold bank selected data is compared against the incoming ADC result
6. The comparison result is sent back to the channel
7. The reaction channel executes modulation action and updates the channel output

In order to execute steps 1 through 7 the Reaction module takes five Module clock cycles.

The reaction channel sets the outputs according to HOD or LOD fields provided by the selected Modulation word.

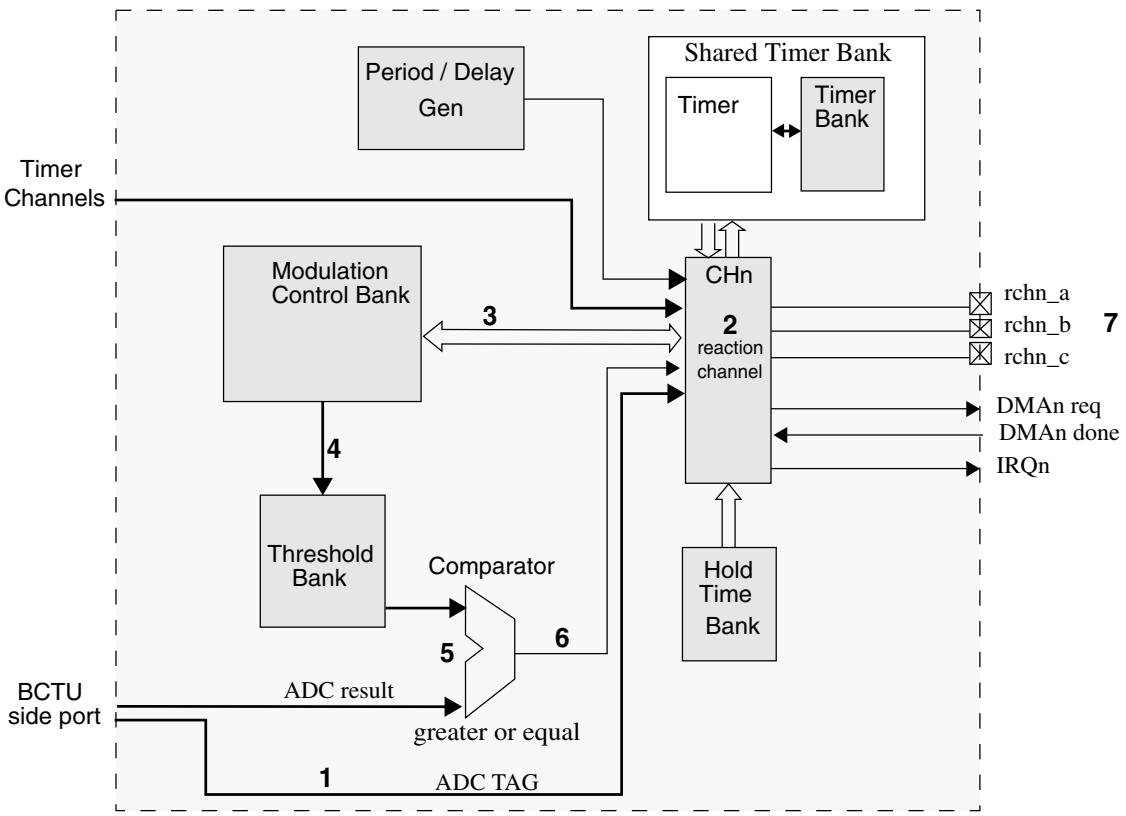

Figure 44-3. Channel Interaction with internal submodules

Figure 44-4 shows the Reaction Module's internal architecture. The channels are controlled by a Modulation Control Word provided by the Modulation Control Bank submodule. The Modulation Word has information about the type of modulation to be executed as well as the addresses for the Threshold and Timer banks. The channel stores information such as the address of the modulation word and initial values for the output pins after the channel is *enabled*.

Note that the modulation process only initiates after the channel is moved to the *active* state. This process will be described in more detail in the following sections.

After the activation, the channel sets the outputs with a predefined value stored in the channel configuration register. Only after this initialization process the channel is ready to start a modulation process. Note that the channel only considers an ADC result as valid if it is within a window defined by the timer input, usually connected to the on-chip eTPU. The Reaction Channel can access more than one Modulation Word by incrementing the internal MODULATION_ADDR field in the channel configuration register. The original value of this field is preserved thus when a new modulation cycle is initiated the same modulation address value can be used.

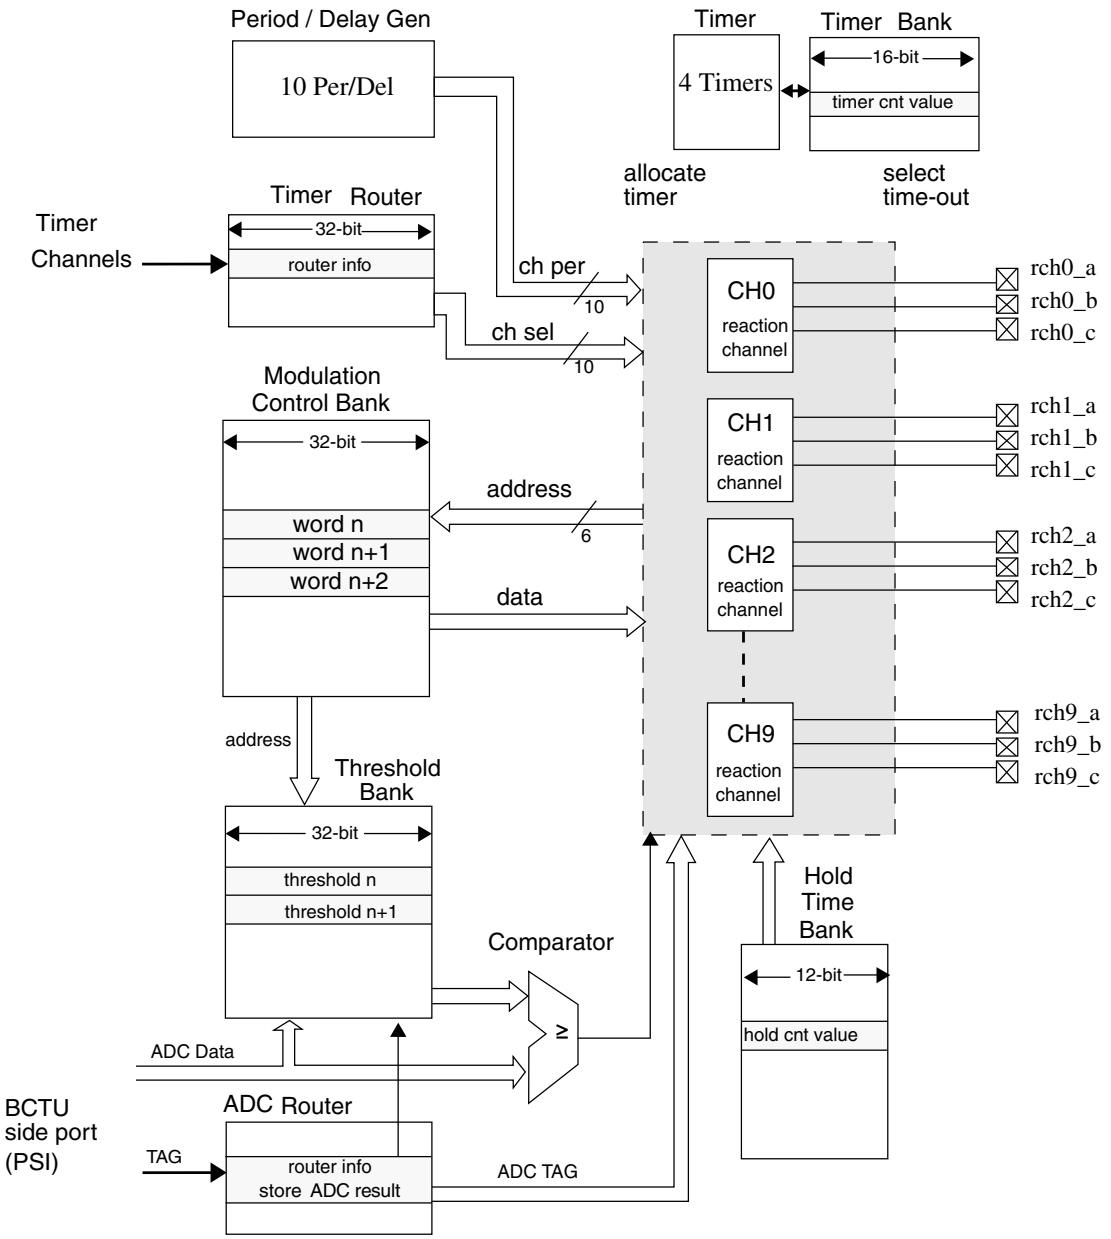

Figure 44-4. Reaction Module Block Diagram

Timer channels, such as eTPU channel outputs, are connected to the Timer Channel Router. This submodule routes each timer channel to a reaction channel. Note that one timer channel can be routed to more than one reaction channel.

The modulation process initiates when an ADC result arrives and the time window is active. The ADC Router sends a trigger signal to all channels indicating that an ADC result is available. The channel address resolution is based on the TAG field received with the incoming ADC result. After decoding the TAG field the channel accesses the Modulation Word using the information stored in the channel configuration register.

The Threshold Bank submodule stores values to be used on the comparison with incoming ADC results. The address for the stored values is generated by the Modulation Control Bank. This address generation is actually executed in a two-step process since the Modulation Word is first addressed by the channel which then generates the address for the Threshold Bank. After having both inputs defined the Comparator generates the comparison result back to the channels.

The Hold timer bank address is also stored in the modulation word. The reaction channel uses that information for the modulation process which requires the output to remain ON or OFF during a certain amount of time. The Hold counter itself is located inside each channel.

The Period Delay generator provides timing signals for the channels operating in the threshold-period modulation mode. It provides period starting signal for each channel with a configurable constant delay between two consecutive channels.

44.3 Signal Description

The following table shows the chip level signals for the Reaction module.

Table 44-2. Signal Properties

Name	Function
RCHn_a	Output pin 'a' of Reaction Channel 'n'
RCHn_b	Output pin 'b' of Reaction Channel 'n'
RCHn_c	Output pin 'c' of Reaction Channel 'n'

44.3.1 REACM2_RCHn — REACM Channel (n) Output Pin a, b and c

Each Reaction Channel provides three outputs to be connected to device primary output PADs. These outputs can be configured as necessary in order to meet application requirements. Thus the active state as well as overall functionality are defined by the registers within the Reaction Module and the defined sequence of operation. The reset state for these outputs is zero.

44.4 Memory Map and Register Definition

This section provides a detailed description of all Reaction Module registers accessible to the end user.

The REACM2 is in the eTPU address space to allow the eTPU direct access to the registers.

NOTE

For reset value of the REACM2_MCR, refer to the section describing this register.

44.4.1 Module Configuration (REACM2_MCR)

The REACM_MCR contains the control bits to configure the general operation of the Reaction Module.

Address: 0h base + 0h offset = 0h

REACM2_MCR field descriptions

Field	Description
0 OVRC	Overrun Detection Flag Clear The OVRC clears the OVR flag if "1" is written. This bit reads always as 0x0. If a set event occurs at the same time a flag clear is done, the set event has precedence over the clear thus the flag remains set. 0 No action 1 Clears OVR bit
1 MDIS	Module Disable The MDIS bit puts the Reaction Module in low power mode. Communication through the slave-bus Interface is ignored in this mode except writes to the REAC_MCR register which are allowed, except for the FRZ and FREN bits. The global debug signal state is not changed internally while in low power mode. 0 Normal Mode 1 Low Power Mode
2 FRZ	Freeze Control The FRZ bit controls the state of the Reaction Module regarding debug operation. If both FREN and FRZ bits are set the module enters debug mode. In this mode all time bases are halted and the outputs of channels are controlled solely by software. See section Debug Mode.This bit cannot be written if MDIS bit is set. 0 Normal Mode 1 Debug Mode
3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4 FREN	Freeze Enable The FREN bit enables the Reaction Module to enter debug mode. The debug mode is controlled either by the FRZ bit or by a global debug signal. This bit cannot be written if MDIS bit is set. 0 Debug Mode disabled 1 Debug Mode enable
5 TPREN	Timer Prescaler Enable The TPREN bit enables the Shared Timer Prescaler in the Reaction Module. 0 Prescaler Disabled 1 Prescaler Enabled
6 HPREN	Hold Timer Prescaler Enable The HPREN bit enables the Hold Prescaler in the Reaction Module. 0 Prescaler Disabled 1 Prescaler Enabled
7 GIEN	Global Interrupt Enable The GIEN bit enables the assertion of the global interrupt request to the CPU when any of the channel interrupts is set or when the OVR flag and its corresponding enable OVREN are both set. Note that this signal does not control the individual channel interrupt request. See section Global Interrupt and Channel Interrupt for more details.

Table continues on the next page...

REACM2_MCR field descriptions (continued)

Field	Description
	0 Interrupt disabled 1 Interrupt enabled
8 OVREN	Overrun Detection Interrupt Enable The OVREN enables the OVR flag, when set, to generate a global interrupt request for the CPU. 0 Interrupt disabled 1 Interrupt enabled
9–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

44.4.2 Timer Configuration (REACM2_TCR)

The REACM_TCR Timer Configuration Register contains the prescaler settings to configure the operation of the Reaction Module Hold Timer and Shared Timers. It is mandatory to change the value of the prescalers either when the prescalers are disabled by its control enable bits HPREN and TPREN in the Configuration Register or when the counters are not being used by any channel. Note that the prescalers are completely independent and thus modifying HPRE does not affect TPRE and vice-versa.

Address: 0h base + 4h offset = 4h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0				HPRE												0								TPRE							
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

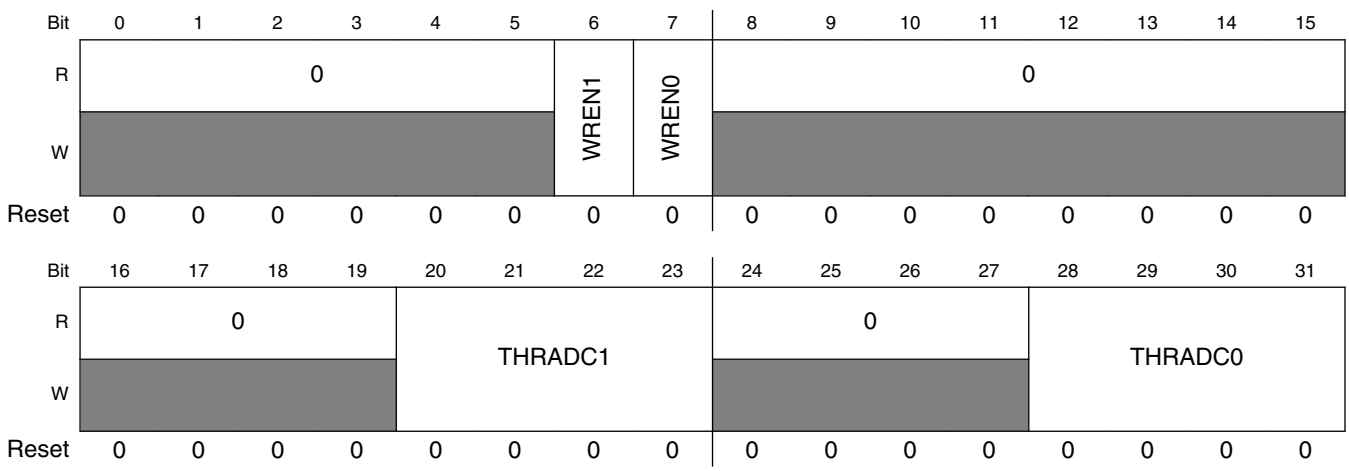
REACM2_TCR field descriptions

Field	Description
0–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4–15 HPRE	Hold Timer Prescaler The HPRE field defines the rate of the Hold Timers on each Reaction Channel. If its value is zero the prescaler is bypassed thus the Hold timer operates at the module clock rate. If HPRE = 0x01 the module operates at module clock divide by two and so forth up to HPRE = 0xFFF which defines system clock divided by 4096.
16–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–31 TPRE	Timer Prescaler The TPRE field defines the rate of the Timers on the Timer bank. If its value is zero the prescaler is bypassed thus the Timer operates at the module clock rate. If TPRE = 0x01 the Timer operates at module

Table continues on the next page...

REACM2_TCR field descriptions (continued)

Field	Description
	clock divide by two and so forth up to TPRE = 0xFF which defines module clock divided by 256 as the frequency of operation for the Timer.



44.4.3 Threshold Router Register (REACM2_THRR)

The Reaction Module Threshold Router Register routes the ADC result to the Threshold Bank. Since a TAG is assigned for each ADC result coming from the on-chip ADC module, this TAG is specified in this register and used for the routing process. The ADC result is written to the Threshold Value Bank as soon as it is received by the Reaction Module. Note that THRADC0 and THRADC1 TAG values may also be used by the Reaction Channels. In this case the results are routed to both, the channel and the Threshold Bank.

NOTE

Due to the timing in which these parallel events occur, if the channel uses the same Threshold Bank address in which the incoming ADC result was written to, this ADC result is used for the channel modulation being executed.

Address: 0h base + 8h offset = 8h

REACM2_THRR field descriptions

Field	Description
0–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6 WREN1	Write Enable Bit for THRADC1

Table continues on the next page...

REACM2_THRR field descriptions (continued)

Field	Description
	The WREN1 write enable bit 1 controls if the ADC result having a TAG matching to THRADC1 field will be written into address one of the Threshold Bank 0 Do not write received ADC result to Threshold bank 1 Write received ADC result to Threshold bank address one
7 WREN0	Write Enable Bit for THRADC0 The WREN0 write enable bit 0 controls if the ADC result having a TAG matching to THRADC0 field will be written into address zero of the Threshold Bank 0 Do not write received ADC result to Threshold bank 1 Write received ADC result to Threshold bank address zero
8–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20–23 THRADC1	ADC result Router value for Threshold Bank address one The THRADC1[3:0] field controls the routing from the received ADC result to the Threshold Bank address one. Any ADC result which TAG matching THRADC1 will be routed to Threshold Bank.
24–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28–31 THRADC0	ADC result Router for Threshold Bank address zero The THRADC0[3:0] field controls the routing from the received ADC result to the Threshold Bank address zero. Any ADC result which TAG matching THRADC0 will be routed to Threshold Bank.

44.4.4 ADC Sensor Input Register (REACM2_SINR)

The Reaction Module ADC Sensor Input Register is used to monitor the ADC Interface (see section ADC Interface) and allows the software to define the ADC result and TAG values for the Reaction Module. Also ADC values captured through DMA directly from the ADC interface or after filtering can be transferred to the Reaction Module by the CPU. Writes to this register may overwrite data coming from the ADC interface thus it should be used when no ADC conversion has the Reaction Module as the target. Writing to this register triggers the Reaction Channel selected by the TAG value to execute a comparison and to evaluate an eventually new value for the channel outputs.

Address: 0h base + 10h offset = 10h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

REACM2_SINR field descriptions

Field	Description
0–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12–15 ADC_TAG	TAG value The ADC_TAG[3:0] represents the TAG for the ADC conversion which is used by the Reaction Module to select the Reaction Channel to execute the modulation.
16–31 ADC_RESULT	ADC conversion result value The ADC_RESULT represents the value resulting from an ADC conversion. This value is used for the Reaction Channel Modulation process or for capturing by the Threshold Bank.

44.4.5 Period Generator Configuration Register (REACM2_PCR)

The Reaction Module Period Generator Configuration Register is used to setup the period pulse generator sub-block. See section Period / Delay Generator. This configuration is necessary when running the modulation mode threshold/period.

Address: 0h base + 14h offset = 14h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0								PERPRESC								PER															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

REACM2_PCR field descriptions

Field	Description
0–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8–15 PERPRESC	Period prescaler rate value The PERPRESC field defines the rate of the prescaler to be used by the Period counter and Delay counter. If its value is 0, the rate is 1, and so forth up to PERPRESC= 0xFF which defines to divide the system clock by 256.
16–31 PER	Period time value The PER represents the value for the internal period generator counter. When it is configured to all 0, the counter is stopped. And if not all 0, the period time in clock cycles is given by multiplying (PER+1) by the prescaler value (PERPRESC+1).

44.4.6 Period Shift Delay Configuration Register (REACM2_PSCR)

The Reaction Module Period Shift Delay Configuration Register is used to configure the delay time between period pulses of two consecutive channels. See section Period / Delay Generator. The delay multiplied by the number of channels must be less than or equal to the period.

Address: 0h base + 18h offset = 18h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0																DLY															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

REACM2_PSCR field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 DLY	Delay value between two consecutive channel period pulses The DLY represents the value to configure the shift delay between the period pulses of two consecutive reaction channels (for example, CH0 and CH1). The correct time depends on the prescaler counter. Also, if DLY=0 then the period pulses of all reaction channels occur at the same time. If DLY is not all 0, then the shift delay time in clock cycles is given by multiplying DLY with the prescaler (PERPRESC+1).

44.4.7 Global Error Flag Register (REACM2_GEFR)

The Reaction Module Global Error Flag Register helps the software in the resolution of error conditions signaled by the Reaction Channels. This allows a faster service in error handling. This register mirrors the Error Flag in the Channel Configuration and Status registers.

Address: 0h base + 20h offset = 20h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	OVR	0														
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

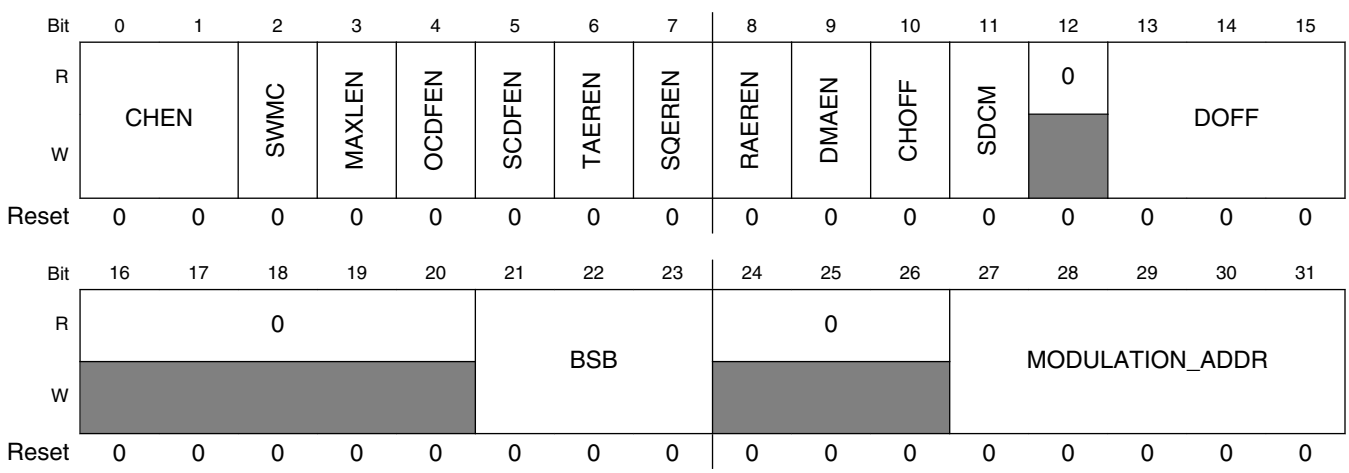
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

REACM2_GEFR field descriptions

Field	Description
0 OVR	Overrun Detection Flag The OVR flag is used to indicate that an overrun condition was detected at the ADC Interface. See section ADC Interface. 0 Overrun not detected 1 Overrun detected
1–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22 EF9	Error Flag The EFn error flag bit indicates an error condition occurred in channel n. This bit is provided for a fast channel error resolution in the Reaction module. The condition could be any error indicated by MAXL, OCDF, SCDF, SQER, RAER or TAER error flags as described in section “REACM2 Channel Status Register (REACM2_CHSR)". The EFn bit is automatically cleared if the corresponding channel flags are all cleared.
23 EF8	Error Flag See description for EF9.
24 EF7	Error Flag See description for EF9.
25 EF6	Error Flag See description for EF9.

Table continues on the next page...



REACM2_GEFR field descriptions (continued)

Field	Description
26 EF5	Error Flag See description for EF9.
27 EF4	Error Flag See description for EF9.
28 EF3	Error Flag See description for EF9.

30 EF1	Error Flag See description for EF9.
31 EF0	Error Flag See description for EF9.

44.4.8 Channel n Configuration Register (REACM2_CHCR*n*)

The Reaction Module Channel Configuration Register controls the channel behavior.

Address: 0h base + 100h offset + (16d × i), where i=0d to 9d

REACM2_CHCR*n* field descriptions

Field	Description
0–1 CHEN	Channel Enable Bits The CHEN[1:0] bits control the activation of the Reaction Channel. Once changed from disabled, CHEN = 00, to any enabled state, the channel reads the first Modulation Word and initializes itself in order to be

Table continues on the next page...

REACM2_CHCR*n* field descriptions (continued)

Field	Description
	ready to execute a modulation as soon as a timer control window is detected or SWMC=1, if software modulation control is selected by CHEN= 11. **NOTE:** If CHEN is programed with 01 or 11 enabling a channel, and the eTPU time window is already active (or SWMC=1), the Reaction Channel disregards this window and waits until the next window activation in order to start the modulation process by moving to the active state. In order to start a modulation controlled by software, it is required to first write CHEN=11 and then to write SWMC=1 only after that. 00 Channel disabled, meaning that it does not execute any modulation even if a timer window is detected or SWMC is made active. In this mode DOFF field in the Channel Configuration register defines the state of the channel outputs. 01 Channel is enabled for timer control only, meaning that as soon as a timer window is detected a modulation sequence starts. 10 Reserved 11 Channel enabled for software control only, meaning that as soon as SWMC bit is set a modulation sequence starts.
2 SWMC	Software Modulation Control bit The SWMC, Software Modulation Control bit, if set, initiates the channel modulation. It is equivalent to the assertion of an eTPU channel connected to the Reaction module. To use this functionality it is required that CHEN[1:0] = 11. 0 Channel does not perform modulation 1 Channel executes modulation
3 MAXLEN	ADC result Maximum Limit Interrupt Enable bit The MAXLEN enables the MAXL flag, when set, to generate an interrupt request for the CPU. 0 Interrupt disabled 1 Interrupt enabled
4 OCDFEN	OCDF Interrupt Enable bit The OCDFEN bit enables the OCDF bit to issue an interrupt request. 0 OCDF interrupt disabled 1 OCDF interrupt enabled
5 SCDFEN	SCDF Interrupt Enable bit The SCDFEN bit enables the SCDF bit to issue an interrupt request. 0 SCDF interrupt disabled 1 SCDF interrupt enabled
6 TAEREN	TAER Interrupt Enable bit The TAEREN bit enables the TAER bit to issue an interrupt request. 0 TAER interrupt disabled 1 TAER interrupt enabled
